EANM Focus Meeting 6 S1023

EANM Clubbing hosted by EARL S1024

Dear Colleagues,

I am very pleased to invite you to the 37th Annual Congress of the European Association of Nuclear Medicine. The EANM'24 will be held in Hamburg, on October 19-23, 2024.

Over the past years, we have seen the EANM's Annual Congress becoming larger, more impactful, and more successful, accompanying and shaping the fantastic growth of our diverse, exciting, and ever-growing specialty.

This year, once again, we will be able to exchange and discuss the latest theranostic advances, the most impactful clinical evidence, the most recently developed radiopharmaceuticals, and the most novel imaging and detection technologies. This is only possible because you send your most exciting works, your most original ideas, and your most accomplished results to the congress team, and I thank you once again for it.

This year, we will highlight with renewed emphasis our partnerships with clinical societies, with whom we work hand in hand to ensure that all patients can benefit from a timely diagnosis and an effective treatment.

We focus specifically on facilitating interactions and exchanges across disciplines, competences, and generations. Indeed, in my vision, one central mission of the EANM's annual congress is to motivate and inspire the youngest members of our community, who will be shaping the future of our field. The only everlasting element in our discipline is change, making adaption essential to guarantee our continued success. This can only be achieved with the contribution and active involvement of younger specialists and collaborators, who will bring our developments and advances forward. New communications technologies also play a pivotal role in knowledge sharing. This is why the online material will be made accessible during and after the congress, to reach the largest possible audience.

For all these reasons, I want to thank you already because I know that each and every one of you in your daily clinical, research, and teaching practice is preparing the content that will be discussed at the EANM'24. Rest assured that from our side, we are doing our best to prepare everything adequately and provide you with the most exciting platform.

I look forward to seeing you in Hamburg!

Valentina Garibotto
EANM Congress Chair 2023–2025

Saturday, October 19, 2024

OP-013

Influence of amino acid chains in mercaptoacetyl-based chelator on biodistribution properties of PSMA inhibitors labelled with 99mTc

E. Bezverkhniaia, *P. Kanellopoulos, U. Rosenström, V. Tolmachev, A. Orlova;*
Uppsala university, Uppsala, SWEDEN.

Aim/Introduction: Development of diagnostic imaging agents for SPECT is needed due to large numbers of cancer patients. Earlier, we have designed EuK-based PSMA ligand [99mTc]Tc-BQ0413 with maEEE chelator [Bezverkhniaia 2023]. It showed efficient tumor targeting, but preclinical and preliminary clinical data have indicated high renal activity accumulation. We hypothesized that it could be reduced by decreasing of ligand's total negative charge, e.g. by substituting glutamate in the chelator with polar serine. We aimed to evaluate the tumor targeting and biodistribution of two new constructs containing maESE and maSSS chelators compared to maEEE in BQ0413. ***Materials and Methods:*** Constructs were radiolabelled with 99mTc using transchelation from gluconate. Labelling stability was evaluated in vitro. In vitro PSMA-binding specificity, cellular processing and binding kinetics were evaluated using PSMA-transfected PC-3.pip cells. Biodistribution was measured in NMRI mice; tumor targeting properties, in vivo specificity and imaging were obtained in xenografted BALB/c nu/nu mice. ***Results:*** New constructs were radiolabelled with radiochemical yield above 95%. The label was stable during 1 h in 300-molar excess of L-cysteine and PBS at room temperature. The octanol-water distribution coefficient showed similar logD values for all three tracers, suggesting that chelator modification did not result in a shift of hydrophilicity. The binding to PC-3.pip cells was PSMA mediated. The internalized fraction was approximately 35% after 8 h. The equilibrium dissociation constants were in picomolar range for new peptides, but worse than for BQ0413. The biodistribution profile demonstrated rapid clearance from all organs and tissues (excluding kidneys). Major clearance was through glomerular filtration. Construct containing maSSS chelator demonstrated the lowest kidney uptake, but higher hepatobiliary excretion, resulting in elevated uptake of activity in gastrointestinal tract compared to other constructs. At the same time BQ-maSSS has demonstrated the highest tumor uptake (35±4%IA/g vs 31±4%IA/g for peptide with maESE and 17±3%IA/g for BQ0413) and the most optimal tumor-to-background ratios, e.g. tumor-to blood ratio for maSSS, maESE and maEEE variants were 300±160, 109±21, 94±3 respectively. In vivo targeting was dependent on PSMA expression in PC3-pip (PSMA+) and PC-3 ($PSMA^-$) xenografts. SPECT/CT imaging has demonstrated that tumors could be visualized already 1 h post injection. ***Conclusion:*** PSMA-targeting peptides containing maESE and maSSS chelators can be easily radiolabelled with technetium-99m using techniques permitting development of a single-vial kit. [99mTc]Tc-BQ-maSSS has demonstrated optimal PSMA-targeting properties and biodistribution profile favourable for imaging shortly after administration. ***References:*** 1. Bezverkhniaia et al. International Journal of Molecular Sciences (Basel). 2023,24:17391.

OP-014

Novel CAIX radioligands for molecular imaging of clear cell renal cell carcinoma

H. Comas Rojas*[1]*, *N. Clemons[1], M. H. Lee[2], H. Chen[3], B. Dyck[3], J. R. Young[3], D. D. Shapiro[4], E. J. Abel[4], R. Hernandez[1];*
[1]Department of Medical Physics, University of Wisconsin-Madison, Madison, WI, UNITED STATES OF AMERICA, [2]University of Wisconsin-Madison, Madison, WI, UNITED STATES OF AMERICA, [3]WARF Therapeutics, Madison, WI, UNITED STATES OF AMERICA, [4]Department of Urology, University of Wisconsin-Madison, Madison, WI, UNITED STATES OF AMERICA.

Aim/Introduction: Carbonic Anhydrase IX (CAIX) is selectively overexpressed in the cell membrane of over 95% of aggressive Clear Cell Renal Cell Carcinomas (ccRCC), making it an attractive tumor-specific antigen for diagnosis and therapy. Despite the striking homology between CAIX and other CA isoforms, we identified several novel chemotypes showing high CAIX potency and selectivity to develop as radiopharmaceuticals for ccRCC imaging. ***Materials and Methods:*** Sulfonamide-based CAIX binders were synthesized, and CAIX binding affinity, kinetics, and half-life were characterized by surface plasmon resonance (SPR). Cellular potency was corroborated by a competitive binding assay in CAIX-expressing SK-RC-52 ccRCC cells. For binders showing high affinity (Kd<0.1 nM) and selectivity (>100X), 111In or 68Ga radioligands were synthesized, and in vivo distribution was assessed by SPECT/CT or PET/CT imaging. Mice bearing subcutaneous SK-RC-52 xenografts or patient-derived xenografts (PDX) derived from ccRCC tumors were intravenously injected 7.0±3.0 MBq of radiotracer and images acquired at 1h and 24h post-injection (p.i.). Region of interest analyses of the images and ex vivo biodistribution, following the last imaging time point, quantified tumor, and normal tissue uptake as injected activity per gram of tissue (%IA/g; mean±SD). ***Results:*** We synthesized and screened over 700 compounds in 3 general structural classes. SPR identified over 50 promising binders and tracer candidates with high affinity, CAIX selectivity (>100x selective against CAIV, CAXII and CAXIV), and a broad range of receptor occupancy half-lives. Further screening using an in vitro competitive cell-binding assay identified about a dozen binders and tracers exhibiting exquisite potency (<5 nM) in CAIX-expressing SK-RC-52 cells. Longitudinal in vivo SPECT/CT imaging showed elevated tumor accumulation (20-40 %IA/g at 1 h p.i.) for several radiotracers. The 111In-labeled lead tracer candidate WT-735-0626, [111In]In-626, showed rapid tumor uptake kinetics (30.3±1.0 %IA/g at 1 h p.i.) and elevated peak uptake as 45.3±1.8 %IA/g at 24 h p.i. Mice bearing ccRCC PDXs displayed rapid tumor uptake and fast clearance of [111In]In-626. [68Ga]Ga-626 PET/CT imaging of SK-RC-52 tumors showed excellent uptake as 15.0±4.0 %IA/g and fast renal clearance, leading to tumor/normal kidney contrast of 1.3 at 1 h p.i. Except for the kidneys and CAIX-expressing stomach, overall normal tissue uptake was low. ***Conclusion:*** We successfully synthesized several exquisitely potent and CAIX-selective radioligands displaying unprecedented imaging properties, such as fast and elevated tumor uptake and rapid normal tissue clearance. [68Ga]Ga-626 showed promising properties as a PET/CT imaging radiotracer, warranting our efforts toward its clinical translation in ccRCC.

OP-015

Dansylated Amino Acid Derived $^{68}Ga/^{177}Lu$-LNC1011 as Prostate Cancer Theranostics

H. Yang[1], *X. Wen[2], H. Guo[1], J. Zhang[2], Z. Zhou[1], X. Chen[2];*
[1]Xiamen University, xiamen, CHINA, [2]Department of Diagnostic Radiology, Yong Loo Lin School of Medicine and Faculty of Engineering, National University of Singapore, Singapore, SINGAPORE.

Aim/Introduction: Targeting prostate-specific membrane antigen (PSMA) with radioligands has demonstrated promising potential in the treatment of metastatic castration-resistant prostate cancer (mCRPC). This study aims to develop PSMA-targeted radioligands by incorporating dansylated amino acids as weak albumin binders to significantly increase tumor accumulation while preserving diagnostic efficiency. This approach allows for a comprehensive investigation that combines diagnosis and therapy within a single molecular framework. ***Materials and Methods:*** The binding affinities of dansylated amino acids (Dan-Gly,Dan-Nva, and Dan-Phe) with human serum albumin (HSA) were determined using biolayer interferometry by interaction with biotinylated HSA. Binding affinity and PSMA targeting specificity were investigated using saturation binding assay and cell uptake in PSMA-positive PC-3 PIP cell. PET imaging in PC-3 PIP tumor-bearing mice were performed to evaluate preclinical pharmacokinetics and diagnostic efficiency of 68Ga-labelled PSMA ligands to select optimum radioligand. Tumor uptake of 177Lu-LNC1011 were evaluated through SPECT/CT imaging and biodistribution studies. Radioligand therapy studies were conducted to systematically assess the therapeutic effect of 177Lu-LNC1011. Additionally, 68Ga-LNC1011 PET imaging demonstrated the distribution in human organs and tumor at various time points. ***Results:*** 68Ga-Dan-Gly-PSMA, 68Ga-Dan-Nva-PSMA and 68Ga-Dan-Phe-PSMA (denoted as 68Ga-LNC1011) were successfully synthesized with >97% radiochemical yield (Figure A). The HSA binding affinity of Dan-Phe (3.21 ± 0.18 μM) was substantially higher than that of Dan-Gly (10.44 ± 2.31 μM, $P < 0.001$) and Dan-Nva (10.88 ± 1.17 μM, $P < 0.001$) (Figure B). Saturation binding assay demonstrated a high binding affinity of 68Ga-LNC1011 (Kd = 15.91 ± 4.26 nM) for PSMA (Figure C). PET and SPECT imaging of 68Ga-LNC1011 and 177Lu-LNC1011 revealed favorable pharmacokinetics and distinguished prominent tumor-to-nontarget ratios (Figure D-H). Biodistribution studies confirmed the significantly higher tumor uptake of 177Lu-LNC1011 (127.36 ± 16.95 %ID/g) over 177Lu-PSMA-617 (17.44 ± 6.29 %ID/g) at 4 h post-injection. Furthermore, there was no notable decrease in the tumor uptake of 177Lu-LNC1011 within 72 h (Figure I). Radioligand therapy results demonstrated a noteworthy inhibition of tumor growth after administration of a single dose of 18.5 MBq 177Lu-LNC1011 (Figure J). Compared to 68Ga-PSMA-11, which detected 35 lesions in three patients, 68Ga-LNC1011 detected an equivalent number of lesions. The SUVmax values were 17.23, 24.97, 34.10, 37.23, and 45.40 at 10, 30, 60, 90, and 150 min, respectively (Figure K). ***Conclusion:*** 68Ga/177Lu-LNC1011, characterized by high tumor uptake and timely clearance from background organs, emerges as a promising candidate for a single-molecule theranostic radioligand in preclinical and clinical.

OP-016

PET Evaluation of Oligonucleotide Structural Effects on Tumor Targeting in HCC1954 Breast Cancer Xenografts

T. Auchynnikava[1,2], *A. Äärelä[2,3], O. Moisio[1], H. Liljenbäck[1,4], P. Andriana[1], I. Iqbal[1], J. Lehtimäki[3], J. Rajander[5], H. Salo[3], P. Virta[2], A. Roivainen[1,4,6], A. J. Airaksinen[1,2];*
[1]Turku PET Centre, University of Turku, Turku, FINLAND, [2]Department of Chemistry, University of Turku, Turku, FINLAND, [3]Research and Development, Orion Pharma, Turku, FINLAND, [4]Turku Center for Disease Modeling, University of Turku, Turku, FINLAND, [5]Accelerator Laboratory, Åbo Akademi University, Turku, FINLAND, [6]InFLAMES Research Flagship, University of Turku, Turku, FINLAND.

Aim/Introduction: Positron emission tomography (PET) is a valuable tool for developing novel therapeutics. It enables quick scanning of various structures to identify one with the most beneficial properties. However, PET requires straightforward and reproducible radiolabeling methods. Click chemistry between tetrazine and trans-cyclooctene (TCO) in this context is a great approach. Here, we utilized 2-[18F]fluoro-2-deoxy-d-glucose conjugated tetrazine ([18F]FDG-Tz)1 to demonstrate the beneficial properties of molecular spherical nucleic acids (MSNAs), highly oriented nanostructures, over linear oligonucleotides (ONs). Additionally, we aimed to evaluate the structural properties affecting their biodistribution. For these purposes, six 18F-labeled MSNA structures were evaluated in HCC1954 tumor-bearing mice and compared to ONs. Influence of folate as a targeting moiety, the effect of phosphodiester (PO) vs. phosphorothioate (PS) backbones, and the percentage of TCO-load were evaluated. ***Materials and Methods:*** [18F]FDG-Tz was synthesized via oxime formation between glucose-free [18F]FDG and aminooxy-derived phenyltetrazine.1 MSNAs were prepared via strain-promoted azide-alkyne cycloaddition between an azide-modified [60] fullerene core and bicyclo[6.1.0]nonyne-modified ONs.2 TCO-PEG4-NHS was used for TCO functionalization, while N-hydroxysuccinimidyl ester was utilized for folate decoration. Dynamic 60-minute PET/CT imaging was conducted in 8-10 weeks old female Rj:Athymic-FOXN1nu/nu mice bearing subcutaneous HER2-expressing HCC1954 tumors after intravenous tracer administration. After imaging animals were euthanized, organs of interest were harvested and measured, and tumors were collected for cryosectioning and in vitro studies. ***Results:*** The biological evaluation revealed notable advantages of MSNAs over linear ON in significantly lower kidney uptake and higher tumor-to-muscle ratios observed across most MSNA structures. Introducing a PS backbone decreased nuclease degradation, prolonging blood circulation and consequently enhancing tumor uptake for [18F]MSNA-PS compared to [18F]MSNA-PO. In addition, the backbone determined the elimination route, with PO backbone structures primarily undergoing urinary excretion, while PS backbone structures tended to accumulate in the liver. Furthermore, folate decoration resulted in increased tumor-to-muscle ratio compared to non-folate structures, suggesting FRs binding, which was confirmed through in vitro binding and blocking study. Additionally, increasing the TCO-load altered the hydrophilicity of the molecules' surface, influencing its biodistribution. ***Conclusion:*** The developed radiolabeled method allowed us to successfully demonstrate the beneficial properties of MSNAs over linear ON and to study the structural effects on biodistribution. ***References:*** 1. T. Auchynnikava et al., ACS Omega. 8, 45326-45336 (2023). 2. A. Äärelä et al., Mol. Pharm. 20, 5043-5051 (2023).

OP-017

Annotating the distribution of stem cell-derived macrophages in non-human primates by PET/CT.

R. Hernandez, *N. Clemons, S. D'Souza, A. Thickens, L. Lambert, J. Kink, E. Aluicio-Sarduy, A. Pinchuk, J. Engle, I. Slukvin; University of Wisconsin-Madison, Madison, WI, UNITED STATES OF AMERICA.*

Aim/Introduction: Cell therapies, such as therapeutic macrophages (Mφ), are hampered by the limited availability of these cells at scale. Deriving macrophages from induced pluripotent stem cells (iPSC) addresses supply concerns, but whether iPSC-derived macrophages (iMφ) cells traffic similarly to autologous cells in vivo remains unknown. Herein, using innovative radiochemistry, we tracked iMφ biodistribution in mice and non-human primates (NHP) by PET/CT. ***Materials and Methods:*** Monocyte radiolabeling with 89Zr involved direct Deferoxamine (DFO) conjugation to oxidized cell-surface glycans using NaIO4. The process was optimized using immortalized U937 monocytes. Oxidized cells (1-5x106) were incubated with aminooxy-DFO (AOD: 200 µM) in aniline (10 mM), then radiolabeled with 89Zr (33-37 MBq). Cell viability was measured at each step via trypan blue staining, and radiochemical yield and purity were determined via iTLC. For imaging studies, human peripheral blood CD14+ Mφ (HPB-Mφ) or NHP iPSCs (NHP-iMφ) were radiolabeled, and [89Zr]Zr-HPB-Mφ (4.6x105 cells, 3.3 MBq) or [89Zr]Zr-NHP-Mφ (1.3-1.5x106 cells, 4.6-5.6 MBq) were injected IV in NSG mice (N=6) and serial PET/CT imaging was performed at 2, 24, 72, 144 and 192 h p.i. Mauritius macaques (N=2) were given [89Zr]Zr-NHP-Mφ 11.1 MBq (~2x106) IV and scanned in a clinical PET/CT scanner at 0.5, 24, 72, and 168 h p.i. Region-of-interest (ROI) analysis data was reported as percent injected activity per gram (%IA/g) or standardized uptake values (SUVmean). ***Results:*** Mφ were efficiently radiolabeled with 89Zr (4.3-7.1 MBq per 1x106 cells) with excellent purity (93-95%) and viability (>75%). Mice administered [89Zr]Zr-HPB-Mφ or [89Zr]Zr-NHP-iMφ showed similar in vivo biodistribution with initial cell accumulation in the lungs (25.6±5.1 vs. 21.9±10.2 %IA/g) and liver (39.7±2.8 vs. 42.5±6.5 %IA/g) at 2h followed by redistribution to the liver (41.5±3.8 %IA/g) and spleen (6.85±0.5 vs. 10.7±0.96 %IA/g) at 168h. Similarly, [89Zr]Zr-NHP-iMφ distribution in NHP displayed initially elevated lung (10.5±3.3 SUVmean), liver (25.2±1.1 SUVmean), and spleen (18.3±5.0 SUVmean) accumulation at 30 min p.i. Later time points revealed a steady decline in lung activity and stable signal in the liver and spleen at day 7. Overall, negligible normal tissue uptake and minimal whole-body radioactivity excretion in both mice and NHP indicated cell persistence and excellent radiolabel stability in vivo. ***Conclusion:*** Our 89Zr radiolabeling protocol showed unprecedented efficiency and biocompatibility, allowing in vivo tracking of multiple macrophage subtypes. PET/CT studies in Mauritius macaques evidenced the clinical utility of our tracking methodology and the potential of iPSC-derived therapeutic Mφ.

OP-018

Population Pharmacokinetic Model to Assess Bone Marrow Absorbed Dose after ^{177}Lu-DOTATATE Administration

L. O. Dierickx[1], *M. Lambert[2], S. Brillouet[1], D. Vallot[1], L. Vija[1], F. Courbon[1], J. Texier[1], M. Krim[3], E. Chatelut[2]; [1]Institut Claudius Regaud, Institut Universitaire de Cancer Toulouse-Oncopole, Toulouse, FRANCE, [2]Centre de recherche en cancérologie de Toulouse, Toulouse, FRANCE, [3]CHU Toulouse, Hôpital de Rangueil, Toulouse, FRANCE.*

Aim/Introduction: Lutetium-177 (177Lu)-Dotatate (Lutathera®) is a peptide receptor radionuclide therapy (PRRT) used to treat unresectable or metastatic somatostatin-receptor-positive (SSTR) gastroenteropancreatic neuroendocrine tumors (GEP-NET). PRRT may induce early and late hematological toxicity. The aim of our monocentric study is to determine bone marrow absorbed dose by simultaneously analysing plasma and imaging data with PKPOP modeling and to compare them with results obtained by standard practices using image-based dosimetry in our institution. ***Materials and Methods:*** Patients with GEP-NET were treated with PRRT between May 2015 and December 2021. Nine blood samples (5 mL) were collected at each cycle: at the end of 177Lu-Dotatate infusion and 1, 2, 4, 8, 16, 24, 72, and 144 h post-dose. Radioactivity was measured using a WIZARD 2 2480-0010 Gamma Counter. These data were used to calculate area-under-the-curve of 177Lu-Dotatate plasma (AUCBL) and bone marrow (AUCRM) concentrations by PKPOP approach using Nonlinear mixed-effects modeling with NONMEM®. The medullary absorbed dose (ADref) was calculated by dosimetric approach using PlanetDose®. AUCBL and AUCRM were converted to absorbed dose using Medical Internal Radiation Dose (MIRD) formalism to resp. ADBL and ADRM. Generated plots were observed (OBS) versus population (PRED) and individual (IPRED) predicted concentrations ***Results:*** 111 patients of which 71 were included with bone marrow data. For the 15 patients with imaging dosimetry, 14 AUC were available at cycle 1 and 6 AUC at cycle 4, corresponding to a total of 20 cycles. 2139 plasma concentrations are included in the PKPOP model. Goodness-of-fit plots show that the PRED and IPRED concentrations concurred with OBS data for plasma and bone marrow concentrations. The mean [range] at cycle 1 was : AUCBL = 4547 MBq/L.h [1987 - 7036] and AUCRM = 4362 MBq/L.h [1907 - 6389]. The mean [range] of ADref = 0.044 Gy [0.021 - 0.087] at cycle 1 and 0.048 Gy [0.031 - 0.067] at cycle 4. The mean [range] of ADBL = 0.030 Gy [0.013 - 0.044] and of ADRM = 0.029 Gy [0.012- 0.042]. The mean [range] percentage of difference between absorbed dose as determined by PkPOP vs dosimetry was -31.8 % [-75 ; 19]. ***Conclusion:*** These results suggest that the population pharmacokinetic approach can be used to determine bone marrow absorbed dose. Moreover, this model can be based on plasma data only, and does not require imaging data. This new approach can allow for more robust and practical monitoring of bone marrow exposure.

OP-019

Real-time characterization of ^{177}Lu-DOTATATE binding, internalization and excretion

S. Lundsten Salomonsson[1,2], *H. Berglund[1], M. Nestor[1], S.* Bondza[1,2]; *[1]Uppsala University, Uppsala, SWEDEN, [2]Ridgeview Instruments AB, Uppsala, SWEDEN.*

Aim/Introduction: The efficacy of molecular radiotherapy is influenced by the cellular binding and retention of the compounds. Methods to determine these characteristics are cumbersome, therefore this study aimed to develop a new methodology to deepen the knowledge of 177Lu-Tyr3-DOTA-octreotate (177Lu-DOTATATE) binding, internalization, and excretion on cancer cells in vitro. ***Materials and Methods:*** The interaction between 177Lu-DOTATATE and U2OS-SSTR cells was studied in real-time at 37oC with varying concentrations and incubation times. Non-internalizing controls were performed at 8oC, or by addition of 0.5M sucrose. The obtained real-time interaction curves were analysed with kinetic binding models to evaluate binding rate constants

as well as internalization. The distribution between internalized and membrane-bound 177Lu-DOTATATE was quantified using a manual acid wash assay and an acid wash step was also implemented into the real-time binding assay. Furthermore, additional inhibitors of receptor trafficking were applied to investigate intracellular sorting of the ligand-receptor complex. ***Results:*** The kinetic modelling of 177Lu-DOTATATE interacting with U2OS-SSTR cells revealed two main interactions with differing dissociation rates, representing binding and internalization. Different modelling approaches gave similar binding kinetics with an association rate of 3.1-8.8*104 M-1s-1 and dissociation rate of 2.8-15*10-4 s-1 resulting in an affinity of 6.8-50.9 nM. The internalized fraction at 4 hours was predicted to be 75-88% which was in good agreement with manual acid wash data. Inhibition of internalization resulted in a drastic reduction of ligand uptake, supporting the results for the binding rate constants and internalized fraction. However, kinetic modelling seemed to over-estimate the amount of internalized 177Lu-DOTATATE for early time points, presumably due to re-binding effects. Negating re-binding by addition of unlabelled DOTATATE decreased the amount of cell-associated 177Lu-DOTATATE more than expected, implying excretion of the internalized fraction. Removing surface-bound receptors by acid wash reversed this effect, suggesting that 177Lu-DOTATATE excretion is depended on the presence of cell-surface bound ligand. ***Conclusion:*** This data exemplifies how combining real-time binding assays with kinetic modelling and acid wash procedures allows quantification of cellular binding, internalization as well as excretion of radiopharmaceuticals. Deepening the understanding of sub-cellular localization and dynamics of radiopharmaceuticals can improve several aspects of radionuclide therapy, including decision-making in drug development and dosimetry calculations.***References:*** Nonnekens J, et. al. OP-020

Impact of molar activity on [^{203}Pb]Pb-VMT-α-NET biodistribution profile in mice bearing neuroendocrine tumor xenograft

D. Liu[1], *M. Li[1], Z. Dai[2], B. Cagle[1], S. Rodman[1], F. Johnson[1], M. Puhlmann[1], M. K. Schultz[1,2];*
[1]Perspective Therapeutics Inc, Coralville, IA, UNITED STATES OF AMERICA, [2]University of Iowa, Iowa City, IA, UNITED STATES OF AMERICA.

Aim/Introduction: Hematotoxicity limits radiopharmaceutical therapy (RPT) targeting SSTR2. Somatostatin agonists and antagonists bind to bone marrow cells and lymphocytes in humans and mice. Therefore, these radiotherapeutics have the potential to induce hematoxicity. The molar activity (MA) of a given RPT impacts radioactivity absorbed dose to normal tissues and tumors by changing the "hot" to "cold" stoichiometry. Here, we aimed to develop understanding of how the MA of SSTR2 agonist [203Pb] VMT-α-NET (an imaging surrogate for [212Pb]VMT-α-NET) impacts its biodistribution in tumor-free and SSTR2+ tumor bearing mice. These studies provide insights into how MA can be modified to change bone marrow radiation dose and potentially limit the risk of hematotoxicity. ***Materials and Methods:*** [203Pb]Pb-VMT-α-NET was radiolabeled according to established methods and adjusted to MA of 0.148 -155.4 MBq/nmol. 74 kBq of [203Pb]Pb-VMT-α-NET was administered to CD1 Elite mice, or athymic nude mice bearing AR42J tumor xenografts. 1.85 MBq of [203Pb]VMT-α-NET was administered for sequential planar gamma-eye imaging. Organs and tissues were collected at different time points and normalized to %ID/g. ***Results:*** In CD-1 mice (at 14.8 MBq/nmol) [203Pb]Pb-VMT-α-NET accumulated in kidneys, but was excreted rapidly (13.127 %ID/g at 1 hour and 0.175% ID/g at 24 hours). There was moderate uptake in lung, adrenal glands, pancreas, and bones. When [203Pb]Pb-VMT-α-NET was administered at 18.5 MBq/nmol in AR42J-bearing mice, a similar biodistribution profile was observed, with high accumulation in kidneys (37.268 %ID/g and 1.678 ID/g), and tumor (13.469 %ID/g and 8.249 %ID/g at 1 hour and 24 hours, respectively. [203Pb]Pb-VMT-α-NET administered at 155.4, 18.5, 0.74 or 0.148 MBq/nmol revealed that lower MA resulted in significant lower bone marrow uptake, but comparable tumor uptake at 1,3,6 hours, except at 24 hours where the tumor uptake dropped 40% for the 0.148 MBq/nmol group. When tumor-bearing mice were administered 1.2 nmol of [203Pb]Pb-VMT-α-NET as compared to 12 pmol, tumor uptake of 1.38%ID/g and 4.85 %ID/g, and bone uptake of 0.022 %ID/g and 0.138 %ID/g, respectively at 27-hour post-injection were observed. ***Conclusion:*** The MA of [203Pb]VMT-α-NET impacts the uptake in low-SSTR2 expressing organs. Results suggest that a "sweet spot" of total injected mass of [203Pb]VMT-α-NET (<0.5 nmol) can be found in which tumor to normal ratio can be optimized. These findings provide a potential new strategy that could be used to optimize this aspect of RPT.

2-$^{[18F]}$FDG µPET/CT reveals the direction of glucose distribution in mice receiving peritoneal dialysis fluids

E. Patronas, *R. Herzog, F. Eibensteiner, C. Aufricht, L. Breyer, J. Stanek, T. Wanek, U. Ustsinau, S. Gruenert, M. Hacker, C. Philippe; Medical University of Vienna, Vienna, AUSTRIA.*

Aim/Introduction: Peritoneal dialysis (PD) as renal replacement therapy is a cost-effective and patient-friendly alternative to hemodialysis (1). However, instilled PD fluids are generally hypertonic glucose-based solutions that, over time, can lead to reduced ultrafiltration capacity, and treatment failure due to peritoneal inflammation and fibrosis (2). Although PD has been applied since the 1960s, the distribution and kinetics of glucose upon PD fluid instillation are unclear. Understanding these mechanisms could help to optimize PD and reduce treatment failure. ***Materials and Methods:*** Approximately12 week old female, healthy C57BL/6 mice (fasted for 4 hours) were injected intraperitoneally with around 10 MBq 2-$^{[18F]}$FDG in either 2 mL ELO-MEL (vehicle group) or PD fluid containing 3.86% glucose (PD group) (n=3 each). Subsequently, 60 min dynamic µPET and anatomical CT data were acquired. At the end of the procedure, mice were euthanized and organs of interest were harvested for gamma counter measurements. Dynamic tracer uptake data was evaluated using a dedicated image quantification software. ***Results:*** In the liver of vehicle group animals, 2-$^{[18F]}$FDG uptake started earlier, reaching a low plateau already after approximately 4 min post injection, whereas a higher plateau was reached after 16 min in the PD group. The summed liver SUVaver of the last 7 time frames (9-55 min) of the PET scan was significantly higher in the PD group (1.08 ± 0.17 vs. 0.76 ± 0.06 in the vehicle group, $p = 0.038$). In gamma counter measurements, a trend towards increased 2-$^{[18F]}$FDG uptake was observed in the PD group for liver and kidneys. Conversely, there was a trend towards decreased 2-$^{[18F]}$FDG uptake in the other organs (stomach, spleen, pancreas, ileum, colon, brain, heart) when compared to the vehicle group.

Conclusion: Although 2-[18F]FDG was administered in a solution containing 77.2 mg glucose in the PD group, tracer uptake was boosted rather than reduced specifically in the liver. The dynamic 2-[18F]FDG uptake data from the liver and heart suggest that glucose from PD fluids may be reabsorbed from the peritoneum by an early and fast phase via the peritoneum viscerale, followed by a much slower resorption via the peritoneum parietale. Interestingly, this clearance pattern differed in time between the PD and vehicle group. Follow-up studies using a uremic PD mouse model and µPET/MR are planned to further characterize the observed effects. ***References:*** (1) P.K. Li, et al. (2017). Nat Rev Nephrol, 13. (2) R. Mehrotra, et al. (2016). J Am Soc Nephrol, 27.

Unravelling radiobiological and immunological mechanisms driving effective CAIX-TRT and ICI combination therapy

S. Kleinendorst[1], *M. Konijnenberg[1], G. Franssen[1], J. Molkenboer-Kuenen[1], K. Twumasi-Boateng[2], M. Wheatcroft[2], E. Oosterwijk[1], S. Heskamp[1];*
[1]RadboudUMC, Nijmegen, NETHERLANDS, [2]Telix Pharmaceuticals Ltd., Melbourne, AUSTRALIA.

Aim/Introduction: Preclinical studies have demonstrated the potential of combining targeted radionuclide therapy (TRT) and immune checkpoint inhibition (ICI). Understanding which factors determine treatment outcome is crucial for effective clinical translation. In our previous work we demonstrated complete therapeutic responses in a murine Renca-hCAIX tumour model using TRT with CAIX-targeting antibody hG250 combined with aPD-1/aCTLA4 ICI. Here, we aim to deepen our understanding of the underlying mechanisms driving this effective combination treatment by assessing 1) tumour RNA expression and 2) growth inhibition and survival after various combination strategies. ***Materials and Methods:*** Renca-hCAIX tumour-bearing mice were injected with 4 MBq [177Lu]Lu-DOTA-hG250 with or without aPD1/aCTLA4 ICI. Subgroups of mice were followed to monitor tumour growth and survival (n=10 mice per group), while other mice were sacrificed at pre-defined timepoints to assess the biodistribution and determine the tumour radiation absorbed dose (n=3 mice per group), and to perform profiling of tumours using bulk RNA expression analysis (murine PanCancer IO 360 Gene Expression Panel, NanoString Technologies, Inc.) (n=5-6 mice per group). ***Results:*** Biodistribution studies revealed high tumour uptake of [177Lu]Lu-DOTA-hG250 (66±7 %IA/g at 24h post-injection) with relatively low uptake in healthy organs, with the exception of the liver (11±0.3 %IA/g at 24h post-injection). Estimated tumour-absorbed radiation dose was 27±15 Gy. RNA pathway analysis in TRT-treated tumours indicated DNA damage repair induction. Other pathways represented overlapping effects of TRT and ICI, including IFN signalling, cytotoxicity, lymphoid compartment, and antigen presentation. Furthermore, dynamic changes in Ctla4, Pdcd1 (PD-1), and Cd274 (PD-L1) expression within the tumour were observed following ICI and combination treatment. Notably, the changing expression patterns of Ctla4 and Pdcd1 largely corresponded to patterns observed for T-cell infiltration using flow cytometry analysis. Ongoing experiments are focused on combining CAIX-TRT with distinct ICI dosing regimens. Mice are currently in the follow-up phase of the study, and so far data indicates the ICI dosing regimen influences outcomes. ***Conclusion:*** These findings provide valuable insights into the temporal dynamics and immune responses within the tumour microenvironment following TRT and ICI combination therapy. Based on these results, future research should prioritize investigating the role of specific immune cell subsets and optimizing treatment application, particularly focusing on dosing and timing strategies.

OP-023

The dose-reponse effects of the additional Auger and IC electrons of ^{161}Tb- compared to ^{177}Lu- labelled agonists and antagonists

K. Spoormans[1,2], *L. Struelens[1], K. Vermeulen[1], M. De Saint-Hubert[1], M. Koole[2], M. Crabbé[1];*
[1]SCK CEN, Mol, BELGIUM, [2]KU Leuven, Leuven, BELGIUM.

Aim/Introduction: Preclinical data have shown that 161Tb-labelled peptides targeting the somatostatin receptor (SSTR) are therapeutically more effective for peptide receptor radionuclide therapy (PRRT) compared to their 177Lu-labelled counterparts. To further substantiate this enhanced therapeutic effect, we performed cellular dosimetry to quantify the absorbed dose to the cell nucleus and compared dose-response curves to evaluate differences in relative biological effectiveness (RBE) in vitro. ***Materials and Methods:*** CA20948 cell survival was assessed after treatment with [161Tb]Tb- and [177Lu]Lu-DOTA-TATE (agonist) and with [161Tb]Tb- and [177Lu]Lu-DOTA-LM3 (antagonist) via a clonogenic assay. Cell binding, internalization and dissociation assays were performed up to 7 days to acquire time-integrated activity coefficients. Separate S-values for each type of particle emission (Auger/Internal Conversion (IC) electrons and β-particles) were computed via Monte Carlo simulations, while considering a concentric sphere model to mimic the CA20948 cell geometry. The implementation of more realistic cell geometries is ongoing. Once the absorbed dose to the cell nucleus was calculated, survival curves were fitted to the appropriate linear or linear-quadratic model and corresponding RBE were evaluated. ***Results:*** While the radiopeptides had an equal cellular uptake independent of the radionuclide, [161Tb]Tb-DOTA-TATE and [161Tb]Tb-DOTA-LM3 delivered a 3.6 and 3.8 times higher dose to the cell nucleus, respectively, compared to their 177Lu-labelled counterparts. This increased absorbed dose was mainly due to the additional emission of IC and not Auger electrons by 161Tb. When considering activity concentrations, cell survival curves showed a lower survival fraction for both [161Tb]Tb-DOTA-TATE and [161Tb]Tb-DOTA-LM3 compared to a labelling with 177Lu. After conversion to absorbed dose, no significant difference could be observed between the dose-response curves of 161Tb- and 177Lu-labelled DOTA-TATE, in line with corresponding RBE values. [161Tb]Tb-DOTA-LM3 showed a linear-quadratic dose-response, while [161Tb]Tb-DOTA-TATE showed only a linear dose-response, suggesting additional cell membrane damage by Auger electrons when using a SSTR-antagonist. ***Conclusion:*** The IC, rather than Auger electrons, emitted by 161Tb resulted in a higher absorbed dose to the cell nucleus and lower clonogenic survival for 161Tb-labelled DOTA-TATE and DOTA-LM3 compared to the 177Lu-

labelled analogues. In contrast, 161Tb- instead of 177Lu-labelling, did not result in a higher dose-response for DOTA-TATE while for [161Tb]Tb-DOTA-LM3 an additional quadratic response was observed. Due to this quadratic response, potentially caused by cell membrane damage, DOTA-LM3 is a more effective peptide compared to DOTA-TATE for labelling with 161Tb.

OP-024

Transcriptional repression of double-strand DNA damage repair potentiates targeted alpha therapy efficacy in advanced prostate cancer.

M. Bio Idrissou[1], *J. Tromp[1], A. Carston[1], E. Santos[2], Y. Medina[1], O. Kwon[1], H. Comas Rojas[1], L. Lambert[1], A. Pinchuk[3], A. Thickens[1], B. Bednarz[1], G. Iyer[2], R. Hernandez[1];*
[1]Departments of Medical Physics, University of Wisconsin-Madison, Madison, WI, UNITED STATES OF AMERICA,
[2]Department of Human Oncology, University of Wisconsin-Madison, Madison, WI, UNITED STATES OF AMERICA,
[3]Departments of Radiology, University of Wisconsin-MadisonDepartments of Medical Physics, University of Wisconsin-Madison, Madison, WI, UNITED STATES OF AMERICA.

Aim/Introduction: A significant proportion of metastatic castration-resistant prostate cancer (mCRPC) patients do not respond or relapse following 225Ac-PSMA targeted alpha therapy (TAT). Unfortunately, injected activity escalation is limited by severe xerostomia. Therefore, we investigated the ability of Bromodomain and Extraterminal protein inhibitors (BETi) to reduce the transcription of a network of double-strand DNA damage repair (DDR) genes and amplify the genomic instability driven by 225Ac radiation, thus enhancing the lethality of 225Ac-PSMA TATs in CRPC cells. ***Materials and Methods:*** We developed ART-101, a longer-acting PSMA-targeting molecule with protracted pharmacology, and employed 225Ac-ART-101 for our in vivo studies. In vitro, cytotoxicity was determined in PC3-PIP, LNCaP, and 22Rv1 cells treated with BETi (JQ1 or next-generation inhibitor ABBV-075: 0.3 nM-1 mM). Expression of the DDR genes BRCA1/2 and RAD51 were measured by qPCR 24 h-post treatment with JQ1/ABBV-075. In vitro Monte Carlo-based 225Ac dosimetry estimates enabled viability and clonogenic survival measurements in cells treated with 225Ac (0.03-1 Gy) or the combination 225Ac+JQ1/ABBV-075. γH2AX immunofluorescence staining was performed to confirm enhanced DNA damage by 225Ac+BETi. Therapy studies employed groups of 8-week-old nude male mice (n=5-10) bearing PC3-PIP xenografts treated with daily oral JQ1 (50mg/kg) or ABBV-075 (1 mg/kg) for 14 days, a single 225Ac-ART-101 (18.5 or 37 kBq) IV injection, or combined 225Ac-ART-101 + JQ1/ABBV-075. Tumor growth, overall survival, and toxicity events were recorded thrice weekly for up to 120 days. ***Results:*** 225Ac+JQ1 treatment showed marked ($p<0.02$) antiproliferative effects compared to 225Ac or JQ1 alone in all cell lines. The enhanced cytotoxicity of the 225Ac+JQ1 combination was corroborated in clonogenic survival assays using either JQ1 or ABBV-075. qPCR revealed significant repression of BRCA1/2, and RAD51 in JQ1 and 225Ac+JQ1 treatments, but not 225Ac alone. Increased γH2AX foci in 225Ac+JQ1-treated cells suggest that this treatment increases genomic instability, buttressing the rationale for the 225Ac and BETi combination. In vivo, 225Ac-ART-101 + JQ1 and 225Ac-ART-101 + ABBV-075 elicited a stronger tumor growth inhibition ($p<0.01$) compared to single treatments 225Ac-ART-101, JQ1/ABBV-075, or control, evidencing a potential synergism between 225Ac-ART-101 and BETi. Consequently, overall survival was significantly extended in the combination treatment arms. None of the therapeutic interventions resulted in attributable severe toxicities or death. ***Conclusion:*** DDR disruption through BETi proved a promising strategy to boost 225Ac's lethality in CRPC cells. Combining BETi with 225Ac-ART-101 or other TAT agents is mechanistically justified and merits further therapeutic optimization and toxicological evaluations toward its potential clinical implementation.

OP-025

Quantitative assessment of Relative Biological Effectiveness for^{177}Lu-DOTATATE versus External Beam Radiotherapy: Unveiling critical gaps in the current models?

G. Tamborino[1], *P. Engbers[1,2], T. Reuvers[1,2], T. de Wolf[2], M. Konijnenberg[1], J. Nonnekens[1];*
[1]Department of Radiology and Nuclear Medicine, Erasmus University Medical Center, Rotterdam, NETHERLANDS,
[2]Department of Molecular Genetics, Erasmus University Medical Center, Rotterdam, NETHERLANDS.

Aim/Introduction: This work aims to model the dose-response and dose-dependent relative biological effectiveness (RBE) of 177Lu-DOTATATE in comparison to external beam radiotherapy (EBRT) for cell survival in 3 cell lines. ***Materials and Methods:*** Geant4 was used to model 3 cell-lines, with different proliferation speeds and geometrical properties: GOT1 (spherical cells -2D bilayer clusters), NCI-H69 (spherical cells - 3D floating randomly shaped clusters) and U2OS (polygonal mesh shaped cells - isolated plated cells).177Lu-DOTATATE uptake (4h in medium) and subsequent excretion was assessed by performing cellular uptake assays. The MIRD formalism was adopted to determine the absorbed dose rate to cell nuclei. Cell death was assessed at day 7 of exposure for 0.1-1 MBq/ml of 177Lu-DOTATATE using cell survival assays. For comparison, response to 0.5-2Gy x-ray irradiation was measured. The linear (L), linear-quadratic (LQ), repairable-conditionally repairable (RCR) model were employed to fit the data. ***Results:*** The absorbed dose ranges for 0.1-1 MBq/mL of added activity were 0.2-1.3Gy (5-31 mGy/h), 0.98-1.78Gy (26-39 mGy/h) and 2.55-4.89Gy (30-53 mGy/h) for U2OS, NCI-H69 and GOT1, respectively. The dose rate heterogeneity due to cellular placement and cluster sizes caused a variation in maximum dose rate up to -43% and +66% for GOT1. The best fitting dose-response models ($R2 > 0.85$) following 177Lu-DOTATATE treatment were: RCR for U2OS ($a=3.5\pm0.8$/Gy, $b=0.98\pm0.26$/Gy, $c= 0.70\pm0.14$/Gy), LQ for NCI-H69 ($\alpha=0.03\pm0.10$/Gy, $\beta=0.09\pm0.07$/Gy2) and L for GOT1 ($\alpha=0.05\pm0.02$/Gy). In contrast, the EBRT dose-response was similar across all cell-lines ($\alpha = 0.24$-0.27 1/Gy), with significant additional sublethal damage for U2OS only ($\beta=0.22\pm0.06$ /Gy2).The RBE for U2OS followed an exponential decay behavior ($R2=0.99$), with RBE = 5.1 ± 1.7 at 0.1 MBq/mL and 60% survival and 0.5 ± 0.2 at 2.5 MBq/mL and 40% survival. Fitting linear dose-response models, the RBEmax was 0.43 ± 0.07 (range: 0.35-0.72) and 0.22 ± 0.02 (range: 0.18-0.29) for NCI-H69 and GOT1, respectively. However, the absorbed dose-RBE relationship was characterized by a non-linear, in first approximation quadratic, behavior for both cell-lines. ***Conclusion:*** We challenge the use of a constant, cell-line independent value to explain the radiobiological differences between 177Lu-DOTATATE and EBRT. Our results indicate an overkill effect at low dose rates, which might be obscured by biological and physical heterogeneity in the response. Establishing a novel mechanistic model, rather than empirical linear-quadratic dose-responses, is imperative to elucidate the cell-dependent interplay between maximum dose-rate levels and activation of repair mechanisms during 177Lu-DOTATATE therapy.

OP-026

In vitro comparative analysis of the neuroendocrine tumor response to peptide receptor radionuclide therapy and external beam radiotherap

J. Nonnekens, *T. Reuvers, J. Heredia-Genestar, J. Zink, G. Tamborino;*
Erasmus MC, Rotterdam, NETHERLANDS.

Aim/Introduction: Peptide receptor radionuclide therapy (PRRT) with [177Lu]Lu-DOTA-TATE shows promise in treating neuroendocrine tumors (NETs). However, enhancing clinical outcomes may be achieved by incorporating radiosensitizers. Understanding PRRT radiobiology is crucial for developing effective combination therapies. Currently, this knowledge is generally extrapolated from conventional external beam radiotherapy (EBRT), however this is probably not accurate due to the physical differences between these radiation types (e.g. timing, dose rate, absorbed dose). Here, we compared the NET cellular response to EBRT and PRRT and verified the potential effect of this response on the efficacy of several radiosensitizers between both radiation types. ***Materials and Methods:*** A direct comparative transcriptomic analysis was carried out between EBRT and PRRT in the NET cell line GOT1 using bulk mRNA-sequencing. Considering the central role of the DNA damage response (DDR) in the radiation response, we then performed a high throughput screen with DDR-/cell cycle-targeted compounds as potential radiosensitizers in the context of PRRT in GOT1 and NCI-H69 cells. Subsequently, the radiosensitizing potential of hit compounds was directly compared between EBRT and PRRT in both cell lines using cellular survival assays and dosimetric modeling with GEANT4. ***Results:*** EBRT and PRRT shared a large part of the induced transcriptomic radiation response, primarily involving DNA- and cell cycle-based pathways. However, PRRT exhibited a delayed peak response compared to EBRT. Identified targets for PRRT-based radiosensitization included DNA-PK, ATM, ATR, HSP90, PARP, and CDK2, with variable efficacy between cell lines. The radiosensitization potential of these inhibitors was comparable between EBRT and PRRT. ***Conclusion:*** Early transcriptomic responses and radiosensitizing potential were akin between EBRT and PRRT, with larger magnitude differences appearing at a later timepoint as could be expected by the type of radiation source. Variations in radiosensitization efficacy among cell lines underscore the need for further research into factors influencing radiosensitization in combination with PRRT for NETs.

OP-027

Enhancing [^{177}Lu]Lu-DOTA-TATE therapeutic efficacy in vitro by combining it with chemotherapy

S. Terry[1], *J. Zink[2], E. O'Neill[3], B. Cornelissen[4,3], J. Nonnekens[5], L. Livieratos[1], J. Cheng[1];*
[1]King's College London, London, UNITED KINGDOM, [2]Erasmus University Medical Center, Rotterdam, NETHERLANDS, [3]University of Oxford, Oxford, UNITED KINGDOM, [4]University Medical Center Groningen, Groningen, NETHERLANDS, [5]Erasmus University Medical Cente, Rotterdam, NETHERLANDS.

Aim/Introduction: Peptide receptor radionuclide therapy (PRRT) uses [177Lu]Lu-[DOTA0-Tyr3]octreotate ([177Lu]Lu-DOTA-TATE) to treat patients with neuroendocrine tumors (NETs) overexpressing the somatostatin receptor 2A (SSTR2A). It has shown significant short-term improvements in survival and symptom alleviation, but there remains room for improvement. Here, we investigated whether combining [177Lu]Lu-DOTA-TATE with chemotherapeutics enhanced the in vitro therapeutic efficacy of [177Lu]Lu-DOTA-TATE. ***Materials and Methods:*** Transfected human bone osteosarcoma (U2OS+SSTR2A, high SSTR2A expression) and pancreatic NET (BON1+STTR2A, medium SSTR2A expression) cells were subjected to hydroxyurea, gemcitabine or triapine for 24 hours at 37oC and 5% CO2. Cells then recovered for 4 hours prior to a 24-hour incubation with 0.7-0.9 MBq [177Lu]Lu-DOTA-TATE (25 nM) for uptake and metabolic viability studies. Controls included untreated SSTR2A-expressing cells and cells incubated with 177Lu or unlabelled DOTA-TATE, or treated with X-ray radiation. Non-SSTR2A-expressing cells were also incubated with [177Lu]Lu-DOTA-TATE. Finally, cells were harvested to assess cell cycle progression, SSTR2A expression, and cell size by flow cytometry. ***Results:*** Uptake of [177Lu]Lu-DOTA-TATE was SSTR2A-mediated and incubation of U2OS+SSTR2A cells with hydroxyurea, gemcitabine, and triapine enhanced uptake of [177Lu]Lu-DOTA-TATE from 0.2 ± 0.1 in untreated cells to 0.4 ± 0.1, 1.1 ± 0.2, and 0.9 ± 0.2 Bq/cell in U2OS+SSTR2A cells, respectively. Subcellular localisation remained mostly cytoplasmic. Cell viability post treatment with [177Lu]Lu-DOTA-TATE in cells pre-treated with chemotherapeutics was decreased compared to cells treated with [177Lu]Lu-DOTA-TATE monotherapy. For example, the viability of U2OS+SSTR2A cells incubated with [177Lu]Lu-DOTA-TATE decreased from 59.5 ± 22.3% to 18.8 ± 5.2% when pre-treated with hydroxyurea. Control conditions showed no reduced metabolic viability. Hydroxyurea, gemcitabine, and triapine increased SSTR2A expression and cell size in U2OS+SSTR2A and BON1+STTR2A cells. The S-phase sub-population of asynchronous U2OS+SSTR2A cell cultures was increased from 45.5 ± 3.3% to 84.8 ± 2.5%, 85.9 ± 1.9%, and 86.6 ± 2.2% when treated with hydroxyurea, gemcitabine, and triapine, respectively. ***Conclusion:*** Hydroxyurea, gemcitabine and triapine all increased cell size, SSTR2A expression, and [177Lu]Lu-DOTA-TATE uptake, whilst further reducing cell metabolic viability in U2OS+SSTR2A cells when compared to [177Lu]Lu-DOTA-TATE monotherapy. Further investigations could transform patient care and positively increase outcomes for patients treated with [177Lu]Lu-DOTA-TATE.

OP-028

Biodistribution of free francium-221 and bismuth-213 in tumour-bearing SCID mice after successful establishment of actinium-225/francium-221 radionuclide generator set-ups

S. Zitzmann-Kolbe[1], *Y. Remde[2], I. Moen[3], F. Suurs[3], B. Madas[4], S. Happel[5], C. Schatz[1], H. Taş[2], U. B. Hagemann[1], M. Benešová-Schäfer[2];*
[1]Bayer AG, Berlin, GERMANY, [2]German Cancer Research Center (DKFZ), Heidelberg, GERMANY, [3]Bayer AS, Oslo, NORWAY, [4]HUN-REN Centre for Energy Research, Budapest, HUNGARY, [5]TrisKem International, Bruz, FRANCE.

Aim/Introduction: Despite the success of first targeted alpha therapies in the management of highly resistant cancer diseases, optimised treatment regimens are nevertheless needed to improve overall survival rates and combat side-effects such as xerostomia or renal dysfunction. The factors accounting for the undesired non-targeted uptake to organs remain elusive and under investigation. The nuclear recoil effect of actinium-225 has been hypothesised to contribute to the non-targeted uptake, and francium-221 is a striking example of an unevaluated recoiling daughter radionuclide, mainly due to a lack of generator concepts for direct in vivo applications and its short half-life (4.8 min). Here, we report on the first successful application of an actinium-225/francium-221 generator concept using HDEHP-based LN2 resin. The biodistribution of successfully acquired francium-221 and its

daughter bismuth-213 were further evaluated in vivo. ***Materials and Methods:*** The elution of francium-221 was performed on a LN2-resin column. 225Ac(NO3)3 was loaded onto a column pre-conditioned with 0.1M HNO3. After a series of washes, multiple francium-221 elutions were performed with 0.1M NaOAc (pH 6.5) after sufficient francium-221 in-growth time of 25-30 minutes. The biodistribution of francium-221 and bismuth-213 was investigated in male SCID mice with LNCaP tumours. The mice were injected with single doses of francium-221 and bismuth-213 and sacrificed 5, 10, or 15 minutes post-injection. Uptake to organs was examined by gamma spectrometry measurements (high-purity germanium detector) and a gamma detector. ***Results:*** Our results indicate that LN2 is a highly potent resin for selective and consecutive francium-221 elutions. The application of 0.1M NaOAc facilitated a continuous pH equilibrium leaving additional pH adjustments for in vivo application unnecessary. The 25-minute intervals between elutions were ideal for obtaining high activity francium-221 with only minimal bismuth-213 contaminations. The biodistribution study revealed a very fast distribution of francium-221 and bismuth-213 with almost complete clearance in blood already after 5 minutes. We observed a strong accumulation of francium-221 to the kidneys (30-40% ID/g), salivary glands (20-30% ID/g) and small intestine (~10% ID/g), and accumulation of bismuth-213 to the kidneys and liver (10-20% ID/g). Other organs including tumours showed little to no accumulation. ***Conclusion:*** We present an unprecedented concept utilising LN2 resin in actinium-225/francium-221 generator applications. Successfully eluted francium-221 fractions were deployed in a biodistribution study, showing strong accumulation of francium-221 and bismuth-213 into key organs. Our data provide preliminary evidence of the potential contribution of recoiled (grand)daughter radionuclides to side-effects in non-targeted organs.

OP-029

Single Time point Dosimetry of ^{64}Cu-DOTA-rituximab using mean effective half-life

S. Woo[1,2], *M. Al-Maslamani[1,2], J. Yang[1], K. Kim[1], I. Lim[3], K. Lee[1];*
[1]Division of Applied RI, Korea Institute of Radiological and Medical Sciences, Seoul, KOREA, REPUBLIC OF, [2]Radiological & Medico-Oncological Sciences, University of Science & Technology, Daejeon, KOREA, REPUBLIC OF, [3]Department of Nuclear Medicine, Korea Institute of Radiological and Medical Sciences, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: Dosimetry for radionuclide therapy often involves multiple scans points (Tsc) to determine the time-integrated activity (TIA). However, this traditional dosimetry procedure causes additional data collection effort. The aim of this study was to investigate the feasibility of 64Cu-DOTA-rituximab dosimetry by using single time point (STP) scan. ***Materials and Methods:*** Four mice were intravenously injected with 50 µCi/100µl of 64Cu-DOTA-rituximab. Kinetics were assessed via gamma camera scans of heart, liver, lungs, spleen and kidney at 1, 2, 6, 24, 48 and 72 hours. The Effective half-life was calculated by fitting a mono-exponential function to the data measured in each organ. S-values were calculated using Monte Carlo approach. Two STP approaches (STP1 and STP2) that eliminate the patient-specific effective half-life (Teff) were utilized to calculate organ's absorbed doses. STP1 proposes that TIA can be calculated as $\tilde{A} = (A(Tsc)/\ln(2))\times 2Tsc$ indicating that if the Tsc remains within 0.75-2.5 times the Teff, errors in dose estimates would be below 10%. STP2 suggests that utilizing the population mean effective half-life (Teff-p) $\tilde{A} = (A(Tsc)/\ln(2))\times\exp(\ln(2)\times Tsc/Teff\text{-}p)\times Teff\text{-}p$ would improve the accuracy. The accuracy of each approach was evaluated in terms of error resulting from comparison with Multiple Time Point (MTP) dosimetry approach. ***Results:*** Effective half-lives of heart, liver, lungs, spleen and kidney have ranged from 22 to 33.8 (mean: 27.2), 22.5 to 36.7 (mean: 31.2), 22.8 to 39.8 (mean: 34.3), 26.2 to 41.3 (mean: 31) and 23.1 to 30.8 (mean: 26.1) hours, respectively. Absorbed dose showed significant errors at early and 72 hours for both approaches as compared to MTP. STP1 showed a maximum error of -95%, -90%, -73%, -22% and -32% at 1, 2, 6, 24 and 72 hours, respectively. The errors of STP2 were 48%, 47%, 41%, 17%, and -27% at 1, 2, 6, 24 and 72 hours, respectively. However, absorbed dose calculated from data collected at time point of 48 hours have an excellent agreement with MTP for both approaches, with error ranges of -0.51% to 6.1% in STP1 and 0.21% to -8% in STP2. Furthermore, the use of Teff-p notably enhanced the absorbed dose estimates by 3% to 6%. ***Conclusion:*** In this study, we investigated the feasibility of 64Cu-DOTA-rituximab STP dosimetry using two distinct STP approaches. Our results indicate that STP dosimetry for 64Cu-DOTA-rituximab is achievable at 48 hours scan time point. While both approaches exhibited low dose estimation errors at 48 hours, STP2 was superior with up to 6% improvement.

OP-030

Repair of DNA damage in PBMCs after mixed ex vivo irradiation with different mixtures of α- and β-emitters

I. Strobel[1], *H. Scherthan[2], S. Schumann[1], J. Müller[2], A. K. Buck[1], M. Port[2], M. Lassmann[1], U. Eberlein[1];*
[1]Department of Nuclear Medicine, University Hospital Würzburg, Würzburg, GERMANY, [2]Bundeswehr Institute of Radiobiology affiliated to the University of Ulm, Munich, GERMANY.

Aim/Introduction: The aim of this study was to investigate DNA damage and its repair in peripheral blood mononuclear cells (PBMCs) after ex vivo internal irradiation of whole blood with different mixtures of an α- and a β-emitter. ***Materials and Methods:*** Blood samples of 10 healthy volunteers were collected and divided in four aliquots each, of which one served as non-irradiated baseline. The remaining blood samples were incubated for 1 h with varying [223Ra]RaCl2 and [177Lu]LuCl3 activities to achieve total absorbed doses to the blood of 100mGy (ratio α-dose:β-dose 3:1, 1:1, 1:3). The PBMCs were then isolated and divided into 3 subsamples. These were fixed with ethanol either directly, or after culture in RPMI for 4 h or 24 h to analyse the time course of DNA repair. Immunostaining of DNA double-strand break (DSB) markers γ-H2AX and 53BP1 revealed co-localised DSB foci and γ-H2AX-positive α-tracks in the PBMCs' nuclei that were counted microscopically in 100 nuclei per sample. The repair was described by a monoexponential model: $(N(t)=N0\cdot((1-Q)\cdot\exp(-R\cdot t))+Q)$ (N0: max. number of induced tracks in 100 cells/RIF per cell, R: repair rate, Q: unrepaired fraction)[1]. ***Results:*** Mean β-doses of (26.7±1.2)mGy, (51.3±2.7)mGy, (75.7±3.1)mGy and the corresponding mean α-doses of (76.5±2.5)mGy, (50.6±1.8) mGy and (25.3±0.7)mGy were achieved. Directly after 1 h internal irradiation, the mean of the average number of radiation-induced foci (RIF) per cell were 0.65±0.18 (β-dose: 25mGy), 0.81±0.32 (β-dose: 50mGy) and 0.98±0.25 (β-dose: 75mGy). The mean of the number of α-tracks in 100 cells directly after internal irradiation were 5.9±2.2 (α-dose: 25mGy), 8.1±2.2 (α-dose: 50mGy), 13.1±3.1 (α-dose: 75mGy).The results showed comparable repair rates between mixed (Rβ: (0.25±0.12)h-1 (25 mGy), r2=0.49; (0.29±0.13) h-1(50 mGy), r2=0.53; (0.31±0.09)h-1 (75mGy), r2=0.75 and Rα: (0.22±0.07)h-1 (25mGy), r2=0.69; (0.16±0.05)h-1 (50mGy), r2=0.73; (0.26±0.05)h-1 (75mGy), r2=0.82) and single irradiation (Rβ,pure: (0.28±0.03)h-1 (50mGy)[1] and Rα,pure: (0.24±0.05)h-1 (25mGy),

(0.16±0.04)h-1(50mGy) [2]), for both RIF and α-tracks. However, mixed irradiation resulted in a higher proportion of unrepaired RIF per cell at 24 h (Qβ: 0.35±0.10 (25mGy), 0.23±0.10 (50mGy), 0.14±0.07 (75mGy)) compared to pure β-irradiation (Qβ,pure: (0.06±0.02) (50mGy)[1]). ***Conclusion:*** Mixed internal irradiation seems not to affect the repair rate of focal DNA damage. For the α-tracks, there is no difference between mixed and pure irradiation. However, a higher proportion of unrepaired RIF/cell at late time points was observed relative to pure β-irradiation, most likely caused by incomplete repair of α-induced DSB damage. ***References:*** [1] Schumann et al, EJNMMI, 2022 [2] Göring et al, EJNMMI, 2022

OP-031

A Preliminary Study on the Clinical Utility of ^{18}F-FES and ^{68}Ga-HER2-affibody in Patients with Metastatic Breast Cancer

C. Liu, *Z. Yang, S. Song;*
Department of Nuclear Medicine, Fudan University Shanghai Cancer Center, Shanghai, CHINA.

Aim/Introduction: The heterogeneity of breast cancer as a malignant tumor is characterized by significant variations in the expression of ER or HER2, posing a substantial challenge for the determination of their expression through biopsy. The purpose of this study was to investigate the utility of 18F-FES and 68Ga-HER2-affibody PET imaging for noninvasive assessment of ER and HER2 status in patients with metastatic breast cancer, aiming to enhance their clinical applicability. ***Materials and Methods:*** A total of 19 patients with metastatic breast cancer were enrolled. 18F-FES and 68Ga-HER2-affibody PET/CT were performed, and the interval between the two scans was not more than 1 month. A positive PET result is defined as a lesion showing higher uptake compared to the surrounding normal tissue. The identification and localization of all lesions need to be confirmed through 18F-FDG PET/CT or traditional imaging examinations. The SUVmax values of two tracers are measured to compare the relationship between PET uptake levels and receptor status using non-parametric testing, specifically the Mann Whitney U test. Additionally, this study aims to investigate the potential utility of 18F-FES and 68Ga-HER2-affibody PET/CT in guiding subsequent treatment. ***Results:*** A total of 226 lesions were found in 19 patients with metastatic breast cancer, of which 15 were liver metastases, and 18F-FES and 68Ga-HER2-affibody PET could not be evaluated (high biological uptake of liver). In total, 211 lesions were included in the analysis, with 92 (43.6%) lesions showing positive results in 18F-FES PET and 144 (68.2%) lesions showing positive results in 68Ga-HER2-affibody PET. The 18F-FES SUVmax of ER-positive patients was significantly higher than that of ER-negative patients among the 14 patients with metastatic biopsy pathology (median SUVmax: 4.1 vs. 1.0, P<0.001). However, there was no significant difference in the 68Ga-HER2-affibody SUVmax between HER2-positive and HER2-negative patients (median SUVmax: 3.6 vs. 3.4, P=0.901). It is noteworthy that among patients with 18F-FES positivity, 81.8% received endocrine therapy, while among those with 68Ga-HER2-affibody positivity, 61.5% received anti-HER2 therapy; the proportion was even higher in patients with 100% 18F-FES or 68Ga-HER2-affibody positive lesions at 88.9% and 80.0%, respectively. However, patients lacking 18F-FES or 68Ga-HER2-affibody positive lesions were not administered endocrine or anti HER2 therapy. ***Conclusion:*** The use of 18F-FES and 68Ga-HER2-affibody PET imaging enables the assessment of ER and HER2 status in patients with metastatic breast cancer, thereby providing valuable insights into the heterogeneity of receptor expression and potentially guiding subsequent treatment strategies.

OP-032

Prognostic Role and Importance of ^{18}F-FDG PET/CT in Patients with Breast Cancer:12-Year Experience

Z. Tosunoglu, *A. E. Ozturk, M. C. Baloğlu, R. Sahin, Ö. F. Sahin, E. Beyhan, Ö. Erol Fenercioglu, G. Alcin, N. Ergul, T. F. Cermik, E. Arslan;*
Istanbul Training and Research Hospital, Department of Nuclear Medicine, University of Health and Sciences, Turkiye, Istanbul, TÜRKIYE.

Aim/Introduction: The use of Fluorine-18 fluorodeoxyglucose positron emission tomography/computed tomography (18F-FDG PET/CT) in oncology is of increasing importance. The aim of this study is to investigate the role of parameters obtained from 18F-FDG PET/CT for staging in predicting the prognosis of patients with breast cancer. ***Materials and Methods:*** Totally 1250 patients 18-90 years who diagnosed with BC and underwent 18F-FDG PET/CT imaging between April 2009-June 2021 screened, and 333 patients (mean age: 54.7±14.03) complete data could accessed, retrospectively included in study. ^{18}F-FDG PET/CT images re-evaluated, and metabolic parameters SUVmax, SUVmean for primary lesions, axillary lymph nodes, and distant metastases were calculated. The relationship between parameters and clinicopathological features; histopathological-molecular subtypes, sizes, lymph node (LN) positivity, presence of distant organ metastasis, and progression-free survival (PFS), overall survival (OS) was evaluated. ***Results:*** 333 patients; 259 (77%) IDC, and 74 (23%) other invasive histopathological subtypes. Axillary LN metastasis was detected in 193, while distant nodal metastasis found in 67 cases. 140 patients had distant organ metastasis, while 193 patients were in a local or locally advanced stage. SUVmax of primary lesions calculated mean±SD: 12.20±8.73. Median follow-up period; 45.57±36.54 months (minimum: 0.33-maximum: 157.24 months), during which progression was observed in 115 (34%) and 151 patients died. Total OS calculated 51.75±36.54 months. PFS and OS were significantly shorter in axillary LN metastatic patients (p=0.04). There was no statistically significant relationship between primary lesion size and metabolic parameters with overall survival. A statistically significant relationship found between tumor size and SUVmax, axillary LN SUVmax, and PFS with p-values calculated as (<0.001, 0.01, 0.002) respectively. Correlations and p-values between tumor and axillary LN SUVmax, tumor size, OS, and PFS are given in Table 1. ***Conclusion:*** 18F-FDG PET/CT recommended in current guidelines for stage 3a (T3, N1, and M0) and more advanced cases. Although there are many parameters available to predict tumor prognosis, in our study, the role of PET metabolic parameters in predicting BC prognosis, especially PFS, has clearly defined with long follow-up period. In our study that PET parameters obtained from 18F-FDG PET/CT imaging at the staging phase can contribute to prognosis determination by revealing their importance in long-term patient follow-up.

OP-033

Comparison of Ga-68 FAPI PET/CT and F^{18}-FDG PET/CT in primary staging of breast cancer

M. Araz, *C. Soydal, E. Dursun, I. Mesci, C. Konca, E. Ozkan, M. K. Kır, N. O. Kucuk;*
Ankara University, Ankara, TÜRKIYE.

Aim/Introduction: To evaluate the role of Ga-68 FAPI PET/CT in breast cancer staging in comparison with F^{18}-FDG PET/CT. ***Materials and Methods:*** This prospective study was supported by Scientificand Technological ResearchCouncil of Turkey(TUBITAK) under the Grant Number 221N370.The authors thank TUBITAK for their supports. Following ethics committe approval, 29 breast cancer patients (28F,1M,mean age:54) were included. F-18F-FDG and Ga-68 FAPI PET/CT were performed for staging. Patient based sensitivity,specificity,PPV,NPV and accuracy is calculated for each modality. Uptake intensity of the primary breast lesions, axillary lymph nodes and other metastatic sites were compared between two imaging modalities. Correlation between SUVmax of the lesions and histopathological parameters and significance of difference of medians between different histpothological groups were analyzed. ***Results:*** The sensitivity,PPV and accuracy for detection of primary breast lesions of Ga-68 FAPI were slightly higher than F^{18}-FDG (96%,100% and 96% vs 93%,100% and 93% respectively). There were no false positive cases in both modalities. For axillary LN metastasis, sensitivity,specificity,PPV, NPV and accuracy of Ga-68 FAPI PET/CT were higher than F18-FDG PET/CT (88%, 100%,100%,87% and 93% vs 87%,86%,87%,86%,86% respectively). Median SUVmax of Ga-68 FAPI uptake of primary breast lesions were significantly higher than F^{18}-FDG uptake ($p<0.001$). For axillary lymph nodes, no significant difference was detected. Among histopatholohical variables, Ki-67 proliferation index of the primary tumors was significantly correlated with SUVmax of axillary LN on Ga-68 FAPI PET/CT. No other correlation was found between Ki-67 and other SUVparameters. Medians of SUVmax of the primary breast and metastatic lesions did not differ among groups with or without lymphovascular invasion, perineural invasion, lymphocytic infiltration, Her2 positivity, invasive ductal or lobular cancer. Ga-68 FAPI PET/CT changed management in 5/29 patients(17%) (axillary dissection was performed for Ga-68 FAPI positive, F^{18}-FDG negative metastatic LN in 3 patients, shift from surgery to neoadjuvant therapy due to Ga-68 FAPI positive, F^{18}-FDG negative metastatic parasternal lymph node in 1 patient, bilateral mastectomy due to Ga-68 FAPI positivity in the contralateral breast in 1 patient). There was only 1 patient with distant organ metastasis. Brain metastasis was both F^{18}-FDG and Ga-68 FAPI negative and skeletal metastasis were both F18-FDG and Ga-68 FAPI avid. ***Conclusion:*** Accuracy and specificity of Ga-68 FAPI PET/CT is higher than F18-FDG PET/CT for detection of primary breast lesions and axillary lymph node metastasis in primary staging of breast cancer. Ga-68 FAPI changes management in a significant number of cases and can be used complementary to F^{18}-FDG PET/CT

OP-034

Association between PET-based features reflecting intensity and heterogeneity of [^{18F}]FDG uptake and immunohistochemical markers in breast cancer of no special type and lobular type

C. Oliveira[1], *F. Oliveira[1], C. Constantino[1], M. J. Brito[2,3], F. Cardoso[2], D. C. Costa[1];*
[1]Nuclear Medicine-Radiopharmacology, Champalimaud Clinical Centre/Champalimaud Foundation, Lisbon, PORTUGAL, [2]Breast Unit, Champalimaud Clinical Centre/ Champalimaud Foundation, Lisbon, PORTUGAL, [3]Pathology Department, Champalimaud Clinical Centre/ Champalimaud Foundation, Lisbon, PORTUGAL.

Aim/Introduction: In breast cancer (BC), a higher [^{18F}]FDG uptake has been associated with hormone receptor-negative status, HER2 overexpression, high Nottingham Grade and high Ki67 index. We aimed to analyze the association between standardized uptake value (SUV)-based features reflecting the intensity and heterogeneity of [^{18F}]FDG uptake in BC and immunohistochemical (IHC) markers. ***Materials and Methods:*** This retrospective study included 200 histologically confirmed invasive breast carcinomas [170 of no special type (NST) and 30 of the lobular type] from patients staged with [^{18F}]FDG-PET/CT. The primary tumour was delineated through a robust semiautomatic method using a Bayesian classifier (Constantino et al, J Digit Imaging, 2023). SUVmax, SUVmean, SUVpeak, metabolic tumour volume (MTV), total lesion glycolysis (TLG), entropy, kurtosis, skewness, uniformity, range, standard deviation (SD) and coefficient of variation (CoV) were extracted from the delineated tumours. In NST tumours, these variables were compared in subgroups defined by the estrogen receptors (ER) and progesterone receptors (PgR) status, HER2 IHC and in situ hybridization (ISH) expression [score 0, 1+ and 2+ non-amplified by ISH vs score 2+ amplified by ISH or score 3+] and Nottingham Grade (1-2 vs 3) using Mann-Whitney U test. In both NST and lobular carcinomas, the same features were correlated with Ki67 index using the Spearman coefficient. Uncorrected $p<0.05$ was considered statistically significant. ***Results:*** In NST BC, SUVmax, SUVmean, SUVmedian, SUVpeak, entropy, range, skewness, SD and CoV were higher and uniformity was lower in ER/PgR-negative than in ER/PgR-positive tumours ($p<0.05$). TLG was also higher in ER-negative than in ER-positive tumours ($p<0.05$). SUVmax, SUVmean, SUVmedian, SUVpeak, TLG, entropy, range, SD and CoV were higher and uniformity was lower in grade 3 than in grade 1-2 tumours ($p<0.05$). The higher the Ki67 index, the higher the SUVmax ($r=0.391$), SUVmean ($r=0.335$), SUVmedian ($r=0.309$), MTV ($r=0.220$), TLG ($r=0.295$), entropy ($r=0.395$), range ($r=0.409$), SD ($r=0.403$), CoV ($r=0.427$) and SUVpeak ($r=0.363$) and the lower the uniformity ($r=-0.386$) ($p<0.05$). None of the measured features was significantly associated with HER2 expression. In lobular BC, the higher the Ki67 index, the higher the entropy ($r=0.413$) and SD ($r=0.415$) and the lower the uniformity ($r=-0.412$) ($p<0.05$). ***Conclusion:*** Higher intensity and heterogeneity of [^{18F}]FDG uptake in NST BC were associated with poorer prognostic biomarkers, namely ER- and PgR-negative status, higher Nottingham Grade and higher Ki67 index. None of the [^{18F}]FDG-based features was associated with HER2 expression. In lobular BC, higher heterogeneity of [^{18F}]FDG uptake was also associated with higher Ki67 index.

OP-035

The Role of [^{68}Ga]Ga FAPi PET/CT in Staging and Restaging in Breast Cancer with Low FDG Uptake

N. Alan-Selcuk[1], *G. Beydagi[1], K. Akcay[1], B. B. Oven[2], S. Celik[2], L. Kabasakal[3];*
[1]Yeditepe University, Department of Nuclear Medicine, Istanbul, TÜRKIYE, [2]Yeditepe University, Department of Medical Oncology, Istanbul, TÜRKIYE, [3]Istanbul Unıversity-Cerrahpasa, Department of Nuclear Medicine, Istanbul, TÜRKIYE.

Aim/Introduction: The aim of this study is to assess the potential efficacy of [68Ga]Ga FAPi PET/CT in staging and restaging in breast cancer patients with FDG-negative or low FDG uptake lesions. ***Materials and Methods:*** Between October 2020 and February

2024, 25 female patients with pathologically confirmed breast cancer were prospectively enrolled. These patients underwent [68Ga]Ga FAPi and [18F]-FDG PET/CT imaging within one week for staging or restaging. All imaging was reviewed in consensus by three experienced nuclear medicine physicians. The maximum standard uptake values (SUVmax) of the primary tumor areas and metastases in the [68Ga]Ga FAPi and [18F]-FDG PET/CT images were recorded and statistically compared using the paired t-test. A p-value of <0.05 was considered statistically significant. ***Results:*** 25 female patients with suspicious primary malignancy recurrence or metastases but low FDG affinity on [18F]-FDG PET/CT were imaged with [68Ga]Ga FAPi PET/CT. The mean age was 57.1±11.7 years. Histopathologic examination from previous surgeries/biopsies available for 20 patients revealed lobular carcinoma in 10 cases, ductal carcinoma in 8 cases, signet ring cell carcinoma in one patient and squamous cell carcinoma in one patient. In six patients (24%), neither the [18F]-FDG PET/CT nor the [68Ga]Ga FAPi PET/CT revealed any findings indicating recurrence or metastasis. Disease stage increased in 36% (n=9) of patients after [68Ga]Ga FAPi PET/CT imaging, with 8 of them showing no pathologic findings on [18F]-FDG PET/CT; after [68Ga]Ga FAPi PET/CT imaging, 7 patients progressed to stage 4 and 1 to stage 3. One patient progressed from stage 2 to stage 3 according to AJCC 8. edition. 60% (n=6) of the lobular carcinomas were upstaged after [68Ga]Ga FAPi PET/CT. The detection of lymph nodes and distant metastases in lobular carcinoma was higher with [68Ga]Ga FAPi PET/CT than with [18F]-FDG PET/CT (Table 1). Only one patient had a primary lesion that was negative on both [18F]-FDG and [68Ga]Ga FAPi PET/CT. Furthermore, [68Ga]Ga FAPi PET/CT showed a higher SUVmax in primary tumor foci and metastases (Table 2) (p<0.05). ***Conclusion:*** [68Ga]Ga FAPi PET/CT has been shown to be superior for staging and restaging indications in breast cancer, especially for tumors such as lobular carcinoma with low FDG affinity. It is anticipated that [68Ga]Ga FAPi PET/CT will be included in future guidelines for primary diagnosis and staging in breast cancer patients, especially in patients with the lobular histopathologic subtype. Further multicenter prospective studies are needed in this area.

OP-036

Contribution of Ga-68 DOTA-Bombesin PET/CT to Staging and Restaging in Breast Cancer: Preliminary Findings

M. Baloglu[1], *R. Şahin[1], Z. Tosunoglu[1], A. E. Ozturk[1], Ö. F. Sahin[1], E. Beyhan[1], Ö. Erol Fenercioglu[1], G. Alcin[1], N. Ergul[1], T. F. Cermik[1], Ç. Usul Afsar[2], E. Arslan[1];*
[1]Istanbul Training and Research Hospital, Department of Nuclear Medicine, University of Health and Sciences, Turkiye, Istanbul, TÜRKIYE, [2]Istanbul Training and Research Hospital, Department of Medical Oncology, University of Health and Sciences, Turkiye, Istanbul, TÜRKIYE.

Aim/Introduction: Bombesin (BBN) is 14-amino acid peptide selectively binds to gastrin-releasing peptide receptor (GRPR). GRPR has detected in prostate, lung, central nervous system, colon, pancreatic cancers, and also highly expressed in breast cancer .These tumors synthesize BBN-associated peptides and function as autocrine growth factors by excessively expressing BBN receptors. Study aims to evaluate the diagnostic, staging-restaging role and significance of GRPR imaging in breast cancer using GRPR analogue 68Ga-DOTA-Bombesin PET/CT. ***Materials and Methods:*** Our prospective study has local ethical board approval. Total 23 patients histopathologically confirmed breast carcinoma, 22 women [(mean ± STD: 54.26 ± 13.21 years), (21/22 staging, 1/22 restaging)] ,1 man (71 years), underwent staging 68Ga-DOTA-Bombesin PET/CT and 18F-FDG PET/CT within same 2week. In vivo tumor uptake obtained from 68Ga-DOTA-Bombesin, axillary lymph node uptake, and uptake values for distant metastasis, as well as metabolic parameters from ^{18}F-FDG PET/CT, estrogen (ER) and progesterone (PR) receptor and HER2/neu status, and Ki-67 index in biopsy samples, tumor, and axillary lymph node sizes evaluated comparatively. ***Results:*** Histopathologically, 15 patients had invasive ductal, 6 invasive lobular, 2 tubulolobular breast carcinoma diagnoses. Regarding hormone receptor status, 8 Luminal A, 14 Luminal B and 1 Triple Negative. Normal breast tissue showed moderate GRPR binding (SUVmax: 1.2 ± 1.0), while physiological uptake in other organs was minimal, except for pancreas and kidneys. Mean FDG SUVmax of primary tumor was 10.39 ± 8.79, and the mean Bombesin SUVmax was 5.52 ± 2.16, with a statistically significant difference betweenprimary tumor SUVmax (p = 0.01). When comparing axillary LN FDG SUVmax (mean ± STD: 10.65 ± 9.67) and Bombesin SUVmax (mean ± STD: 7.02 ± 2.61), no statistically significant difference was observed, but a negatively low correlation was observed (r: -0.35) (Table 1). In the assessment of distant organ metastasis, when compared with 18F-FDG PET/CT, 68Ga-DOTA-Bombesin PET/CT showed additional lesions in one patient with a total of 3 liver metastases (Figure 1). Additionally, in one out of a total of 4 patients with bone metastasis, additional bone metastases were observed with 68Ga-DOTA-Bombesin PET/CT compared to 18F-FDG PET/CT. ***Conclusion:*** Preliminary findings of ongoing study demonstrate that 68Ga-DOTA-Bombesin PET/CT is a promising imaging method in breast cancer. However, further studies with larger patient cohorts are needed to determine whether radiolabeled GRPR analogues can be used in the diagnosis and staging of breast cancer. Additionally, Lu-177-conjugated GRPR analogues may also be considered for the treatment of metastatic breast cancer.

OP-037

Head-to-Head Comparison of [18F]PSMA-1007 and [18F] FDG PET/CT in Patients with Triple-Negative Breast Cancer

N. Andryszak[1,2], *D. Świniuch[3], E. Wójcik[4], R. Ramlau[3], M. Ruchała[1], R. Czepczyński[1,2];*
[1]Department of Endocrinology, Metabolism and Internal Medicine, Poznan University of Medical Sciences, Poznan, POLAND, [2]Department of Nuclear Medicine, Affidea, Poznań, POLAND, [3]Department of Oncology, Poznan University of Medical Sciences, Poznan, POLAND, [4]Department of Oncology Medical Center HCP, Poznan, POLAND.

Aim/Introduction: Triple-negative breast cancer (TNBC) exhibits high aggressiveness and a notably poorer prognosis at advanced stages. Treatment options for TNBC patients are limited, often leading to recurrence and therapy resistance. Nuclear medicine offers new possibilities, not only diagnostically but also potentially promising therapeutic strategies. Prostate-specific membrane antigen (PSMA) expression primarily associated with prostate cancer, has also been identified in breast cancer, showing a positive correlation with its aggressiveness. The aim of our study was to assess the expression of PSMA in vivo in TNBC patients by means of PET/CT using 18F-PSMA-1007. Additionally, we performed a head-to-head comparison of 18F-PSMA-1007 versus standard-of-care 18F-FDG-PET/CT in TNBC patients. ***Materials and Methods:*** This prospective study involved ten patients diagnosed with advanced-stage TNBC. Each patient underwent both 18F-FDG PET/CT and 18F-PSMA-1007 PET/CT examinations, with no more

than one month between the scans. All visible lesions displaying radionuclide uptakewere evaluated and compared. ***Results:*** A total of 10 patients were included: 5 post-mastectomy and chemotherapy, 4 undergoing chemotherapy (CTH): 1 neoadjuvant, 3 palliative CTH, and 1 untreated patient. The uptake of 18F-PSMA in primary and metastatic cancer lesions was comparable to 18F-FDG. 18F-PSMA indicated one additional primary lesion not detected in 18F-FDG PET/CT. Lymph nodes with positive uptake, typical for nodal metastases were found in 8 patients, showing similar SUV max values in both modalities. Two patients had uncountable lung metastases positive inboth 18F-FDG and 18F-PSMA scans. PET-positive osteolytic lesions characteristic for bone metastases were identified in the 18F-PSMA PET/CT in 4 patients, while elevated 18F-FDG uptake in bone metastases was found only in 3 of them. Distant metastases to the liver and adrenals displayed higher SUV max values in the 18F-PSMA PET/CT. Approximately ten small brain metastases (ranging from 4 to 7 mm in diameter) were exclusively detected using 18F-PSMA PET/CT. ***Conclusion:*** The study confirms the expression of PSMA in TNBC. To the best of our knowledge, this is the first prospective study directly comparing 18F-PSMA and 18F-FDG PET/CT in TNBC. The comparison suggests the potential superiority of 18F-PSMA PET/CT particularly in case of brain metastases. The documented expression of PSMA not only offers a novel diagnostic pathway but also implies potential therapeutic applications by means of targeted radionuclide therapy (theranostic approach).

OP-038

Contribution of ^{18}F-FDG MAMMI-PET Imaging in Breast Cancer Staging

K. Aslaner[1], *D. Has Simsek[1], D. Arslan[1], R. Yilmaz[2], S. Onder[3], N. Cabioglu[4], E. Isik[1], Z. Ozkan[1], Y. Sanli[1], S. Kuyumcu[1];*

Aim/Introduction: 18F-FDG PET/CT has limited role in T staging of breast cancer. Dedicated breast PET (MAMMI-PET) imaging has improved spatial resolution and sensitivity which may contribute T staging of breast cancer. In present study, we evaluate the diagnostic performance of additional 18F-FDG MAMMI-PET imaging in breast cancer patients. ***Materials and Methods:*** Biopsy-confirmed breast cancer patients were performed skull base to mid-thigh 18F-FDG PET/CT and MAMMI-PET for staging. Lesions were categorized as invasive tumor, insitu tumor or benign based on PET findings. Lesion location and number, skin/nipple involvement were interpreted with clinical and histopathological data. PET findings were correlated either with histopathological results or MRI/USG/mammography findings. Sensitivity, specificity, accuracy, PPV, and NPV were calculated for each imaging modality, excluding multicentric cases. ***Results:*** All PET images of 80 female patients (Table 1) were interpreted retrospectively. In 40 patients, only one tumor was detected, while tumors were multifocal in 40 patients, and multicentric in 13 patients. After the exclusion of multicentric cases, a total of 168 lesions were determined in 67 patients. Of these, 92 were invasive tumors, 34 were in situ tumors, and 42 were benign lesions. Skin/nipple involvement was detected in 25 patients. Final diagnosis was confirmed by histopathological in %48 of patients, while remaining lesions were concluded by radiologically. 18F-FDG PET/CT detected 73/92(79%) invasive carcinoma and 9/34 (26%) in situ tumors, while MAMMI-PET detected 82/92 (89.1%) invasive carcinoma and 31/34(91%) in situ tumors. MAMMI-PET could not detect 5/126 lesions (%4) located adjacent to pectoralis muscle which were outside the FOV, and 4 of them were shown by 18F-FDG PET/CT. 18F-FDG PET/CT defined skin/nipple involvement in 19/25 (76%) patients, while MAMMI-PET identified 23 (92%) of them. Lesion-based sensitivity, specificity, accuracy, PPV and NPV were 65%, 93%,72%, 96%, 47% for 18F-FDG PET/CT; 88%, 90%, 88%, 96%, 71% for MAMMI PET, and 92%, 90%, 91%, 96%, 79% for combination of 18F-FDG PET/CT and MAMMI PET, respectively. ***Conclusion:*** Our study findings demonstrate that, 18F-FDG MAMMI-PET has high level accuracy in determining invasive/in situ tumors and skin/nipple involvement in breast cancer, in correlate with previous studies (1). Combination of MAMMI-PET and 18F-FDG PET/CT seems contribute T staging of breast cancer, and may reduce the need of additional breast MRI in clinical practice. ***References:*** 1)Nishimatsu, K., Nakamoto, Y., Miyake, K. Aim/Introduction: triple-negative (TN) is recognized as the most aggressive breast cancer (BC) subtype and is still associated to short life expectancy. Although TNBC is a well-established $^{[18F]}$-FDG (FDG)-avid tumor at Positron Emission Tomography/Computed tomography (PET/CT), literature lacks of evidence regarding the prognostic value of FDG PET in these patients. The objective of TRINE-PET, a retrospective multicenter Italian study, aims to correlate FDG PET/CT results and survival outcomes in TNBC patients across various clinical settings of the disease. ***Materials and Methods:*** 23 Italian centers retrospectively collected data relative to FDG PET/CT scans performed in TNBC patients, either at baseline or after neoadjuvant chemotherapy (NAC), with a minimum of 2 years of follow-up. In patients who underwent NAC, pathological complete response (pCR) and response according to PERCIST criteria at FDG PET/CT were collected. A per-site PET based analysis was conducted and the survival outcomes (progression

and death) were compared in each category by using log-rank test. The correlation between categorial variables was assessed using the chi-squared test. ***Results:*** FDG PET/CT scans from 130 patients at baseline and 66 patients post-NAC were considered. Overall, lymph node and distant metastases were detected in 69 (53%) and 11 (8.5%) patients at baseline, and in 19 (28.8%) and 9 (13.6%) patients post NAC. In the baseline group (median follow-up of 3.5 years), 34 (26.2%) patients had disease progression, and 20 (15.4%) passed away. In the post-NAC group (median follow-up of 3.7 years), 21 (31.8%) patients had disease progression, and 17 (25.8%) passed away. The presence of N+ and M+ disease on FDG PET strongly correlated with both progression (all $p<0.05$) and death (al $p<0.01$) in both clinical settings. pCR after NAC was achieved in 29 (56.9%) out of 51 patients with available data. According to PERCIST criteria, a complete metabolic response was observed in 34 (51.5%) patients. PERCIST response on FDG PET/CT significantly correlated with pCR ($p <0.0001$) and with both progression ($p<0.0001$) and death ($p<0.0001$). ***Conclusion:*** a strong correlation was observed between N+ or M+ disease at baseline or post-NAC FDG PET/CT and survival outcomes in TNBC patients. Response to NAC assessed according to PERCIST criteria at FDG PET/CT was significantly correlated with both pCR and survival outcomes.

Disialoganglioside GD2 targeted PET imaging of high-risk children neuroblastoma with newly synthesized 68Ga labeling bicyclic peptide

Y. Zhao[1,2], *Z. Zhao[1], G. Shao[1,2], H. Yang[2], Y. He[2];*
[1]Department of Nuclear Medicine, Nanjing First Hospital, Nanjing Medical University, Nanjing, CHINA, [2]Department of Nuclear Medicine, Maanshan People´s Hospital, Maanshan, CHINA.

Aim/Introduction: Disialoganglioside GD2 has limited expression in normal tissues but is overexpressed in children neuroblastoma. It is considered a tumor-associated antigen and used successfully as a target for cancer immunotherapy. Anti-GD2 monoclonal antibodies target GD2-expressing tumor cells, leading to phagocytosis and destruction by means of antibody-dependent cell-mediated cytotoxicity, lysis by complement-dependent cytotoxicity. The aim of this study was to synthesize GD2 targeted 68Ga labeling bicyclic peptide (68Ga-GD2BP) and evaluate the value of 68Ga-GD2BP PET-CT imaging for GD2 expression quantification in neuroblastoma. ***Materials and Methods:*** GD2BP were designed based on the structure of GD2 targeted antibody and prepared via solid phase peptide synthesis, mixed with TATA for cyclization and radiolabeled with 68Gallium. In vitro cell binding affinity and specificity experiments of 68Ga-GD2BP were performed in neuroblastoma tumor cells with varying levels of GD2 expression. Ex vivo biodistribution and Animal PET/CT imaging of 68Ga-GD2BP were performed in mice bearing Neuroblastoma, breast cancer and osteoblastoma xenografts. Tumor uptake of 68Ga-GD2BP (percentage of injected dose, %ID/g) was compared with GD2 expression based on IHC results from tumor xenografts. ***Results:*** 68Ga-GD2BP was synthesized with high radiochemical purity. It was stable in PBS for 3 hours with radiochemical purity ranging from 96% to 98%. Cell binding specificity was confirmed by GD2 blockage. Positive correlation was found between tumor cell uptake of 68Ga-GD2BP and GD2 expression with R2 being 0.86. 68Ga-GD2BP was excreted rapidly via kidney and its retention in blood circulation was short. Tumor uptake of 68Ga-GD2BP (%ID/g) at 1h, 2h, 3h was (2.9±0.25), (3.8±0.7) (2.6±0.1) and (0.65±0.1 on 2h) at the block group. Tumor uptake of 68Ga-GD2BP at 2h post tail vein injection was positively corelated with GD2 expression revealed on IHC with R2 being 0.85. ***Conclusion:*** 68Ga-GD2BP, as one newly prepared GD2 targeted radiolabeled peptide, maybe promising for GD2 expression evaluation and patient screen for Anti-GD2 immunotherapy. ***References:*** 1.Marjolein C Stip, Mitchell Evers , Maaike Nederend , et al. The value of ^{18}F-FDG PET/MR radiomic features in predicting MYCN amplification, 1p and 11q aberrations in pediatric neuroblastoma

J. Liang;
Hangzhou Universal Medical Imaging Diagnostic Center, Hangzhou, CHINA.

Aim/Introduction: The aim of this study is to evaluate the predictive ability of ^{18}F-FDG PET/MR radiomics features in MYCN amplification, 1p and 11q aberrations in pediatric neuroblastoma(NB). ***Materials and Methods:*** 139 pediatric patients (median age 3.5 years, range from 0.3 to 13.5 years) with NB were retrospectively enrolled. Preserve significant features through multivariate logistic regression and establish a clinical model (C_model) that included clinical features.^{18}F-FDG PET/MR radiomic features were extracted by Computational Environment for Radiological Research. Use the Least Absolute Shrinkage and Selection Operator (LASSO) regression to select radiomic features and establish a model (R model). Compare the predictive performance of models constructed from clinical features (C_ model), radiomics features (R_model), and their combination (CR_model) using receiver operating curve (ROC). A nomogram was developed based on radiomics score (rad score) and clinical parameters. ***Results:*** The patients were divided into a training set (n = 97) and a testing set (n = 42). Accordingly, 5, 7, and 6 radiomic features were selected to establish R_models for predicting MYCN, 1p and 11q status. The R_ model demonstrated a strong ability to recognize these aberrations, with ROC area under the curve (AUC) of 0.89, 0.91, and 0.90 in the training set, and 0.91, 0.90, and 0.89 in the testing set, respectively. When combining clinical and radiomics features, the AUCs in the training set increased to 0.97, 0.95, and 0.98, while the AUCs in the test set increased to 0.97, 0.90,

and 0.92. The CR_models had the highest predictive performance for MYCN, 1p and 11q predictions ($P < 0.05$). ***Conclusion:*** The pre-therapy ^{18}F-FDG PET/MR radiomics features can predict MYCN amplification and 1p and 11q aberrations in pediatric NB, thereby aiding in tumor staging, risk stratification, and disease management in clinical practice.

Significant Dose Reduction employing Dual-Low-Dose Total-Body PET/CT in Pediatric Lymphoma while Maintaining Diagnostic, Staging and Response-assessing Efficacy

Y. Huang[1], *S. Tang[1], T. Wang[1], Y. Li[1], L. Cao[1], W. Chen[1], L. Liu[1], W. Fan[1], Y. Zhang[2], Y. Hu[1];*
[1]Department of Nuclear Medicine, Sun Yat-sen University Cancer Center, Guangdong, CHINA, [2]Department of Pediatrics, Sun Yat-sen University Cancer Center, Guangdong, CHINA.

Aim/Introduction: To explore a clinical dual-low-dose total-body (TB) PET/CT strategy on pediatric lymphoma patients by using low-dose PET and two different low-dose CT protocols, and estimate the corresponding clinical efficacy. ***Materials and Methods:*** Total 246 pediatric patients were retrospectively enrolled and divided into low-dose PET/low-dose CT group (LDCT, n=127), and low-dose PET/ultra-low-dose CT group (ULDCT, n=119). Image quality was evaluated based on subjective and objective metrics. The sensitivity, specificity and area under curve (AUC) for detecting involvements of lymph node, spleen, bone marrow and other extranodal organs were compared. The accuracies of staging, treatment response assessment and effective dose (ED) were calculated and compared. ***Results:*** ULDCT had comparable CT objective scores relative to LDCT in terms of liver, blood pool and muscle. Both protocols had good or high diagnosing efficiency in all patterns of lymphoma involvement, with AUCs ranging from 0.883 to 1.00. The staging and response assessment accuracy were 93.2% and 94.0% for LDCT group, and 94.0% and 97.6% for ULDCT group, with no significance (p=0.221). The total ED was 9.7±3.2 mSv for LDCT and 5.6±1.9 mSv for ULDCT (p<0.001). ***Conclusion:*** Dual-low-dose TB PET/CT has demonstrated sufficient image quality and performed well in diagnosing, staging and response assessing in pediatric lymphoma patients. The ULDCT protocol can significantly reduce total ED relative to LDCT without compromising the performance in diagnostic, staging and treatment response assessment.

OP-044

^{18}F-FDG PET/MR in pediatric Langerhans cell histiocytosis

J. Liang;
Hangzhou Universal Medical Imaging Diagnostic Center, Hangzhou, CHINA.

Aim/Introduction: Langerhans cell histiocytosis (LCH) in pediatric patients is a disease that can affect single or multiple systems. Accurate staging is crucial for selecting a precise treatment plan ranging from local surgery to chemotherapy. ***Materials and Methods:*** A retrospective review was undertaken of reported ^{18}F-Fludeoxyglucose (FDG) PET/MR scans performed in pediatric LCH from June 2017 to June 2023. Research results were compared with a reference standard of biopsy or informed clinical follow-up. ***Results:*** 134 scans were performed in 44 patients (age 9 weeks to 14 years). 28 patients had single-system, bone unifocal disease; 8 patients had single-system, bone multifocal disease; 5 patients had single-system, skin unifocal disease; 1 patients had multisystem disease; and 2 patient had single-system, lymph node disease. 35 scans were performed to stage biopsy-proven LCH, and 99 scans were performed during follow-up to assess treatment response or recurrence after therapy completion. At staging, PET/MR detected all sites of biopsy-proven LCH. The per-patient false-positive rate of PET/MR at staging was 5.7% (2/35). During follow-up, 6 LCH recurrences and 2 case of progressive disease on therapy occurred, all positive on PETMR. During follow-up 3 patients had PET/MR scans with false-positive findings and 2 patient with a magnetic resonance imaging false-positive finding. The per-scan false-positive rate of PET/MR during follow-up was 3% (3/99). ***Conclusion:*** ^{18}F-FDG PET/MR is highly sensitive for the staging and follow-up of pediatric patients with LCH, and has a very low false-positive rate.

OP-045

The value of ^{18}F-FDG PET/MR radiomics nomogram in predicting bone marrow involvement in pediatric neuroblastoma

J. Liang;
Hangzhou Universal Medical Imaging Diagnostic Center, Hangzhou, CHINA.

Aim/Introduction: To develop and validate a radiomics nomogram based on ^{18}F-fluorodeoxyglucose (FDG) PET/MR for non-invasive prediction of bone marrow involvement (BMI) in pediatric neuroblastoma. ***Materials and Methods:*** A total of 120 patients with neuroblastoma were retrospectively included and randomized into the training set (n = 84) and test set (n = 36). Radiomics features were extracted from both T2WI and PET images. The radiomics signature was developed. Independent clinical risk factors were identified using the univariate and multivariate logistic regression analyses to construct the clinical model. The clinical-radiomics model, which integrated the radiomics signature and the independent clinical risk factors, was constructed using multivariate logistic regression analysis and finally presented as a radiomics nomogram. The predictive performance of the clinical-radiomics model was evaluated by receiver operating characteristic curves, calibration curves and decision curve analysis (DCA). ***Results:*** Ten radiomics features were selected to construct the radiomics signature. Neuron-specific enolase and vanillylmandelic acid were identified as independent predictors to establish the clinical model. In the training set, the clinical-radiomics model outperformed the radiomics model or clinical model (AUC: 0.939 vs. 0.911, 0.899) in predicting the BMI, which was then confirmed in the test set (AUC: 0.931 vs. 0.900, 0.909). The calibration curve and DCA demonstrated that the radiomics nomogram had a good consistency and clinical utility. ***Conclusion:*** The ^{18}F-FDG PET/MR-based radiomics nomogram which incorporates radiomics signature and independent clinical risk factors could non-invasively predict BMI in pediatric neuroblastoma.

OP-046

The value of radiomic features and quantitative parameters based on PET/MRI in predicting MYCN gene amplification in pediatric neuroblastoma

J. Liang;
Hangzhou Universal Medical Imaging Diagnostic Center, Hangzhou, CHINA.

Aim/Introduction: To explore the value of radiomics features and quantitative parameters based on 18F-FDG PET/MRI in predicting MYCN gene amplification in pediatric neuroblastoma (NB).

Materials and Methods: A retrospective analysis was conducted on the PET/MRI imaging data of 125 pediatric patients (56 males and 69 females, aged 0.5 to 13.5 years) who were pathologically confirmed by pathology as NB in our hospital from April 2017 to December 2023. According to the copy number of the target gene, the children were divided into amplification group and non amplification group. Preserve salient features through multiple logistic regression and establish a parameter model (Q_model) that includes quantitative parameters. Extract radiomics features from PET and T2WI images separately and perform feature screening.Using logistic regression to construct an R_model based on radiomics features, and calculating the radiomics score (Rad_score). Based on R_ Model, Q_ Model construction joint model (RQ_model). Evaluate the predictive performance of the model using Receiver Operating Characteristic (ROC) curves. ***Results:*** The training set includes 87 children with NB (53 in the MYCN amplification group and 34 in the non amplification group), and the validation set includes 38 children with NB (25 in the MYCN amplification group and 13 in the non amplification group). Four radiomics features were obtained through screening, two of which were based on T2WI images and the other two were based on PET images. In the training set, the ROC area under the curve (AUC) of the R_ Model, Q_ Model, RQ_Model predicting the MYCN gene amplification status in NB were 0.92, 0.87, and 0.96, respectively;In the validation set, the AUCs of the R_ Model, Q_ Model, RQ_Model predicting the MYCN gene amplification status in NB were 0.91, 0.83, and 0.98, respectively. RQ_ model has the highest predictive performance for MYCN gene amplification. ***Conclusion:*** The radiomics features of PET/MRI can accurately predict the MYCN gene amplification status in NB. By combining metabolic parameters, the accuracy of predicting MYCN gene amplification can be further improved, providing assistance for the development of personalized and precise treatment plans for NB.

OP-047

Interim PET in Pediatric High Grade B Lymphomas; Future is Predictable

G. Kaya[1], *B. Volkan Salanci[1], B. Aydın[2], P. Özgen Kıratlı[1];*
[1]Hacettepe University Medical School Department of Nuclear Medicine, Ankara, TÜRKIYE, [2]Hacettepe University Medical School Department of Paediatric Oncology, Ankara, TÜRKIYE.

Aim/Introduction: Pediatric Non-Hodgkin Lymphomas (NHL) are highly heterogenous and it is hard to determine residual disease on interim PET-CT. High-grade B-cell lymphoma (HGBCL) is the most common type of NHL that differs from other types. It has been shown that, the use of metabolic parameters such as metabolic tumor volume (MTV) and total lesion glycolysis (TLG) can be more advantageous than Deauville-Score (DS), especially in terms of predicting prognosis. The aim of the study is to compare the performance of DS and MTV&TLG in predicting disease recurrence in pediatric HGBCL. ***Materials and Methods:*** HGBCL patients under 18 years of age with interim PET-CT images were included. In this retrospective-single-center study; DS, whole-body TLG of the pediatric patients were evaluated. SUVmax-2.5 threshold was used for TLG. Patients with DS3-4 and TLG values higher than median were considered having residual disease. Follow-up data of the patients was obtained. The performance of interim imaging about predicting early recurrence after completion of treatment was investigated. Disease recurrence and disease-related-death are defined as events; survival analyses were performed. ***Results:*** A total of 56 patients (39 male) were included to the study. The mean age was 9.9 years (± 4.5 years). The mean follow-up period was 88 months (± 5.3 months). Recurrence was observed in 6 (%11) patients. The median DS, MTV and TLG in interim PET-CT were 1 (min-max: 1-5), 0 cm3 (min-max: 0-216) and 0 (min-max: 0-3163), respectively. The number of patients considered positive for residual disease in DS3, DSTLG was 18, 12 and 11, respectively. All patients considered positive on TLG were also positive for DS. Kaplan-Meier survival-analyses showed no statistically-significant difference between the survival curves according to the DS3-4 prediction values. The median survival was not reached for all assessment type. Best mean-survival-difference obtained from the TLG-positivity (147 vs 100 months), and event-free survival was the worst in the TLG-positive group (p= 0.01). ***Conclusion:*** This study, in a larger cohort; metabolic markers obtained from interim PET-CT showed a better performance on prediction for the recurrence than DS. This high prediction performance can change the treatment plan and follow-up process with contribution to the clinical-judgement. Metabolic parameters can be helpful, especially in cases with DS3 and DS4. Studies on accurate TLG threshold values can be determined by ongoing studies in the future.

Preliminary Study on the Feasibility of Fast Low-dose (FLow) One-day Dynamic CZT-SPECT Protocol Acquisition

A. D'Antonio, *R. Assante, E. Zampella, T. Mannarino, V. Cantoni, R. Green, P. Buongiorno, V. Gaudieri, C. Nappi, A. Cuocolo, W. Acampa;*
Department of Advanced Biomedical Sciences, University of Naples "Federico II", Napoli, ITALY.

Aim/Introduction: Non-invasive assessment of myocardial blood flow (MBF) and perfusion reserve (MPR) by low-dose dynamic cadmium-zinc-telluride single-photon emission computed tomography (CZT-SPECT) is a well-known tool evaluating coronary artery disease (CAD). Standard acquisition protocols require waiting time between rest and stress dynamic and perfusion scans, with consequent patient motion. Residual Activity Correction (RAC) is a recommended tool evaluating quantitative data obtained by SPECT with 99mTc-labeled tracers performing one-day studies. Thus, we aimed to evaluate the feasibility of a Fast Low-dose (FLow) one-day dynamic CZT-SPECT protocol acquisition, with and without RAC, compared to 82Rb-PET/CT, in a selected cohort. ***Materials and Methods:*** We evaluated 20 patients with suspected or known CAD. All patients underwent fast low-dose one-day dynamic rest/stress CZT-SPECT: dynamic rest and stress scans were immediately followed by standard rest and stress myocardial perfusion imaging (MPI), with no waiting time between rest and stress. All patients underwent 82Rb-PET/CT within 3 weeks after dynamic CZT-SPECT imaging, according to clinical decision. For both PET and CZT-SPECT, MBF for each of the three vascular territories were computed from dynamic rest and stress scans. Global and regional MPR were defined as the ratio of hyperemic to baseline MBF. Moreover, RAC was applied to

stress MBF and MPR by CZT-SPECT, and the results were compared to both PET and CZT-SPECT without RAC. ***Results:*** The mean scan duration by CZT-SPECT FLow protocol was 29±3 minutes. MPI by both PET and CZT-SPECT resulted concordant in each patient. Comparison of hyperemic MBF and MPR values by CZT-SPECT, with and without RAC, showed no significant differences in the mean values (2.51±0.79 vs 2.33±0.77, p=0.303; 2.68±0.79 vs 2.56±1.13, p=0.622). When compared to PET, absolute baseline and hyperemic MBF by CZT-SPECT resulted significantly lower, both without (0.97±0.30 vs 1.30±0.32, p=0.002; 2.51±0.79 vs 3.52±0.79, p<0.001, respectively) and with RAC (2.33±0.77 vs 3.52±0.79, p<0.001). Meanwhile, no significant difference emerged between CZT-SPECT and PET MPR, both without (2.68±0.79 vs 2.81±0.74, p=0.466) and with RAC (2.56±1.13 vs 2.81±0.74, p=0.350). Similar results were obtained for regional baseline and hyperemic MBF and MPR. Moreover, at univariate Cox's logistic regression analysis only CZT-SPECT MPR with RAC resulted significant predictor of reduced MPR obtained by PET (p<0.05). ***Conclusion:*** These preliminary results show that fast low-dose one-day dynamic CZT-SPECT may be a feasible and useful tool to evaluate coronary vascular function, providing results comparable to 82Rb-PET/CT, and shortening dramatically acquisition time, with less motion and waiting time for the patient.

OP-050

Radiomics Nomogram Derived from Gated Myocardial Perfusion Imaging for Identifying Ischemic Cardiomyopathy

M. Zhao[1], *C. Zhou[2], Y. Xiao[3], L. Li[4], Y. Liu[5], F. Zhu[6], W. Zhou[7]; [1]Third Xiangya Hospital of Central South University, Changsha, CHINA, [2]Third Xiangya Hospital of Central South University, Changsha, CHINA, [3]Xiangya Hospital of Central South University, Changsha, CHINA, [4]Zhengzhou University of Light Industry, Zhenzhou, CHINA, [5]Xidian University & Engineering Research Center of Molecular and Neuro Imaging, Xian, CHINA, [6]Zhenzhou University of Light Industry, Zhenzhou, CHINA, [7]Michigan Technological University, Unite State of America, MI, UNITED STATES OF AMERICA.*

Aim/Introduction: Personalized management involving heart failure (HF) etiology is crucial for better prognoses. We aim to evaluate the utility of a radiomics nomogram based on gated myocardial perfusion imaging (GMPI) in distinguishing ischemic from non-ischemic origins of HF. ***Materials and Methods:*** A total of 172 heart failure patients with reduced left ventricular ejection fraction (HFrEF) who underwent GMPI scan were divided into a training (n=122) and validation set (n=50) based on chronological order of scans. Radiomics features extracted from the resting GMPI were calculated for the Radscore. A radiomics nomogram was constructed based on the Radscore and independent clinical factors. Finally, the model performance was validated using operating characteristic curves, calibration curve, decision curve analysis, integrated discrimination improvement values (IDI) and the net reclassification index (NRI). ***Results:*** Three optimal radiomics features were used to build a radiomics model. Total perfusion deficit (TPD) was identified as the independent factors of conventional GMPI metrics for building the GMPI model. In the validation set, the radiomics nomogram integrating the Radscore, age, systolic blood pressure, and TPD significantly outperformed the GMPI model in distinguishing ischemic cardiomyopathy (ICM) from non-ischemic cardiomyopathy (NICM) (AUC 0.853 vs. 0.707, p=0.038). IDI analysis indicated that the nomogram improved diagnostic accuracy by 28.3% compared to the GMPI model in the validation set. ***Conclusion:*** By combining radiomics signatures with clinical indicators, we developed a GMPI-based radiomics nomogram that helps to identify the ischemic etiology of HFrEF.

OP-051

The relationship between left ventricle mechanical dyssynchrony and increased clearance of ^{99m}Tc-MIBI in chronic heart failure patients

A. Mishkina, *T. Atabekov, S. Sazonova, R. Batalov, K. Zavadovsky; Cardiology Research Institute, Tomsk National Research Medical Centre, Russian Academy of Sciences, Tomsk, RUSSIAN FEDERATION.*

Aim/Introduction: The radiopharmaceutical 99mTc-methoxy-isobutyl-isonitrile (99mTc-MIBI) is a widely used perfusion radiotracer, which accumulated and store in the mitochondria of cardiomyocytes for a long time without further redistribution. It is known that increased washout of 99mTc-MIBI from cardiomyocytes, according to myocardial perfusion imaging (MPI), may reflect mitochondrial dysfunction. There are limited studies that have examined 99mTc-MIBI clearance from the myocardium in chronic heart failure (CHF) patients. Currently, it remains unclear, whether there is a relationship between the mitochondrial dysfunction in CHF patients, impaired contractility and LV dyssynchrony. The aim of this study was to evaluate the 99mTc-MIBI washout rate (WR) from the myocardium and its relationship with left ventricle (LV) contractility and mechanical dyssynchrony indices in non-ischemic CHF patients. ***Materials and Methods:*** The study included 20 non-ischemic CHF patients who had indications for cardiac resynchronization therapy (CRT). Ten patients without CHF were included in the control group. All patients underwent rest gated MPI with 99mTc-MIBI, according to the early (1 hour) and delayed (3 hours) acquisition protocol for evaluating 99mTc-MIBI WR, contractility, and mechanical dyssynchrony. Follow LV contractility indices were evaluated: wall motion, wall thickening. Follow LV mechanical dyssynchrony indices were evaluated by phase analysis: phase standard deviation (PSD), phase histogram bandwidth (HBW), skewness, and kurtosis. Six months after CRT, 15 patients underwent MPI to assess the changes of 99mTc-MIBI clearance. ***Results:*** According to MPI data, CHF patients had a higher 99mTc-MIBI WR from the myocardium compared to the control group (10.9 (8.49-13.8)% versus 3.98 (0.9-9.8)%, p=0.0001), as well as higher LV mechanical dyssynchrony (PSD: 66 (55.11-73.24) degrees versus 13.1 (10.1-19.6) degrees, p<0.0001; HBW: 207 (165-246) degrees versus 40 (33-66) degrees, p<0.0001). The 99mTc-MIBI WR was positively correlated with LV end-diastolic (r=0.46, p<0.001) and LV end-systolic (r=0.44, p<0.001) volumes and negatively correlated with LV ejection fraction (r=0.41, p<0.001). A moderate correlation was found between 99mTc-MIBI WR and indices of LV mechanical dyssynchrony and contractility: HBW (r=0.412, p<0.001), skewness (r=-0.41, p<0.001), kurtosis (r=-0 .44, p<0.001), wall motion (r=-0.45, p=0.001), wall thickening (r=-0.54, p<0.001). Six months after CRT, 99mTc-MIBI WR significantly decreased from 12.4 (10.3-14.9)% to 8.14 (3.37-8.88)%, p = 0.0006. ***Conclusion:*** In non-ischemic CHF patients, an increase of 99mTc-MIBI WR from the LV myocardium is associated with the severity of impaired contractility and heart mechanical dyssynchrony. MPI with 99mTc-MIBI can be used as non-invasive method for assessing mitochondrial dysfunction of cardiomyocytes.

OP-052

A study for prediction of CRT super response using left ventricle mechanical dyssynchrony parameters in short-term period

T. Atabekov, *A. Mishkina, M. Khlynin, S. Sazonova, S. Krivolapov, R. Batalov, S. Popov;*
Cardiology Research Institute, Tomsk National Research Medical Centre, Russian Academy of Sciences, Tomsk, RUSSIAN FEDERATION.

Aim/Introduction: The left bundle branch block, nonischemic heart failure (HF) and female gender are the most powerful predictors of a super response to cardiac resynchronization therapy (CRT). It is important to identify super responders who can derive most benefits from CRT. It is known that a serious impact to the HF progression is made by mechanical dyssynchrony (MD), which is characterized by temporary heterogeneity of activation and contractility in various ventricular segments of the heart. The predictive values of MD assessed by nuclear medicine techniques in CRT candidates have been reported in a number of studies. We aimed to establish a predicting model that could be used for prognosis of a super response to CRT in short-term period. ***Materials and Methods:*** Patients with QRS ≥ 130 ms, New York Heart Association (NYHA) II-III class of HF, left ventricle ejection fraction (LVEF) ≤ 35% and indications for CRT were included in the study. Before and 6 month after CRT the electrocardiography, transthoracic echocardiography and cardiac scintigraphy were performed. The study's primary endpoint was the NYHA class improvement ≥ 1 and left ventricle end systolic volume decrease > 30% or LVEF improvement > 15% after 6 month CRT. Based on collected data, we developed a predictive model regarding a super response to CRT. ***Results:*** In overall 49 (100.0%) patients, 32 (65.3%) had a super response to CRT. Patients with a super response were likelier to have a lower cardiac index (p=0.007), higher rates of interventricular delay (IVD) (p=0.003), phase standard deviation of left ventricle anterior wall (PSD LVAW) (p=0.009) and ΔQRS (p=0.02). Only left ventricle MD parameters (IVD and PSD LVAW) were independently associated with a super response to CRT in univariate and multivariate logistic regression (odds ratio [OR] 1.02, 95% confidence interval [CI] 1.00-1.04, p<0.001 and OR 1.06; 95% CI 1.00-1.13; p<0.001, respectively). We created a predictive model of super response to CRT using these MD indicators in logistic equation and calculated a cut-off value. The model demonstrated discrimination ability evidenced by an AUC of 0.812 (sensitivity 90.62%; specificity 70.59%). The developed predictive model resulted in an accuracy of 81.6% in correctly diagnosing the CRT super response in our study cohort. ***Conclusion:*** We have developed a predictive model using left ventricle MD indicators, which could be applied for the prediction of a super response to CRT in short-term period and selection of most suitable patients in clinical practices.

OP-053

A study for risk stratification of sustained ventricular tachycardia with cardiac ^{123}I-MIBG scintigraphy parameters in patients with CAD and ICD

T. Atabekov, *S. Sazonova, M. Khlynin, E. Muslimova, S. Krivolapov, I. Kurlov, T. Rebrova, A. Mishkina, S. Afanasiev, R. Batalov, S. Popov;*
Cardiology Research Institute, Tomsk National Research Medical Centre, Russian Academy of Sciences, Tomsk, RUSSIAN FEDERATION.

Aim/Introduction: Multiple lines of evidence point to a pivotal role of the cardiac autonomic nervous system (CANS) in the development and maintenance of ventricular tachycardia (VT). The impaired heart sympathetic innervation and increased sensitivity of the myocardium to catecholamines can serve as VT trigger factors. Most of the trials devoted to the CANS activity assessment show the importance of one of various methods such as cardiac scintigraphy, heart rate variability (HRV) or erythrocyte membranes β-adrenoreactivity (EMA) assessment. This prospective study aimed to investigate the ability of CANS activity assessment in stratifying for sustained VT in patients with coronary artery disease (CAD) and implanted cardioverter-defibrillator (ICD) during mid-term follow-up period. ***Materials and Methods:*** We enrolled patients with CAD and ICD implantation indications. Before ICD implantation CANS was assessed by using HRV, myocardium scintigraphy with 123I-meta-iodobenzylguanidine (123I-MIBG) and EMA. The study's primary endpoint was the documentation of sustained VT according to ICD endogram recordings. Based on collected data, we developed a risk model regarding a sustained VT. ***Results:*** In overall 45 (100.0%) patients with ICD, 15 (33.3%) had sustained VT event during 30.0 [28.0; 52.0] months follow-up period. Patients with sustained VT were likelier to have a higher summed 123I-MIBG score delayed (p<0.001) and lower 123I-MIBG washout rate (p=0.008) indicators. These parameters were independently associated with endpoint in univariate and multivariate logistic regression (odds ratio [OR] 1.234, 1.079-1.412, p<0.001 and OR 0.665, 0.501-0.883, p<0.001, respectively). We created a logistic equation and calculated a cut-off value. The resulting ROC curve revealed a discriminative ability with AUC of 0.933 (sensitivity 100.00% and specificity 93.33%). The developed risk stratification model resulted in an accuracy of 95.56% in correctly diagnosing sustained VT in our study cohort. ***Conclusion:*** In patients with CAD and ICD occurrence of sustained VT associated with the CANS activity dysfunction. Our risk model including cardiac 123I-MIBG scintigraphy parameters is able to predict sustained VT in patients with CAD during mid-term follow-up period after ICD implantation. Independent prospective cohort studies should further validate our risk stratification model.

OP-054

Transient ischemic dilatation evaluated using non-gated ^{15}O-water PET

J. Sigfridsson, *P. Svanström, H. Harms, T. Kero, M. Lubberink, J. Sörensen;*
Uppsala University, Department of Surgical Sciences, Molecular Imaging and Medical Physics, Uppsala, SWEDEN.

Aim/Introduction: Left ventricular (LV) transient ischemic dilatation (TID) during myocardial perfusion imaging is a known cardiac risk marker. TID can be assessed by measuring the ratio of LV end-diastolic volume (EDV) during rest and stress. 15O-water PET allows simultaneous assessment of myocardial blood flow (MBF) and LV-volumes, and thus, it should be possible to evaluate both perfusion and TID during routine PET-scanning. Blood-pool gated 15O-water has been shown a feasible alternative to assess LV-volumes but requires extra post-processing. It would therefore relevant to assess the possibility to quantify TID without ECG-gating. The aim of this study was to assess the prognostic value of TID calculated with non-gated 15O-water PET. ***Materials and Methods:*** We retrospectively evaluated 783 consecutive patients with suspected CAD who performed rest/adenosine-stress 15O-water PET. Additionally, 44 patients with primary mitral regurgitation (MiR) with same-day PET and CMR and 15 subjects with same-day test-retest PET were included. LV EDV was automatically quantified using non-gated parametric blood volume images (1) and compared to

CMR measurements. Repeatability was assessed in the test-retest group. EDV ratio was defined as EDV stress/EDV rest*100. Patients in the CAD cohort were followed and major adverse cardiac events (MACE) were defined as cardiovascular death or hospitalization for myocardial infarction, unstable angina pectoris and acute heart failure. The prognostic value of EDV ratio was evaluated using Cox hazard ratios (HR[95% confidence interval]) and compared to stress MBF and myocardial flow reserve (MFR). ***Results:*** In the MiR patients, EDV from PET and CMR correlated well (r=0.88, p<0.001) with small bias (-10±26 ml, p=0.02). In the test-retest group, EDV was highly repeatable (172±67 vs 169±71 mL, p=0.4; repeatability coefficient 29 mL (17%)). In the CAD cohort, MACE was registered in 102 patients (median follow-up 3.6 years). Patients with MACE had significantly higher EDV ratio (95.3±14.3% vs 89.3±12.5%, p<0.001). EDV ratio was negatively correlated to stress MBF and MFR (r=-0.22 and -0.29, p<0.001). Correcting for age and sex, the EDV ratio was prognostic (HR 1.02[1.01-1.04]), but lost independent significance when adding stress MBF or MFR to the model. ***Conclusion:*** LV EDV and TID can be evaluated with non-gated 15O-water PET. EDV ratio was associated with reduced perfusion and adverse outcomes in patients with suspected CAD, but stress MBF and MFR remained stronger predictors of cardiac events. ***References:*** 1.Harms H J et al. OP-055

Stress myocardial blood flow would predict all-cause, cardiovascular and non-cardiovascular mortality in hemodialysis population.

S. Ohshima[1], *N. Umemoto[2];*
[1]Kaikoukai Nagoya Kyoritsu Hospital, Nagoya, JAPAN,
[2]Ichinomiya Municipal Hospital, Ichinomiya, JAPAN.

Aim/Introduction: N13-ammonia positron emission tomography (PET) is an established diagnostic test for IHD. We have reported that stress myocardial blood flow (MBF) and coronary flow reserve (CFR) derived from N13-ammonia PET would predict all-cause mortality in hemodialysis (HD) population in previous studies. We investigated their cardiovascular (CV) and non-CV mortality in HD population in this study. ***Materials and Methods:*** 1,020 HD patients who undergone N13-ammonia PET for suspected IHD from May 2013 to May 2022 were enrolled. They were divided into two groups according to median value of stress MBF; the lower stress MBF group (stress MBF<1.96, n=504) and the higher stress MBF group (stress MBF>= 1.96, n=516). We have followed them in 1282 days (median, 1st-3rd quartile was 510-2116). We collected their prognosis; all-cause, cardiovascular and non-cardiovascular mortality. Cardiovascular mortality included sudden death. ***Results:*** Kaplan-Meyer and cox univariate analysis showed intergroup difference in all-cause mortality (log rank p<0.001, hazard ratio (HR): 1.967, 95% confident interval (CI); 1.549-2.500), CV mortality (log rank p<0.001, HR: 2.016, 95%CI 1.395-2.914) and non-CV mortality (log rank p< 0.001, HR: 1.932, 95%CI 1.411-2.644). Multivariate cox analysis showed that stress MBF (continuous value) was an independent predictor for all-cause (p<0.001, HR: 0.4822, 95%CI 0.384-0.604), CV mortality (p<0.001, HR: 0.426, 95%CI 0.298-0.603) and non-CV mortality (p<0.01, HR: 0.529, 95%CI 0.393-0.711). ***Conclusion:*** In HD population, stress MBF would be an important predictor for all-cause, CV and non-CV mortality.

OP-056

Incremental prognostic value of ^{18}F-FDG myocardial ischemic memory imaging for major adverse cardiovascular events in patients with suspected unstable angina

F. Zhang, *Y. Wang;*
The Third Affiliated Hospital of Soochow University, Changzhou, CHINA.

Aim/Introduction: ^{18}F-FDG PET myocardial ischemia memory imaging can be used for diagnosing myocardial ischemia. It may potentially enhance risk stratification. However, its incremental prognostic value for suspected unstable angina (UA) patients remains unclear. This study aimed to evaluate whether ^{18}F-FDG PET myocardial ischemic memory imaging provides additional prognostic value for major adverse cardiac events (MACE) compared to clinical risk factors, GRACE score, and coronary artery calcium score (CACS) in suspected UA patients. ***Materials and Methods:*** This study conducted a post-hoc analysis based on a prospective study, including 265 suspected UA patients (62.3% male, mean age 65.0 ± 9.4 years). All patients underwent rest ^{18}F-FDG PET myocardial ischemic memory imaging and coronary angiography. ^{18}F-FDG positive was defined as focal or focal on diffuse uptake patterns. MACE was defined as a composite of cardiovascular death, acute myocardial infarction, heart failure, rehospitalization for unstable angina, unplanned coronary revascularization, and stroke. Multivariable Cox regression analysis was used to identify risk factors for MACE in suspected UA patients. The incremental prognostic value of ^{18}F-FDG PET myocardial ischemic memory imaging relative to clinical risk factors, GRACE score, and CACS was evaluated using C-index, net reclassification improvement (NRI) and integrated discrimination improvement (IDI). ***Results:*** During a median follow-up of 25 months, 51 (19.2%) patients experienced MACE. Multivariable Cox regression analysis showed that after adjusting for coronary revascularization and other confounding variables, ^{18}F-FDG positive was an independent predictor of MACE in suspected UA patients (HR=3.220, 95% CI: 1.630-6.360, P<0.001). ^{18}F-FDG PET myocardial ischemic memory imaging significantly improved risk stratification for suspected UA patients compared to clinical risk factors, GRACE score, and CACS (C index, 0.769 vs 0.688, P=0.045; NRI, 0.324, P=0.020; IDI, 0.055, P=0.027). ***Conclusion:*** Compared to clinical risk factors, GRACE score, and CACS, ^{18}F-FDG PET myocardial ischemic memory imaging has significantly increased prognostic value in predicting MACE in suspected UA patients. Submitting patients with suspected UA to ^{18}F-FDG PET myocardial ischemic memory imaging can help to improve their risk stratification.

OP-057

Utility of myocardial angiogenesis imaging with 99mTc HYNIC Cyclo(RGDfk)2 (RGD) SPECT/CT for myocardial viability assessment

K. Dhayalan, *M. Ponnusamy, S. Adithan, A. Anantharaj, R. Sankar;*
Jawaharlal institute of Postgraduate Medical Education and Research, Puducherry, INDIA.

Aim/Introduction: Obstructive coronary artery disease is treated by revascularization. The benefits of revascularization are most notable when hibernating myocardium is present. Myocardial viability is assessed with MIBI and FDG scans, which have shortcomings1. Radiolabelled RGD-peptide is used to image areas of neoangiogenesis. We compared RGD and FDG scans for myocardial viability assessment. ***Materials and Methods:*** In this

prospective study, CAD patients considered for revascularization underwent 99mTc-HYNIC-Cyclo(RGDfk)2 SPECT/CT in addition to the routine myocardial viability imaging. Patterns of RGD distribution were visually analysed. Segmental scores from 0 to 4 were assigned based on the degree of RGD uptake (0 = no uptake and 4 = intense uptake). Viability was defined as reduced perfusion with increased RGD or FDG uptake. Per-segment myocardial viability was compared between MIBI/RGD and MIBI/FDG pairs. Summed rest scores (SRS) and summed RGD scores (SRGS) were also analysed alongside cardiac MRI parameters. ***Results:*** Scans of 33 patients were included for analysis (30 males and 3 females). 22/33 patients had perfusion defects in a total of 150 segments. RGD uptake was noted in 31/33 (94%) patients and 93/150 (62%) perfusion defects. In 37 (24.7%) segments, RGD uptake was more than FDG; in 27 (18%) segments, FDG uptake was more than RGD. The two viability assessment methods were concordant in 57.3% and discordant in 42.7% of segments (Cohen's κ = 0.124). 23 patients had a previous history of MI, and 22 (96%) of them showed focal RGD uptake. 10 patients had no history of MI, and 7 (70%) of them showed diffuse RGD uptake (7/10). A negative correlation was observed between SRS (mean = 19.47, SD = 13.26) and SRGS (mean = 49.5, SD = 14.07), with r= -0.57 ($p < 0.001$). SRGS showed positive correlations with LVEF (r = 0.43, p=0.032) and LV Global function index (r = 0.49, p=0.01). ***Conclusion:*** RGD uptake was higher than FDG uptake in rest perfusion defects. In 43% of the patients, there was discordance in viability assessments made with RGD and FDG scans. RGD uptake was noted in areas with no FDG uptake and, therefore, may not represent viable myocardium. A higher RGD uptake was noted in patients with no severe LV dysfunction.

Evaluation of the Diagnostic Utility of Amyloid PET/MRI in Cerebral Amyloid Angiopathy

M. Pudis[1], *M. Suarez-Piñera[1], L. Rodríguez-Bel[1], F. Garay-Buitron[2], M. Cos-Domingo[2], S. Bondia-Bescós[1], B. Hervás-Sanz[1], J. Diaz-Moreno[1], G. Reynes-Llompart[3], M. Cortés-Romera[1];*
[1]Nuclear Medicine - PET (IDI), Bellvitge University Hospital, L'Hospitalet de Llobregat, Barcelona, SPAIN, [2]Radiology, Bellvitge University Hospital, L'Hospitalet de Llobregat, Barcelona, SPAIN, [3]Medical Physics and Radiation Protection Department, Hospital Duran i Reynals, L'Hospitalet de Llobregat, Barcelona, SPAIN.

Aim/Introduction: Cerebral amyloid angiopathy (CAA) is an age-related degenerative condition caused by deposition of beta-amyloid in the walls of cerebral small vessels. The gold standard for diagnosis remains histopathological examination, although the Boston criteria provide clinicians with a probabilistic approach for diagnosis based on MRI imaging characteristics. This study aimed to evaluate the efficacy of amyloid PET (A-PET) in detecting CAA among individuals with mild cognitive impairment (MCI) and to understand associated uptake patterns. ***Materials and Methods:*** This prospective study enrolled 144 patients (76 women; median age: 71 years [range: 51-88]) previously diagnosed with mild cognitive impairment. All participants underwent PET/MRI using $^{[18F]}$Flutemetamol (GE Signa), with imaging conducted 90 minutes after the injection of 5 mCi. Image interpretation was carried out by radiologists and nuclear medicine physicians. A-PET images underwent both visual and quantitative assessments to detect the presence and localization of amyloid deposits. In the quantitative analysis, the pons served as a reference region, with average SUVR values up to 0.6 considered normal. Additionally, the deposition pattern of patients with CAA and those not meeting CAA criteria were analyzed visually (anterior or posterior deposition pattern) and quantitatively (comparing Z-scores of the occipital lobe with the prefrontal and global regions using Mann-Whitney statistical analysis). MRI sequences were evaluated using the Boston 2.0 criteria for cerebral amyloid angiopathy (CAA) diagnosis. ***Results:*** A-PET yielded positive results in 79 patients (55%), negative in 59 (41%), and uncertain in 6 (4%). MRI identified CAA in 11 patients; among them, 9 exhibited A-PET positivity while 2 were A-PET negative in both visual and quantitative analysis. Two out of eleven patients with CAA showed a predominantly posterior deposition pattern visually, while quantitative analysis comparing CAA with the rest of the patients yielded non-significant results when compared with the prefrontal lobe (p=0.82588) as well as globally (p=0.77182). A-PET demonstrated a sensitivity of 82% in detecting CAA when considering MRI as the gold standard for diagnosis of this disease. ***Conclusion:*** Our study revealed a limited sensitivity of A-PET in diagnosing CAA within our patient cohort, with 100% concordance between visual and quantitative analysis. Notably, among A-PET positive CAA patients, no distinct pattern emerged compared to other positive cases. While PET/MRI evaluations proved beneficial in this cohort, further research is necessary to delineate the precise role of A-PET in patients with cognitive impairment suspected of having Alzheimer's disease, particularly given the notable percentage presenting with angiopathy.

EPS-002

Imaging Amyloid in motor regions in Alzheimer's disease

E. Jaeger[1], *G. N. Bischof[1,2], K. Giehl[1,2], F. Jessen[3,4], O. A. Onur[5,6], P. H. Weiss[5,6], A. Drzezga[1,2,4];*
[1]University of Cologne, University Hospital of Cologne, Department of Nuclear Medicine, Multimodal Neuroimaging Group, Cologne, GERMANY, [2]Research Center Juelich, Institute for Neuroscience and Medicine II, Molecular Organization of the Brain, Juelich, GERMANY, [3]University of Cologne, University Hospital of Cologne, Department of Psychiatry, Cologne, GERMANY, [4]German Center for Neurodegenerative Diseases, Bonn, GERMANY, [5]University of Cologne, University Hospital of Cologne, Department of Neurology, Cologne, GERMANY, [6]Research Center Juelich, Institute for Neuroscience and Medicine III, Cognitive Neuroscience, Juelich, GERMANY.

Aim/Introduction: Alzheimer's disease is characterized by abnormal deposits of ß-amyloid and accumulation of phosphorylated tau-protein. Amyloid deposition has been described in AD not only in brain regions associated with cognitive functions but also in motor-regions such as the

basal ganglia. These depositions have rarely been the focus of pathomechanistic studies, and it is not well studied whether they develop similarly to amyloid-deposits in other regions of the brain. Thus, the aim of this study was to investigate the development of amyloid-deposition in motor-relevant regions of the brain with advancing symptomatic disease. ***Materials and Methods:*** We included 1300 amyloid PET scans using [F^{18}]FBB or [F^{18}] AV-45 from the Alzheimer's Disease Neuroimaging Initiative (ADNI) cohort, including 502 cognitively unimpaired individuals (CU), 600 patients with mild cognitive impairment (MCI) and 198 patients with Alzheimer's Dementia (AD). SUVRs were calculated for cortical and subcortical motor-related brain regions (primary motor cortex, supplementary motor area, putamen, globus-pallidus). For comparison, a standard ROI was used which includes four large cortical regions (frontal, cingulate, parietal, temporal cortices). A repeated measurement ANOVA was performed to assess the group-related differences in amyloid pathology in each region. A partial correlation analysis was conducted in the clinical groups (MCI, AD) to assess the association between cognitive impairment (ADAS 13) and amyloid-deposits. ***Results:*** All examined brain regions, including cortical and subcortical motor-regions as well as AD-typical non-motor cortical regions showed a statistically significant increase in amyloid pathology with advancing disease stage. A significant correlation between cognitive impairment and amyloid burden was detected in non-motor and motor regions of MCI patients. In AD, a significant correlation between cognitive dysfunction and amyloid-burden was observed exclusively in the primary motor cortex and the SMA, whereas no correlation was found between amyloid-load in AD-typical non-motor regions and cognitive impairment. ***Conclusion:*** Amyloid burden increases with disease stage in cortical and subcortical motor-regions of the brain. Whereas amyloid levels in AD-typical as well as in motor-regions correlate with cognitive impairment in MCI, in AD the degree of cognitive impairment is no longer linked to amyloid-levels in AD-typical cortical regions but remains correlated to amyloid-levels in the SMA and the primary motor cortex. The maintained correlation of amyloid-levels in certain motor areas with disease severity even in manifest AD may indicate that these regions could be suitable for staging, in contrast to other brain regions for which a plateau of amyloid-deposition in early stages of dementia has been demonstrated.

EPS-003

MRI-based deep learning 3D Synthesis Amyloid-β PET for Assessment of Alzheimer's Disease

Z. Chen[1,2,3], *S. Yan[1,2,3], S. Bi[1,2,3], Z. Qi[1,2,3], B. Cui[1,2,3], H. Yang[1,2,3], J. Lu[1,2,3];*
[1]Department of Radiology & Nuclear Medicine, Xuanwu Hospital, Capital Medical University, Beijing, CHINA, [2]Beijing Key Laboratory of Magnetic Resonance Imaging and Brain Informatics, Beijing, CHINA, [3]Key laboratory of Neurodegenerative diseases, Ministry of Education, Beijing, CHINA.

Aim/Introduction: Amyloid-β (Aβ) is a core biomarker of Alzheimer's disease (AD), and Aβ PET is significant for early diagnosis and staging. However, the high cost of examination and exposure to radioactive radiation have limited the promotion of Aβ PET in early screening. With the development of deep learning algorithms, it has become possible to synthesize PET images based on MRI. Nevertheless, the current synthesis Aβ PET studies have focused on 2D image without considering meaningful information in other planes. The aim of this study was to generate 3D synthetic Aβ PET from MRI via image-to-image deep learning algorithm as important complement to early screening for AD. ***Materials and Methods:*** The high-resolution T1-weighted image (3D T1WI) and 18F-florbetapir (18F-AV45) PET data were retrospectively collected in pairs from Alzheimer's Disease Imaging Initiative (ADNI) and Xuanwu Hospital, Capital Medical University. Enrolled subjects included healthy control, mild cognitive impairment, AD, and other dementia. 18F-AV45 PET was aligned to paired 3D T1WI and then both were normalized to Montreal Neurologic Institute space. Standardized uptake value ratio map was calculated relative to the cerebellum. The share generative adversarial network (Share-GAN) model was trained on ADNI data and tested on hospital data. Two discriminators were designed based on Patch GAN, using conv3D instead conv2D for 3D image input. Synthetic PET image quality was evaluated using quantitative metrics, including the structural similarity index measure (SSIM), peak signal-to-noise ratio (PSNR), and mean absolute error (MAE). Two senior radiologists assessed Aβ deposition status by synthetic PET. ***Results:*** 676 patients (age, 76.0 ± 7.6 years; 386 female patients; 18F-AV45 = 364.6 ± 27.7 MBq) from ADNI were included in the training set, 163 patients (age, 64.7 ± 7.8 years; 103 female patients; 18F-AV45 = 383.0 ± 14.5 MBq) from Xuanwu Hospital were included in the testing set. A high degree of likeness across the testing set, which had a mean SSIM = 0.909, PSNR = 37.569 and MAE = 0.030. 3D Synthetic Aβ PET showed reliable diagnostic accuracy for Aβ deposition status, with accuracy = 83.4%, sensitivity = 83.2%, specificity = 60.4%, and F1 score = 88.5% in the testing set. ***Conclusion:*** We propose a Share-GAN model to generate 3D synthesize Aβ PET images with comparable image quality to real Aβ PET and excellent discrimination of Aβ deposition status. This may provide a low-cost Aβ PET-like auxiliary imaging method for AD patients to screen those who require real PET.

EPS-004

Amyloid deposition and glymphatic system dysfunction in early Alzheimer's disease

H. Okazawa, *M. Ikawa, M. Nogami, T. Mori, A. Makino, Y. Kiyono, H. Kosaka;*
University of Fukui, Fukui, JAPAN.

Aim/Introduction: The glymphatic system is assumed to play an important role in the clearance of disease proteins in neurodegenerative diseases. A new index using MR-DTI was used to evaluate glymphatic system function in early Alzheimer's disease (eAD) and compared to brain amyloid deposition measured by [^{11}C]Pittsburgh compound-B (PiB) PET/MRI. ***Materials and Methods:*** Sixty patients with mild cognitive impairment (MCI) and eAD (70±11 years) underwent [^{11}C]PiB PET/MRI to assess amyloid deposition and were compared with 30 age-matched cognitive normal subjects (CN: 69±10 years). All subjects were evaluated for cognitive abilities using the Mini Mental State Examination (MMSE) before PET/MRI. Multiple MRI sequences were also acquired during the PET scan including 3D-T1WI, diffusion tensor imaging (DTI), etc. The centiloid scale was obtained using standardized uptake value ratio (SUVR) images calculated from static PiB PET data at 50-70 min post-injection with the reference region of the whole cerebellum. To assess the functional activity of the glymphatic system in the brain, the DTI analysis along the perivascular space (DTI-ALPS) index was calculated. Regional parametric values and other biomarkers were compared using ANOVA and Pearson's regression analysis. ***Results:*** All patients in the eAD group had positive brain [^{11}C]PiB accumulation, while those in the CN group had negative accumulation. There was a significant difference in MMSE scores between eAD (24±4) and CN (28±4) groups. Mean PiB centiloid scales for the two groups were 78.5 ± 33.4 and 0.4 ±

6.7 (P<0.0001), respectively. The ALPS-indexes were significantly lower in the eAD group compared to the CN group for both DTI b=1000 (1.43±0.08 vs. 1.28±0.11, P<0.00001) and DTI b=2000 (1.38±0.11 vs. 1.27±0.12, P<0.005). Correlations between ALPS-index, MMSE and VSRAD Z-score were significant for all pairs of biomarkers. In correlation with PiB centiloid, the ALPS-index for b=1000 showed a better correlation coefficient (r=0.66) than b=2000 (r=0.48), and the variance observed in the confidence interval was smaller for b=1000. When PiB centiloid was compared with other biomarkers after normalization, ALPS-index had a greater slope and better correlation coefficient (0.31, r=0.65) than the other correlations. ***Conclusion:*** Glymphatic system function measured by DTI-ALPS correlates closely with amyloid deposition in eAD. PiB centiloid correlated better with DTI-ALPS than other biomarkers, suggesting that glymphatic system function and disease protein deposition would cause neurodegenerative changes and cognitive dysfunction. ***References:*** [1] Okazawa H, et al. EPS-005

Positivity Thresholds using a Commercial Tau Quantification Tool in a Clinical Population

D. Peretti[1], *R. Fahmi[2], C. Boccalini[1], G. Mathoux[3], B. Spottiswoode[2], A. Arnone[4], G. Frisoni[1,3], V. Garibotto[1,3];*
[1]University of Geneva, Geneva, SWITZERLAND, [2]Siemens Medical Solutions UNITED STATES OF AMERICA, Inc, Malvern, PA, UNITED STATES OF AMERICA, [3]Geneva University Hospitals, Geneva, SWITZERLAND, [4]Azienda Unità Sanitaria Locale IRCCS, Reggio Emilia, ITALY.

Aim/Introduction: 18F-Flortaucipir PET has received approval to estimate density and distribution of neurofibrillary tau tangles in Alzheimer's disease patients based on a set of visual interpretation guidelines. This visual assessment differs from SUVR-based semi-quantification often used in research and clinical trials. The aim of this study was to determine regional 18F-flortaucipir SUVR positivity thresholds calculated using a dedicated commercially available application and compare them with visual interpretation. ***Materials and Methods:*** A cohort of 244 subjects (average age 71±9 years) with tau PET scans acquired 75 minutes post-injection of 197±39MBq of 18F-flortaucipir for 30 minutes, at the Geneva University Hospitals was selected. All images were visually assessed for tau positivity (based on the manufacturer's reading guidelines) and for Braak stage estimation, by an experienced reader (6 years). Images were additionally assessed for tau positivity using the same guidelines by two other nuclear medicine specialists with intermediate (1 year) or low (3 months) experience. Volume-weighted SUVR values were estimated in a meta-temporal VOI for global tau assessment, and in different Braak regions. SUVR-based global tau positivity threshold were calculated using visual ratings as gold standard and Youden's index. For each Braak region, tau positivity was defined as mean+2*SD SUVR within the considered region across 110 subjects visually classified as Braak 0 (i.e., visually tau negative for all Braak regions). ***Results:*** The tau SUVR positivity threshold for the meta-temporal VOI was 1.34 (specificity=0.79, sensitivity=0.95). There were 11.5% (28/244) mismatches between classifications based on meta-temporal SUVR and visual reads, with most cases being classified as tau negative based on SUVR, while positive on visual assessment. SUVR thresholds for Braak regions were: 1.41 (Braak I-II), 1.32 (Braak III), 1.34 (Braak IV), 1.28 (Braak V), and 1.23 (Braak VI). This resulted in a fair agreement compared to visual reads (Cohen's kappa=0.31). In general, subjects were classified with a lower Braak stage in comparison to visual assessment, and 65.6% (160/244) of cases were classified as Braak 0 based on SUVR thresholding. The agreement between the predicted tau status using the semi-quantitative threshold and visual inspection was similar across all raters (0.75 for the experienced, 0.72 for the intermediate, and 0.73 for the low experience reader, p<0.01). ***Conclusion:*** Commercial tau semi-quantification tools might be of aid to determine tau positivity. Thresholds identified in this cohort are comparable with values reported in the literature and resulted in a good agreement between quantitative and visual interpretations.

EPS-006

Diagnostic Yield of [123I]FP-CIT SPECT and [18F]DOPA-PET-CT in Parkinsonian Syndromes

J. Fernandez, *A. Badenes;*
Consorcio Hospitalario Provincial de Castellón, Castellón, SPAIN.

Aim/Introduction: Neurodegenerative pathologies with dopaminergic deficits reach a prevalence of 2% in individuals over 60 years old (1). Their diagnosis is exclusively clinical and constantly requires revisions for confirmation. In this context, dopamine transporter imaging tests are crucial tools to confirm the presence of Parkinsonian Syndromes (PS). Objectives: To compare parallel results of diagnostic yields for Parkinsonian syndromes using [123I]FP-CIT SPECT and [18F]DOPA-PET-CT against the final clinical diagnosis as the reference standard. ***Materials and Methods:*** A retrospective observational study was conducted on a sample of 67 patients with suspected parkinsonian syndromes who underwent diagnostic tests between January and December 2023. The results of each test were compared with the final clinical diagnosis as the reference standard. Sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), overall accuracy, Cohen's kappa index, and other relevant statistical data were calculated using R-studio version 4.3.3 for Windows. ***Results:*** Of the studied sample, 32 (47.8%) subjects underwent [123I]FP-CIT SPECT and 35 (52.2%) [18F]DOPA-PET-CT. The mean age observed was 69 ± 10.3 years, with 53.73% being women. The specificity of [18F]DOPA-PET-CT was 0.9523 (95% CI: 0.86-1.04), compared to 0.73 (95% CI: 0.50-0.95) for [123I]FP-CIT SPECT, with similar sensitivity of 0.92 (95% CI: 0.79-1.06) and 0.94 (95% CI: 0.82-1.05) respectively. The overall accuracy was 0.94 (95% CI: 0.86-1.01) for [18F]DOPA-PET-CT and 0.84 (95% CI: 0.71-0.96) for [123I] FP-CIT SPECT. The unweighted Kappa index was found to be 0.7544 (Z=10.382, p < 0.001), and the weighted Kappa index was 0.6513 (Z=6.434, p < 0.001), indicating substantial and moderate agreement between observers. ***Conclusion:*** The results show, in our population, good diagnostic performance of [18F]DOPA-PET-CT and acceptable performance in [123I]FP-CIT SPECT. Both tests effectively rule out the disease; however, only [18F]DOPA-PET-CT is suitable for confirming it. This is a parallel study where there is no direct comparison between imaging tests, so it is recommended to conduct prospective cross-comparative studies evaluating both tests in the same group of patients. ***References:*** Official clinical recommendations guide for Parkinson's disease. 2019, Spanish Society of Neurology.

EPS-007

The need of age-adjusted cut-offs for Z-score of DaT SPECT striatal binding ratio (SBR) to support the differential diagnosis between Parkinson's Disease (PD) and Essential Tremor (ET)

***F. Lanfranchi*[1]**, *D. Zogala*[2], *D. Arnaldi*[3,4], *P. Dušek*[5], *S. Raffa*[3], *F. Massa*[3,4], *M. Pardini*[3,4], *L. Sofia*[1], *B. Orso*[4], *P. Mattioli*[4], *T. Di Raimondo*[1], *F. D'Amico*[1], *G. Rovera*[6], *G. Sambuceti*[1,3], *M. Bauckneht*[1,3], *S. Morbelli*[6];**

[1]Nuclear Medicine, Department of Health Sciences (DISSAL), University of Genoa, Genoa, ITALY, [2]Institute of Nuclear Medicine, First Faculty of Medicine, Charles University and the General University Hospital in Prague, Prague, CZECH REPUBLIC, [3]IRCCS Ospedale Policlinico San Martino, Genoa, ITALY, [4]Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOGMI), University of Genoa, Genoa, ITALY, [5]Department of Neurology and Center of Clinical Neuroscience, First Faculty of Medicine, Charles University and the General University Hospital in Prague, Prague, CZECH REPUBLIC, [6]Nuclear Medicine, University of Turin, Turin, ITALY.

Aim/Introduction: A cut-off of -2 z-score for DaT SPECT SBR has been arbitrarily proposed to define abnormal scans in patients with suspected neurodegenerative parkinsonism. We previously demonstrated that different and less conservative semiquantitative cut-offs increase sensitivity without decreasing test's specificity in the diagnosis of either PD or Dementia with Lewy Bodies. Aging is a further source of heterogeneity linked to the expected progressive loss of dopaminergic neurons. Here, we tested the accuracy of DaT SPECT parameters and z-score cut-offs in distinguishing PD from essential tremor (ET) in patients grouped by age. ***Materials and Methods:*** We retrospectively enrolled 275 patients (175 PD and 100 ET; age 68.7±8.7 vs. 70.5±7.7; females 40% vs. 57%) who underwent DaT SPECT in two centers (Genoa and Prague). The gold-standard was final clinical diagnosis after at least 2 years, irrespective from DaT SPECT result. Images were flipped obtaining the most affected hemisphere (MAH) on the same side and were analyzed with Datquant® version 2 to compute z-scores of striatum, substriatal regions and putamen/caudate (P/C) ratio. Patients were tested all together and binarized by median age (90 PD and 44 ET, range: 50-69 vs. 85 PD and 56 ET, range: 70-84). ROC curves, with a 5-fold cross-validation approach, were used to compute AUCs, sensitivity (Se), specificity (Sp) and Youden's index (YI) of Datquant-derived parameters and z-scores. AUCs were compared with the Hanley-McNeil method. ***Results:*** Clinical characteristics between the two subgroups of PD patients were not significantly different. The posterior putamen of the MAH was confirmed as the most accurate parameter for discriminating between PD and ET in the whole sample (AUC=0.99), with -1.1 as the most accurate z-score (Se=0.98, Sp=0.99, YI=0.97). Most accurate z-scores were -1.4 (Se=0.98, Sp=1, YI=0.98) for younger patients and -0.8 (Se=0.99, Sp=0.98, YI=0.97) for older patients. In all cases, -2 resulted less accurate compared to experimentally-identified age-tailored cut-offs (YI=0.90, 0.95, and 0.82), showing lower sensitivities (0.90, 0.95, and 0.82) with small or absent gains in specificity. The accuracy of the P/C ratio (AUC=0.88 in the whole sample) resulted significantly lower in the older subgroup when compared to younger patients (AUC=0.84 vs. 0.94; p=0.005). ***Conclusion:*** Age affects value and accuracy of z-score cut-offs for SBR. Regardless of aging, less conservative cut-offs are more sensitive but not less specific than -2. The added value of the P/C ratio is more pronounced in younger patients. These results have practical repercussions for the clinical settings.

EPS-008

Disease-tailored parameters and cut-offs for the diagnosis of Progressive Supranuclear Palsy (PSP): a semiquantitative approach to Dopamine Transporter (DaT) imaging in the memory clinic setting

***F. Lanfranchi*[1,2]**, *S. Bondia-Bescós*[3], *M. Losa*[2,4], *W. Kreshpa*[2,4], *B. Orso*[4], *B. Sambucco*[1,2], *S. Raffa*[2], *M. Bauckneht*[1,2], *L. Sofia*[1,2], *G. Rovera*[5,6], *G. Sambuceti*[1,2], *M. Pardini*[2,4], *F. Massa*[2,4], *D. Arnaldi*[2,7], *S. Morbelli*[5,6];**

[1]Nuclear Medicine, Department of Health Sciences (DISSAL), University of Genoa, Genoa, ITALY, [2]IRCCS Ospedale Policlinico San Martino, Genoa, ITALY, [3]Nuclear Medicine - PET (IDI) Department, Bellvitge University Hospital, L'Hospitalet de Llobregat, Barcelona, SPAIN, [4]Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOGMI), University of Genoa, Genoa, ITALY, [5]Department of Medical Sciences, University of Turin, Turin, ITALY, [6]Nuclear Medicine Unit, AOU Citta' della Salute e della Scienza di Torino, Turin, ITALY, [7]Division of Neurophysiology and Epilepsy Centre, IRCCS Ospedale Policlinico San Martino, Genoa, ITALY.

Aim/Introduction: DaT-SPECT is a valuable tool to support the diagnosis of PSP. Peculiar alterations (a more prominent involvement of the caudatus) have been suggested as potential features to identify PSP at visual-analysis. By contrast, semiquantitative approaches to DaT-SPECT has been tuned to define abnormal scans in Parkinson's Disease and Dementia with Lewy Bodies (DLB), but there's lack of studies tailoring semiquantification to support the suspect of PSP. We targeted most accurate z-score cut-offs for striatal binding ratio (SBR) to identify PSP with a specific focus on the memory clinic setting, when a differential diagnosis is needed with respect to patients presenting cognitive impairment with parkinsonism and/or frontal features. ***Materials and Methods:*** One-hundred nineteen consecutive patients (35 PSP, 20 Alzheimer's Disease (AD), 14 Fronto-temporal Dementia (FTD), and 50 DLB) referred to our memory clinic and submitted to DaT-SPECT were included. Cortico-basal syndrome/degeneration was not included given the low-accuracy of clinical diagnosis. Patients' clinical diagnosis after a 2-years follow-up was the gold-standard (regardless of DaT-SPECT results). For all patients' subgroups, striatal/substriatal regions' SBR were computed and z-scores were obtained with Datquant® in comparison with 118 healthy volunteers belonging to the Parkinson›s Progression Markers Initiative. ROC analysis was used to calculate accuracy (AUC), sensitivity (Se), specificity (Sp), and Youden's index (YI) to identify the most accurate z-score cut-offs in PSP compared to all other subgroups. ***Results:*** Severity of cognitive impairment (MMSE score 23.42±4.35 for the entire population) and mean age (76.35±6.33) were superimposable between PSP and other subgroups (p=ns). The most accurate parameter to discriminate between PSP and all other patients was the posterior-putamen in both hemispheres (AUC=0.71). The same substriatal region distinguished PSP from AD (highest accuracy -0.7 z-score; AUC=0.95, Se=0.87, Sp=0.90, YI=0.77) as well as PSP from FTD patients, although a more conservative cut-off was needed (-1.6 z-score; AUC=0.80, Se=0.74, Sp=0.71, YI=0.46). Only when comparing PSP and DLB, the bilateral caudatus resulted the most accurate parameter, but its diagnostic value was poor (AUC=0.59). ***Conclusion:*** The posterior-putamen was confirmed as the most accurate semiquantitative parameter also to support the diagnosis of PSP even in the memory clinic setting. A more pronounced alteration is needed to tell apart PSP with respect to FTD. The present semiquantitative approach confirmed a more prominent involvement of the caudatus nucleus in PSP compared to DLB, although the added diagnostic value was

low and this feature might only represent a red-flag to increase sensitivity for PSP.

EPS-009

Measurement of extrastriatal ^{18}F-FDOPA uptake in idiopathic Parkinson disease

J. Darcourt, *P. Koulibaly, C. Maurel, N. Sapin, O. Humbert; Centre Antoine Lacassagne, Nice, FRANCE.*

Aim/Introduction: Extrastriatal (ES) 18F-FDOPA uptake sites have been investigated previously with dynamic imaging and dedicated brain PET cameras. Visualization of midbrain "Mickey mouse" shape uptake is one of the visual landmark of 18F-FDOPA in current static imaging of idiopathic Parkinson disease (IPD) (1). We investigated the feasibility of semi-quantitative analysis of 18F-FDOPA midbrain and other ES structures on routine static 18F-FDOPA PET imaging. ***Materials and Methods:*** 40 IPD patients (mean age 70±9) H&Y 1 and 2 and 31 patients with essential tremor (ET) (mean age 69±12) were retrospectively analysed. One hour after Carbidopa premedication, patients were injected with 3 MBq/kg of 18F-FDOPA and scanned 90 minutes later. A SiPM PET/CT camera was used (Siemens Biograph Vision 600®). Static acquisition lasted 6 minutes; images were reconstructed including PSF correction. For each ES region, a 3D VOI was manually centered on maximal uptake and an isocontour adjusted to the volume of the corresponding structure: 0.5 cm3 for the substantia nigra pars compacta (SN); 1.5 cm3 for the periaqueductal gray (PAG) around the mesencephalic aqueduct. Beside these midbrain structures pineal gland (PG), anterior cingulate (AC) and entorhinal cortex (EC) uptake were measured as well as striatal to occipital uptake ratios (SOR using automatical VOI positioning; Siemens Striatal Analysis®). Striatal anteroposterior gradient was calculated. ***Results:*** As expected SORs were significantly decreased and posteroanterior gradient significantly increased in IPD vs ET ($p<0.001$) and were more severely reduced on the side contralateral to the dominant symptoms ($p< 0.001$) in IPD. SN contralateral SUVs were lower than on the ipsilateral side in IPD but no significant difference was found with ET. Original findings were higher PAG and EC SUVs in IPD than in ET ($p<0.01$). There was no other significant difference. ***Conclusion:*** PAG and EC increased uptake in IPD most likely reflects increased amino-acid decarboxylase activity in serotoninergic neurons, DOPA acting as a "false transmitter". These results show the feasibility of midbrain structure analysis using routine fast static imaging with a SiPM modern camera and open the way to serotonin-related PAG imaging with 18F-FDOPA PET. ***References:*** 1- Morbelli S et al. EANM practice guideline/SNMMI procedure standard for dopaminergic imaging in Parkinsonian syndromes 1.0. EJNMMI (2020) 47: 1885-1912.

EPS-010

A combined PET/MRI study on the interplay between dopamine D_1 receptor availability and iron levels in Gilles de la Tourette syndrome (GTS)

M. Rullmann[1], *D. Gkotsoulias[2], S. Schmitt[3], C. Fremer[3], C. Klages[3], K. Hartung[3], A. Bujanow[2], F. Zientek[1], K. Messerschmidt[1], M. Patt[1], O. Sabri[1], K. Müller-Vahl[3], H. Möller[2], H. Barthel[1];*
[1]Department of Nuclear Medicine, University of Leipzig, Leipzig, GERMANY, [2]Max Planck Institute for Human Cognitive and Brain Sciences, Leipzig, GERMANY, [3]Clinic of Psychiatry, Social Psychiatry and Psychotherapy, Hannover Medical School, Hannover, GERMANY.

Aim/Introduction: Gilles de la Tourette syndrome (GTS) is a neuropsychiatric disorder characterized mainly by motor and vocal tics. Literature suggests a dysregulated dopaminergic system, with a selective dopamine D1 receptor (D1R) antagonist providing promising treatment results. Recently, we reported D1R changes in patients with GTS in relation to the clinical disease severity. We now expand the investigations on our multimodal data to better understand the role of iron in dopamine neurotransmission in GTS. ***Materials and Methods:*** We performed D1R PET using [^{11}C]SCH23390 on a Siemens Biograph hybrid PET/3T MRI system in 20 patients with GTS and 20 age- and sex-matched healthy controls (HCs). After injection of 474 ± 31 MBq, participants underwent a 90 min. dynamic PET scan, whose data was motion-corrected and co-registered to individual T1-MP2RAGE MRI data. We performed kinetic modeling (MRTM2) to generate parametric binding potential (BPND) maps. As a surrogate for iron, Multi-Echo Gradient recalled Echo (ME-GRE) MRI sequence on a 7T MRI (Siemens Magnetom Terra) was used to model quantitative susceptibility mapping (QSM), R2* and paramagnetic component maps. Additionally, we took blood serum to assess ferritin, transferrin and iron levels. Group comparisons were conducted using two sampled t test, correlations were assessed using Spearman. ***Results:*** We found significant QSM signal reductions in patients with GTS compared to HCs in several subcortical brain regions such as pallidum (4.1 ± 2.3 vs. 5.6 ± 2.4, $p = 0.01$), caudate (2.9 ± 1.1 vs. 3.7 ± 1.6, $p = 0.03$) and thalamus (0.3 ± 0.2 vs. 0.5 ± 0.3, $p = 0.002$). This echoes the differences we found in D1R availability (E.g. caudate: 2.0 ± 0.2 vs. 2.2 ± 0.3, $p = 0.02$; thalamus: 0.3 ± 0.04 vs. 0.4 ± 0.1, $p = 0.03$). Iron-related serum markers showed reduced levels in patients for ferritin (95 ± 54 vs. 130 ± 88, $p = 0.04$) and transferrin (2.4 ± 0.2 vs. 2.6 ± 0.3, $p = 0.001$). ***Conclusion:*** These results indicate a potential link between iron brain accumulation and dopaminergic neurotransmission in patients with GTS and controls. Serum results support the hypothesis of disturbed hemic iron homeostasis in GTS.

^{18}F-FDG PET can effectively rule out conversion to dementia and the presence of CSF biomarker of neurodegeneration: a real-world data analysis

S. Heyer[1], *M. Simon[2], M. Doyen[3], A. Mortada[1], V. Roch[1], É. Jeanbert[2], N. Thilly[1], C. Malaplate[4], A. Kearney-Schwartz[5], T. Jonveaux[6], A. Bannay[7], A. Verger[8];*
[1]Université de Lorraine, CHRU Nancy, Department of Nuclear Medicine and Nancyclotep Imaging Platform, Nancy, FRANCE, [2]Université de Lorraine, CHRU-Nancy, Department of Methodology, Promotion and Investigation, NANCY, FRANCE, [3]Université de Lorraine, IADI, INSERM U1254, Nancy, FRANCE, [4]Université de Lorraine, CHRU-Nancy, Department of Biochemistry, Nancy, FRANCE, [5]Université de Lorraine, CHRU-Nancy, Department of Geriatrics and CMRR, University Hospital Nancy, Nancy, FRANCE, [6]CMRR, University Hospital Nancy and Department of Neurology, University Hospital Nancy, Nancy, FRANCE, [7]Medical Assessment and Information Department, Université de Lorraine, CHRU-Nancy, Nancy, FRANCE, [8]Université de Lorraine, CHRU Nancy, Department of Nuclear Medicine and Nancyclotep Imaging Platform and IADI, INSERM U1254, Nancy, FRANCE.

Aim/Introduction: Precisely defining the delay in onset of dementia is a particular challenge for early diagnosis. Brain [18F] fluoro-2-deoxy-2-D-glucose (18F-FDG) Positron Emission Tomography (PET) is a particularly interesting tool for the early diagnosis of neurodegenerative diseases, through the measurement of the cerebral glucose metabolic rate. There is currently a lack of longitudinal studies under real-life conditions,

with sufficient patients, to accurately evaluate the predictive values of brain 18F-FDG PET scans. Here, we aimed to estimate the value of brain 18F-FDG PET for predicting the risk of dementia conversion and the risk of occurrence of a neurodegenerative pathology. ***Materials and Methods:*** Longitudinal data for a cohort of patients with no diagnosis of dementia at the time of recruitment referred by a tertiary memory clinic for brain 18F-FDG PET were matched with (1) data from the French National Health Data System (NHDS), (2) data from the National Alzheimer Bank (NAB), and (3) lumbar puncture (LP) biomarker data. The criteria for dementia conversion were the designation, within the three years after the brain 18F-FDG PET scan, of a long-term condition for dementia in the NHDS and a dementia stage of cognitive impairment in the NAB. The criterion for the identification of a neurodegenerative disease in the medical records was the determination of LP biomarker levels. ***Results:*** Among the 403 patients (69.9±11.4 years old, 177 women) from the initial cohort with data matched with the NHDS data, 137 were matched with the NAB data, and 61 were matched with LP biomarker data. Within three years of the scan, a 18F-FDG PET had negative predictive values of 85% for dementia conversion (according to the NHDS and NAB datasets) and 95% for the presence of LP neurodegeneration biomarkers. It was also shown that a normal brain 18F-FDG PET had an NPV of 96% for the risk of death at 3 years. In addition, the visual and semi-quantitative analyses of brain 18F-FDG PET showed an accuracy of 70% in the diagnosis of neurodegenerative pathologies and 87% in the diagnosis of Alzheimer's disease. ***Conclusion:*** A normal brain 18F-FDG PET scan can help rule out the risk of dementia conversion and the presence of cerebrospinal fluid (CSF) biomarker of neurodegeneration early with high certainty, allowing modifications to patient management regimens in the short term. Brain 18F-FDG PET could thus be utilized in routine first-line complementary investigations for assessing cognitive complaints.

EPS-012

[18F]FDG PET for Differential Diagnosis of Cognitive Impairment in Depression: Incremental Value Compared to Clinical Diagnosis

L. Frings, *S. Hellwig, M. Heibel, N. Schroeter, G. Blazhenets, K. Domschke, J. Brumberg, P. T. Meyer;*
University of Freiburg Medical Center, Freiburg, GERMANY.

Aim/Introduction: Assessment of regional glucose metabolism by [18F]FDG positron emission tomography (PET) is used as a diagnostic biomarker for differential diagnosis of dementia. In contrast, psychiatric disorders like depression with cognitive impairment often referred to as pseudo-dementia show no overt abnormalities on cerebral [18F]FDG PET. The present study validates the incremental diagnostic value of [18F]FDG PET in addition to clinical diagnosis in a real-life geriatric mental health clinical population. ***Materials and Methods:*** Ninety-eight consecutive patients with clinically verified depression and cognitive impairment were included. Baseline clinical diagnoses were independently established before and after disclosure of [18F]FDG PET and dichotomized into cases with neurodegenerative or non-neurodegenerative diseases (ND or NND; level 1). In an additional step, ND cases were allocated to diagnostic subgroups (AD, LBD, FTLD, ND other; level 2). An interdisciplinary, biomarker-supported consensus diagnosis after a median follow-up of 6.6 month after PET served as reference. Changes of clinical diagnoses and diagnostic accuracy were assessed. ***Results:*** After disclosure of [18F]FDG PET, level-1 clinical diagnoses changed in 23% of cases, improving the diagnostic accuracy from 72% to 92% ($p<0.001$). Similar fractions of cases with a final diagnosis of ND (3/50; mostly early AD with pathological AD biomarkers) and NND (3/48) in clinically suspected NND and ND, respectively, were missed by the clinical diagnosis also after [18F]FDG PET disclosure. Still, [18F]FDG PET was of particular value for exclusion of ND. Concerning level-2 decisions, the clinical diagnoses changed in 30% of cases, increasing its accuracy from 64% to 85% ($p<0.001$). A major fraction of cases with incorrect level-2 diagnoses comprised patients with AD that were misdiagnosed with LBD. Stratification by MMSE score, MADRS score and patient age did not significantly affect the results. ***Conclusion:*** [18F]FDG PET has a high impact on the clinical diagnosis and provides a significant incremental diagnostic value beyond the clinical diagnosis in depressive cognitive impairment. Thus, [18F]FDG PET should be considered as an essential part in the diagnostic work-up of patients with psychiatric disorders and cognitive impairment.

EPS-013

Feasibility and initial examination of chemokine receptor-4 (CXCR4) expression using 68Ga-Pentixafor (Pars-Cixafor™) PET-MR image fusion in high-grade gliomas (HGG)

Aim/Introduction: The treatment of brain tumors relies heavily on imaging techniques. While magnetic resonance imaging (MRI) is considered the gold standard, its ability to differentiate between tumor areas and treatment-related changes is limited. Glioma cells, especially in glioblastoma multiforme (GBM), show overexpression of amino acid agents and chemokine receptor-4 (CXCR4). This study aims to assess the feasibility of non-invasive 68Ga-Cixafor™ PET/CT in improving diagnostic accuracy in glioma. ***Materials and Methods:*** Our retrospective analysis used a database of histopathology-proven glioma patients with positive MRI. The patients underwent 68Ga-Cixafor™ PET/CT scans to evaluate CXCR4 expression. Visual and semi-quantitative scores were calculated, including maximum standardized uptake value (SUVmax) and tumor-to-background ratios (TBR). ***Results:*** We enrolled 29 cases in our cohort, including 13 female patients (44.8%) and 16 male patients (55.2%), with a median age of 56

years (range: 11-73). Visual assessment of 68Ga-Cixafor™ PET imaging showed that 27 out of 29 cases were positive, with a median SUVmax of 2.31 (range: 0.49-9.96) and TBR of 20 (range: 6.12-124.5). Among the 29 patients, 17.24% (5/29) had World Health Organization (WHO) grade III and 82.75% (24/29) had grade IV pathologies. The median SUVmax of grade IV lesions was significantly higher than that of grade III lesions (P=0.02). There was no significant difference in median TBR between grade IV (20, range: 8.36-124.5) and grade III (22.37, range: 6.12-51.25). ***Conclusion:*** This study demonstrates that 68Ga-Cixafor™ PET exhibits a high TBR with low background activity in the cortex, suggesting its potential to enhance tumor detection in gliomas. The combination of imaging and therapeutic capabilities further highlights the potential of 68Ga-Cixafor™ as a valuable tool for improved detection and management of gliomas.

EPS-014

FET PET uptake characteristics in IDH-mutant glioma

***E. Barci*[1],** *R. Forbig*[2], *K. J. Müller*[3], *S. Kunte*[1], *L. Kaiser*[1], *C. Schichor*[4], *P. Harter*[5], *M. Preusser*[6], *L. von Baumgarten*[4], *N. Thon*[4], *N. L. Albert*[1]; *[1]Department of Nuclear Medicine, LMU University Hospital, LMU Munich, GERMANY, [2]Department of Neuroradiology, LMU University Hospital, LMU Munich, GERMANY, [3]Department of Neurology, LMU University Hospital, LMU Munich, GERMANY, [4]Department of Neurosurgery, LMU University Hospital, LMU Munich, GERMANY, [5]Center for Neuropathology and Prion Research, LMU University Hospital, LMU Munich, GERMANY, [6]Division of Oncology, Department of Medicine I, Medical University of Vienna, Vienna, AUSTRIA.*

Aim/Introduction: Contrast enhancement in MRI correlates to response to treatment with the IDH inhibitor vorasidenib in IDH-mutant glioma. Tracer uptake on amino acid PET with FET is associated with tumor type and malignancy in gliomas. We investigated the correlation of contrast media and FET uptake in newly diagnosed IDH-mutant glioma as a basis for future biomarker studies for refined prediction of vorasidenib efficacy. ***Materials and Methods:*** Patients with histologically verified IDH-mutant glioma WHO grade 2-4 (WHO 2021 classification) without prior surgery, radio- and / or chemotherapy were included. Static FET PET parameters (maximal and mean tumor-to-background ratios (TBRmax and TBRmean) and PET volume were evaluated and compared to contrast-enhanced MRI as well as neuropathological diagnosis. PET and MRI-based lesions (contrast enhancement; T2 hyperintensity) were compared visually. ***Results:*** Overall, 44/147 (29.9%) cases showed contrast enhancement on MRI. Among the 103 gliomas without contrast enhancement on MRI, 57 (55.3%) presented with [18F]FET uptake. On [18F]FET PET, 98/147 (66.6%) cases were FET-positive, with a higher proportion in oligodendrogliomas compared to astrocytomas (91.2% vs. 44.3%). Among the 49 FET-negative gliomas, only 4 (8.2%) presented with contrast-enhancement on MRI. Both, presence of contrast enhancement as well as FET positivity showed a positive correlation with the WHO grade. [18F]FET uptake intensity showed a correlation with the WHO grade, however, with a high overlap of TBRmax and TBRmean values between WHO grades. Areas of [18F]FET uptake significantly exceeded areas of contrast enhancement in 25/44 (56.8%) cases. In 24/44 (54.5%) of cases, MRI and PET showed divergent hotspots. In 45/103 (43.7%) IDH-mutant gliomas without contrast enhancement, PET revealed a hotspot. ***Conclusion:*** FET PET provides complementary information to contrast-enhanced MRI in IDH-mutant glioma and therefore should be explored as additional biomarker. Future studies should put PET positivity into relation to response to IDH inhibitor therapy.

EPS-015

Correlation between synapse loss and cognitive performance in temporal lobe epilepsy: humans and animals PET imaging study with [18F]SynVesT-1

L. Xiao, *S. Xiang, Y. Tang, L. Feng, S. Hu;*
Xiangya Hospital Central South University, Changsha, CHINA.

Aim/Introduction: Cognitive impairment is a common comorbidity in individuals with temporal lobe epilepsy (TLE), yet the underlying mechanisms remain unknown. This study explored the putative association between in vivo synaptic loss and cognitive outcomes in TLE patients by positron emission tomography (PET) imaging of synaptic vesicle glycoprotein 2A (SV2A). ***Materials and Methods:*** We enrolled 16 TLE patients and 10 cognitively normal controls. All participants underwent SV2A PET imaging using [18F]SynVesT-1 and cognitive assessment. Lithium chloride-pilocarpine-induced rats with status epilepticus (n=20) and controls (n=6) rats received levetiracetam (LEV, specifically binds to SV2A), valproic acid (VPA), or saline for 14 days. Then, synaptic density was quantified by [18F]SynVesT-1 micro-PET/CT. The novel object recognition and Morris water maze tests evaluated TLE-related cognitive function. SV2A expression was examined and confirmed by immunohistochemistry. ***Results:*** TLE patients showed significantly reduced synaptic density in hippocampus, which was associated with cognitive performance. In the rat model of TLE, The expression of SV2A and synaptic density decreased consistently in a wider range of brain regions, including the entorhinal cortex, insula, hippocampus, amygdala, thalamus, and cortex. We treated TLE animal models with LEV or VPA to explore whether synaptic loss contributes to cognitive deficits. It was found that LEV significantly exerted protective effects against brain synaptic deficits and cognitive impairment. ***Conclusion:*** This is the first study to link synaptic loss to cognitive deficits in TLE, suggesting [18F]SynVesT-1 PET could be a promising biomarker for monitoring synaptic loss and cognitive dysfunction. LEV might help reverse synaptic deficits and ameliorate learning and memory impairments in TLE patients.

EPS-016

Synaptic density network dysfunction in temporal lobe epilepsy follows risk gene transcriptional downregulation

L. Xiao, *Y. Tang, L. Feng, S. Hu;*
Xiangya Hospital Central South University, Changsha, CHINA.

Aim/Introduction: Temporal lobe epilepsy (TLE) is a brain network disorder closely associated with synaptic loss and has a genetic basis. However, the in vivo whole-brain synaptic changes at the network-level and the underlying gene expression patterns in patients with TLE remain unclear. ***Materials and Methods:*** In this study, we utilized a positron emission tomography with the synaptic vesicle glycoprotein 2A radioligand [18F]SynVesT-1 cohort and two independent transcriptome datasets to investigate the network properties of whole-brain synaptic connectivity in TLE and its correlation with significantly dysregulated risk genes. ***Results:*** We observed an overall decrease in synaptic connectivity strength, reduced clustering coefficient, and increased path length in TLE, suggesting a loss of synaptic connectivity, particularly long-distance connections, accompanied by network reorganization. These changes were predominantly distributed in the temporo-limbic circuit and fronto-parietal networks. Moreover, these synaptic network changes were spatially correlated with the brain-wide expression of TLE risk genes. In particular, we identified 183 downregulated genes that contribute to the

transcriptional regulation of synaptic network dysfunction, with GABAergic genes such as SLITRK3 and RBFOX1 playing a critical role in TLE pathogenesis. ***Conclusion:*** Our study provides the first evidence that the spatial expression patterns of downregulated risk genes underlie in vivo synaptic network dysfunction in TLE. These imaging-transcriptomic findings have the potential to guide the development of molecular and genetic network-based therapeutic approaches for TLE.

EPS-017

Clinical evaluation of inflammation in neuromyelitis optica spectrum disorders using $^{[18F]}$-DPA714 TSPO PET/MR Imaging

X. Zhou, *S. Hu, T. Jiang, J. Li;*
Xiangya Hospital, Changsha, CHINA.

Aim/Introduction: Neuromyelitis optica spectrum disorder (NMOSD) is an autoimmune demyelinating disorder of the central nervous system, mediated by antibodies against aquaporin-4 water channel protein (AQP4-Abs). Early effective therapy is crucial to prevent long-term disability and preserve quality of life. It is imperative for clinicians to promptly and accurately identify and assess the severity of the patient's condition. This study aims to explore the potential of $^{[18F]}$-DPA714 TSPO PET/MR imaging in evaluating inflammation in NMOSD for early diagnosis, understanding of disease pathogenesis and optimized treatment strategies. ***Materials and Methods:*** Twenty NMOSD patients and 17 healthy controls underwent $^{[18F]}$-DPA714 PET/MRI scans and were included. All participants were genotyped for TSPO polymorphism. Increased regional $^{[18F]}$DPA-714 retention was detected on a voxel basis using statistical parametric mapping analysis, with multiple correspondence analysis conducted to explore patterns of inflammation distribution. PET images were coregistered, normalized and segmented to standard brain templates using SPM12. Standardized uptake value ratios normalized to the whole brain (SUVR) were calculated for quantitative analysis of TSPO PET/MRI features between NMOSD and healthy controls. ***Results:*** All participants of genotypes of rs6971 encoding amino acids were categorized as high-affinity binders. Based on visual assessment, PETMRI could reliably identify increased focal neuroinflammation in NMOSD while enhanced MRI reported normal. NMOSD patients exhibited significantly higher $^{[18F]}$-DPA714 SUVR compared to healthy controls bilaterally in the optic nerve ($p < 0.05$) and brainstem ($p < 0.05$). The uptake in these regions correlated with the severity of motor symptoms but not with the AQP4 antibody titer in serum. Additionally, subgroup analysis based on Expanded Disability Status Scale (EDSS) revealed distinct inflammatory profiles among NMOSD patients, suggesting a potential influence on disease course and response to treatment. ***Conclusion:*** $^{[18F]}$-DPA714 PET/MR imaging demonstrates excellent sensitivity in confirming astrocyte activation in NMOSD, and the SUVR was positively corrected with the EDSS, providing a comprehensive disease-specific evaluation that guides effective management of NMOSD. Further exploration of inflammation patterns could enhance personalized treatment for individual needs.

EPS-018

Exploring Whole-brain Glucose Metabolic PatterntoDistinguish Minimally Conscious state fromUnresponsive Wakefulness Syndrome: an Important Role of Corticothalamic SystemInteractions

K. Guo, *Z. Quan, F. Kang, J. Wang;*
Xijing Hospital, The Fourth Military Medical University, Xian, CHINA.

Aim/Introduction: Detecting conscious awareness poses challenges in accurately identifying unequivocal signs of consciousness, impeding the formulation of individualized rehabilitation strategies. 18F-labeled-fluorodeoxyglucose positron emitting tomography (18F-FDG PET) imaging, which calculated glucose metabolism, emerges as a promising tool for detecting brain function related to residual consciousness. This study aims to explore the glucose metabolic pattern (GMP) detrived from SSM/PCA in patients with minimally conscious state (MCS) and unresponsive wakefulness syndrome (UWS), further assessing the expression of GMP in distinguish MCS from UWS. ***Materials and Methods:*** Fifty-seven patients with disorders of consciousness (21 cases of UWS and 36 cases of MCS) for whom the clinical diagnosis with the repeated standardized Coma Recovery Scale-Revised (CRS-R) were enrolled. All patients and healthy controls (HCs) underwent 18F-labeled-fluorodeoxyglucose positron emitting tomography (18F-FDG-PET) to investigate brain glucose metabolism. Voxel-based scaled subprofile model/principal component analysis (SSM/PCA) was used to generate GMP and the expression score was obtained and compared. The diagnostic accuracy of standard uptake value ratio (SUVR) based on frontoparietal cortex was calcalated. Outcome was assessed after 12 months with the Glasgow Outcome scale-Extended. ***Results:*** Relative to HCs, UWS GMP exhibited widespread hypometabolism in the frontal-parietal cortex and hypermetabolism in subcortical regions including the midbrain, unilateral lentiform nucleus, thalamus, parahippocampal gyrus, anterior cingulate gyrus and bilateral cerebellar hemispheres. In contrast, MCS GMP mainly featured by hypometabolism in the right inferior frontal gyrus. When using the MCS group as the reference, UWS GMP showed hypometabomism in frontal-parietal cortex, including the precuneus, precentral gyrus, postcentral gyrus, paracentral lobule, frontal and parietal lobe, alongside hypermetabolism in the unilateral lentiform nucleus, putamen, and anterior cingulate gyrus. The UWS-MCS-GMP expression score cut-off for distinguishing MCS from UWS was 0.351, yielding an area under the ROC curve of 0.77, which is superior to the SUVR based on frontoparietal cortex. UWS-MCS-GMP expression score demonstrated a correlation with CRS-R score ($r = -0.45$, $P = 0.004$). The GMP accurately predicted 73.7% of patient outcomes and SUVR obtained 50.9%. ***Conclusion:*** Patients with UWS and MCS exhibit specific GMPs, and the application of the SSM/PCA method holds promise for aiding the diagnosis of disorders of consciousness. ***References:*** 1. Giacino JT, Katz DI, Schiff ND, et al. Neurology. 2018; 91:450-460.2. Giacino JT, Fins JJ, Laureys S, et al. Nat Rev Neurol. 2014;10: 99-114. 3. Stender J, Mortensen KN, Thibaut A, et al. EPS-019

Medulla Oblongata Dominated Synaptic Density Network Degeneration in Amyotrophic Lateral Sclerosis

M. Hou, *Y. Tang, S. Hu;*
Central South University, Changsha, CHINA.

Aim/Introduction: The purpose of this study was to investigate the synaptic density network connectivity and the likely sequences of synaptic loss in patients with amyotrophic lateral sclerosis (ALS). ***Materials and Methods:*** We examined data from 21 patients diagnosed with ALS and 25 sex- and age-matched healthy controls (HCs) who underwent PET imaging with the SV2A radioligand 18F-SynVesT-1. The individual synaptic density

connectome was constructed for each patient by calculating the similarity between interregional synaptic density distributions. The synaptic network connectivity changes were investigated, followed by an examination of the local synaptic density in regions that showed significant network alterations. Finally, we constructed the voxel-wise and ROI-wise causal synaptic covariance network (cSCN) to identify the sequence of synaptic loss in these brain regions. ***Results:*** We observed an overall decrease in synaptic density network connectivity in ALS patients compared to controls, with the highest nodal degree in the right medulla oblongata. Specifically, the reduced connections were dominantly between the medulla oblongata and the striatum, frontal lobe, occipital lobe. Patients with ALS displayed significantly synaptic loss in those brain regions. Furthermore, the cSCN analyses showed that as the disease progresses, the cortical synaptic loss sequences of ALS extend from the medulla oblongata to the regions including the striatum, frontal lobe, occipital lobe, and parietal lobe. ***Conclusion:*** These findings suggest that synaptic density network degeneration in ALS may follow a bottom-up transmission pattern, primarily involving in the medulla oblongata-striatum-neocortex network, which have the potential to capture new network-based targets for clinical therapy in the progression of ALS.

[1]Department of Nuclear Medicine, West German Cancer Center, Essen, GERMANY, [2]German Cancer Consortium (DKTK), Partner site University Hospital Essen, GERMANY, [3]Department of Medical Oncology, West German Cancer Center, Essen, GERMANY, [4]Department of Nuclear Medicine and Radiobiology, Universiy of Sherbrooke, Sherbrooke, QC, CANADA, [5]National Center for Tumor Diseases (NCT), West, Campus Essen, Essen, GERMANY, [6]Department of Nuclear Medicine, University Medical Center, Rostock, GERMANY.

Aim/Introduction: FAP is highly expressed on fibroblasts from several solid malignancies,including various sarcomas entites, representing a promising theranostic target. We present an updated retrospective cohort analysis of 90Y-FAPI-46 treatment in patients with advanced solid tumors. ***Materials and Methods:*** Patients with progressive metastatic cancer or sarcoma were deemed eligible for 90Y-FAPI-46 therapy after exhaustion of approved therapies and confirmation of high FAP-expression, defined as SUVmax ≥ 10 in more than 50% of tumor lesions. After therapy, 90Y-FAPI-46 scintigraphy was performed to confirm systemic distribution and tumor uptake, and several 90Y-FAPI-46 PET/CT to determine absorbed doses. Adverse events (AEs) were graded according to the Common Terminology Criteria for Adverse Events (5.0). Imaging response was defined by RECIST for CT and PERCIST for 18F-FDG PET/CT. ***Results:*** gastric cancer, 1/30 (3%) squamous cell carcinoma, 1/30 (3%) cholangiocarcinoma) received a total of n=77 90Y-FAPI-46 cycles between June 2020 and December 2023 at our clinic. The interval between cycles was 4 to 8 weeks. 11/30 (40%) of patients received 4 cycles or more. Patients received a median (IQR) of 3.7 GBq (3.7-3.8) for the first cycle, and a median of 7.4 GBq (7.2-7.4) for subsequent cycles. The median (IQR) absorbed dose was 0.46 Gy/GBq (2.25-5.75) in the kidneys, and 0.03 Gy/GBq (0.03-0.06) in the bone marrow. Tumor lesions received a median (IQR) dose of 1.5 Gy/GBq (0.99-2.37). After treatment, a new onset of hematological AEs of any grade was observed in 18/30 (60%) patients, among which AEs ≥ grade 3 was reported in 6/30 (20%) patients: thrombocytopenia in 3/30 (10%), anemia in 2/30 (6%), and 1/30 (3%) patient demonstrated leukocytopenia and thrombocytopenia. RECIST (n=25) and PERCIST (n=21) response after treatment were assessed. Disease control according to RECIST was achieved in 12/25(48%) patients (9/25(36%) SD; 3/25(12%) PR), of whom 8/12(67%) had a sarcoma. A PERCIST response was noted in 12/21(57%) patients (11/21(52%) SMD; 1/21 (5%) PMR). The best RECIST response under RLT, i.e., any imaging time-point between baseline and restaging after RLT, was obtained in 15/26 (58%) evaluable patients (10/26(38%) SD;

5/26(19%) PR). According to PERCIST best response, 9/22(41%) demonstrated SMD, 5/22(23%) PMR, and 1/22(5%) CMR. ***Conclusion:*** 90Y-FAPI-46 RLT was tolerated well. Objective disease control was achieved in almost half of evaluable patients, almost exclusively sarcomas. Our findings support the role of FAP-RLT in patients with metastatic sarcoma.

OP-063

Therapeutic Potential of ^{177}Lu-TEFAPI-06 in Metastatic Solid Tumor Patients with Limited Treatment Options: Safety, Biodistribution, Preliminary Dosimetry and Efcacy Assessment

X. Tian, *J. Liu, Z. Cui, Y. Teng, J. Liu, B. Ma;*
The Second Hospital of Lanzhou University, Lanzhou, CHINA.

Aim/Introduction: The primary objective of this study is to assess the safety and efficacy of the albumin-bound conjugate of FAP-targeted radiopharmaceutical 177Lu-TEFAPI-06 in the treatment of diverse metastatic solid tumors. ***Materials and Methods:*** Five patients with metastatic solid tumors refractory to conventional therapy were enrolled in the study, including two cases of bone metastasis from prostate cancer, one case of intra-abdominal leiomyosarcoma, one case of gallbladder carcinoma with liver and multiple lymph node metastases, and one case of rectal carcinoma with liver and multiple lymph node metastases. The metastatic lesions were confirmed to exhibit moderate to high uptake on 18F-FAPI-04 PET/CT imaging. Informed consent was obtained from all patients who received intravenous injection of 177Lu-TEFAPI-06 as treatment, at a dose of 30 mCi (range: 24-30mCi), followed by serial whole-body planar imaging and SPECT/CT scans at 2-120 hours post drug injection. The radiation absorbed doses to target organs and whole-body effective doses were calculated using OLINDA/EXM 2.2 software. Toxicities were graded according to the Common Terminology Criteria for Adverse Events (CTCAE v5.0). Patients underwent 18F-FAPI PET/CT scans one month after treatment, and changes in tumor biomarker levels before and after treatment were compared. ***Results:*** Five patients were included in the study, comprising three males and two females, with a median age of 60 years (range: 59-61years). The kidney demonstrated the highest absorbed dose (4.5731±4.1074 mSv/MBq) following administration of 177Lu-TEFAPI-06, followed by the spleen (0.2412±0.2143 mSv/MBq), liver (0.1477±0.0524 mSv/MBq), myocardium (0.1215±0.0757 mSv/MBq), and relatively lower absorbed dose in the red marrow (0.0393±0.0137 mSv/MBq). The average whole-body absorbed dose was 0.0527±0.0197 mSv/MBq, with an effective dose of 0.0503±0.0187 mSv/MBq. A follow-up at 4 weeks post single administration revealed partial efficacy in one prostate cancer patient, with a decrease of 31.10% and 43.85% in serum TPSA and FPAS levels, respectively. Additionally, a significant decrease in SUVmax of metastatic lesions was observed after treatment (baseline median SUVmax: 20.5 (range: 13.4-27.6), post-treatment median SUVmax: 13.9 (range: 8.85-20.2), p=0.015). Two patients experienced grade 3 adverse events: one with leukopenia and one with lymphopenia, although a definite correlation with the investigational drug could not be established. ***Conclusion:*** Preliminary research data suggests the potential feasibility of utilizing 177Lu-TEFAPI-06 in the treatment of various metastatic solid tumors, with relatively good tolerability and acceptable side effects, yet its efficacy awaits further confirmation.

OP-064

Peptide targeted radioligand therapy (PTRT) using Fibroblast Activation Protein (FAP) labelled with 225Actinium as mono- or TANDEM-therapy: A retrospective analysis of long-term safety and survival in patients with progressive, end-stage malignancies

E. Perrone[1], *A. Mishra[2], A. Eismant[2], K. Ghai[2], L. Greifenstein[2], R. P. Baum[2];*
[1]Università Cattolica del Sacro Cuore, Rome, ITALY,
[2]CURANOSTICUM Wiesbaden-Frankfurt, Center for Advanced Radiomolecular Precision Oncology, Wiesbaden, GERMANY.

Aim/Introduction: Targeting tumour microenvironment through α-emitting 225Actinium PTRT is a promising precision medicine approach for end-stage solid tumours expressing FAP on cancer-associated fibroblasts and, sometimes, on cancer cells. This retrospective study assessed the overall survival (OS) and safety after 225Ac-3BP-3940 PTRT (as monotherapy and as TANDEM with 177Lutetium or 90Yttrium) in patients with advanced-progressive solid tumours. ***Materials and Methods:*** Between May 2021 and February 2024, 50 patients (29 men, 21 women; age range 13-81, mean 57.4) received 225Ac-3BP-3940 PTRT after 68Ga-3BP-3940 PET/CT. Primary tumours: pancreas (n=10), colorectal (n=8), NET (n=7), breast (n=5), gastro-oesophageal (n=4), lung (n=4), prostate (n=3), sarcoma (n=2), ovarian (n=1), ovarian and breast (n=1), pancreas and breast (n=1), urothelial (n=1), peritoneal mesothelioma (n=1), tongue (n=1), choroidal melanoma (n=1). Premedication (antiemetics/dexamethasone) and electrolyte infusions for forced diuresis were administered. CTCAE v.5.0 was used to grade haematological, renal, and hepatic adverse events, considering patients with ≥1 follow-up visit (n=37). ***Results:*** In total, 76 225Ac-3BP-3940 cycles were administered over 33 months (19 225Ac-monotherapies, 44 225Ac/177Lu-TANDEM, 13 225Ac/90Y-TANDEM). At the time of analysis, 31 patients had received one cycle, either monotherapy or TANDEM (range 3-19 MBq 225Ac), 13 patients had received two cycles (9.8-30 MBq 225Ac), 6 patients had received ≥three cycles (22.4-47.5 MBq 225Ac). Acute reactions after PTRT were mild and transient, mostly nausea (n=8), and vomiting (n=5). 34 patients died (OS 3 days-14 months) during follow-up, 16 patients are still alive (follow-up 1.5-25 months). After PTRT (vs. baseline): 37 patients developed anaemia G1/G2 (vs. 30), 2 patients anaemia G3. Baseline leukocytopenia G1/G2 (n=8), thrombocytopenia G1 (n=6), and thrombocytopenia G3 (n=1) were not affected by PTRT; 1 patient developed thrombocytopenia G2. After PTRT (vs. baseline): 6 patients showed renal impairment G1/G2 (vs. 4), one patient experienced IRA on IRC two weeks after injection, 13 patients had liver impairment G1/G2 (vs. 11), 2 patients (with extensive liver involvement) developed hepatotoxicity G3. ***Conclusion:*** This retrospective analysis shows that 225Ac-3BP-3940 PTRT is overall safe in terms of acute and long-term severe (G3) adverse effects. Only two cases of anaemia G3 were reported after therapy. Liver and kidney functions were not considerably affected by PTRT, apart from one case of IRA on IRC in a single-kidney patient and two patients with liver metastases developing hepatic impairment G3. 225Ac-3BP-3940 PTRT offers encouraging survival results in advanced patients failing all previous treatments (follow-up > two years).

OP-065

Initial experience with ^{177}Lu-FAP-2286 peptide targeted radionuclide therapy in advanced solid tumors

V. Malasani[1], *S. Dash[1], V. Hari[1], A. Raj[1], D. Parwan[1], N. Singhal[1], S. Chaudhuri[2], D. Pendharkar[1];*

[1]Sarvodaya Healthcare, Faridabad, INDIA,
[2]Pushpanjali Cancer Care Institute, Agra, INDIA.

Aim/Introduction: FAP-2286 is a cyclic compound and hence offers better therapeutic properties for radionuclide therapy in FAP-positive tumors. We are reporting our initial experience of 177Lu-labeled FAP-2286 PTRT in 3 patients with advanced solid cancers who had exhausted standard therapeutic options. ***Materials and Methods:*** All these 3 patients had a performance score (PS) of 2-3 and undergone pre-therapeutic work-up with documented good marrow reserve, and preserved hepatic & renal functions. Baseline 18F-FDG and 68Ga-FAP-2286 PET-CT scans were carried out to document metabolically active disease burden and FAP-2286 tumor uptake respectively. ***Results:*** Treatment protocol: Patients were pre-medicated with I.V. ondansetron, pantoprazole & Dexamethasone. All these patients then received a fixed dose of 150 mCi of 177Lu-FAP-2286 infusion diluted with normal saline while taking adequate renal protection using Aminoven (10%) solution. Subsequent post-therapy sequential gamma scans were acquired for 7-10 days to document tracer distribution, tumor uptake, and retention. Case 1: 56-year-old female, a known case of recurrent metastatic adenocarcinoma endometrium (PDL1ve+). She had progressed despite multiple lines of chemotherapy and was intolerant to immunotherapy. As a last resort, the disease was challenged with 177Lu-FAP-2286 PTRT. Till now the patient has received 4 cycles of therapies with good clinical and objective response with improvement in PS and partial response on FDG PET-CT scans. Case 2: A 52-year-old female with metastatic left TNBC with progressive disease. She was a defaulter after receiving adjuvant chemotherapy. She then progressed to immune-hormonal therapy, chemo, and targeted therapy. She had received 2 cycles of 177Lu-FAP-2286 therapy as per protocol and had a good clinical response with pain relief; however, there was a mixed response on the follow-up FDG PET-CT scan. Case 3: A 63-year-old male with a diagnosed case of metastatic NSCLC (PD L1 +); had received whole brain RT for multiple ICSOLs. He had progressed on immuno-chemotherapy and was challenged with 177Lu-FAP-2286 therapy. He had good clinical (improved PS) and objective response (partial response) post 2 cycles. However, his FDG PET-CT scan after 3rd cycle showed progression. A multidisciplinary tumor board decided to re-challenge the disease with immunotherapy. The patient is yet to be evaluated for response. All these patients had no serious adverse effects. ***Conclusion:*** 177Lu-FAP-2286 PTRT seems to be a viable therapeutic option for FAP-positive tumors. However, due to variability in objective response, use in combination with single-agent chemo or immunotherapeutic agent is to be explored for better results.

OP-066

Impact of Total Tumour Absorbed Dose and Total Metabolic Tumour Volume on Progression Free Survival in the Phase 1/2a Study of [^{177}Lu]Lu-Lilotomab Satetraxetan for Treatment of Relapsed Indolent Non-Hodgkin Lymphoma

A. Loendalen[1,2], *J. Blakkisrud[3], A. Kolstad[4,5], C. Stokke[6,7];*
[1]Department of Nuclear Medicine and PET Phycics Oslo University Hospital, Oslo, NORWAY, [2]DEpartment of Nuclear Medicine Innlandet Hospital, Elverum, NORWAY, [3]Department of Nuclear Medicine and PET Physics Oslo University Hospital, Oslo, NORWAY, [4]Department of Oncology Innlandet Hospital, Gjøvik, NORWAY, [5]Institute of Health Sciences NTNU, Gjøvik, NORWAY, [6]Oslo University Hospital, Oslo, NORWAY, [7]University of Oslo, Oslo, NORWAY.

Aim/Introduction: [177Lu]Lu-lilotomab satetraxetan targets the CD37 antigen on B-cells and was investigated for relapsed indolent non-Hodgkin lymphoma (NHL) patients in the phase 1/2a LYMRIT-37-01 trial. Total metabolic tumour volume (tMTV) and mean absorbed doses to the total tumour volume (tTAD) were calculated [1]. The aim of this study was to investigate the prognostic value of tTAD and tMTV for progression free survival (PFS). ***Materials and Methods:*** Fifteen patients with three different pre-treatment and pre-dosing regimens were included. [177Lu]177Lu-lilotomab satetraxetan was administered at dosage levels of 10, 15 or 20 MBq/kg body mass (2, 3 and 10 patients, respectively). tTAD were calculated from post-treatment SPECT/CT imaging at day 4 and 7 post injection. tMTVbaseline and after 3 months (tMTV3months) were calculated from [18F]FDG PET/CT scans [1]. PFS was analysed using the Kaplan-Meier method and log-rank test. Patients were stratified based on a previously indicated tTAD threshold of 200cGy[1], the tMTVbaseline and tMTV3months analysis and the population median was used to separate the patients. ***Results:*** Overall median values were 130 cGy, 152 cm3 and 14 cm3 for the tTAD, tMTVbaseline and tMTV3months respectively. Thirteen patients reached the endpoint with two remaining in remission as of April 2024. Median PFS was 881 days for patients with tTAD > 200cGy and 209 days for patients with ≤ 200 cGy (p = 0.26). No significant difference was found between the three different activity dosage groups. PFS was not significantly longer for patients with tMTVbaseline lower than the population median (p = 0.52). A statistically significant shorter PFS (p=0.02) was observed for patients with tMTV3months above the population median (median of 209 days vs 881 days). ***Conclusion:*** While a survival benefit was indicated for patients receiving tumour absorbed doses over 200 cGy, the difference was not significant, and further work will focus on establishing a larger data foundation. tMTVbaseline did not predict PFS, which was not surprising since different treatment regimens were explored. However, a significant difference in PFS was found when separating the population based on tMTV3months median, implicating that this parameter may have a prognostic value for patients treated with [177Lu]Lu-lilotomab satetraxetan. ***References:*** 1. OP-067

Feasibility and therapeutic potential of the 68Ga/177Lu-DOTATATE theranostic pair in patients with metastatic medullary thyroid carcinoma

H. Dadgar;
Nuclear Medicine and Molecular imaging research center, RAZAVI Hospital, Mashad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: This study assessed: 1) the clinical efficacy of imaging with 68Ga-DOTATATE PET/CT (SSTR (somatostatin receptor)-PET) to detect medullary thyroid carcinoma (MTC); and 2) the therapeutic efficacy of peptide receptor radionuclide therapy (PRRT) with 177Lu-DOTATATE in MTC patients. ***Materials and Methods:*** Normal 0 false false false EN-US X-NONE AR-SA Patients with histologically proven MTC and suspected recurrence following thyroidectomy, based on raised serum calcitonin levels, underwent SSTR-PET. In addition, to evaluate the clinical efficacy and safety of PRRT, the patients with intense uptake on SSTR-PET or 99mTc-octreotide scintigraphy underwent PRRT. The Common Terminology Criteria for Adverse Events (version 4.03) was used to

grade adverse events after PRRT. Treatment response was classified as complete response (CR), partial response (PR), stable disease (SD), and progressive disease (PD). ***Results:*** Twenty MTC patients (10 male, 10 female) with a median age of 48.5 years underwent SSTR-PET. SSTR-PET was positive in 17/20 patients (85%). Four of the 17 patients with positive SSTR-PET were scheduled for PRRT. In addition, 2 patients had positive 99mTc-octreotide scintigraphy results (Krenning score ≥ 2) and were scheduled for PRRT. Two of the 6 patients who underwent PRRT showed PR, 2 SD and 2 PD. Two patients died during the follow-up period. Median overall survival was 19 months (95% CI: 5.52-29.48). There were no cases of significant toxicity. ***Conclusion:*** Radiolabeled somatostatin analogs are contributive for the management of recurrent MTC. 68Ga-DOTATAE PET-CT showed a relatively high detection rate in recurrent MTC. In addition, PRRT with 177Lu-DOTATATE was found to be a safe alternative therapeutic option for MTC.

Transcriptomic Analysis of Patients Receiving 177LuPSMA Therapy to Decipher Molecular Drivers of Poor Outcome

L. Lopes[1,2], *A. Handke[3], C. Kesch[3], T. Telli[4], S. Karkampouna[5], K. Lueckerath[4], E. Davicioni[6], M. Kruithof de Julio[7], K. Herrmann[4], K. Shi[1], B. Hadaschik[3], W. P. Fendler[4], R. Seifert[1,4];*
[1]Department of Nuclear Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, SWITZERLAND, [2]Graduate School for Cellular and Biomedical Sciences, University of Bern, Bern, SWITZERLAND, [3]Department of Urology, University of Duisburg-Essen and German Cancer Consortium (DKTK)-University Hospital Essen, Essen, GERMANY, [4]Department of Nuclear Medicine, University of Duisburg-Essen and German Cancer Consortium (DKTK)-University Hospital Essen, Essen, GERMANY, [5]Department for BioMedical Research, Urology Research Laboratory, University of Bern, Bern, SWITZERLAND, [6]Veracyte, Inc, Decipher Biosciences Inc, Vancouver, BC, CANADA, [7]Department of Biomedical Research, University of Bern, Bern, SWITZERLAND.

Aim/Introduction: Metastatic castration-resistant prostate cancer (mCRPC) exhibits large heterogeneity resulting in variable treatment outcomes across lesions and individuals. [177Lu] Lutetium-PSMA-617(Lu-PSMA) therapy for mCRPC is promising, however non-responder rate is about 30%. Treatment approaches that combine Lu-PSMA and immune checkpoint inhibition are currently under clinical investigation. Thus, immune-related factors may play a role in the efficacy of Lu-PSMA and other therapies. Our aim was to investigate the immune microenvironment in mCRPC patients treated with Lu-PSMA. ***Materials and Methods:*** We analyzed data from 41 patients referred for Lu-PSMA therapy. Among these, 29 had primary and non-primary tumor samples at initial diagnosis, prior to any treatment - therapy-naïve group. Additionally, we collected 15 primary and non-primary tumor biopsies from patients who received additional therapies (ADT, chemotherapy, ARTA) - under therapy group. Three patients had two biopsies, pre and post additional therapy. Tumor specimens underwent Decipher transcriptomic analysis (Veracyte Inc, San Diego, CA) for gene expression data. Immune cell counts were obtained via MySort Software. The primary outcome was overall survival. We used the Cox Proportional Hazards model to assess the impact of gene expression on survival, applying logarithmic transformation due to non-normal distribution of variables. Spearman's test was used for correlation analysis to explore further gene expression influences. ***Results:*** In the therapy-naïve group, PD-L2 levels were significantly associated with worse survival (HR 1.85x104 [7.30-4.69x107],p=0.014) but PD-L1 levels were not (p=0.535). Under therapy, both PD-L2 and PD-L1 levels were not significant for survival prognosis (p=0.209 and p=0.190 respectively), nor in the combined group (therapy-naïve and under therapy; p=0.825 and p=0.480 respectively). In the therapy-naïve group, in a multivariate cox model with a M1/M0 activated macrophage immune count, PD-L2 and PD-1 levels, all of the previous factors were significant, being PD-L2 and PD-1 levels harmful (HR 3.05x105 [23.03-4.03x109, p=0.009; HR 6.33 [1.01-39.53], p=0.046) and M1/M0 protective (HR 0.91 [0.84-0.99], p=0.034). In the combined group, however, only the macrophage signature was significant and protective (HR 0.91 [0.85-0.98], p=0.017). ***Conclusion:*** PD-L2 levels in therapy-naïve samples are a relevant marker of overall survival after Lu-PSMA. After ADT/chemotherapy/ARTA, there seems to be an influence of M1/M0 macrophages on overall survival, but not of PD-L2 or PD-1. Therefore, the relation between immune escape and pro-inflammatory pathways seems to change by the onset of systemic therapy, suggesting an external regulation. Further studies with bigger sample sizes should study the influence of these therapies in immune microenvironment and Lu-PSMA therapy outcomes.

[1]Department of Nuclear Medicine, University of Münster Medical Center, Münster, GERMANY, [2]Institute of Oncology, Chaim Sheba Medical Center, Ramat Gan, ISRAEL, [3]Faculty of Medicine, Tel Aviv University, Tel Aviv, ISRAEL, [4]Department of Oncology, Rambam Medical Center, Haifa, ISRAEL, [5]Oncology Institute, Shamir Medical Center, Zerifin, ISRAEL, [6]Department of Nuclear Medicine, Technical University of Munich, Munich, GERMANY, [7]Department of Nuclear Medicine and Clinical Molecular Imaging, University Hospital Tübingen, Tübingen, GERMANY, [8]Department of Nuclear Medicine, University of Ulm, Ulm, GERMANY, [9]Department of Nuclear Medicine, German Cancer Consortium (DKTK) University Hospital Essen, Essen, GERMANY, [10]Department of Nuclear Medicine, University Hospital Bonn, Bonn, GERMANY, [11]Bayer HealthCare Pharmaceuticals, Whippany, NJ, UNITED STATES OF AMERICA, [12]Tulane Cancer Center, Tulane Medical School, New Orleans, LA, UNITED STATES OF AMERICA.

Aim/Introduction: 223Ra and 177Lu-PSMA, an alpha and beta emitter, respectively, are each approved for the treatment of patients with metastatic castration-resistant prostate cancer (mCRPC). The clinical feasibility and safety of sequential 223Ra and 177Lu-PSMA use in patients with mCRPC was assessed in RaLu, a real-world multicentre study conducted across Germany and Israel. ***Materials and Methods:*** Clinical data were retrospectively collected at centres in Germany (2021-2022) and Israel (2022-2023) for patients with mCRPC who received ≥1 dose of 177Lu-PSMA who previously received ≥1 dose of 223Ra. Safety and effectiveness of 177Lu-PSMA were evaluated by treatment sequence (223Ra then chemotherapy [Ct] followed by 177Lu-PSMA [RaCt-Lu] or Ct then 223Ra followed by 177Lu-PSMA [CtRa-Lu]), and by time interval (<6 or ≥6 months from last 223Ra dose to first 177Lu-PSMA dose). Data was statistically summarised; overall survival (OS) was estimated using the Kaplan-Meier method. ***Results:*** Overall, 198 patients were evaluated, including

89 and 70 in the Ra-Ct-Lu and Ct-Ra-Lu groups, respectively, and 65 and 132 in the <6 months and ≥6 months groups, respectively. Prior to 177Lu-PSMA, all patients received 223Ra (66% received six 223Ra injections) and 58% received ≥4 life-prolonging therapies. In total, 38% of patients received ≥4 177Lu-PSMA cycles, with a median completion of 3 cycles. During 177Lu-PSMA therapy, any-grade and serious treatment-emergent adverse events occurred in 78% and 26% of patients, respectively. Grade 3-4 haematologic laboratory abnormalities included anaemia (32%), thrombocytopenia (17%) and neutropenia (4%). Grade 3-4 anaemia/thrombocytopenia/neutropenia occurred with an incidence of 30%/21%/3% and 38%/23%/2% in the Ra-Ct-Lu and Ct-Ra-Lu groups respectively, and 34%/17%/5% and 31%/18%/4% in the <6 months or ≥6 months groups, respectively. Median OS from starting 177Lu-PMSA was 12.0 months (95% CI, 10.5-15.1) in the overall population, 10.0 (8.2-14.0) and 12.0 (9.1-16.9) months in the Ra-Ct-Lu and Ct-Ra-Lu groups, respectively, and 12.0 (8.9-19.6) and 12.6 (10.7-15.9) months in the <6 months or ≥6 months groups, respectively. PSA response ≥50% occurred in 37% of patients in the overall population and 35-40% across subgroups; an ALP response ≥50% occurred in 8% of patients in the overall population and 6-11% across subgroups. ***Conclusion:*** These findings further support the clinical feasibility of treating patients with mCRPC with 177Lu-PSMA after being treated with the alpha therapeutic 223Ra, irrespective of the length of time between the two treatments and the positioning of chemotherapy within the treatment sequence (before or after 223Ra).

OP-070

French national Survey on supply and demand of RadioLigand Therapy.

***A. Giraudet*[1],** *F. Courbon*[2], *P. Hamon*[3], *J. Coulot*[4], *P. Salaün*[5];
[1]*Leon Berard Cancer Center, Lyon, FRANCE,* [2]*Institut universitaire du cancer de Toulouse Oncopole, Toulouse, FRANCE,* [3]*Madisphileo, Paris, FRANCE,* [4]*Esprimed, Paris, FRANCE,* [5]*CHRU de Brest, Brest, FRANCE.*

Aim/Introduction: Facing an increasing demand for targeted radioligand therapy (RLT), specifically PSMA-targeted (PRLT), the French Society of Nuclear Medicine (SFMN) has initiated a study to assess the available and potential reservoirs in technical means and human resources to meet the needs and ensure equitable access throughout France. This study was jointly conducted by the health consultancy Madis-Phileo and medical physics consultancy Esprimed. ***Materials and Methods:*** Participation in the study was based on a voluntary approach from Nuclear medicine departments (NMDs) across France, public and private. Evaluators visited these departments for two days to interview RLT professionals and management staff. The analysis tools, evaluation grid and ISHIKAWA diagram were used to establish and present a score from -100 to 100 for each area studied: regulatory requirements, technical investments, decision-making by center management, regional and national health administrations, human resources, care coordination and organization, leading to an overall score that categorized centers into Experienced (EC), Initiated (IC), Medium-Term prospects (MT), and Long-Term prospects (LT). The alignment between the supply and demand for PRLT was finally assessed. ***Results:*** Seventy-nine centers amongst the 322 French NMDs agreed to participate. At the time of the study which started in May 2023 and finished February 2024, 24 were already PRLT active, 23 would start at least during 2024 and 17 were still under consideration. After interviewing 542 individuals, the centers were classified as 27(34%) EC, 13(16%) IC, 23(29%) MT, and 16(20%) LT including 13 private centers. The average scores across 79 centers [LT score to EC score] were: 45[-17.8 to 81.9] for regulatory requirements; 17[-21 to 62.2] for technical investments; 43[24 to 67.4] for decision-making; -12[-33 to 11.9] for human resources ; 15[-59 to 74.8] for care coordination; and 0[-86 to 64.6] for care organization. The overall national score gathering all domains was 18[-34 to 60]. For 70% of the EC, RLT led to substantial investments despite the pricing being perceived as favorable for only 48%. Of the 5,700 patients eligible for PRLT annually in France, 2,485 can be treated in 2024, and 3,955 will be by 2026. ***Conclusion:*** Current resources are sufficient for only half of the necessary PRLT treatments meeting the VISION criteria. To ensure alignment between the supply and the already significantly unmet demand for RLT, major recruitment efforts, improvements in care organization and coordination, and increased technical investments are required, with support from decision-making authorities.

GMP development of the [^{177}Lu]Lu-AKIR001 for clinical translation in first-in-human studies of CD44v6 expressing cancer patients
K. Bratteby[1,2], *E. Jussing[1,2], M. Ferrat[1,2], L. Bylund[2], T. Tegenbratt[2], J. Garousi[2], F. Frejd[3,4,5], T. Furebring[3], P. Frank[3], R. Altena[1,6], A. Mortensen[3,7,8], M. Nestor[3,7], T. T. A. Tran[1,2];*
[1]Department of Oncology-Pathology, Karolinska Institute, Stockholm, SWEDEN, [2]Department of Radiopharmacy, Karolinska University Hospital, Stockholm, SWEDEN, [3]Akiram Therapeutics, Uppsala, SWEDEN, [4]Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, SWEDEN, [5]Affibody AB, Uppsala, SWEDEN, [6]Karolinska Comprehensive Cancer Center, Karolinska University Hospital, Stockholm, SWEDEN, [7]Department of Immunology, Genetics and Pathology, Science for Life Laboratory (SciLifeLab), Uppsala University, Uppsala, SWEDEN, [8]Department of Molecular Medicine and Surgery, Karolinska Institute, Stockholm, SWEDEN.

Aim/Introduction: Recently, a novel high-affinity monoclonal antibody (mAb) targeting the cell surface antigen CD44v6 was generated and characterized for the purpose of using it for molecular radiotherapy of cancers overexpressing CD44v6 (1). The mAb (AKIR001) was radiolabelled with 177Lu and evaluated in several in vitro and in vivo studies. Following a comprehensive toxicological assessment of AKIR001 was found suitable for clinical translation in a first-in-human clinical trial in cancer patients. The aim of this study was to optimize, scale up, and validate the synthesis of [177Lu]Lu-AKIR001 in compliance with cGMP to prepare for the future clinical phase I study. ***Materials and Methods:*** GMP-grade DOTA-conjugated mAb, AKIR001 in 10 mM phosphate buffer was tested in initial small-scale 177Lu-labelling, up to 1 GBq. Critical parameters of pH, amount of mAb, and incubation time were optimized. Aimed maximum patient dose, up to 3 GBq, were developed by stabilizing the product to avoid radiolysis. The quality control (QC) methods were validated to ensure the product could be consistently analysed and quantified, even during worst-case conditions. Following scale up, stability studies and purification were optimized and the production was validated in three consecutive batches. ***Results:*** The manual synthesis of [177Lu]Lu-AKIR001 showed optimal conversion (>95%) in 10 mM phosphate buffer containing ~80 mg/mL sucrose and PS-80 (0.02% w/v) at $5.0 \leq pH \leq 5.3$. To prevent radiolysis, it was essential to stabilize the product by adding sodium ascorbate during the reaction. Purification was effectively carried out using Amicon Ultra 15 spin filters (50 kDa MWCO) with the addition of DTPA, which sufficiently removed unreacted 177Lu. The subsequent formulation in saline/sodium ascorbate was pivotal to obtaining long-term stability of the product (up to 6 days at +4°C + 24 h at room temperature post-EOS). ***Conclusion:*** The scaled up and optimized synthesis of [177Lu]Lu-AKIR001 was robust and validated according to cGMP. Up to 3500 MBq could be produced at a concentration of 198 MBq/mL suitable

for infusion to patients in the clinical phase I trial. ***References:*** 1. (1) Mortensen, A.C.L., Berglund, H., Segerström, L. et al. OP-083

Preliminary assessment of novel HER2-targeted single domain antibody fragment NB46 for theranostic applications

T. Huynh[1], *R. Meshaw[1], X. Zhao[1], L. Ben-Naim[2], N. Papo[2], M. Zalutsky[1];*
[1]Duke University, Durham, NC, UNITED STATES OF AMERICA, [2]Ben-Gurion University of the Negev, Beer-Sheva, ISRAEL.

Aim/Introduction: Progress in HER2-targeted drug development has advanced significantly since Trastuzumab approval. Single domain antibody fragments (sdAbs) are promising candidates due to their small size, stability, and effective tumor targeting. Herein, we've developed NB46, a new HER2-targeted sdAb with high affinity and a distinct binding site, potentially offering earlier-stage use in HER2-positive breast cancers because it is not blocked by Trastuzumab, currently part of standard of care. Moreover, its different HER2 binding site would allow for potential heterodimers to be developed with other sdAbs, notably 5F7. ***Materials and Methods:*** NB46 was conjugated with SGMIB, iso-SGMIB, or their 211At counterparts and evaluated using HER2-positive BT-474 cells and xenografts. SGMTB or iso-SGMTB was labeled with radioiodine or 211At, conjugated to NB46, and assessed for binding, cellular retention, and internalization in HER2-positive BT-474 and HER2-negative MCF-7 cells. Paired-label biodistribution was performed to compare different isomers, while a single-label biodistribution was done to examine 211At-labeled NB46 in mice bearing BT-474 tumors. To verify binding to an epitope distinct from the one targeted by both 5F7 and Trastuzumab, a paired-label biodistribution was conducted using [125I]SGMIB-NB46 and [131I]SGMIB-5F7 under Trastuzumab blocking conditions. ***Results:*** Using HER2-expressing BT-474 cells, [*I]SGMIB-NB46 and iso-[*I]SGMIB-NB46 demonstrated high affinities after labeling - 7.3 ± 4.0 nM and 5.3 ± 2.2 nM, respectively. Paired-label biodistribution indicated comparable tumor uptake between isomers. Thyroid and stomach uptake were low for both isomers but significantly lower for [*I]SGMIB-NB46 at all time points. [*I]SGMIB-NB46 showed better clearance in other normal tissues and thus we selected this isomer for further assessment with 211At. [211At]SAGMB-NB46 showed good tumor uptake of 9.9 ± 1.4 %ID/g at 1 h, 14.7 ± 2.5 %ID/g at 4 h and 8.0 ± 1.6 %ID/g at 21 h, with minimal uptake in stomach and thyroid. In the paired-label experiment, [125I]SGMIB-NB46 and [131I]SGMIB-5F7 demonstrated similar tumor uptake (11.1 ± 2.6 %ID/g for NB46 vs 13.5 ± 3.4 %ID/g for 5F7 at 1 h; P>0.05); importantly, binding of NB46 sdAb was not blocked by Trastuzumab (9.5 ± 1.7 %ID/g at 1 h) while binding of 5F7 sdAb was blocked (0.8 ± 0.1 %ID/g), confirming their distinct binding epitopes. ***Conclusion:*** NB46 radioconjugates showed excellent HER2-specific binding to BT-474 cells, promising tumor uptake and minimal retention in stomach and thyroid with no blocking by Trastuzumab. Taken together, these results suggest NB46 warrants further investigation either alone or in combination with Trastuzumab or 5F7 for HER2-positive cancer treatment.

OP-084

Redistribution of the daughter radionuclides generated from ^{225}Ac-pelgifatamab and their contribution to therapeutic efficacy in LNCaP/KUCaP prostate cancer xenograft models

C. Schatz[1], *M. Große[1], F. Suurs[2], A. Papple[2], I. Moen[2], H. Nguyen[1], U. B. Hagemann[1], S. Zitzmann-Kolbe[1];*
[1]Bayer AG, Berlin, GERMANY, [2]Bayer AS, Oslo, NORWAY.

Aim/Introduction: Prostate-specific membrane antigen (PSMA) is highly expressed in prostate cancer. 225Ac-pelgifatamab, a targeted alpha therapy (TAT) consisting of the PSMA antibody pelgifatamab linked to a macropa chelator and labelled with the alpha-emitting radionuclide actinium-225, has showed robust antitumour efficacy in preclinical models of prostate cancer. Actinium-225 decays via its alpha-emitting daughters francium-221 (t1/2 = 4.8 min), astatine-217 (t1/2 = 32.3 ms), bismuth-213 (t1/2 = 45.6 min) and polonium-213 (t1/2 = 3.4 µs) to stable, nonradioactive bismuth-209. 225Ac-pelgifatamab containing actinium-225 is targeted to the tumour, but the clearance of its in vivo generated daughter radionuclides is unknown. As the daughter radionuclides may have an impact on therapeutic efficacy, we studied the distribution of actinium-225 and the redistribution of the measurable daughters francium-221 and bismuth-213 after 225Ac-pelgifatamab treatment in tumour-bearing mice. ***Materials and Methods:*** The biodistribution of 225Ac-pelgifatamab and a radiolabelled isotype control was evaluated using subcutaneous LNCaP and KUCaP human prostate cancer xenograft models in SCID male mice, respectively. The mice were treated with a single i.v. injection of 225Ac-pelgifatamab (250 kBq/kg) or a radiolabelled isotype control antibody (250 kBq/kg), and sacrificed either 10-15 minutes or 1, 24, 72, 168, or 336 hours post injection. Organs were measured either immediately or 24 hours after sacrifice using a germanium detector and a gamma detector. Dosimetry calculations to evaluate the gray dose for actinium-225, francium-221 and bismuth-213 were based on actinium-225 and francium-221 at both timepoints and the immediate bismuth-213 measurements. ***Results:*** 225Ac-pelgifatamab showed prominent LNCaP tumour accumulation (~250 %ID/g), peaking 240 hours (10 days) post injection. Furthermore, 225Ac-pelgifatamab exhibited slow clearance from the blood and low accumulation into most of the other organs. Importantly, actinium-225 decaying in the tumour generated bismuth-213 and francium-221, which were effectively retained within the tumour. In contrast, minor fractions of the bismuth-213 generated in the blood were redistributed into the kidneys. The redistribution of francium-221 occurred in a similar fashion. This is reflected by an increase of total absorbed dose to the kidneys from 0.40 (no daughter redistribution considered) to 2.16 Gy. Contrary to 225Ac-pelgifatamab, the isotype control did not accumulate into the KUCaP tumour, resulting in a higher rate of daughter radionuclide redistribution into the kidneys and other organs. ***Conclusion:*** Both bismuth-213 and francium-221, the alpha-emitting daughter radionuclides of actinium-225, are mostly retained in the tumour. Only minor amounts of the daughter radionuclides generated in the blood were redistributed to the kidneys.

OP-085

A Novel ^{177}Lu-labelled Affibody Molecule with Deimmunized ABD: Enhanced Biodistribution Profile and Anti-tumour Efficacy

Y. Liu[1], *M. Oroujeni[1,2], Y. Liao[1], A. Vorobyeva[1], V. Bodenko[3], A. Orlova[1], M. Konijnenberg[4], M. Carlqvist[2], E. Wahlberg[2], A. Loftenius[2], F. Y. Frejd[1,2], V. Tolmachev[1];*
[1]Uppsala University, Uppsala, SWEDEN, [2]Affibody AB, Solna, SWEDEN, [3]Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION, [4]Erasmus MC, Rotterdam, NETHERLANDS.

Aim/Introduction: We have previously demonstrated that [177Lu]Lu-ABY-027, HER2-binding Affibody molecule fused with an albumin-binding domain (ABD035), provides HER2-specific targeting of human xenografts and a strong anti-tumour effect in preclinical radionuclide therapy studies [1, 2]. The Affibody molecule ZHER2:2891 fused with a deimmunized ABD variant, denoted PEP49989, was designed to reduce immunogenic potential, which is crucial for clinical translation. In this preclinical study, the targeting characteristics and therapeutic efficacy of the novel construct, PEP49989, were evaluated. ***Materials and Methods:*** PEP49989 was labelled with 177Lu via DOTA, which was conjugated to a unique C-terminal cysteine. In vitro evaluation of affinity, specificity, and cellular processing were performed using HER2-expressing SKOV3 and BT474 cell lines. In vivo specificity and biodistribution of [177Lu]Lu-PEP49989 were characterised in tumour-bearing Balb/c nu/nu mice, followed by dosimetry calculation. Experimental therapy was evaluated in mice with human HER2-expressing xenografts. ***Results:*** The labelling of PEP49989 with 177Lu provided radiochemical yield exceeding 95%. The binding of [177Lu]Lu-PEP49989 to HER2-expressing cells was specific both in vitro and in vivo. The affinity of [177Lu]Lu-PEP49989 binding to SKOV3 cells was 363±112 pM, which was similar to the affinity of [177Lu]Lu-ABY-027 (333±45 pM) containing the parental ABD035 variant. The uptake of [177Lu]Lu-PEP49989 was 1.4-fold higher than the uptake of [177Lu]Lu-ABY-027 in kidney, but 1.7-2-fold lower in liver and spleen. The tumour uptake of [177Lu]Lu-PEP49989 was 1.5-fold higher than the uptake of [177Lu]Lu-ABY-027. Treatment of mice with SKOV3 xenografts using 21 MBq [177Lu]Lu-PEP49989 significantly prolonged the median survival (>90 days) compared to mice treated with vehicle (38 days) or trastuzumab (45 days). Co-treatment of [177Lu]Lu-PEP49989 and trastuzumab both extended the median survival to over 90 days and led to a higher number of complete tumour remissions. ***Conclusion:*** In novel Affibody-based construct, [177Lu]Lu-PEP49989, fusion with a deimmunized ABD did not affect the affinity and specificity of binding to HER2. [177Lu]Lu-PEP49989 demonstrated advantageous biodistribution profile in the mice model, compared with [177Lu]Lu-ABY-027, containing parental ABD035. In an experimental therapy, [177Lu]Lu-PEP49989 demonstrated strong anti-tumour effect both alone and co-treated with trastuzumab, which creates preconditions for clinical translation. ***References:*** 1. OP-086

A fully automated process and a generic kit to reduce development and production costs of [^{89}Zr]mABs in clinical trial settings

C. Vanasschen[1], *S. Degueldre[1], A. Dubart[1], J. Masset[1], M. Hawotte[1], S. Garifo[2], T. Vangijzegem[2], S. Laurent[2], C. Warnier[1];*
[1]Trasis, Ans, BELGIUM, [2]General, Organic and Biomedical Chemistry Unit, NMR and Molecular Imaging Laboratory, University of Mons, Mons, BELGIUM.

Aim/Introduction: ImmunoPET using 89Zr-labeled antibodies (mABs) is gaining importance in nuclear medicine given the impressive potential of this imaging technology platform. Currently, [89Zr]mAB batches are mostly produced manually, requiring highly qualified personnel while exposing them to the high radiation doses due to the intense 909 keV emission of Zr-89. We herein report the development of a fully automated, cassette-based process for the production of 89Zr-labelled antibodies that makes antibody radiolabeling a plug-and-play, time-saving, cost-effective and safe procedure. ***Materials and Methods:*** Zr-89 was used at 1M and 0.05M oxalic acid concentration. PD-10 and HiTrap size-exclusion chromatography (SEC) cartridges were purchased and used on the disposable cassettes. Panitumumab-DFO, Trastuzumab-DFO and Cetuximab-DFO were chosen as model compounds for the development of the process ; in all radiolabeling experiments, CAR values were in the range of 0.7 - 2.1. The automated process was developed on the miniAllinOne synthesis module. ***Results:*** A disposable cassette as well as a reagent kit were designed for standardized process automation. The process includes Zr-89 and bulk vial rinsing, reagents transfer, radiolabeling and purification on either one PD-10 or two HiTrap SEC columns. Process fluidics were carefully designed to maximize the accuracy of small volume transfers and to suppress the risk of channeling and drying effects to guarantee the outcome of the SEC purification. Manual radiolabeling experiments were performed to define Na2CO3 and HEPES volumes maximizing radiochemical conversions across an activity range of 0 - 400 MBq (≈ 0 - 400 µL 89Zr-oxalate). Those conditions were transferred to the programmed miniAllinOne sequence so that the 89Zr-oxalate volume was the only required user input during the process. The resulting fully automated process yielded [89Zr]Panitumumab, [89Zr]Trastuzumab and [89Zr]Cetuximab with 70-87% RCY (n.d.c.) in ≈ 80 minutes starting from 50 - 400 µL 89Zr-oxalate, with radiochemical purities >98%. ***Conclusion:*** We report the availability of a generic, fully automated process and kit for antibody radiolabeling with Zr-89 on the miniAllinOne. The developed process offers a cost-effective approach to the use of [89Zr]mABs in clinical trials while allowing for an effortless transfer to subsequent routine production. The process is compatible with potentially any mAB-DFO conjugate, with both PD-10 and HiTrap purification cartridges, a wide range of 89Zr-oxalate volumes and concentrations while delivering state-of-the-art production yields. Efforts to render the process and consumables compatible with Lu-177 and Ac-225 mAB labeling are actively ongoing.

OP-087

AI Optimized Target Selection for Cocktails of Targeted Alpha Particle Radiopharmaceutical Therapy against Metastatic Liver Cancers

H. Tallam[1], *S. Singh[1], F. E. Escorcia[2], R. W. Howell[1];*
[1]Rutgers New Jersey Medical School, Newark, NJ, UNITED STATES OF AMERICA, [2]National Cancer Institute, National Institutes of Health, Bethesda, MD, UNITED STATES OF AMERICA.

Aim/Introduction: Radiopharmaceutical therapies (RPT) using alpha-particle-emitting radionuclides conjugated to target specific antibodies are being actively investigated to treat cancer. However, intrinsic tumor cell heterogeneity limits the efficacy of single targeting agents due to the consequent non-uniform distribution of radiopharmaceuticals. Overcoming these challenges necessitates the optimization of targeted RPT through dosimetry and personalized treatment planning. We hypothesize that using 2-3 distinct types of antibody-based radioconjugates (e.g "cocktail") administered based on the distribution of target expression on tumor cells can therapeutically outperform treatment with a single radioconjugate against liver cancers, and their associated circulating and disseminated tumor cells. ***Materials and Methods:*** Human hepatocellular carcinoma and hepatoblastoma cell lines, Hep3B and HepG2, were tested for the distribution of antibody targets that have shown promise (GPC3, EGFR, CD147, ROBO1, MET, and MUC13) through flow cytometry. Using these measured distributions, MIRDcell V4, an AI based treatment planning software developed by the Howell lab, we determined the best cocktail of these antibodies to radiolabel with the alpha particle emitter, actinium-225 (225Ac) for treatment. Specifically, MIRDcell AI determines the molar activity of 225Ac required for each antibody in the cocktail to achieve a specified cell kill while minimizing the total decays required. The absorbed dose calculations made by the model are for cells in suspension which are representative of isolated circulating or disseminated tumor cells. ***Results:*** Preliminary data shows that for the Hep3B cell line, no single 225Ac-labeled antibody can achieve the specified surviving fraction of 0.001 (2 surviving cells out of 1500 cells). In contrast, a combination of 225Ac-anti-EGFR and 225Ac-anti-CD147 with optimized molar activities of 5.3 × 107 and 5.6 × 107 GBq/mol are able to achieve a surviving fraction of 0.001. The results for HepG2 show that although 225Ac-anti-CD147 alone could kill the cell population at the specified cell death, a combination of two agents like 225Ac-anti-EGFR and 225Ac-anti-GPC3 can kill at the same effectiveness with less than one-third the number of total 225Ac decays (8.8 × 105 compared to 2.8 × 106 Bq s). ***Conclusion:*** Our results predict that personalized RPT cocktails have higher therapeutic efficacy than monotherapies and require less administered activity to do so. They also imply that antibodies that fail as monotherapies can be effectively repurposed in a cocktail as is shown with the HepG2 cell line. Our approach will be further tested in the future with in vitro and in vivo studies.

OP-088

Efficacy and safety of novel [^{225}Ac]Ac-labeled anti-HER2 antibody drug radioconjugates against HER2 positive breast cancer xenografts

J. Pougoue Ketchemen, *A. Monzar, F. Ngoh Njotu, H. Babeker, A. Tikum, E. Nwangele, N. Henning, N. Hassani, A. Doroudi, H. Fonge; University of Saskatchewan, Saskatoon, SK, CANADA.*

Aim/Introduction: Breast cancer (BC) is the leading cause of morbidity and mortality in women worldwide. Human epidermal growth factor receptor 2 (HER2) is overexpressed in 25-30% of BC. Actinium-225 (225Ac) has an ideal half-life of 9.9 days with 5.8 MeV mean energy, and decays into 4-alpha, 3-beta, and 2-gamma emitters hence a potent candidate for targeted alpha therapies. Again, pertuzumab is a domain II anti-HER2 monoclonal antibody and causes a complete blockade of HER2 heterodimerization critical for tumor growth. Also, antibody-drug conjugates (ADCs) are highly cytotoxic, have antitumor activities, with good therapeutic index. We, therefore, intend to develop an antibody-drug radio-conjugate (ADR) based on pertuzumab ([225Ac]Ac-Macropa-pertuzumab-PEG6-DM1) and determine its efficacy against this disease. ***Materials and Methods:*** [67Cu]Cu-DOTA-pertuzumab-PEG6-DM1 and [225Ac]Ac-Macropa-pertuzumab-PEG6-DM1 were developed with drug linker NHS-PEG6-DM1 and bifunctional chelators p-SCN-DOTA and p-SCN-Macropa respectively. Quality control was done. Biodistribution and safety evaluation of [225Ac]Ac-Macropa-pertuzumab-PEG6-DM1 were done in healthy female Balb/c mice (pharmacokinetics, toxicology/histology, and dosimetry) and HCC1954/JIMT-1 athymic Balb/c nude mice. ImmunoSPECT/CT imaging and biodistribution using [67Cu]Cu-DOTA-pertuzumab-PEG6-DM1 and radiotherapy using [225Ac]Ac-Macropa-pertuzumab-PEG6-DM1 were done in nude mice bearing trastuzumab-resistant HCC1954 and T-DM1/trastuzumab-resistant JIMT-1 tumors. ***Results:*** Pure pertuzumab ADCs and ADRs were obtained. [67Cu]Cu-DOTA-pertuzumab-PEG6-DM1 and [225Ac]Ac-Macropa-pertuzumab-PEG6-DM1 had a radiochemical purity of 92-97% at specific activity of 1 MBq/µg, and 1MBq/150-300µg, respectively. Low EC50 values of Macropa-pertuzumab-PEG6-DM1 in HCC1954 (33 ± 0.4 nM) and JIMT-1 (25.2 ± 0.6 nM) were obtained. After 7 days of incubation at 37°C, [225Ac]Ac-Macropa-pertuzumab-PEG6-DM1 showed good stability in both human serum (86.6 ± 0.4%) and PBS (83.6 ± 0.5%). Internalization in HCC1954 and JIMT-1 cells was HER2 density-dependent with pertuzumab-PEG6-DM1 total red object area (14696573 ± 697882 vs 3879041 ± 129076) significantly higher than pertuzumab (5786017 ± 343453 vs 179200 ± 11481), respectively ($p<0.0001$). Imaging and biodistribution of [67Cu]Cu-DOTA-pertuzumab-PEG6-DM1 in athymic Balb/c nude mice showed high tumor uptakes of 30 ± 7.3% IA/g (HCC1954) and 17.2 ± 2.3% IA/g (JIMT-1) after 24 h post-injection. Pertuzumab-PEG6-DM1 (8 mg/Kg) and [225Ac]Ac-pertuzumab-PEG6-DM1(3 X 18 KBq) administered separately in healthy Balb/c mice, 10 days apart was well tolerated biochemically and haematologically for 20 days. In HCC1954-mice xenografts, all treatment groups had complete remission, while in T-DM1-resistant JIMT-1 tumor-bearing mice at 28 days post-treatment, tumor volumes were 104.7 ± 8.7 mm3 ([225Ac]Ac-Macropa-P-PEG6-DM1), 386.4 ± 86.3 mm3 (P-PEG6-DM1), and 359 ± 102 mm3 (saline). ***Conclusion:*** The ADR [225Ac]Ac-Macropa-pertuzumab-PEG6-DM1 is more potent than its ADC pertuzumab-PEG6-DM1 against trastuzumab- or T-DM1-resistant BC necessitating clinical investigation.

OP-089

Construction and preclinical evaluation of a radioiodinated nanobody probe for the detection of CD147-overexpressing cancer

X. Ma[1], *T. Liu[2], H. Zhu[2], Z. Yang[2];*
[1]Peking university, Beijing, CHINA, [2]Peking university, Beijing, CHINA.

Aim/Introduction: The extracellular matrix metalloproteinase inducer CD147, which is significantly over-expressed in various solid tumors but scarcely found in normal tissues, offers an optimal target for molecular imaging and targeted therapy. Nanobodies are the smallest fragments derived from antibodies and are easily modified for conjugation with functional reagents. In this study, we developed a novel CD147-targeted nanobody radiotracer, 124I-NB147, providing guidance for the detection of CD147-overexpressing cancer. ***Materials and Methods:*** Flow cytometry, Western blot, and Immunofluorescence were used to verify the expression of CD147 on the surface of Human pancreatic

cancer cells ASPC1 and BXPC3, human malignant melanoma cells A375 and SK-MEL-28, human triple-negative breast cancer cells MDA-MB-435, and mouse triple-negative breast cancer cells 4T1. The CD147 nanobody was labeled with 124I using the Iodogen method and purified by the PD-10 column. The physicochemical properties, affinity, metabolic characteristics, biodistribution and immunoPET imaging of 124I-NB147 were performed. Finally, CD147 expression analysis was performed by immunohistochemistry, tissue microarray and autoradiography on human cancer specimens. ***Results:*** The labeled 124I-NB147 was purified by PD-10. The results showed that the radiochemical purity was over 99% and maintained over 95% in both 0.01 moL/L PBS and 10 % HSA for more than 4 h. The molecular weight of NB147 was 17.1 kDa as measured by MALDI-TOF-MS and SDS-PAGE. FCM, WB and IF showed that the cell lines A375, ASPC1 and MDA-MB-435 expressed CD147 highly, while SK-MEL-28, BXPC3 and 4T1 showed low expression of CD147. The radio-ELISA indicated that 124I-NB147 had high binding affinity to CD147. The cell uptake test showed that there was a significant difference in 124I-NB147 uptake between CD147 high-expression cells and CD147 low-expression cells (P<0.01). The biological half-life of distribution and clearance phases were 0.05 h and 1.58 h, respectively. The imaging results show that in CD147-positive tumor models, the probe accumulates at the tumor sites of A375, ASPC1 and MDA-MB-435. However, in CD147-negative tumor models, no significant uptake was observed at the tumor site of SK-MEL-28, BXPC3 and 4T1. Finally, the correlation analysis between tumor uptake and CD147 expression level was established. ***Conclusion:*** In this study, we successfully validated one specific CD147 nanobody, NB147, and the derived immunoPET probe 124I-NB147 showed precise visualization for accurate diagnosis of CD147-expressing lesions. Based on high yield, high radiochemical purity, and good stability, biological evaluation has shown its specificity and affinity for CD147. It will be promising for dynamically monitoring CD147 expression in pan-cancer.

OP-090

Evaluation of ^{68}Ga-NOTA-Mal-NB147 for the detection of CD147 expression onmalignant tumors

X. Ma[1], *T. Liu[2], H. Zhu[2], Z. Yang[2];*
[1]Peking university, Beijing, CHINA, [2]Peking university, Beijing, CHINA.

Aim/Introduction: Recent studies have demonstrated that extracellular matrix metalloproteinase inducer (CD147) contributes to pan-cancer immunity and progression. Nanobodies are the smallest fragments derived from antibodies and are easily modified for conjugation with functional reagents. They possess ideal characteristics suitable for PET imaging applications, such as a rapid clearance rate and excellent distribution curves, allowing for same-day imaging with sufficient contrast. In this study, we developed a novel CD147-targeted nanobody radiotracer, 68Ga-NOTA-Mal-NB147, providing guidance for the detection of CD147 on malignant tumors. ***Materials and Methods:*** In this study, we utilized the dual-function chelator NOTA-Mal for the specific site-specific labeling of the CD147-targeted nanobody NB147 with nuclide 68Ga. Then the probe was purified by PD-10 column, and its quality control and in vitro stability were determined by a radio-TLC. The in vitro stability of the 68Ga-NOTA-Mal-NB147 in normal saline and 5% HSA was analyzed. Flow cytometry, Western blot, Immunohistochemistry, and immunofluorescence were used to verify the expression of CD147 on the surface of human colon cancer cells LS174T, human pancreatic cancer cells BXPC3, human liver cancer cells SMMC-7721 and human gastric cancer cells NCI-N87, and screen high and low expression models. The physicochemical properties, affinity, metabolic characteristics, biodistribution, and immunoPET imaging of 68Ga-NOTA-Mal-NB147 were performed. ***Results:*** The labeled 68Ga-NOTA-Mal-NB147 was purified by PD-10. The results showed that the radiochemical purity was over 98% and maintained over 95% in both 0.01 moL/L PBS and 10 % HSA for more than 4 h. FCM, WB, IHC and IF showed that the cell lines LS174T, BXPC3 and SMMC-7721 expressed CD147 highly, while NCI-N87 showed low expression of CD147. The radio-ELISA indicated that 68Ga-NOTA-Mal-NB147 had high binding affinity to CD147. The imaging results show that in CD147-positive tumor models, the probe accumulates at the tumor sites of LS174T, BXPC3, and SMMC-7721. However, in CD147-negative tumor models, no significant uptake was observed at the tumor site of NCI-N87. Simultaneously, the co-injection of an excess amount of cold antibody significantly reduces the uptake of the probe in LS174T tumors, indicating the specific targeting binding of 68Ga-NOTA-Mal-NB147 to CD147 high-expression tumor models. ***Conclusion:*** We successfully validated one specific CD147 nanobody, NB147, and the derived immunoPET probe 68Ga-NOTA-Mal-NB147 showed precise visualization for accurate diagnosis of CD147-expressing lesions. Based on high yield, radiochemical purity and stability, biological evaluation showed its specificity and affinity for CD147, and immunoPET/CT imaging confirmed the feasibility of visualizing tumor CD147 in vivo.

Establishing a ^{177}Lu-PSMA treatment site in an oncology outpatient day-ward

T. Noponen[1], *A. Saikkonen[1], L. Kääriä[1], M. Seppänen[2], K. Mattila[3], A. Ålgars[4];*
[1]Department of Clinical Physiology, Nuclear Medicine, Turku PET Centre and Medical Physics, Turku University Hospital and Wellbeing services county of Southwest Finland, Turku, FINLAND, [2]Department of Clinical Physiology, Nuclear Medicine and Turku PET Centre, Turku University Hospital and Wellbeing services county of Southwest Finland, Turku, FINLAND, [3]Department of Oncology, Turku University Hospital and Wellbeing services county of Southwest Finland., Turku, FINLAND, [4]Department of Oncology, Turku University Hospital and Wellbeing services county of Southwest Finland, Turku, FINLAND.

Aim/Introduction: 177Lu-PSMA treatment is an emerging therapy for patients with metastatic castration-resistant prostate cancer. Radiation-safety precautions often raise concerns and may cause unnecessary investments when starting a novel radionuclide-therapy site. We introduced a treatment site established in an oncology outpatient day-ward meanwhile optimizing the therapy practice, treatment and radiation-protection facilities and utilization of staff. ***Materials and***

Methods: A typical single outpatient day-ward room with a private toilet was equipped for the therapy use. The 7.4-GBq 177Lu-PSMA was administrated with a 30–60 s injection, after which the patient remains in the treatment room for 3–4 h in hydration and radiation isolation. The room is equipped with a mobile barrier with a 2.0-mm lead-equivalent panel to attenuate an external radiation especially to the neighboring room. A patient isolation-discharge measurement is conducted 3–4 hours after receiving the treatment using a remote dose-rate meter installed in the celling of the treatment room. After discharging the patient, he is transferred to the SPECT-CT imaging. A four-days intensive training was given to the lutetium nurses who previously worked in the oncology outpatient clinic to familiarize them to radiation work including contamination and waste management actions. During the injection the nurse wears personal dosimeter and a lead apron. After completing the handling of radioactivity, a possible hand-contamination is measured using a portable monitor. Radioactive waste and the possible contamination of the room are measured after the treatment. ***Results:*** The lutetium patient induces approximately 1.8 μSv/h radiation exposure into the neighboring room behind the lead barrier 1-m away from the patient bed. In the other surrounding rooms 4.4-6.2 m from the bed the radiation exposure was negligible. The nurse administrating the 177Lu-PSMA received a mean effective dose of 4.3 μSv during the therapy day. The patient waste and laundry radiated 0.05-1.11 μSv/h, when measured on the surface of packages. The external dose-rate from the patients after the mean isolation period of 3.7 h was 12.6 μSv/h converted to the 1-m distance. The investments made for the therapy room amounted to approximately 15000 euros. After fourth therapy session our nurses took over all the practical duties including radioprotection tasks and measurements. ***Conclusion:*** The 177Lu-PSMA therapy site can be launched with a reasonable investment on a normal oncology outpatient day-ward with nurses without any previous radiation-work experience. The radiation-safety actions are straightforward and radiation exposure to the environment from a 177Lu-PSMA patient is rather moderate.

OP-094

Radiation Exposure to Children and Others During Therapy for Pediatric Neuroblastoma With Lu-177 DOTATATE

Z. Lu[1,2], ***X. Sun[1],*** *Y. Sun[2], D. Zuo[1], P. Li[1];*
[1]Department of Nuclear Medicine, Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan, CHINA, [2]Department of Graduate, Shandong First Medical University, Jinan, CHINA.

Aim/Introduction: The objective of this study is to evaluate the clearance of Lu-177 DOTATATE in children with neuroblastoma and the resulting radiation dose to the child, family caregivers and medical staff during the therapy. ***Materials and Methods:*** Twenty-three consecutive children (rang 3-13 years) with neuroblastoma treated with Lu-177DOTATATE were enrolled. External dose rates were measured at various distances from the patient at 1, 2, 4, 6, 24, 48 and 96 hours to estimate Lu-177DOTATATE clearance, effective half-life and maximum potential cumulative dose around the patient. Measurement of whole-body and red marrow absorbed dose in children based on Lu-177 DOTATATE SPECT/CT multitemporal imaging and HERMES workstation. The whole-body radiation dose to family caregivers and medical staff was measured by means of TLDs (Thermoluminescence Personal Dosimeters), and the radiation dose to the fingers of medical staff measured by means of ring TLDs. ***Results:*** The median administered activity of Lu-177 DOTATATE was 145.01 MBq/kg, and the whole-body retention rates at 1, 2, 4, 6, 24, 48 and 96 hours after administration were 63.4%, 51.9%, 38.7%, 33.7%, 21.7%,17.4% and 9.5%, respectively. The retention of Lu-177 DOTATATE within the body as a bi-exponential decay process, with short and long effective half-lives of 1.4 ± 0.8 hours and 52.4 ± 18.4hours, respectively. The maximum potential average radiation dose at 1m and 2m from the patient was estimated to be 0.233 ± 0.046 mSv/GBq and 0.071 ± 0.015 mSv/GBq, respectively. The mean dose for children were 4.186 ± 2.155 mGy/MBq to whole body and 0.611 ± 0.416 mGy/MBq to red marrow. The mean whole-body radiation dose for the family caregivers was 0.24 ± 0.06 mSv (ranging from 0.13 to 0.39 mSv, 0.077 ± 0.037 mSv/GBq). The mean whole-body and fingers radiation dose to the radiopharmacists were 3.7 ± 1.8 μSv/per patient and 155.3 ± 73.0 μSv/per patient, respectively. The mean whole-body radiation dose and median fingers radiation dose to the nurses were 4.7 ± 1.4 μSv/per patient and 16.7 μSv/per patient, respectively. ***Conclusion:*** Lu-177 DOTATATE is cleared more rapidly in children with neuroblastoma, and all radiation exposures to others are below personal dose limits.

OP-095

^{177}Lu-Dotatate effective half-life estimation for personalized radiation protection recommendations

M. Sanchez-Perez, *S. Pena, C. Andrés, C. Villar, R. Soto, N. Álvarez, F. Sebastián, R. Ruano, R. Torres;*
Hospital Clínico Universitario, Valladolid, SPAIN.

Aim/Introduction: The incidence of neuroendocrine tumors has increased in recent years. Metabolic therapy with 177Lu-Dotatate has shown promising results in pain and symptom control, presenting itself as an effective alternative for patients with inoperable or even metastatic disease. The use of this radiopharmaceutical implies exposure to radiation of family members, close people and general public. The usual treatment consists in 4 dose administered 8 weeks apart, so the radiation protection restrictions may be important although dose rates at medical discharge are low. The aim of this work is to determine the 177Lu-Dotatate average effective half-life that will allow us to calculate individualized radiological protection recommendations. ***Materials and Methods:*** A retrospective analysis of 40 cycles from 15 patients treated with 177Lu-Dotatate in our Hospital (aged between 50 and 70 years old) is presented. All of them completed the whole treatment. The average injected activity was 7.2 GBq/cycle, and gets the medical discharge 24 hours after injection. The measurements of dose rate at one meter were performed using an environmental radiation monitor in anteroposterior and posteroanterior projections at different stages of each cycle: 24 hours, 4 days and 7 days from injection. The average dose rate for each patient was obtained by a geometric mean. The effective decay was performed using a mono-exponential fit. ***Results:*** The average dose rate was 6.2±2.5 μSv/h and the median was 5.4 μSv/h. The obtained values for effective half-life result in a mean value of 2.9±0.5 days and 3.0 days for percentile 75. ***Conclusion:*** The results show lower discharge dose rate and effective half-life values than other metabolic treatments, such as 131I for thyroid cancer disease. It suggests that the treatment may be safe, under normal living conditions, for both the patient and those close to them. However, as it is administered in four separate cycles, cumulative doses throughout the whole treatment may involve a certain risk. On the basis of the results obtained in this study, the personalization of the radiation protection recommendations at discharge may be a powerful strategy to reduce this risk. Nevertheless, even though obtained results are encouraging,

further data is needed to improve statistics. In any case, radiation protection measures are necessary in this type of procedures, especially considering the emergence of new treatments, such as 177Lu-PSMA for patients with metastatic castration-resistant prostate cancer.

OP-096

Development of the world's largest High Dose Therapy ward (Radioiodine ward) facility by radiation dose and delay tank activity simulation: the challenges and opportunities

A. Jha[1], *S. Mithun[1], P. Dwivedi[2], M. Chauhan[2], V. Rangarajan[1]; [1]Department of Nuclear Medicine, Tata Memorial Hospital, Mumbai, INDIA, [2]Department of Nuclear Medicine, Advanced Centre for Treatment, Research and Education in Cancer (ACTREC), Navi Mumbai, INDIA.*

Aim/Introduction: I-131 has Beta and gamma emission and has a half-life of 8 days and a gamma energy of 364 keV. Its gamma energy makes it difficult to manage the radiation safety aspect. I-131 therapy has been categorized as high-dose more than 30 mCi and low-dose therapy less than 30 mCi. Performing high-dose therapy requires a specialized high-dose therapy ward with a delay-decay tank in India. This study aimed to propose a method to develop a high-dose therapy facility within the ambit of existing regulation. ***Materials and Methods:*** In this study, we designed a 41-bed radionuclide facility over two floors; the 4th and 5th floors of the hospital building covering a 260 square meter carpet area. we performed a theoretical simulation of radiation exposure and residual activity in the delay and decay tank at the time of discharge of effluent in the municipal sewer system. Theoretical calculation of radiation exposure at a point inside and outside of the therapy ward. Theoretical calculation of residual activity in the tank: The formulae in the table cell 2 were proposed for the calculation: ***Results:*** Radiation exposure outside the radionuclide therapy ward: 0.10 mSv yearly dose was considered the constraint for exposure calculation outside the ward (10 times less than the prescribed limit of 1mSv/year for the general public) The maximum dose calculated was well within the constraint set by our institution for the general public. Radiation exposure inside the radionuclide therapy ward: 1mSv yearly dose was considered the constraint for exposure calculation outside the ward (20 times less than the prescribed limit of 20mSv/year for the radiation workers)The maximum dose calculated was well within the constraint set by our institution for the radiation worker. Activity in the delay tank before the discharge in the main municipal sewer: Total activity in the delay tank was found to be 15 MBq total and 8.3kBq/m3 which was well within the permissible limit of discharge prescribed by the regulator (AERB). ***Conclusion:*** The formulae proposed in this study may be used to calculate the wall thickness, and radiation exposure inside and outside the radionuclide therapy ward and the size of the delay tank during the site designing phase of the high-volume radionuclide therapy ward adhering to the regulatory norms and ALARA principle. ***References:*** A) Regulatory requirement by AERB, https://www.barc.gov.in/about/05.pdf B) water consumption pattern in domestic households in major cityhttp://indiaenvironmentportal.org.in/files/Water%20consumption%20patterns.pdf

OP-097

Modeling-based Assessment of Exposure Measurements After High-Dose Targeted ^{131}I-apamistamab: Results and Analyses from the Phase III SIERRA Trial

N. Pandit-Taskar[1], *L. Chen[2], B. Serencsits[3], K. Prasad[4], T. Senglaub[5], M. Zgaljardic[6], J. Spross[7], A. Desai[7], P. Brodin[7]; [1]Molecular Imaging and Therapy, Memorial Sloan Kettering Cancer Center, New York, NY, UNITED STATES OF AMERICA, [2]Banner MD Anderson Cancer Center, Gilbert, AZ, UNITED STATES OF AMERICA, [3]Memorial Sloan Kettering Cancer Center, New York, NY, UNITED STATES OF AMERICA, [4]Columbia University, New York, NY, UNITED STATES OF AMERICA, [5]Medical College of Wisconsin, Milwaukee, WI, UNITED STATES OF AMERICA, [6]Weill Cornell Medical Center, New York, NY, UNITED STATES OF AMERICA, [7]Actinium Pharmaceuticals, New York, NY, UNITED STATES OF AMERICA.*

Aim/Introduction: SIERRA investigated targeted induction and conditioning prior to hematopoietic cell transplant using 131I-apamistamab. The activity of this high-dose targeted therapy ranged from 300 to 1030 mCi, requiring administration in an in-patient setting with subsequent radiation isolation. Here, we analyzed exposure readings from patients treated on the SIERRA trial and determined the clearance dynamics and time to reaching the specified radiation release criteria at different administered activity levels. ***Materials and Methods:*** 131I-apamistamab was administered to patients 55 years or older with relapsed/refractory AML as an intravenous infusion over median 5 hours. Site-specific radiation safety protocols were developed for nuclear medicine and transplant staff to minimize exposure. Administered activity of 131I-apamistamab was determined for each patient following a dosimetric infusion and evaluation, with 24 Gy to the liver being dose limiting. This ensured safe delivery of this high-dose targeted therapy, with a wide range of administered activity between patients. In this analysis we used the exposure readings acquired at 1 meter distance starting after infusion until release from isolation. A single exponential function was fit to the exposure readings over time and the clearance half-life and time until reaching the U.S. 131I release criteria of 0.07 mSv/hr was calculated for each patient. ***Results:*** Out of 106 patients receiving the 131I-apamistamab therapeutic infusion, exposure readings were evaluable for 96 patients, with a median 6 measurements per patient (range: 2 - 8). The effective clearance of 131I-apamistamab closely followed a single exponential fit (median R2=0.98), with median effective clearance half-life 35.2h (range: 3.3 - 66.9h). Median time to reach release criteria was calculated to 5.0 days (IQR: 3.9 - 6.1 days), and this was similar between varying levels of administered activity. This relates to the personalized dosing of 131I-apamistamab as patients with a faster biological clearance were prescribed a higher activity. This is further shown by the difference in median clearance half-lives, with 40.0h for those receiving <450 mCi, 38.2h for 450-600 mCi, 32.5h for 600-800 mCi and 35.2h for >800 mCi. ***Conclusion:*** Exposure readings following radiation isolation showed considerable variability in clearance rate between patients, although no difference was seen in estimated time needed to reach release criteria by administered activity level, with a median of only 5 days even for patients receiving activities over 800 mCi. This ensured that patients were well below the 131I release criteria at the time of transplant, typically 12 days following the 131I-apamistamab infusion.

OP-098

Measurement of ^{225}Ac in the air in nuclear medicine treatment rooms and assessment of the internal dose to clinical staff and caregivers

***S. Galvez Febles*[1],** *K. Hürkamp[1], W. Li[1], V. Oeser[2], V. Spielmann[1], W. Rühm[1];*
[1]BfS | Bundesamt für Strahlenschutz, Munich, GERMANY, [2]SARAD GmbH, Dresden, GERMANY.

Aim/Introduction: In the nuclear medical treatment of metastatic castration-resistant prostate cancer, targeted alpha therapies (TAT) with intravenous injection of radiopharmaceuticals such as [225Ac]Ac-PSMA are applied. Patients may excrete this radionuclide, posing a risk of radiation exposure to clinical staff. This work aims to investigate the presence of 225Ac in treatment room air due to patients' breathing. Further, the eventual dose due to inhalation of the radionuclide will be estimated by an implemented biokinetic model that takes into consideration the size distribution of the inhaled particles. ***Materials and Methods:*** An aerosol monitor is employed to measure the air in TAT treatment rooms. Inside a specifically built calibration chamber, an 225Ac-aerosol was produced and characterized using an impactor to classify the particles by size and an alpha/beta counter to determine the activity per impactor stage. In addition, a biokinetic compartment model for the inhalation of 225Ac was implemented using the parameters provided by the International Commission on Radiation Protection (ICRP). First, systemic models of actinium and its progeny were built up for the Reference Adult Male[1]. Subsequently, the human respiratory tract[2,3] and the human alimentary tract[4] models, also developed by the ICRP, were added. ***Results:*** It was possible to generate a radioactive aerosol with a size distribution similar to that in human breath. The activity increased with particle concentration in the range of interest (< 0.3 µm). Time-integrated activity coefficients were computed for the systemic model, showing rapid blood clearance and high absorbed doses of 225Ac progeny: 155 mGy/MBq in kidneys, 943 mGy/MBq in the liver, and 82 mGy/MBq in the bone marrow. The inhalation model was validated by comparing retention data in liver and lungs for a 0.1 µm 225Ac-aerosol to ICRP values. ***Conclusion:*** In this study, experimental data on room and breathing air are collected. Although the systemic model was implemented for unlabelled 225Ac, owing to the recoil of α-decay, the daughters can leave the radiopharmaceutical compound and distribute independently of the parent radionuclide. Therefore, the dose contribution of the progeny is expected to be the same as in [225Ac]Ac-PSMA treatments. In conclusion, the described inhalation model of 225Ac can provide a realistic estimate of the radiation exposure of the clinical staff. ***References:*** (1) ICRP, 2019. Aim/Introduction: The administration of radiopharmaceuticals potentially results in radioactive waste produced by the patient like potentially radioactive tissues, pads, etc. and, in case of incontinent patients, potentially radioactive diapers. In some European countries, radiation portal monitors (RPM's) are installed at waste incineration plants to prevent the inadvertent incineration of (high-activity) orphan sources leading to the potential exposure of personnel and environment as well as the contamination of the facility. Due to the notably high sensitivity of modern RPM's, they are capable of detecting even trace amounts of radiation potentially triggering an alarm. This radiation could be emanating from a (high-activity) orphan source but also from (low-activity) radioactive waste produced by patients. The increasing use of radionuclide therapies contributes to a rising number of alarms which have to be effectively managed by the personnel at waste incineration plants. The Heads of the European Radiological Protection Competent Authorities (HERCA) Working Group Medical Applications (WGMA) wants to evaluate current regulation and deployment of measuring devices at waste incineration plants as well as the prevalence of radionuclide therapies across Europe. The objective is to develop strategies to help minimise this type of alarms at the waste incineration plants and establish efficient and straightforward protocols for managing this. ***Materials and Methods:*** A survey was sent to the 27 countries represented in the HERCA WGMA regarding radiation measuring devices at waste incineration plants (regulations, implementation, threshold levels, procedures and statistics) and the current practices for radionuclide therapies (release criteria and instructions on potentially radioactive patient waste given to the non-incontinent or incontinent patient). ***Results:*** Preliminary results from 13 responders show a wide variation in regulations and deployment of radiation measuring devices at waste incineration plants. Also, release criteria and content of instructions given to patients differs significantly potentially impacting the number of alarms. ***Conclusion:*** Although RPM's at waste incineration plants were not installed for the purpose of finding radioactive patient waste, this specific type of waste is a frequent trigger for alarms resulting in an extra workload (measurements with portable devices to identify the nuclides, sorting out of the waste, ···), and frustration for its personnel. Hence, it is crucial to minimize the frequency of these alarms and/or the workload associated with each alarm in order to keep the personnel vigilant and motivated to respond appropriately, thereby preventing the inadvertent incineration of the real (high-activity) orphan sources they were originally tasked to detect.

Covalent FAPI PET enables accurate management of medullary thyroid carcinoma: a prospective single-arm comparative clinical trial

Z. Li*[1]*, *Z. Kong*[2]*, X. Cui*[3]*, Z. Yang*[1]*, Z. Liu*[4]*, S. Liu*[2]*;*
[1]Peking University Cancer Hospital & Institute, Beijing, CHINA, [2]Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, CHINA, [3]Changping Laboratory, Beijing, CHINA, [4]College of Chemistry and Molecular Engineering, Peking University, Beijing, CHINA.

Aim/Introduction: Localizing medullary thyroid carcinoma (MTC) is crucial for treatment decision, but the detection using the current imaging modalities is unsatisfied, and the therapeutic strategy (i.e., surgical extent) was therefore inaccurate. Previously, we reported a paradigm-shift platform technology by adding a targeted covalent radioligand (TCR) to fibroblast activation protein inhibitor (FAPI) for improved and sustained tumor targeting. In this first-in-class comparative clinical trial, we assessed the detection rate and diagnostic accuracy of 68Ga-TCR-FAPI PET/CT in 50 MTC patients and head-to-head compared with the currently approved 18F-FDG PET/CT, aiming to provide a new standard of imaging for MTC. ***Materials and Methods:*** This study was a prospective, single-center, open-labeled, single-arm comparative clinical trial, designed to assess the effectiveness of 68Ga-TCR-FAPI PET/CT compared to the currently approved 18F-FDG PET/CT in evaluating MTC patients. Patients with newly diagnosed, recurrent or metastatic MTC with biochemical residual disease (serum calcitonin > 10 pg/ml) and no previously/currently administrated targeted therapy were enrolled between May 11th, 2023 and Feb. 1st, 2024, and 68Ga-TCR-FAPI PET/CT, 18F-FDG PET/CT and serum calcitonin level were performed on separate days. ***Results:*** On manual evaluation by independent physicians, 68Ga-TCR-FAPI exhibited significantly higher patient-based detection rate than 18F-FDG PET/CT (98% vs. 66%, p=0.0002) and displayed 16-38% improved region-based detection rate (p=0.0001-0.0269), facilitating MTC detection at patient level. The superior detection can be attributed to covalent ligation of 68Ga-TCR-FAPI for elevated tumor activity than 18F-FDG (SUVmax 11.71±9.16 vs. 2.55±1.73, p<0.0001). The diagnostic accuracy, for the first time, was validated on 60 lesions available for point-to-point matching of PET/CT images and histopathology, and was substantially greater with 68Ga-TCR-FAPI than 18F-FDG (96.7% vs. 43.3%, p<0.0001). Notably, 60% patients directly benefited from 68Ga-TCR-FAPI PET/CT, with 66.7% experiencing changes in surgical plans, and 100% of the newly diagnosed MTC with R0 resection achieved biochemical cure at 1-month post-surgery. ***Conclusion:*** In conclusions, 68Ga-TCR-FAPI PET/CT has demonstrated superior detection rate, metabolic value and diagnostic accuracy compared to 18F-FDG PET/CT in MTC patients, which aid the disease localization and surgical planning. Together with the previous reports that 68Ga-TCR-FAPI outperformed the original FAPI, 68Ga-TCR-FAPI PET/CT has the potentiality to be the standard of imaging for MTC patients.

OP-101

Head-to-head evaluation of ^{18}F-FDG and ^{68}Ga-FAPI PET/CT in surveillance of postradiotherapy recurrence of EBV-associated nasopharyngeal carcinoma

B. Gu, *Z. Yang, S. Song;*
Fudan University Shanghai Cancer Center, Shanghai, CHINA.

Aim/Introduction: This study aims to investigate the potential role of 68Ga-labeled fibroblast activation protein inhibitor (FAPI) positron emission tomography/computed tomography (PET/CT) for the surveillance of postradiotherapy recurrence of nasopharyngeal carcinoma (NPC), compared with 18F-fluorodeoxyglucose (18F-FDG) and Epstein-Barr virus-DNA (EBV-DNA). ***Materials and Methods:*** In this prospective comparative imaging trial conducted at Fudan University Shanghai Cancer Center (ChiCTR2100054163, Chinese Clinical Trial Registry), 36 patients with elevated EBV-DNA load or equivocal findings of conventional imaging (CT or magnetic resonance imaging (MRI)) were enrolled from August 2021 to April 2023. Presence of local recurrence and distant metastasis were recorded by two experienced nuclear medicine physicians. Malignant lesions were validated by histopathologic analysis and a composite reference standard. ***Results:*** Of the 36 patients (8 females, 28 males; median age: 50.5 years, range: 29-66 years), 25 (69.44%) patients suffered recurrences and received further treatment. Compared to EBV-DNA, contrast-enhanced MRI/CT and 18F-FDG PET/CT, 68Ga-FAPI PET/CT showed the highest diagnostic accuracy rate (94.44% vs. 47.22%, 50.00% and 83.33%, respectively; $p < 0.001$, $= 0.033$ and $= 0.004$, respectively). Regarding to the lesion-based analysis, a total of 78 lesions (64 malignant lesions and 14 benign lesions) were detected by 18F-FDG and 68Ga-FAPI PET/CT. Compared to 18F-FDG, 68Ga-FAPI PET/CT outperformed in sensitivity, specificity, positive predictive value, negative predictive value, and accuracy for the detection of lesions (96.88% vs. 90.63%, 64.29% vs. 7.14%, 92.54% vs. 81.69%, 81.82% vs. 14.29%, and 91.03% vs. 75.64%, respectively; $p = 0.004$). ***Conclusion:*** 68Ga-FAPI PET/CT outperforms EBV-DNA, contrast-enhanced MRI/CT and 18F-FDG PET/CT in detecting local recurrence and distant metastasis, and could serve as an accurate, reliable and reproducible surveillance modality for NPC patients.

OP-102

Diagnostic Performance of 68Ga-Trivehexin PET-CT in Follow-Up Head and Neck Squamous Cell Carcinomas (HNSCC) and Comparison with ^{18}F-FDG PET-CT

V. Malasani*[1]*, *S. Dash*[1]*, A. Raj*[1]*, V. Hari*[1]*, D. Parwan*[1]*, N. Singhal*[1]*, S. Chaudhuri*[2]*, D. Pendharkar*[1]*;*
[1]Sarvodaya hospitals, Faridabad, INDIA, [2]Pushpanjali cancer care institute, Agra, INDIA.

Aim/Introduction: Trivehexin is a cancer-specific (αvβ6) integrin targeting agent over-expressed in the tumor microenvironment and is responsible for tumor growth and proliferation·. The study aims to perform tandem 68Ga Trivehexin & 18F-FDG PET-CT scans on treated head and neck squamous cell carcinoma patients who had a clinical suspicion for loco-regional residual or recurrent disease and to evaluate the incremental advantage of Trivehexin PET over FDG PET. ***Materials and Methods:*** This a single institutional non-blinded interventional study conducted from October 2022 to December 2023· A total of 30 post-treated HNSCC patients with suspected locoregional residual or recurrent disease were included· Both 68Ga Trivehexin & 18F FDG PET-CT scans were done on two different days with a time gap of not more than 7 days. Any well-defined focus of increased tracer uptake

greater than the background activity in the expected anatomical region was regarded as a positive finding for both scans. All the dual tracer study data were analyzed by two experienced nuclear medicine physicians. Histopathological sampling / radiological follow-up data was considered as gold standard ***Results:*** Loco-regional Analysis- 30 patients had a total of 17 suspicious locoregional recurrent/residual lesions with only 12 being true positive (histopathologically) for local and/or regional disease. 17 lesions were detected by FDG and 15 lesions by Trivehexin· The true positive, false positive, true negative, and false negative of FDG and Trivehexin were 10,7,13,2 and 12,3,17,0 respectively. Metastatic disease analysis- A total of 5 (5/30) patients were found to have 6 true metastatic lesions in our study· The distant lesions include lung and bone· Of these 5(5/6) lesions show true positive findings in both the scans and false negative finding in 1(1/6). Additionally there was no statistical difference between the SUV max of both the tracers in benign (two-tailed P-value 0.7922) and malignant (P -value 0.48 at 95% CI) lesions. ***Conclusion:*** The diagnostic accuracy of 68Ga-TRIVEHEXIN is better than 18F-FDG PET-CT in the early detection of active loco-regional residual/ recurrent disease in HNSCC with the advantage of differentiating osteoradionecrosis from true recurrences. However, the incremental role of Trivehexin PET CT in metastatic disease particularly in the lung is questionable. A larger study with a larger study population is required to conclude any further.

OP-103

Exploring ^{18}F-FDG PET/CT as a Screening Tool for Boron Neutron Capture Therapy: Correlation Analysis with ^{18}F-FBPA Uptake in Malignant Tumors.

Y. Shi, S. Zou, J. Zhou, S. Song, X. Zhu;
Department of Nuclear Medicine and PET, Tongji Hospital, Tongji Medical College, Huazhong University, Wuhan, CHINA.

Aim/Introduction: In the clinical practice of boron neutron capture therapy (BNCT) using BPA as a boron carrier, 18F-FBPA PET/CT is essential for candidate selection. However, due to its challenging preparation, not all medical institutions are able to use this probe for patient screening. In contrast, 18F-FDG, as a conventional probe, is widely available in most medical institutions. Therefore, exploring the correlation in tumor uptake between 18F-FDG and 18F-FBPA and considering the feasibility of 18F-FDG as an alternative for 18F-FBPA in patient screening may potentially extend treatment opportunities to a broader patient population. ***Materials and Methods:*** 27 patients with histologically confirmed malignant tumors were enrolled between January 2022 and April 2024, comprising 11 head and neck cancer patients and 16 high-grade glioma patients. All patients underwent both whole-body 18F-FBPA and 18F-FDG PET/CT within two weeks. The correlation of maximum standardized uptake value (SUVmax), maximum tumor-to-normal tissue ratio (TNRmax), metabolic tumor volume (MTV), and total lesion activity/glycolysis (TLA/G) between 18F-FBPA and 18F-FDG were evaluated. Receiver operating characteristic (ROC) analysis of 18F-FDG SUVmax was conducted to determine the optimal threshold for quantitative discrimination. ***Results:*** The accumulation of 18F-FDG was correlated with that of 18F-FBPA. Among all parameters, MTV and TLG exhibited a strong correlation in head and neck cancers and high-grade gliomas. In high-grade gliomas, a strong correlation was observed between the SUVmax. The remaining parameters showed a moderate correlation in both types of cancers. The SUVmax of 9.45 for 18F-FDG in head and neck cancers and 8.20 in high-grade gliomas are considered as the optimal threshold values for predicting a TNR of 2.5 for 18F-FBPA. ***Conclusion:*** The tumor uptake in 18F-FDG PET/CT is correlated with 18F-FBPA. Performing 18F-FDG PET/CT may serve as an effective screening method to identify suitable patients for BNCT treatment when 18F-FBPA PET/CT is unavailable.

Machine Learning-Based Analysis of Cachexia and Survival in HNSCC via$^{[18F]}$FDG PET/CT Metabolic Profiling

J. Yu[1], *C. Spielvogel[1], D. Haberl[1], Z. Jiang[1], D. Ferrara[2], O. Oezer[1], S. Pusitz[1], S. Kandathil[3], E. Yildiz[3], K. Kumpf[4], T. Wu[5], Z. Zhang[6], Y. Chen[7], S. Grünert[1], M. Hacker[1], C. Vraka[1];*
[1]Department of Biomedical Imaging and Image-Guided Therapy, Division of Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA, [2]QIMP Team, Medical University of Vienna, Vienna, AUSTRIA, [3]Department of Otorhinolaryngology, Head and Neck Surgery, Medical University of Vienna, Vienna, AUSTRIA, [4]IT4Science, Medical University of Vienna, Vienna, AUSTRIA, [5]Department of Cardiology, Xiangya Hospital Central South University, Changsha, CHINA, [6]Department of Nuclear Medicine, The Fourth Hospital of Hebei Medical University, Shijiazhuang, CHINA, [7]Teaching Center, Medical University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: Cancer-associated cachexia in head and neck squamous cell carcinoma (HNSCC) presents significant diagnostic challenges due to its complex pathophysiology and the absence of precise diagnostic tools. We investigated potential metabolic biomarkers linked to cachexia and survival in patients with HNSCC through 18F-FDG PET/CT imaging and machine learning analysis. ***Materials and Methods:*** We conducted a retrospective analysis of 253 histologically confirmed HNSCC patients from Vienna General Hospital and MD Anderson Cancer Center (The Cancer Imaging Archive1). For quantitative analysis, we utilized MOOSE (Multi-Organ Objective Segmentation2), an in-house developed tool, to automatically segment tissues of interest and derive volumetric and metabolic value (SUVbw) from [18]F-FDG PET/CT scans. We assessed image-based parameters in 26 tissues and organs (e.g., mean SUVbw and volume of skeletal muscle, subcutaneous fat and visceral adipose tissue) and evaluated their association with 17 clinical parameters (e.g., gender, clinical staging, smoking history, HPV and therapy regimen). Patients were categorized by cachexia severity using the Weight Loss Grading System (WLGS). Additionally, a machine learning-based model and Cox regression analysis were employed to identify predictors for patient survival. The machine learning model incorporated organ-level metabolic activities, volumes of anatomical structures, and clinical parameters. Shapley additive explanation (SHAP) analysis was employed to demonstrate the importance of various features in predicting cachexia severity and patient survival. ***Results:*** Patients with severe cachexia (WLGS 3/4) exhibited significant metabolic changes, notably increased glucose metabolism in skeletal muscle and adipose tissue, contrasted by decreased lung metabolism in those with less severe cachexia (WLGS 0/1/2). The one-year survival rates were significantly different: 84.11% in WLGS 0/1/2 versus 69.18% in WLGS 3/4 ($p<0.05$). Interestingly, pancreatic volume was identified as a crucial metabolic biomarker through SHAP analysis. The predictive model demonstrated robust performance, achieving an AUC of 0.79 (95% CI 0.77-0.80) and accuracy 0.82 (95% CI 0.81-0.83). Additionally, a multivariate Cox regression analysis confirmed the significance of pancreatic volume as an independent prognostic factor (HR: 0.66, 95% CI: 0.46-0.95; $p<0.05$). ***Conclusion:*** By integrating advanced [18] F-FDG PET/CT with computational analysis, this study underscores

the significance of pancreatic volume in understanding the metabolic complexities associated with cachexia in HNSCC. Our findings enhance understanding of the complex organ interactions in cachexia development in HNSCC, highlighting new avenues for therapeutic intervention. ***References:*** 1 AJ Grossberg JAMA Oncol 2016, 2 LKS Sundar J Nucl Med 2022.

OP-105

The Prognostic Value of PARS Deep Learning Software in Patients with Nasopharyngeal Carcinoma

D. Zheng, *Y. Lv, Z. Zhou, X. Lan, C. Qin;*
Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA.

Aim/Introduction: The development of Deep learning software PET-Assisted Reporting System (PARS) assists clinicians to identify lesions and measure metabolic tumor volume (MTV) and total lesion glycolysis (TLG). This study aimed to evaluate the value of PARS software for prognostic assessment of patients with nasopharyngeal carcinoma (NPC). ***Materials and Methods:*** This study retrospectively enrolled NPC patients who underwent 18F-FDG PET/CT at the PET center of Wuhan Union Hospital in 2018. Clinical characteristics were collected, and patients were followed up through the Hospital Information System (HIS) and by telephone. Survival analysis endpoints include disease progression or all-cause death. Progress Free Survival (PFS) and overall survival (OS) were defined as the duration from the date of pathologic diagnosis until the first disease progression (local recurrence or distant metastasis) or all-cause death, respectively. The reconstructed images were imported into the PARS software and analyzed with SUVmax > 2.5 and 40% of region SUVmax as thresholds. SUVmax, SUVpeak, SUVmean, CV40%, MTV, and TLG at the primary lesion were collected, and Heterogeneity index (HI) was defined as the SUVmean divided by SUVmax. Two senior nuclear medicine physicians performed benign-malignant discrimination of all suspicious foci and physiological uptakes drawn by the PARS software and summarized the total-body MTV (TB-MTV) and TLG (TB-TLG). Univariate and multivariate COX regression were used to screen survival-related factors. ***Results:*** A total of 69 patients were included, of whom 48 were males. The average age was 49.07±1.38 years. The median follow-up time for PFS was 832 (725.5, 971) days, with 14 patients experiencing disease progression, the median PFS time was 867 (95% CI: 837.15, 896.85) days, and the 2-year progression-free survival rate was 81.25%. The median follow-up time for OS was 840 (757, 935) days, with 5 all-cause deaths (all with disease progression), the median survival time was 865 (95% CI: 835.67, 894.33) days, and the 2-year OS rate of 91.94%. In univariate COX regression models, age, TB-MTV, and MTV were selected as independent factors for disease progression; while age, lymphocytes, albumin, and HI were selected as independent factors for all-cause death ($P < 0.05$). Age, albumin, TB-MTV, TB-TLG, MTV, and HI were independent factors for disease progression, while age, albumin, neutrophils, and lymphocytes were selected as independent predictors of all-cause death. ***Conclusion:*** The PARS software is capable of recognizing primary and metastatic lesions of NPC, and its acquired image information is beneficial for the prognosis assessment of NPC patients.

OP-106

Radiomics and Machine Learning in Head and Neck Cancer: Differentiating Post-Intervention Changes from Tumor Recurrence

P. Singh, *T. Singhal, G. K. Parida, D. K. Das, P. S. Patro, K. Agrawal;*
AIIMS Bhubaneswar, Bhubaneshwar, INDIA.

Aim/Introduction: Head and neck (H&N) cancers constitute the seventh most common cancer globally. The main management strategy includes surgery+chemo-radiotherapy whenever possible. However, one major predicament post-primary management is differentiation of post-interventional changes from recurrent disease. Thus, we evaluated the utility of 18F FDG PET-CT derived radiomic features (RF) and machine learning model (MLM) to correctly differentiate post-interventional changes from recurrent disease. ***Materials and Methods:*** Patients with suspicion of recurrent H&N cancer who underwent 18F FDG PET-CECT imaging were included in the study. Experienced nuclear medicine physicians manually delineated the regions of interest (ROIs), and intensity-threshold restrictions of 25% and 35% were applied to create three distinct sets of ROIs and high-dimensional RF were extracted using LIFEx (v7.6).Statistical analysis included the Mann-Whitney test to identify the difference of mean of all individual RF and their statistical significance in differentiating patients with post-interventional changes versus recurrent disease. RF with an area under the curve(AUC) greater than 0.7 on receiver operator curve(ROC) were retained. Subsequently, the least absolute shrinkage and operator (LASSO) algorithm was used to further refine the feature selection by removing low-weight features. A support vector machine(SVM) -based MLM was developed using R v.4.1.3, with 75% of the data for training and 25% for validation. The model's performance was assessed using ROC curves, with histopathological examination(HPE) or follow-up as the gold standard. Key metrics such as sensitivity, specificity, negative predictive value (NPV), positive predictive value (PPV), and accuracy were calculated to evaluate the model's effectiveness. ***Results:*** The study included 142 H&N cancer patients (120 males, median age-51, range: 25-89 years). Among these, 74 had post-interventional changes and 68 had recurrence as confirmed by HPE or follow-up. A total of 161 RF were extracted from each 18F FDG PET-CT image at three intensity thresholds, with the most significant results observed at the 35% threshold. Univariate analysis revealed 134 RF were statistically significant predictors of outcome ($P<0.05$). Among these, 81 features with AUC>0.7 were selected for multivariate analysis using the LASSO algorithm. The LASSO algorithm identified 8 high-weightage parameters, forming the basis for the SVM-MLM. The SVM-MLM achieved a sensitivity, specificity, PPV, NPV and accuracy of 82.3%, 77.7%, 77.7%, 82.3% and 80% respectively with AUC of 0.873. ***Conclusion:*** SVM-MLM using RF can effectively differentiate interventional changes from disease recurrence in H&N cancer patients, demonstrating its potential clinical utility in addressing this perplexing clinical scenario.

OP-107

Total tumor burden measured by FDG-PET in patients with oropharyngeal squamous cell carcinoma predicts distant metastases

F. Hofheinz[1], *M. Hajiyianni[2], P. Nikulin[1], C. Furth[3], J. Rogasch[3], P. Cegla[4], W. Cholewinski[4], J. Kaźmierska[5], I. Strouthos[6], K. Ferentinos[6], G. Landry[7], E. Lombardo[7], N. Albert[8], A. Holzgreve[8], J. Kotzerke[9], J. van den Hoff[1], S. Zschaeck[10];*
[1]Helmholtz-Center Dresden-Rossendorf, Institute of Radiopharmaceutical Cancer Research, Dresden, GERMANY,

[2]Department of Internal Medicine V, University Hospital Heidelberg and National Center for Tumor Diseases (NCT), Heidelberg, GERMANY, [3]Department of Nuclear Medicine, Charite – Universitaetsmedizin, Berlin, GERMANY, [4]Department of Nuclear Medicine, Greater Poland Cancer Centre, Poznan, POLAND, [5]Electroradiology Department, University of Medical Sciences, Poznan, POLAND, [6]Department of Radiation Oncology, German Oncology Center, European University Cyprus, Limassol, CYPRUS, [7]Department of Radiation Oncology, University Hospital, Ludwig-Maximilians-University (LMU), Munich, GERMANY, [8]Department of Nuclear Medicine, University Hospital, Ludwig-Maximilians-University (LMU), Munich, GERMANY, [9]Department of Nuclear Medicine, University Hospital Carl Gustav Carus, Technische Universität Dresden, Dresden, GERMANY, [10]Department of Radiation Oncology, Charite – Universitaetsmedizin, Berlin, GERMANY.

Aim/Introduction: The incidence of oropharyngeal squamous cell carcinoma is steadily rising, the tumor is often diagnosed in locally advanced stages (LOPC). Chemoradiation (CRT) is a frequently chosen primary treatment approach with considerable toxicities and high rates of loco-regional control, especially in human papillomavirus positive disease. Therefore, treatment de-escalation is an ongoing issue with mutliple clinical trials investigating its feasibility. Metachronous distant metastasis is less common compared to other locally advanced squamous cell malignancies but affects up to 20% of patients. A biomarker based selection of patients with high risk for development of distant metastases is urgently needed. This biomarker could be used for consolidative checkpoint inhibition or other pharmacological interventions. Here, we investigated the prognostic utility of total tumor burden (TTB) in LOPC for prediction of distant metastases. ***Materials and Methods:*** Altogether, 431 patients ((61+/-9)y, 335 male) with newly diagnosed LOPC were included. All patients received FDG-PET/CT prior to definitive radiochemotherapy. In the PET images, the metabolically active volume of the primary tumor (MTV) and of all FDG avid lymph nodes was delineated with an adaptive threshold method. TTB was computed as the cumulative volume of primary tumor and lymph nodes. Survival analysis with respect to freedom from distant metastases (FFDM) was performed. ***Results:*** Survival analysis revealed MTV and TTB as prognostic factors for FFDM (P<0.001). Hazard ratio (HR) for TTB was significantly higher than HR for MTV (4.1 vs. 2.7, P=0.02). In multivariate analysis with clinical parameters (age, sex T, N, UICC) as confounding factors a significant effect was found only for TTB (P<0.001). ***Conclusion:*** In the investigated group of patients, TTB has a significantly larger prognostic value with respect to FFDM compared to MTV. Further investigations are necessary to confirm these promising results.

OP-108

Sentinel lymph node biopsy with ^{99m}Technetium-labeled nanocolloidal albumin in patients with oral cavity squamous cell carcinoma. Our 7 year experience.

S. Angiolillo Grau, *P. Zaragoza-Ballester, X. Guarnizo Poma, M. Avilés Jurado, S. Ruiz Solís, E. Martínez Albero, D. Vega Pérez, M. Sarandeses Fernández, A. Saviatto Nardi, A. Galiana Morón, A. Gómez Grande, E. López Llobet, B. Manzarbeitia Arroba, R. Delgado, M. Tabuenca Mateo;*
Hospital Universitario 12 de Octubre, Madrid, SPAIN.

Aim/Introduction: Lymph node status is the most important prognostic factor in oral squamous cell carcinoma (OSCC). Around 30% of patients with early-stage(T1-T2) disease will have occult cervical metastasis. The management of these patients has traditionally involved therapeutic elective neck dissection (END). Our aim was to describe our 7-year experience performing sentinel lymph node biopsy (SLNB) in patients with early-stage and cN0 OSCC. ***Materials and Methods:*** A descriptive-retrospective study of 65 patients diagnosed with cT1-T2 cN0 OSCC was performed. Stage was clinically and radiologically assessed (CT or MRI). Exclusion criteria included history of external-radiotherapy and/or cervical surgery. Peritumoral and submucosal injection of 74MBq of 99mTc-Nanocolloidal albumin (99mTc-Nanocoll) was performed, followed by acquisition of lymphoscintigraphic images, and cervical SPECT/TC. Two nuclear medicine experts interpreted the images, describing the presence of lymphatic migration and its characteristics. Subsequently, the patients underwent surgery with complete resection of the primary tumor and gamma-probe-guided SNLB. The histopathological analysis evaluated the presence (pN+) or absense (pN0) of cervical lymphatic metastasis. Finally, the evolution of the patients with a pN0 result was investigated, describing the presence of lymphatic recurrence during a follow-up of at least 2 years. ***Results:*** We studied 34 male and 31 female patients, aged 24-91 years (mean 69.27) and diagnosed with early-stage OSCC (T1:81.54%; T2:18.46%), located in: lip(35.38%), tongue(33.85%), floor of the mouth(15.38%), gingiva(10.77%), or jugal mucosa(4.62%). Lymphatic migration was observed on 95.38% of patients, of which 64.52% had unilateral drainage. Patients with bilateral drainage (35.48%) had a tumor located near the midline in 63.64% of cases. The histopathological analysis found pN+ in 7 patients (10.77%), 4 of whom showed no metastatic involvement of any other lymph node after END, meaning that SLNB itself succesfully treated local cervical disease in 90.77% of cases (58 pN0 and 4 pN+). There were 3 patients without radiotracer migration, 2 of whom showed pN+ after lymphadenectomy was performed. 33 (60%) of the patients with pN0 after SLNB, completed a minimun follow-upof 2 years (mean 2.7), showing zero cases of lymphatic recurrence after SLNB. ***Conclusion:*** SLNB with 99Tc-Nanocoll demonstrated a high efficiency in the cervical staging of the patients with early-stage and node-negative OSCC, with a high percentage of lymphatic migration, a high rate of local cervical disease control, and with a very low rate of lymphatic recurrence. SLNB presents an opportunity to decrease more invasive surgical interventions and potentially associated morbidity for patients who are ultimately N0.

First experience with^{18}F-FAZA PET in kidney allografts dysfunction

S. Mirshahvalad[1], *A. Farag[1], A. Kohan[1], A. Konvalinka[2,3,4], P. Veit-Haibach[1];*
[1]University Medical Imaging Toronto, Toronto Joint Department Medical Imaging, University Health Network, Sinai Health System, Women's College Hospital, University of Toronto, Toronto, ON, Canada, Toronto, ON, CANADA, [2]Department of Medicine, Division of Nephrology, University Health Network,

University of Toronto, Toronto, ON, Canada, Toronto, ON, CANADA, [3]Ajmera Transplant Centre, University Health Network, Toronto, ON, Canada, Toronto, ON, CANADA, [4]Toronto General Hospital Research Institute, University Health Network, Toronto, ON, Canada, Toronto, ON, CANADA.

Aim/Introduction: Investigate if 18F-FAZA-PET can be used to evaluate post-transplant kidney allografts to determine the extent, location and severity of renal injury; Evaluate the correlation of 18F-FAZA-PET-derived parameters with histopathology findings on a concomitant biopsy. ***Materials and Methods:*** This IRB-approved, prospective pilot study evaluated renal transplant patients with a dedicated PET/MR protocol between 2018 and 2023. We included 20 patients with impaired kidney graft function, as evidenced by elevated serum creatinine (Cr), or significant proteinuria, and 10 sex- and graft age-matched control patients with stable graft function. For all patients, standard-of-care investigations were performed. Patients with graft impairment also underwent an ultrasound-guided biopsy to identify the underlying impairment cause. 18F-FAZA-PET was performed on a 3.0T PET/MR scanner. Patients were injected with up to 5MBq/kg 18F-FAZA and imaged simultaneously with the injection for the initial 20min. Two hours after injection, a static PET was acquired for 20min. Volumes of interest (VOIs) were contoured manually in consensus post PET and MR registration. The kinetic modelling and parameters (k1,k2,k3,k4, as well as VT -total volume distribution) were derived from the dynamic PET. On the delayed PET, the average standardized uptake value (SUVmean) was measured. ***Results:*** Overall, 30 patients (mean age=53y; Male%=48%; mean estimated glomerular filtration rate [eGFR]=45ml/min; mean Cr=174µmol/L) underwent PET/MR. The kinetic parameters, k1, k3, k3/k4, and VT were 2.45±1.06, 0.92±0.75, 0.75±0.66, 2.11±0.55 in non-biopsied, stable patients versus 1.74±0.79, 0.68±0.66, 0.76±0.69 and 1.62±0.45 in biopsied patients. VT was significantly lower in the biopsied patients (Mann-Whitney U; p=0.026). The delayed SUVmean was 4.83±0.88 versus 5.13±0.83 (p=0.501). Correlating the PET parameters with the clinical factors, VT was significantly inversely correlated with the serum Cr (rs=-0.446;p=0.008) and directly correlated with eGFR (rs=0.467;p=0.005). Furthermore, in the biopsied patients, we evaluated the correlations between PET parameters and histopathology findings. K1 was significantly correlated with vascular fibrous intimal thickening (p=0.036), k3 with arteriolar hyalinosis (p=0.006), k3/k4 with globally sclerotic glomeruli and arteriolar hyalinosis (p=0.009 and 0.038, respectively), VT with interstitial inflammation (p=0.032), and SUVmean with globally sclerotic glomeruli (0.012). ***Conclusion:*** 18F-FAZA-PET is potentially a valuable modality in post-transplant allografts. In particular, the kinetic parameters correlated significantly with clinical factors (e.g., Cr, eGFR) and various pathological parameters, making 18F-FAZA-PET a potential non-invasive alternative for allograft assessment; not only visualizing impairment, but more importantly, determining the underlying cause of renal dysfunction. Further analyses of the correlation between PET-derived parameters and biomarkers of kidney injury are ongoing.

OP-110

Using Clinical and Imaging Data to Forecast [^{99m}Tc]Tc-DMSA Scan Findings

S. Paiva[1], *G. Costa[1,2];*
[1]Nuclear Medicine Department, ULS Coimbra - Hospitais da Universidade de Coimbra, Coimbra, PORTUGAL, [2]Faculdade de Medicina, Universidade de Coimbra, Coimbra, PORTUGAL.

Aim/Introduction: Renal scan using technetium-99m labelled dimercaptosuccinic acid ([99mTc]Tc-DMSA) is a valuable sensitivity tool to detect permanent renal parenchymal scarring at least six months following an acute urinary tract infection (UTI). However, because most of [99mTc]Tc-DMSA scan do not show any abnormalities, a risk assessment is necessary for the selective use of this imaging test. We aimed to assess the association of the [99mTc]Tc-DMSA results with risk factors for renal scar, such as urine culture growth results (UC), the number of previous UTIs, as well as imaging abnormalities detected by kidney ultrasound (US) and cystography. ***Materials and Methods:*** We conducted a retrospective cohort study involving paediatric patients referred, between January 2015 and December 2017, for [99mTc]Tc-DMSA scan to detect renal scar. We collected clinical and imaging data, including age at presentation, number of previous UTIs, UC results, kidney US findings and cystography results. A Binomial Logistic Regression model (utilizing SPSS Statistics 29.0.2.0) was employed to examine the associations between US results, UC results, presence of previous UTI, and [99mTc]Tc-DMSA scan findings. ***Results:*** Out of 633 patients included in the study, the [99mTc]Tc-DMSA scan was considered normal in 481 (75.9%). The remain 152 (24.1%) scans, showed findings consistent with renal scarring, including 100 (15.8%) with impact in split renal function. The analysis revealed that the presence of non-Multidrug Resistant (MDR) bacteria was independently linked to normal [99mTc]Tc-DMSA scan results, with an odds ratio (OR) of 2.79 (95% CI: 1.548 to 5.004, P<0.001). Additionally, the absence of a prior UTI was significantly associated with normal [99mTc] Tc-DMSA scan findings, indicated by an OR of 13.03 (95% CI: 7.91 to 21.48, P<0.001). Furthermore, a normal kidney US was strongly predictive of normal [99mTc]Tc-DMSA results, with an OR of 14.51 (95% CI: 7.38 to 28.55, P<0.001). ***Conclusion:*** Our results emphasize the statistical significance and the strength of the associations between clinical/imaging factors with [99mTc]Tc-DMSA scan outcomes. This model is potentially helpful in patient triage, particularly in the presence of a normal US, non-MDR bacteria, and no previous history of UTI, where the likelihood of normal [99mTc]Tc-DMSA scan results is high.

OP-111

Potential for Shortening Acquisition Time or Administered Activity in Paediatric DMSA Scans with a 360-degree CZT Digital SPECT/CT Camera

Z. Bar-Sever[1,2], *S. Caduri[1], A. P. Steinmetz[3];*
[1]Schneider Children's Medical Center of Israel, Petach Tikva, ISRAEL, [2]Tel Aviv University, Tel Aviv, ISRAEL, [3]Rabin Medical Center, Belinson Campus, Petach Tikva, ISRAEL.

Aim/Introduction: New 360-degree CZT Digital SPECT/CT cameras are superior in sensitivity and spatial resolution to conventional SPECT/CT. This pilot study investigated the potential of these cameras to shorten acquisition time or injected activity in pediatric DMSA scans. ***Materials and Methods:*** Fifteen successive DMSA scans of children 2-17 years old (median age 7 years) were analyzed. The original, vendor recommended, acquisition time was 5 minutes. Injected activities were based on the EANM dosage calculator. Original study counts were retrospectively truncated by 25%, 50%, and 75% to simulate similar reductions in acquisition time or dose. All 4 count groups were reconstructed using similar OSEM parameters. Altogether, 60 reconstructions were presented twice in random order to an experienced reader blinded to clinical, acquisition, and count group information. Each reconstruction was evaluated for image quality using a Likert scale

(1-unacceptable, 2-poor, 3- 3-acceptable, 4-good, 5-excellent), interpretation confidence level (1-low, 2-intermediate, 3-high) the number of cortical defects and relative function of the kidneys. Differences between the original full-time group and the 3 count truncation groups were statistically analyzed by ANOVA. Intra-observer variability was evaluated by paired t-test. ***Results:*** The mean image quality score was 4.2 in the full-time and 3.8, 3.4, and 2.7 in the 25%,50%, and 75% count groups respectively. The difference was statistically significant between the full-time and the 50% and 75% groups, but not between the full-time and 25% groups. Interpretation confidence was 2.7, 2.4, 2.2, and 1.8 in the full-time, 25%, 50%, and 75% groups respectively. The difference between the mean confidence scores of the 50% and 75% count truncation groups and the full-time group was statistically significant. No significant difference was observed between the full-time and 25% count groups. A good correlation was found between image quality and confidence scores (Spearman's rank correlation- 0.78, P-value <0.001). The mean number of cortical defects was 0.9, 0.8, 1.2, and 1.3 in the full-time, 25%,50%, and 75% groups respectively. The differences were not statistically significant. The kidneys' differential function was similar in all groups. Intra-observer variability was non-significant. ***Conclusion:*** Performing pediatric DMSA scans with a 360-degree CZT Digital SPECT/CT camera can potentially reduce the default 5-minute acquisition or the standard radiopharmaceutical activity by 25%. Interpretation confidence can be affected when the reduction is greater than 25%. These preliminary observations should be substantiated in larger patient cohorts.

OP-112

Diagnostic utility of ^{68}Ga-DOTANOC PET/CT in paediatric neuroblastic tumours presenting as Opsoclonus myoclonus ataxia syndrome - a retrospective analysis

K. Subramanian, *A. Meena, R. Kumar, J. Raja;*
Post graduate institute of medical education and research, Chandigarh, INDIA.

Aim/Introduction: Paediatric neuroblastoma may initially manifest with Opsoclonus myoclonus ataxia syndrome (OMAS) (Kinsbourne syndrome/ Dancing eye syndrome), a paraneoplastic neurological syndrome, in approximately 2 - 3% of children. But in as many as 50% of children with this syndrome, neuroblastoma is the cause. In children with OMAS, therapy with steroids or immunosuppressive or cytotoxic drugs is required, along with treating the primary cause. Routine tests to detect occult neuroblastoma include anatomical imaging of chest and abdomen with USG/ CT/ MRI. 131I-MIBG scintigraphy has also been used, but, limited by its availability, strenuous patient preparation and high radiation exposure. Hence, a single screening study which is sensitive, readily available, detect metastasis and simultaneously staging is required. ***Materials and Methods:*** Retrospective data of 68Ga-DOTANOC PET/CT of 74 paediatric patients presenting with OMAS from March 2012 2019 to December 2023 was evaluated. Somatostatin receptor (SSTR) expressing lesion (lesion uptake greater than physiological adrenal uptake) with corresponding morphological change on CT image was considered PET-positive, while no abnormal SSTR expression or lesion was considered PET-negative. Reference standards for comparing the PET/CT results included histopathology and/or clinical/imaging follow-up (at least a year). ***Results:*** Of 74 patients, (29 males, 45 females, with mean age 1.5 years), 43 (58.1%) patients had SSTR expressing lesions (PET-positive). Histopathology revealed neuroblastic tumours in 39/43 lesions and reactive hyperplasia in 4/43 patients. The remaining 31/74 (41.9%) patients did not demonstrate any SSTR expressing lesion (PET negative). The mean SUVmax of PET-positive lesions was 10.5 (SD = 6.3). The PET/CT results revealed 39 true-positive, four false-positive, 31 true-negative, and zero false-negative. The sensitivity, specificity, positive predictive value, negative predictive value, and accuracy were 100%, 88.57%, 90.7%, 100%, and 94.6% respectively. ***Conclusion:*** In this retrospective analysis, neuroblastic tumours were the cause for OMAS in 52.7% of the patients. 68Ga-DOTANOC PET/CT can identify neuroblastic tumours with high accuracy and can provide rapid diagnosis, and hence guide optimal management.

OP-113

How Does Clinical Prognosis In Antenatal Hydronephrosis Correlate With Diuretic ^{99m}Tc MAG3 Renal Scintigraphy Retention Parameters?

B. Cagdas[1], *A. Kilicaslan[1], B. Karabulut[2], H. T. Tiryaki[2], N. C. M. Gülaldi[1];*
[1]University of Health Sciences, Ankara Bilkent City Hospital, Department of Nuclear Medicine, Ankara, TÜRKIYE,
[2]University of Health Sciences, Ankara Bilkent City Hospital, Department of Pediatric Surgery, Ankara, TÜRKIYE.

Aim/Introduction: This retrospective study aimed to evaluate the predictive value of renal pelvic retention ratios at specific time points on 99mTc MAG3 renal scintigraphy for the clinical decision and outcome of patients with antenatal hydronephrosis. ***Materials and Methods:*** 156 patients who underwent diuretic 99mTc MAG3 renal scintigraphy for antenatal hydronephrosis were included in the study. The mean age was 2.98 ± 1.45 years (0.5-6 years). Furosemide adjusted per kg was administered i.v. after 20 minutes of the study. 40-minute, post-void images and 2-hour late images were evaluated for their ratio to maximal activity and 1-2 minute activity (NORAmax) using an Excel sheet created for this purpose. Patients were divided into 4 groups: (A) 90 patients with a normal diuretic pattern, (B) 23 patients who recovered during follow-up, (C) 34 patients who recovered after pyeloplasty and double-J catheter insertion, or (D) 9 patients who ended up with atrophy/dysfunctional kidney despite interventional procedure. Wilcoxon signed-rank test for comparison of means and ROC curve analysis for sensitivity and specificity values were used. ***Results:*** No significant difference was observed between the 40-minute/maximum activity ratios of patients with normal renal function and patients who recovered during follow-up, whereas a significant difference was observed between all other groups ($p < 0.05$). The most sensitive method for determining which patients would recover at follow-up was the extent of retention on postvoid imaging, while the most sensitive values for the patients who benefited from the interventional procedure were the retention rates on late imaging. The NORAmax values were not meaningful enough to differentiate the prognosis of the patients. The mean values for the 40 min/max, post-void/max, and 2-hour image/max ratios were 15.6%, 9.6%, 3.4% for group A, 31.7%, 25.5%, 10% for group B, 85.5%, 67.1%, 49.3% for group C, 91.7%, 78% and 39.8% for group D, respectively. The ROC curve analysis showed that post-void and 2-hour images increased the accuracy of the test for differentiating the patients who needed an intervention. ***Conclusion:*** Maximum activity-based retention ratios can be used more sensitively and specifically to differentiate patients with the potential for spontaneous resolution. Patients with renal retention values of 25% post-void and less than 10% on 2-hour images are more likely to benefit from clinical follow-up, while patients with post-void retention values of 67%, and 2-hour retention values of 50% are more likely to benefit from interventional procedures.

Aim/Introduction: Liver fibrosis occurs as a result of chronic liver injury of different etiologies, leading to a scar formation with excessive deposition of extracellular matrix. Progression of fibrosis is usually a latent process, which leads to impaired liver architecture and irreversible organ failure. Although fibrosis was previously assumed to be irreversible, recent evidence shows that fibrosis may recover, which highlights the importance of earlier detection. Fibroblast activation protein inhibitor (FAPI) PET/CT is a novel imaging method to visualize the activated fibroblasts with the possibility of noninvasively quantifying fibrosis relevant activity. The aim of this retrospective study is to evaluate the diagnostic potential of FAPI-PET/CT in liver fibrosis. ***Materials and Methods:*** 124 patients with various oncological diseases, who had undergone FAPI-PET/CT between July 2017 and Oct 2020 at the University of Heidelberg, were retrospectively analyzed and the SUVmax and SUVmean of liver were measured. In 82 of 124 patients with laboratory findings of serum transaminases and platelet count within 3 months from the date of PET/CT scan, three known fibrosis indices (APRI, FIB-4 and FibroIndex) were calculated. Correlation between these values was analyzed. ***Results:*** Mean standardized uptake value (SUVmean) of FAPI-PET correlated strongly with CT parameter (Hounsfield Unit; $p<0.005$). All of the evaluated fibrosis indices (APRI, FIB-4, FibroIndex) showed a mild positive correlation with SUVmean ($r=0.2$-0.3). Although the grade of correlation was moderate, the observed correlation was statistically significant for all indices (SUVmean vs. APRI: $p<0.01$, SUVmean vs. FIB-4: $p<0.05$, SUVmean vs. FibroIndex: $p<0.01$). ***Conclusion:*** FAPI-PET/CT is a promising method of imaging liver fibrosis with the possibility of visualizing and quantifying disease activity. Its potential use in disease monitoring and noninvasive assessment of clinically relevant disease activity should be warranted in the future study.

OP-116

Visualisation of Superficial Peritoneal Endometriosis with ^{99m}Tc-maraciclatide

J. Barnett[1]*,* ***M. Ghesani*[2]*,*** *T. Gibbons*[3]*, D. Burch*[1,4]*, S. Cade*[5]*, R. Graham*[5]*, N. Patel*[4]*, K. Zondervan*[3]*, C. Becker*[3]*;*

[4]*John Radcliffe Hospital, Oxford, UNITED KINGDOM,*
[5]*Royal United Hospital, Bath, UNITED KINGDOM.*

Aim/Introduction: Superficial peritoneal endometriosis (SPE) is the most common form of endometriosis, comprising approximately 80% of all diagnoses. However, due to the plaque-like nature and generally small size of lesions, SPE is not well visualised with current non-invasive imaging tools (US and MRI) and definitive diagnosis requires laparoscopy. 99mTc-maraciclatide contains the RGD motif (Arg-Gly-Asp) and binds to αvβ3 integrin which plays a key role in cell proliferation, inflammation, and angiogenesis, which are hallmarks of endometriosis. Maraciclatide has been shown to bind to ectopic endometriotic lesions in preclinical studies and 99mTc-maraciclatide has demonstrated diagnostic promise in other inflammatory conditions, such as rheumatoid arthritis. The current study aims to evaluate the potential of 99mTc-maraciclatide in detecting endometriosis and specifically, SPE. ***Materials and Methods:*** Up to 25 women with confirmed or suspected endometriosis are being recruited into a study to determine whether SPECT/CT imaging following intravenous injection of 740 MBq 99mTc-maraciclatide can detect endometriotic lesions, in particular superficial peritoneal lesions, in the pelvis and elsewhere. Images were acquired ranging from 10 mins to 21 hours post-injection. A range of image processing tools were employed to enhance lesion visualisation. To evaluate effectiveness, laparoscopic/histopathology and SPECT/CT findings were compared. ***Results:*** Evaluation of images from the first 12 participants suggests 10 minutes post-injection to be the optimal imaging time point allowing clearance of the agent from the blood pool and minimising bladder activity. 99mTc-maraciclatide uptake has been observed in superficial peritoneal and deep endometriosis lesions seen on laparoscopy. For example 99mTc-maraciclatide image showed uptake into a superficial lesion seen on laparoscopy, the 22 year old subject had a recent negative ultrasound study for endometriosis. Recruitment and scanning are ongoing, and supplementary findings and insights, in particular with reference to the detection of disease subtypes will be presented. ***Conclusion:*** These encouraging preliminary data suggest that 99mTc-maraciclatide could have the potential to be the first non-invasive imaging test for superficial peritoneal endometriosis and impact the lives of millions of women. If confirmed, it could expand our understanding of the pathogenesis of endometriosis, increase diagnostic imaging sensitivity, contribute to a reduction in the diagnostic delay (average of 7.5 years from symptom onset), and complement the existing diagnostic pathway by mitigating current imaging modalities' limitations by aiding in the detection of superficial, deep and extra-pelvic lesions.

OP-117

Head-to-head comparison of perfusion SPECT and volumetric CT for predicting post-segmentectomy lung function

S. Melki, *L. Wilhelm, I. Imbert, U. Gerhard, S. Renaud, A. Verger;*
CHRU Nancy, Vandoeuvre-lès-Nancy, FRANCE.

Aim/Introduction: Lung perfusion single-photon emission computed tomography (SPECT) has already shown to be predictive of post-operative lung function after lobectomy for advanced lung cancers. The objective of this study was to compare the accuracy of quantitative lung perfusion SPECT and volumetric computed tomography (CT) fused images for predicting lung function after segmentectomy in early-stage lung cancer patients. ***Materials and Methods:*** From April 2021 to June 2023, all early-stage lung cancer patients planned for therapeutic segmental lung resections underwent lung perfusion SPECT/CT prior to surgery. Segment contouring on the CT images was manually performed by two experienced nuclear physicians. The function of lung segments planned for resection were obtained from pre-operative perfusion SPECT and from volumetric CT and were compared with parameters obtained from spirometry at 1- and 6-months post-surgery, namely the predicted forced expiratory volume in one second (FEV1), the lung carbon monoxide diffusion capacity (DLCO), and the vital capacity (VC). Multivariate analyses for the prediction of FEV1 at 1- and 6-months post-surgery, including perfusion SPECT and volumetric CT values as well as age, sex and number of segments resected, were also performed.

Results: Fifty-two consecutive patients (67 years [Q1:65, Q3:72], 21 women), with a median of 1 [Q1:1, Q3:2] segment resected, were included in this retrospective analysis. Significant associations were found between the lung function values of planned resected segments according to perfusion SPECT and the 1-month post-operative FEV1 (R=0.33, p=0.019), DLCO (R=0.32, p=0.033), and CV (R=0.39, p=0.009). By contrast, only CV showed significant association with function values of planned resected segments according to perfusion SPECT at 6 months (R=0.35, p= 0.017). No significant association was found using the function of the planned resected lung segment(s) obtained with pre-operative volumetric CT at either 1 month or 6 months. In multivariate analysis, only age and quantitative SPECT were significantly related with the FEV1 at 1 month (p=0.01). ***Conclusion:*** Lung function values of planned resected segments are more accurate when determined from perfusion SPECT than from volumetric CT for prediction of post-segmentectomy lung function. This prediction showed better correlation with spirometry at 1 month rather than at 6 months post-segmentectomy, probably due to patient rehabilitation program effects. Perfusion SPECT, with relatively low associated irradiation (median of 6,49 mSv [Q1: 6,14, Q3:7,18]), is an interesting tool to pre-operatively assess the immediate risk of post-operative dyspnea and to help manage patient rehabilitation in early-lung cancer patients undergoing therapeutic segmental lung resection.

Condylar hyperplasia - assessment of the temporomandibular joints' asymmetry using ^{99m}Tc-HDP bone SPECT with voxel-based evaluation: 10-years' experience.
D. Chroustova[1], *V. Machoň[2], J. Trnka[1], V. Ptačník[1], D. Zogala[1];*
[1]Institute of Nuclear Medicine, Charles University - 1st Faculty of Medicine and General University Hospital, Prague, CZECH REPUBLIC, [2]School of Dentistry, Department of Oral and Maxillofacial Surgery, Charles University - 1st Faculty of Medicine and General University Hospital, Prague, CZECH REPUBLIC.

Aim/Introduction: Enlargement of the articular head or joint capsule can occur as a result of persistent growth activity (idiopathic condylar hyperplasia ICH), tumours or bone disease (fibrous dysplasia, Paget's disease). Joint head shrinkage can occur due to resorptive activities (post-traumatic changes, degenerative changes, idiopathic condylar resorption). The most often cause of the temporomandibular joints (TMJ) asymmetry is ICH. Its diagnosis is based on combination of clinical symptoms observation and imaging methods. Single photon emission computed tomography (SPECT) or SPECT/CT is used for detection of positive or negative growth activity. The aim of the study was to quantify TMJ asymmetry using 99mTc-HDP bone SPECT with voxel-based assessment for selection of a suitable surgery or another therapy. ***Materials and Methods:*** Our experience covers 725 patients (490 female a 235 male, mean age 22 years) with a diagnosis of facial asymmetry due to the enlargement of articular process examined in our department within 2013-2022. A tumorous condyle was ruled out using a panoramic radiograph and cone-beam CT. All patients underwent bone SPECT, which was performed 2-3 hours after injection of 300-700MBq 99mTc-HDP on dual-head gamma camera GE Infinia using low-energy, high-resolution collimator, with the following acquisition parameters:120 projections, 20s per projection, matrix 128x128 pixels, auto-contouring. TMJ asymmetry was evaluated in terms of right/left uptake ratio. Counts on either side were calculated as the sum within VOI defined as the intersection of two spatial masks. One mask was defined via an intensity threshold and served to separate out the background. The other mask was defined as a sphere and served to separate out objects outside the condyle. Total counts from each VOI (L from left condyle, R from right condyle) served as inputs to the calculation of left-to-right ratio: L/(L+R)·100% vs. R/(R+L)·100%. ***Results:*** 119 patients had uptake difference higher than 10 percentage points (pp). These patients were indicated for condylar shaving to stop the condyle growth, however 4 of them refused this solution. In 606 patients no pathological growth activity was observed having uptake difference of 10pp or lower, which disproved working diagnosis of ICH. These patients underwent planned orthodontic therapy (422 patients) and orthodontic-surgical therapy (184 patients) to correct facial asymmetry. ***Conclusion:*** TMJ growth asymmetry assessed by 99mTc-HDP bone SPECT with voxel-based evaluation is crucial in diagnosis of ICH and for choosing the proper surgery or other suitable therapy.

EPS-023

Clinical impact of the 75 taurosecolic (75SeHCAT) scintigraphy on chronic diarrhoea and bile acid malabsorption

O. Hernandez Cristancho, *A. Cardozo Saavedra, E. Mariscal Labrador, A. Palomar Muñoz, S. Asadurova, J. Echeverri Díaz, F. Velasquez, N. Calviño, M. Marusso Fizzani, A. García Burillo, C. Gamez Cenzano;*
Hospital universitari Vall d'Hebron, Barcelona, SPAIN.

Aim/Introduction: To assess the clinical impact of 75SeHCAT scintigraphy diagnosing patients with chronic diarrhoea and suspected bile acid malabsorption (BAM) and evaluating the guided treatment and tolerability with cholestyramine resin. ***Materials and Methods:*** Retrospective analysis of patients who underwent 75SeHCAT scintigraphy for chronic diarrhoea in our nuclear medicine department (1st January and 31st December 2022). A positive result of BAM was defined as a retention of less than 15% of bile acids 7 days after oral intake of 75SeHCAT. Bile acid malabsorption was further subclassified as mild (<15%), moderate (<10%), or severe (<5%). We also, classified BAM by types: 1) BAM from ileal disease or ileal resection/bypass; 2) primary (idiopathic) and 3) all other causes not included within type 1 or 2. ***Results:*** 75SeHCAT scintigraphy was performed in 269 patients (173 women, mean age 49,8 years [15-90]).It was positive in 144 patients (53,5%): 41 mild (type1=4; type2=28; type3=9), 48 moderate (type1=4; type2=27; type3=17), and 55 severe (type1=7; type2=33; type3=15). Ninety-eight received cholestyramine resin treatment: 22 mild (type1=2; type2=14; type3=6), 28 moderate (type1=1; type2=12; type3=15), and 48 severe (type1=6; type2=29; type3=13). Eighty-two showed clinical improvement: 14 mild (type1=1; type2=9; type3=4), 25 moderate (type1=1; type2=10; type3=14), 43 severe (type1=5; type2=26; type3=12). In terms of treatment tolerance, 21 (21,4%) needed to suspend treatment due to intolerance or adverse effects: 3 mild; (type1=1, type2=2), 5 moderate; (type2=2, type3=3) and 13 severe; (type2=8, type3=5).Forty-six patients with positive result did not receive cholestyramine treatment. Of these, 3 improved by using a different bile acid sequestrant, 7 by making changes in their diet and two by modifying oral antidiabetic treatment (switching metformin for GLP1 receptor agonist).The scintigraphy result was negative in 125 patients. Of these, 31 received cholestyramine treatment and 13 showed clinical improvement (mean retention of 75SeHCAT was 21,8% and 13 showed intolerance. They were subclassified into two groups, using a cut-off point of 22 % of retention, 16 patients with ≥ 22% of retention and 15 <22%. The first group showed intolerance in 56 % of the patients (9) and the second group in 26,6% (4). ***Conclusion:*** 75SeHCAT scintigraphy is a diagnostic tool that helps in the selection of patients with BAM who are potentially candidates for treatment with cholestyramine; consequently, it avoids unnecessary side effect. Most patients with a negative scan who benefited from cholestyramine treatment had a mean retention rate of less than 22 % on day 7.

EPS-024

Exploring the Potential Value of [68Ga]Ga-FAPI-46 PET-CT for Molecular Assessment of Fibroblast Activation in Interstitial Lung Disease: a single-center pilot study

M. Assadi[1], *M. Bahtouee[2], E. Jafari[3], M. Khazaei[4], N. Aram[2], A. Amini[5], N. Jokar[3], H. Ahmadzadehfar[6], A. Gholamrezanezhad[7];*
[1]Bushehr University of Medical Sciences (BUMS), Bushehr, IRAN, ISLAMIC REPUBLIC OF, [2]Department of Internal Medicine (Divisions of Respiratory& Critical Care medicine), Bushehr Medical University Hospital, School of Medicine, Bushehr University of Medical Sciences, Bushehr, IRAN, ISLAMIC REPUBLIC OF, [3]The Persian Gulf Nuclear Medicine Research Center, Department of Nuclear Medicine, Molecular Imaging and Theranostics, Bushehr Medical University Hospital, School of Medicine, Bushehr, IRAN, ISLAMIC REPUBLIC OF, [4]Department of Radiology, Bushehr Medical University Hospital, School of Medicine, Bushehr, IRAN, ISLAMIC REPUBLIC OF, [5]Department of Internal Medicine (Division of Rheumatology), Bushehr Medical University Hospital, School of Medicine, Bushehr, IRAN, ISLAMIC REPUBLIC OF, [6]Department of Nuclear Medicine, Klinikum Westfalen, Dortmund, GERMANY, [7]Department of Radiology, Keck School of Medicine, University of Southern California (USC), Los Angeles, CA, UNITED STATES OF AMERICA.

Aim/Introduction: The aim of the study was to evaluate the association of high-resolution computed tomography (HRCT) findings with pulmonary fibrotic activity in the corresponding regions using [68Ga]Ga-FAPI PET/CT in patients with interstitial lung disease (ILD). Additionally, the potential of [68Ga]Ga-FAPI-46 PET/CT for evaluating the active fibrosis process and 99mTc-MIBI scintigraphy for assessing the inflammatory process in ILD patients was also assessed. ***Materials and Methods:*** In this pilot study, 20 ILD patients underwent [68Ga]Ga-FAPI-46 PET/CT and 99mTc-MIBI SPECT/CT. Additionally, 10 patients without lung or thoracic involvement who were undergoing [68Ga]Ga-FAPI PET/CT for cancer detection were enrolled in the control group. The images were evaluated both visually and quantitatively and compared with HRCT and pulmonary function tests (PFTs). Multiple quantitative parameters were derived from the lung segments in the PET scan, including SUVmax, SUVmean, maximum target-to-liver ratio (TLRmax), TLRmean, and total lesion FAPI-expression (TL-FAPI) for the entire lung as well as its lobes and zones. Additionally, the maximum Hounsfield unit (HUmax) and mean HU (HUmean) in HRCT were calculated for the whole lung as well as its lobes and zones. Furthermore, an HRCT fibrosis score (HFS) was defined according to the HRCT findings. ***Results:*** Based on visual assessment, the FAPI scan was positive in 12 (60%) of the patients. Similarly, the MIBI scan was positive in 12 (60%) of the patients. In the 20 ILD cases, both scans were positive in six cases and both were negative in two cases. Six cases showed FAPI-negative and MIBI-positive results, while another six cases showed FAPI-positive and MIBI-negative results. Comparing the control and ILD patients, there was a significant difference in SUVmax, SUVmean, TL-FAPI, TLRmean, HUmax, and HUmean ($p<0.05$). When comparing TFS with PET-derived parameters in zones, a significant positive correlation was found between TFS and SUVmean, SUVmax, TLRmax, and TLRmean ($p<0.05$). Additionally, a significant difference was noted between FAPI results and TFS ($p=0.003$). An ancillary finding, 9 out of 20 (45%) ILD patient showed intensely FAPI uptakes in gallbladder while none of 10-control group showed such uptake. ***Conclusion:*** The present study may suggest that combining [68Ga]Ga-FAPI PET/CT and 99mTc-MIBI SPECT/CT yields an additive effect for evaluating ILD-related fibrosis and inflammatory processes over using either modality alone. Furthermore, it appears that [68Ga]Ga-FAPI PET/CT has the potential to ascertain levels of fibrotic activity from population of resident fibroblasts, active fibroblasts, and scar maturation among ILD patients based on their HRCT patterns.

EPS-025

Analysis of the relationship between radionuclide post-treatment scintigraphic imaging data and hematological toxicity in patients with bone metastases

*G. Grushka[1], **A. Savchenko[2],** V. Bobrova[3];*
[1]Kharkiv National Medical University, Kharkiv, UKRAINE, [2]Kharkiv National University named after V. N. Karazin, Kharkiv, UKRAINE, [3]Grigorev Institute for Medical Radiology and Oncology, Kharkiv, UKRAINE.

Aim/Introduction: In order to identify prognostic factors for complications of radionuclide therapy with 153Sm-oxabiphore and further prevent their development, the relationship between hematological toxicity (HT) and the maximum percentage of 153Sm-oxabiphor uptake in pathological foci on post-treatment scintigraphic images (A max.) was studied in patients with bone metastases. ***Materials and Methods:*** The ranges of hemoglobin, leukocyte, granulocytes and platelets were analyzed in 45 patients three times: on days 2-6, days 10-14 and 3-4 weeks after administration 153Sm-oxabiphore. HT levels ranging from zero to three were determined. During computer processing of scintigraphic data, A max. was quite varied and ranged from 119% to 626%. There were 5 subgroups of patients according to level A max..The range of A max. in the first subgroup (11 patients) there was: 119 % - 150 %; in the second subgroup (15 patients): 151 % - 200 %; in the third subgroup (8 patients): 201 % - 295 %; in the fourth subgroup (4 patients): 309 % - 329 %; in the fifth subgroup (7 patients): 420 % - 626 %. ***Results:*** Among all patients, regardless of the level of 153Sm-oxabiphore uptake in pathological metastatic foci and specific activity upon intravenous administration, a low level of HT was detected. According to the hemoglobin level, the zero degree of HT was established in 88.8 %, the first degree of HT - in 10.6 %, the second - in 0.8 %, the third - never recorded. For leukocyte, the zero degree of HT was recorded in 76.8 %, the first - in 13.0 %, the second - in 7.4 %, the third - in 2.8 %. For granulocytes, the zero degree of HT was established in 89.8 %, the first degree of HT - 7.9 %, the second - 0.8 %, the third - 1.5 %. For platelets, the zero degree of HT was detected in 99.5 %, the first degree of HT was found in 0.4 %, the second and third were not observed. ***Conclusion:*** The above indicates a relatively safe prognosis on the HT, regardless of A max.. No correlation was found between these indicators. Thus, A max. cannot be a predictive factor for the occurrence of HT for therapy with 153Sm-oxabiphore.

EPS-026

Generalizability of an Adult-Trained Lymphoma PET/CT Metabolic Tumor Volume Segmentation Model to Pediatric Hodgkin Lymphoma Patients

***F. Yousefirizi[1],** X. Tie[2], T. Bradshaw[2], S. Cho[2], S. Perlman[2], M. Shin[2], S. Castellino[2], K. Kelly[2], C. Gowdy[3], C. Garrett[4], P. Sheikhzadeh[5], S. Farzanehfar[5], C. Uribe[1], A. Rahmim[6];*
[1]BC Cancer Research Institute, Vancouver, BC, CANADA, [2]Department of Radiology, University of WI–Madison, Madison, WI, UNITED STATES OF AMERICA, [3]BC Children's Hospital, Vancouver, BC, CANADA, [4]Provincial Digital Health and Information Services, Vancouver, BC, CANADA, [5]Faculty of Medicine, Tehran University of Medical Science, Tehran, IRAN, ISLAMIC REPUBLIC OF, [6]University of British Columbia, Vancouver, BC, CANADA.

Aim/Introduction: In pediatric lymphoma cases, assessing total metabolic tumor volume (TMTV) via FDG PET/CT scans is crucial for prognosis and risk stratification. However, accurately delineating tumor volume through segmentation poses significant challenges due to variations in tumor characteristics and the presence of brown fat. To ensure accurate assessment and optimal patient management, there is a pressing need for robust and efficient segmentation techniques tailored specifically to pediatric lymphoma cases. This study aims to evaluate the generalizability and applicability of a segmentation model trained and tested initially on adult lymphoma cases when applied to pediatric cases. ***Materials and Methods:*** This retrospective study analyzed 200 pediatric patients with high-risk Hodgkin lymphoma using 18F-FDG PET/CT images from the Children's Oncology Group AHOD1331 clinical trial. Reference contours were created by three experienced physicians using MIM software after multi-reader adjudication. Additionally, 8 and 18 cases from other centers were included, with segmentation performed by a nuclear medicine physician using MIM software. TMTV-Net resamples PET/CT images, trains multiple 3D U-Net models with cross-validation, combines their outputs, feeds them into another 3D U-Net with original data, and uses a semi-supervised loss function. ***Results:*** TMTV-Net was able to accurately segment lymphoma in pediatric patients with a Dice score of 0.70±0.19 (precision/recall: 0.71/0.74) on data from Center I, which is comparable to the overall performance of the external multi-site testing set (0.66 ± 0.16) consisting of adult patients. Dice scores of 0.40±0.0 (precision/recall: 0.61/0.33) and 0.59±0.26 (precision/recall: 0.79/0.56) were achieved on the data from two other centers. Additionally, Pearson's r correlation for TMTV between physician and AI measurements was notably high at 0.90 on data from centers I, II, and III. The relative error of TMTV measurement were 0.32, 0.46, and 0.44 for centers I, II, and III respectively. ***Conclusion:*** We validated a fully automated segmentation network designed for adult lymphoma in pediatric cases across three centers. The model showed promising results in quantifying TMTV in pediatric patients at Center I, comparable to adult patients in an external testing set. However, results from Centers II and III suggest a need for fine-tuning the model for pediatric cases, possibly due to variations in imaging protocols or differences in segmentation methods, highlighting the importance of post-processing adjustments. ***References:*** Yousefirizi F, et al. TMTV-Net: fully automated total metabolic tumor volume segmentation in lymphoma PET/CT images—a multi-center generalizability analysis. European Journal of Nuclear Medicine and Molecular Imaging. 2024 Feb 8:1-8.

EPS-027

Feasibility Study of Advanced Renal Function Assessment Using Dynamic ^{99m}Tc-DTPA SPECT-CT

S. Hvidsten;
Odense University Hospital, Odense C, DENMARK.

Aim/Introduction: Glomerular filtration rate (GFR) assessment plays a crucial role in managing renal function. We introduce an advanced novel method utilizing dynamic 99mTc-DTPA SPECT-CT for evaluating both renal plasma flow and GFR. The SPECT estimated GRFSPECT is compared against GFRplasma estimated through conventional blood plasma sampling. Our approach employs a simple model to estimate GFRSPECT for each kidney. Additionally, the method provides advanced insights through estimates of renal plasma flow and plasma mean transit times through both the renal vascular bed and renal tissue. ***Materials and Methods:*** Two healthy volunteers underwent renal function assessment using our novel technique. We performed a dynamic scan using a 12-headed CZT SPECT-CT scanner following a bolus injection of approximately 200 MBq 99mTc-DTPA. To correct

the SPECT images for attenuation and accurately delineate the kidney structure and volume, we acquired a low-dose CT scan prior to the SPECT scan. We modeled individual kidney time-activity curves by convolution of the plasma input curve with a retention function. This retention function is composed of two smooth step functions, the first step function models the non-filtered tracer and the second step function models the tissue-filtered tracer. Both functions are characterized by a flat portion corresponding to the model parameters kidney plasma flow and GFRSPECT, respectively. The width of each step function simulates the mean transit time of non-filtered tracer through the renal capillaries/vascular bed (MTTcapillary) and the filtered tracer through renal tissue (MTTrenal) respectively. We also estimated total GFRplasma using plasma samples collected at various time points from 10 minutes to 6 hours post-injection. ***Results:*** We found GFRSPECT from both kidneys to be 142 ml/min, compared to GFRplasma of 106.5 ml/min. We measured plasma flow per kidney to be 247 ml/min, with a summed kidney flow value of 495 ml/min. We estimated MTTcapillary to be 15.8 seconds and transit time through the kidney tissue (MTTrenal) to be 192 seconds. All estimates represent mean values from both volunteers. ***Conclusion:*** Our study demonstrates the feasibility of simultaneous renal function assessment using GFRSPECT and advanced renal functional measures as plasma flow and transit times through both the vascular bed and the renal tissue. The observed plasma flow values fall within the expected normal range indicating the potential utility of our method. Importantly, our study successfully demonstrated a pioneering technique using both the tissue filtered and non-filtered characteristics of 99mTc-DTPA, marking a significant advancement in renal function assessment methods.

EPS-028

A long-term follow-up in conservative management of unilateral pelviureteric stenosis with impaired drainage and good renal function

R. Belakroum, *H. Bouzidi, M. L. Derai;*
Regional Military Hospital, Constantine, ALGERIA.

Aim/Introduction: In the last few decades, an increased understanding of the natural history of hydronephrosis related to the ureteropelvic junction (UPJ) stenosis has been accompanied by a change in management, from systematic surgical approach to active surveillance and selective surgery. The aim of our study was to prospectively determine, in children with antenatally detected UPJ stenosis with a good renal function and abnormal renal drainage at the first diuretic renal scan, the predictive value of an impaired renal drainage in case of conservative attitude. ***Materials and Methods:*** We have followed 80 consecutive children with antenatally diagnosed PUJ stenosis during a 5-year period (between 2016 and 2020). From this cohort, we retained 80 children with unilateral PUJ and strictly normal contralateral kidney with a median follow up of 42 months. Repeated ultrasounds and 99mTc-ethylene-dicysteine (EC) renograms were performed in all children. The quality of renal drainage was evaluated on the basis of the post micturition post erect normalized residual activity (NORA.PM). Drainage was described as poor (NORA>2), good (NORA<0.5), or partial (0.5<NORA<2). DRF of 45%-55% was considered as normal. ***Results:*** Among the 80 patients of the study, 52 patients did not underwent a surgical intervention (65%), while surgical repair (Anderson-Hynes dismembered pyeloplasty) was performed in 28 (35 %). During conservative follow-up, DRF deterioration was observed in 11.5% of cases. When analyzing the DRF evolution in function of the quality of renal drainage, the rate of DRF deterioration was not significantly different, whatever the quality of drainage. In 61.5% of patients with poor renal drainage and 92.5% with partial drainage, no DRF deterioration could be observed. The quality of drainage was not predictive of DRF deterioration in case of conservative approach. ***Conclusion:*** impaired drainage does not mean the presence of UPJ obstruction and therefore the need of systematic surgery, spontaneous improvement may occur. Scheduled controls are needed for early discovery of functional renal deterioration. ***References:*** [1]- Koff SA, Campbell KD. Role of Preoperative Hepatobiliary Scintigraphy in Children Requiring Liver Resection

E. Kireeva, *K. Chaurasiya, M. Dunaykin, M. Yadgarov, D. Akhaladze, Y. Likar;*
Dmitry Rogachev National Medical Research Center of Pediatric Hematology, Oncology and Immunology, Moscow, RUSSIAN FEDERATION.

Aim/Introduction: Post-hepatectomy liver failure (PHLF) is still a significant concern after major liver resection, particularly in adults. The assessment of future remnant liver function (FRLF) through hepatobiliary scintigraphy has proven to be important in preventing PHLF, with a threshold value of FRLF > 2.7%/min/m2. However, there are no such data available for pediatric population. The objective of this study was to determine the role of preoperative assessment of FRLF using HBS and its comparative analysis with FRLV and RLV-BWR values in children requiring liver resection. ***Materials and Methods:*** Seventy-seven pediatric patients with liver tumors who underwent one-stage liver resection were enrolled in this study. Prior to surgery, an evaluation of future remnant liver function (FRLF), future remnant liver volume (FRLV), and the ratio of remnant liver volume to body weight (RLV-BWR) was assessed. ***Results:*** Our findings showed that every patient had RLV-BWR values exceeding 0.5%/kg. FRLV values varied from 19 to 89%, while FRLF values ranged from 1.8 to 31.8%/min/m2. It was observed that only 7 out of the 77 patients had FRLV values below 25%, but their FRLF values surpassed 2.7%/min/m2. Additionally, two patients developed grade-A and grade-B PHLF. The values of FRLV and FRLF were 19% and 4.1%/min/m2 respectively for the patient with grade-A PHLF: and 31% and 1.8 %/min/m2 respectively for the patient with grade-B PHLF. It is worth noting that patient with grade-B PHLF developed severe intraoperative complications due to massive blood loss. ***Conclusion:*** In conclusion, both FRLV and the RLV-BWR are suitable for evaluating the liver in pediatric patients prior to hepatectomy. According to our data, implementation of FRLF assessment using HBS can be most beneficial for children with FRLV < 25%. The cut-off value of FRLV > 25% can be slightly decreased with minimal risk of developing PHLF. However, further prospective studies with larger numbers of patients with FRLV < 25% are necessary to establish a new cut-off value for FRLV in children. Keywords: future remnant liver function, hepatobiliary scintigraphy, liver volumetry, liver tumor.

EPS-030

^{18}F-fluorocholine PET/CT in detecting abnormal parathyroid glands in patients younger than 19

J. Talbot[1], *J. Zhang-Yin[1], L. Noskovicova[2], C. Aveline[1], B. Jonca[1], S. Irtan[3], I. Keller-Petrot[3], F. Montravers[1], S. Balogova[4]; [1]APRAMEN Hopital Tenon, Paris, FRANCE, [2]Comenius Univeristy, Bratislava, SLOVAKIA, [3]Hôpital Trousseau, Paris, FRANCE, [4]Comenius University, Bratislava, SLOVAKIA.*

Aim/Introduction: The diagnostic performance, reproducibility and impact of ^{18}F-fluorocholine (FCH) PET/CT in patients with hyperparathyroidism (HPT) aged <19 was never reported. ***Materials and Methods:*** Our dual-centre retrospective study included 24 patients, 14 girls and 10 boys, who underwent 28 FCH PET/CTs at an average age of 13.9 years (4.6-18.4 years), 19 for primary HPT (PHPT), including one case of mutation of the HPRT2 gene but no MEN1, and 9 for renal HPT (RHPT). PET/CT acquisition started 20 to 30 min after injection of 141 MBq on average (65-232) of FCH. In 25 cases, ultrasonography (US) was performed during the same imaging work-up, generally before PET (22/25). After re-evaluation, the diagnosis of HPT was abandoned in 3 patients with negative PET and US. Were determined, overall and separately for PHPT and RHPT, the positivity rate, and then, in operated (PTX) patients, the patient-based sensitivity (Se), the gland-based Se, with the histology of the resected PTs as a standard of truth, equivocal FCH or US foci being considered as negative. The results of FCH PET/CT vs. US were compared using the Mc Nemar test, * notes a significant difference p<0.05. Were also determined for FCH PET/CT the impact of on patient management initially based on US. and the accordance between open and masked readings. ***Results:*** Open reading (FCH & US). Positivity rate. Overall: 22/25=88% & 9/23=39%*; PHPT: 15/16=94% & 6/16=38%*; RHPT: 7/9=78% & 3/7=43%. 4 examinations not followed by PTX were excluded from further analysis. Patient-based Se. Overall: 20/21=95% & 8/21=38%*; PHPT: 15/15=100% & 5/15=33%*; RHPT: 5/6= 83% & 3/6=50% Gland-based Se. Overall: 25/29=86% & 10/29=34%*; PHPT: 16/16=100% & 5/16=31%*; RHPT: 9/13=69% & 5/13=38%. Se according to histology. Adenoma: 14/14=100% & 4/14=29%*; Hyperplasia: 11/15=73% & 6/15=40%. True-negative results. Patient-based 3/3 & 2/2; gland-based (2 normal PT resected) FCH=US=2/2. FCH PET/CT induced a change in management based on US in 12/22=55% of cases. The management was adequate in all cases as no PTX was futile. A post-PTX persistence of HPT was observed only in two cases of RHPT corresponding to a PT that was not resected despite FCH-positivity. Concordance between open and masked readings was 20/28=71% for the patient-based number of PTs detected as abnormal (Kappa=0.53) and 34/46=74% concerning identification of PTs (Kappa=0.44). ***Conclusion:*** FCH PET/CT was suited for detecting abnormal PTs in primary or renal hyperparathyroidism, was quite reproducible between observers and influenced favourably the management in half of patients.

EPS-031

Is ^{18}F-Fluorodexyglucose testicular uptake using PET/CT correlated with the results of a testicular sperm extraction procedure in the case of azoospermia (results of the French prospective multicenter AZOPREDHISTOTEP study)?

L. O. Dierickx[1], *C. Bettiol[2], D. Huglo[3], F. Marcelli[3], L. Sibert[4], P. Gouel[5], N. Balamoutoff[6], L. Feretti[6], F. Orlhac[7], E. Huyghe[8]; [1]Institut Claudius Regaud, Institut Universitaire de Cancer Toulouse-Oncopole, Toulouse, FRANCE, [2]CHU de Toulouse, Hôpital Paule de Viguier, Toulouse, FRANCE, [3]Centre Hospitalier Regional Universitaire de Lille, Lille, FRANCE, [4]CHU de Rouen, Rouen, FRANCE, [5]Centre Henri Becquerel, Rouen, FRANCE, [6]CHU Bordeaux GH Pellegrin, Bordeaux, FRANCE, [7]Institut Curie Centre de Recherche Orsay, Orsay, FRANCE, [8]CHU Toulouse, Hôpital Paule de Viguier, Toulouse, FRANCE.*

Aim/Introduction: Positron emission tomography/computed tomography with 18F-Fluorodeoxyglucose (PET/CT FDG) shows testicular uptake, possibly related to spermatogenesis (1) and thus maybe correlated with the positivity rate of the surgical sperm extraction procedure (TESE), which has only a success rate of about 50%, in men with azoospermia. The aim of this study is to assess if testicular FDG uptake with PET/CT is correlated with the positivity rate of TESE. ***Materials and Methods:*** In this prospective multicenter trial, men with secretory azoospermia (SA), with excretory azoospermia (EA) and with normal spermogram (C) were included from february 2014 to may 2020. The baseline FDG PET/CT parameters that included peak, maximum and mean standardized uptake value and the functional testicular volume (FTV) were correlated with the TESE positivity and the standard clinical work up and the hormonal work up (FSH and inhibin and testosterone). A bivariate analysis was performed for the comparison between the two groups (positive or negative biopsy) and for the comparison between SA, EA and C with a significance level of 5%. ***Results:*** The study included 84 SA, 26 EA and 25 C . TESE was positive for 46 of the 88 men (52.2%) with PET/CT FDG. There was a significant correlation between the FTV and the positivity of TESE as well as with the FSH and inhibin and not with testosterone. The sum and the averaged FTV is significantly different between the three groups (SA, EA and C). FTV is significantly different from the testicular volume as determined via ultrasound or CT. We found no significant correlation or difference for the intensity or the heterogeneity of FDG testicular uptake. ***Conclusion:*** FTV obtained via PET/CT FDG is correlated with positivity of TESE in azoospermic men and is significantly different between the 3 groups (EA, SA and C). Furthermore, FTV is correlated with FSH and inhibin, which are parameters of the spermatogenesis and not with testosterone, a parameter of the steroidogenesis. ***References:*** 1. Dierickx LO, Huyghe E, Nogueira D, Zerdoud S, Filleron T, Brillouet S, et al. Functional testicular evaluation using PET/CT with 18F-fluorodeoxyglucose. EPS-032

Comparison of planar and SPECT/CT lung perfusion scintigraphy before surgery

F. Bergant[1], ***M. Grdadolnik[1],*** *J. Jamšek[2], M. Štalc[2]; [1]Faculty of Medicine, University of Ljubljana, Ljubljana, SLOVENIA, [2]Department of Nuclear Medicine, University Medical Centre Ljubljana, Ljubljana, SLOVENIA.*

Aim/Introduction: SPECT/CT systems are replacing planar gamma cameras, prompting a comparison of lung perfusion scintigraphy (LPS) methods to determine if SPECT/CT offers a more accurate assessment of relative lung perfusion (rLP) than conventional planar scans. We aimed to compare the LPS results, potential clinical impact and reproducibility of SPECT/CT against the classic planar technique. ***Materials and Methods:*** We analysed 27 patients (17 males, 10 females; average age 63.6 years) who underwent preoperative planar and SPECT/CT LPS at the Department of Nuclear Medicine, UMC Ljubljana. Using a dedicated commercial software, we compared rLP lobar values calculated from planar and SPECT/CT scans, assessed their potential clinical impact (predicted postoperative FEV1) and

compared the reproducibility of SPECT/CT rLP measurements in two scenarios: (i) automated computer segmentation (ACS) versusmanual segmentation by a nuclear medicine specialist (MSp) and (ii) manual segmentation by a trained medical student (MSt) versus MSp. Additionally, we measured the average time required to perform the analysis using both methods.Results with $p < 0.05$ were deemed statistically significant. ***Results:*** We observed statistically significant differences in rLP values between planar and SPECT/CT methods in the three right lung lobes: right upper ($p < 0.001$), right middle ($p < 0.0001$), and right lower lobe ($p = 0.02$). Predicted postoperative FEV1 could be calculated only in 7 patients due to limited clinical data availability, but showing no significant difference between planar and SPECT/CT methods ($p = 0.307$). Comparing the reproducibility of segmentation methods, rLP values from ACS versus MSp showed no statistical difference (ICC > 0.9 for all lobes; table 1). Similarly, values from analysis by nuclear medicine specialist versus medical student were not statistically different, with ICC values > 0.8. SPECT/CT scans required significantly more time to complete (264 s for SPECT/CT vs. 86 s for planar scans, $p = 0.006$). ***Conclusion:*** Planar and SPECT/CT LPS methods are highly comparable for assessing rPLP. Significant differences in rPLP assessment were observed in the right lung lobes. SPECT/CT method showed high reproducibility and comparability, suggesting its potential to replace planar analysis in clinical practice, especially if novel automated segmentation methods diminish the need for manual corrections of segmented lung lobes.

EPS-033

Diagnosis of pulmonary embolism in cancer patients: contribution of personalized QSPECT-CT

E. Nazim[1], *M. Benrabah[2], M. Yamouni[3];*
[1]Hôpital M, ORAN, ALGERIA, [2]Hôpital M, Oran, ALGERIA, [3]CHU Oran, Oran, ALGERIA.

Aim/Introduction: Pulmonary embolism (PE) is a potentially fatal condition requiring accurate diagnosis for appropriate treatment initiation and improved outcomes. The diagnostic workup for suspected PE commonly involves imaging modalities like ventilation-perfusion (V/Q) scintigraphy or computed tomography pulmonary angiography (CTPA). While CTPA is considered the reference standard, it exposes patients to substantial radiation doses, a significant concern for radiosensitive populations such as cancer patients. Hybrid imaging techniques combining functional and anatomical data have emerged as promising approaches to optimize diagnostic accuracy while minimizing radiation exposure. ***Materials and Methods:*** This prospective, unicentric study evaluated the diagnostic accuracy of perfusion single-photon emission computed tomography combined with low-dose computed tomography (QSPECT-CT) for PE. Consecutive patients with suspected PE underwent QSPECT-CT between January 2020 and May 2022 and were stratified into cancer (n=88) and non-cancer (n=96) cohorts. The QSPECT-CT algorithm involved perfusion SPECT imaging, chest radiography, and selective incorporation of low-dose CT when SPECT defects lacked corresponding radiographic abnormalities. The final diagnosis of PE was established at 3-month clinical follow-up. The primary outcome measures were the sensitivity and specificity of QSPECT-CT for identifying PE in each cohort. ***Results:*** QSPECT-CT demonstrated excellent diagnostic performance in both cohorts. In the cancer group, the sensitivity was 92% (95% CI: 84-97%), and specificity was 86% (95% CI: 77-92%). In the non-cancer group, sensitivity was 95% (95% CI: 89-98%), and specificity was 90% (95% CI: 82-95%) The area under the receiver operating characteristic curve was 0.93 (95% CI: 0.88-0.97) for the cancer group and 0.96 (95% CI: 0.92-0.99) for the non-cancer group, with no statistically significant difference (p=0.28) Comparison of diagnostic accuracy using Fisher's exact test did not reveal significant differences in sensitivity (p=0.56) or specificity (p=0.45) between cohorts. ***Conclusion:*** This study demonstrated the high diagnostic accuracy of the hybrid QSPECT-CT imaging technique for PE in both cancer and non-cancer patient populations, with no statistically significant performance differences between cohorts. A key strength was the personalized diagnostic algorithm, integrating perfusion SPECT with chest radiography and selectively adding low-dose CT only when necessary, potentially minimizing radiation exposure compared to strategies universally employing CT. Despite promising results, the study had limitations, highlighting the need for larger, multicenter trials with methodological refinements. Nevertheless, QSPECT-CT with its personalized algorithm may represent an accurate and judicious diagnostic pathway for PE evaluation, particularly valuable in radiation-sensitive populations like cancer patients. Future research should directly compare QSPECT-CT's diagnostic performance against established reference standards.

EPS-034

99Tcm-HAS SPECT/CT imaging can improve the specificity and diagnostic accuracy of PLE diagnosis

Y. Liu;
Zhengzhou University, Zhengzhou, CHINA.

Aim/Introduction: To investigate the value of 99Tcm-human serum albumin (HSA) SPECT/CT imaging in the diagnosis of protein-losing enteropathy (PLE). ***Materials and Methods:*** A retrospective analysis was conducted on 112 patients who underwent 99Tcm-HAS abdominal dynamic planar imaging and SPECT/CT imaging at the Department of Nuclear Medicine, the First Affiliated Hospital of Zhengzhou University, due to hypoalbuminemia from October 2016 to October 2023. Among them, there were 46 males and 66 females, with ages ranging from 5 to 80 years (mean age, 49 ± 18 years). The diagnostic efficacy of 99Tcm-HAS abdominal dynamic planar imaging and SPECT/CT imaging for protein-losing enteropathy was calculated based on the final clinical diagnosis. ***Results:*** Among the 112 patients, a total of 94 were clinically diagnosed with PLE. Among them, systemic lupus erythematosus accounted for the highest proportion of primary diseases, reaching 34% (32/94). Positive findings were observed in 91 cases on planar imaging, with the highest proportion of patients showing positivity on the 8-hour imaging being 25% (23/91). There were 96 cases with positive findings on SPECT/CT imaging, with the highest proportion of colon positivity being 41% (39/96). According to the final clinical diagnosis, out of the 112 patients, 94 were diagnosed with PLE and 18 were non-PLE cases. The sensitivity, specificity, and accuracy of diagnosing PLE using planar dynamic imaging were 90.40% (85/94), 66.70% (12/18), and 86.70% (97/112), respectively; while for SPECT/CT imaging, the corresponding values were 100% (94/94), 88.90% (16/18), and 98.20% (110/112). The difference in specificity between the two diagnostic methods was statistically significant (Fisher exact probability test, P=0.005), and the difference in accuracy indicators between the two methods was also statistically significant (X2=9.166, P=0.002). ***Conclusion:*** 99Tcm-HAS SPECT/CT tomographic imaging can improve the specificity and diagnostic accuracy of PLE diagnosis. ***References:***

2023 Aug 24;389(8):733-748. [2]Castellón Méndez AJ, Bodán Campbell A, Rosales Obregón V, Zahran M. Waldmann's disease: Primary intestinal lymphangiectasia diagnosed by 99mTc-labeled albumin macroaggregate scintigraphy-A case report in an adult patient. Clin Case Rep. 2024 Apr 17;12(4):e8772.

EPS-035

Could ^{18}F-Dopa PET/CT replace ^{123}I-MIBG scintigraphy in childhood Neuroblastoma management?

J. Montalvá Pastor, *A. Mari Hualde, J. Orcajo Rincon, J. Ardila Mantilla, M. Casallas Cepeda, S. Salcedo Cortes, E. Ardila Manjarrez, I. Gómez Fernández, L. Reguera Berenguer, R. Pérez Pascual, D. Zamudio Rodriguez, V. Castillo Morales, A. Guzmán Cruz, J. Alonso Farto;*
Hospital General Universitario Gregorio Marañón, Madrid, SPAIN.

Aim/Introduction: Neuroblastoma (NB) is the most frequent extracranial solid tumour in childhood, representing 8-10% of cases of childhood cancer. Approximately 50% of cases are metastatic at presentation with a poor prognosis in high-risk NB. Exquisite staging is crucial, so imaging features before surgery, determine patient management. At the moment, 123I-MIBG scan, is considered the Gold Standard radionuclide imaging in NB, with limited sensitivity mainly for detecting osteomedullary metastases. The aim of the study is to compare the value of 18F-Dopa PET/CT and 123I-MIBG scan in initial diagnosis and relapse of patients with NB. ***Materials and Methods:*** 10 patients were included (5M:5F), with an average of 24 months old (0-9 years) at the time of diagnosis, including 3 congenital disease. 7/10 patients were intermediate or high risk. 11 paired 18F-Dopa PET/CT and 123I-MIBG scintigraphy, were retrospectively evaluated, taken less than one month apart. 8 of 11 scans were performed at the time of diagnosis and 3 when relapse was suspected. A patient-base and a lesion-based analysis was done for 18F-Dopa PET/CT, 123I-MIBG scintigraphy and 123I-MIBG SPECT/TC. Follow up was based on clinical, imaging and histological data. ***Results:*** All NB were localized in the abdomen (6 adrenal and 4 retroperitoneal). 60% were metastasic at initial diagnosis: 3bone, 1 bone and liver, 1 liver and lung and 1 pleura. Main lesion was detected in 9 (81,8%) and 8 (72,7%) for 18F-Dopa and 123I-MIBG scans respectively. Not detected lesion by conventional imaging corresponded to low grade NB. On patient-based analysis 18F-Dopa PET/CT showed a 100% sensitivity while 123I-MIBG scintigraphy adding SPECT/TC reached 88,8%. No significant difference in terms of specificity was found. No real change in patient management was done according to PET/TC image.84 lesions (68 bone and 16 soft tissue) were found by 18F-DopaPET/CT of which 27 were correctly detected by 123I-MIBG scintigraphy, increasing to 35 by 123I-MIBG SPECT/TC. On lesion-based analysis 123I-MIBGscintigraphy showed a poor sensitivity of 32% improving to 41,7% when using SPECT/TC compared to 18F-Dopa PET/CT. ***Conclusion:*** In our NB population 18F-Dopa PET/CT is able to diagnose more lesions than 123I-MIBG, mainly in bone structures. Despite the small sample size and taking into account that, as far as we know, there are only two studies including more than 10 patients with paired scans yielding similar results, we suggest that 18F-Dopa PET/CT can be used instead of 123I-MIBG and its inclusion in guidelines should be analyzed, firstly in High-Risk NB.:

EPS-036

Improving Accuracy of SUV Estimates in Paediatric Oncology: Recommending against the use of the Body Weight-Based Correction in [18F]FDG PET

I. S. A. de Vries[1], *S. N. Lodema[2], A. J. A. T. Braat[1,2], J. H. M. Merks[1], R. van Rooij[2], B. de Keizer[1,2];*
[1]Princess Maxima Center, Utrecht, NETHERLANDS,
[2]Radiology and Nuclear Medicine Department, University Medical Center Utrecht, Utrecht, NETHERLANDS.

Aim/Introduction: Fluorine-18-fluorodeoxyglucose positron emission tomography computed tomography ([18F]FDG PET/CT) is an important imaging technique for diagnosing and staging paediatric oncology patients. Standardized Uptake Value (SUV) measurements are used to quantify [18F]FDG-uptake, which is typically normalized to body weight. However, as fat contributes to the body weight but accumulates only minimal [18F]FDG, heavier patients show higher SUV. Few studies have investigated body weight dependency of SUV formulations in paediatric patients. Our aim is to compare different SUV formulations measured in the liver in a large cohort of paediatric oncology patients and determine which correction has the least body weight dependency. ***Materials and Methods:*** A retrospective analysis was conducted of [18F]FDG PET/CT scans performed at the Princess Maxima Center of Pediatric Oncology between December 2018 and August 2022. Measurements were performed in the liver on EARL1 PET reconstructions. The mean SUV was calculated using formulations corrected for body weight (SUVBW), for lean body mass (LBM) according to James (SUVLBMJames) and Janmahasatian (SUVLBMJanma), and for body surface area (BSA) according to DuBois (SUVBSADuBois) and Haycock (SUVBSAHaycock). The correlation between the SUV formulations and body weight was assessed using Pearson's correlation coefficients and linear regression coefficients. The linear regression coefficients were used to assess the relative increase of SUV per kg. ***Results:*** In total, 462 scans were analysed, including 185 of girls (40%). The mean age was 11.5±6.7 years (range, 2 months - 23 years). The mean height was 150±29.6 cm (range, 54 - 201 cm) and mean body weight was 46.6±22.4 kg (range, 3.8 - 125 kg). The mean SUVBW was 1.49±0.43, the mean SUVLBMJames 1.22±0.29, the mean SUVLBMJanma 1.17±0.29, the mean SUVBSADuBois 0.046±0.008, and the mean SUVBSAHaycock was 0.046±0.008. The relative SUV increase per kg for SUVBW was 2.60%, for SUVLBMJames 1.17%, for SUVLBMJanma 1.18%, for SUVBSADuBois 0.28%, and for SUVBSAHaycock 0.35%. The correlation between body weight and SUVBW was r=0.81, p<0.001, for SUVLBMJames r=0.71, p<0.001, for SUVLBMJanma r=0.69, p<0.001, for SUVBSADuBois r=0.30, p<0.001, and for SUVBSAHaycock r=0.30, p<0.001. ***Conclusion:*** For paediatric patients, we recommend to avoid the use of SUVBW, as it shows the least consistency when measured in the liver and results in elevated SUV measurements in heavier patients. Formulations corrected for LBM also tend to increase SUV, although to a lesser extent. Corrections based on BSA are shown to have the lowest dependency on body weight.

EPS-037

Incremental value of varied time point imaging and SPECT/CT in diagnosis of Duplication Cysts.

R. Kumar, *A. Khurana, V. Jain, S. Sagar, D. Khan, R. Wakankar, Y. Dharmashaktu;*
All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: The aim of our study was to see the incremental valueof 99mTc-Pertechnetate multi time point imaging and

SPECT/CT in patients who were referred to department of nuclear medicine for evaluating and diagnosing ectopic gastric mucosa in foregut and midgut duplication cysts. ***Materials and Methods:*** This hospital based, retrospective cum prospective research spans over a period of 10 years from April 2014 to January 2024. Previous hospital medical records were analysed and subsequently a database was prepared which included the age, sex, clinical indication of a 99mTc-Pertechnetate scan, the planar& SPECT-CT imaging findings and post operative histopathology whenever available. Dynamic and planar static imaging was performed. We included delayed imaging and SPECT-CT in suspected duplication cysts to increase the sensitivity and negative predictive value. A total of 103 patients were subjected to a 99mTc-Pertechnetate scan for suspected foregut or midgut duplication cysts. All were subjected to dynamic planar and delayed static images up to 24 hours or until focal uptake of radiotracer was noted which corroborated to the anatomical findings, whichever was earlier. SPECT-CT was performed along with the planar study in 55 patients which confirmed the findings. Previously performed CT scans were used for anatomical correlation in the remaining ones. ***Results:*** Duplication cysts were localized in a total of 40 patients (foregut duplication cysts and small bowel duplications-4 patients had dual duplication cysts, both foregut and midgut). 63 patients had no scintigraphic evidence of ectopic gastric mucosa. Of these 103 patients, histopathological diagnosis was available for 35 patients. The report was concordant with the scan findings in 27 patients and 8 patients showed discordance in histopathological diagnosis and scan findings. The sensitivity with conventional Meckel's scan for duplication cyst was 50% and negative predictive value was 65.2%. This increased to 87.5% and 86.6% respectively with additional delayed static images and SPECT/CT. ***Conclusion:*** In conclusion, multi time point imaging with SPECT/CT is the key to diagnosing ectopic gastric mucosa of various sizes and in various locations. There was a significant improvement in the diagnostic performance of the study when we included various time points and SPECT/CT and thus we recommend its use on a routine basis.

EPS-038

Peritoneal scintigraphy to detect dialysate leakage: a 15 year experience

B. Pereira, *A. Fernandes;*
Centro Hospitalar Universitário de São João, Porto, PORTUGAL.

Aim/Introduction: Patients with renal failure typically need dialysis to replace the lost kidney function. Continuous Ambulatory Peritoneal Dialysis (CAPD) offers advantages such as the ability to be performed at home and a more flexible lifestyle compared to in-center hemodialysis. However, it has some disadvantages, including risk of infection, fluid imbalance, hernia development, toxin clearance limitations, and potential membrane function decline. Dialysate leakage in CAPD can occur due to various reasons and prompt evaluation of the leakage site and intervention are essential to prevent complications. While the main diagnostic imaging studies include ultrasound, computed tomography, or magnetic resonance, peritoneal scintigraphy can give valuable information regarding the leakage site. We aim to analyse the main clinical indications and the diagnostic value of peritoneal scintigraphy. ***Materials and Methods:*** We selected all the patients who underwent peritoneal scintigraphy at our nuclear medicine department from 2008 to 2023 (n=127). Electronic records were analysed including imaging and clinical data. Indirect follow-up criteria were used to confirm or exclude leakage: surgical intervention related to the identified leak/CAPD suspension - "confirmation"; maintenance of CAPD without further surgical interventions - "non-confirmation". Our protocol for peritoneal scintigraphy includes the infusion of 185 MBq of [99mTc] Tc-MAA in 1L of dialysate solution through the peritoneal catheter. Images are acquired approximately 5 hours after administration and again after drainage of the dialysate. The protocol includes anterior and lateral views of the peritoneal cavity, with the patient in a supine position and standing-up. SPECT/CT is performed in most patients. ***Results:*** The clinical reasons for performing the scintigraphy were the identification of abdominal wall swelling (54,3%), of poor drainage/ultrafiltration (26,1%), of pleural fluid (10,9%), or of inguinal/genital swelling (8,7%).We detected leaks in 91 patients (71,1%), 10 with multiple sites, resulting in 106 leaks (umbilical region - 52.8%; hypogastric region - 12.3%; iliac region - 15.1%, lumbar region - 4.7%; pleural cavity - 5.7%, genital region - 7.5%; other - 1.9%). Leakage was confirmed in 66 patients; 19 patients maintained CAPD without any further intervention; 11 patients lost follow-up. Of the 36 negative studies, 28 maintained CAPD without any further intervention; 3 had otherwise diagnosed leakage; 3 discontinued CAPD; and there were no records on the follow-up of 2 patients. ***Conclusion:*** Peritoneal scintigraphy is a straightforward, safe and non-invasive method that determines the site of dialysate leak with great sensitivity and specificity, highlighting its value in guiding clinical management decisions, such as surgical interventions.

EPS-039

Individualized calibration of estimated glomerular filtration rate for serial renal function monitoring

B. W. Mekonnen[2,1], ***J. Warwick[1],*** *B. D. Berndorfler[1], C. J. Lombard[1], J. L. Holness[1];*
[1]Stellenbosch University, Cape Town, SOUTH AFRICA, [2]Addis Ababa University, Tikur Anbessa Specialized hospital, Addis Ababa, ETHIOPIA.

Aim/Introduction: Serum creatinine based estimates of glomerular filtration rate (eGFR) are known to be imprecise compared to GFR measurement (mGFR). In addition eGFR is frequently inaccurate in many patient populations. While inaccuracy can be reduced by applying a population specific calibration (pceGFR), the problem of imprecision remains. We aim to investigate the performance of individually calibrated estimated GFR (iceGFR) for estimation of GFR by comparison with measured GFR (mGFR). ***Materials and Methods:*** Retrospective data from January 2009 and December 2022 were included. All patients underwent radionuclide based mGFR on two separate occasions during this period, with each mGFR also having serum creatinine measurement available within 3 months. A patient specific calibration factor (Kpt) was derived from the ratio of the initial mGFR and eGFR values. At the time of the second mGFR measurement, iceGFR was calculated from the product of Kpt and the second eGFR value, and pceGFR was determined using a previously described methodology.1 Bland-Altman analyses were used to compare the performance of eGFR, pceGFR and iceGFR relative to mGFR. Lin's concordance correlation coefficient (CCC) was estimated for mGFR and each of eGFR, pceGFR and iceGFR as a summary measure of agreement. The test for the comparison of paired correlations was used to compare the three CCC's pairwise. ***Results:*** Fifty-three patients (24 women and 29 men; median age, 60.5 y; age range, 25-75 y) were included. Using Bland-Altman analyses, the bias for eGFR, pceGFR and iceGFR was -16, -5 and -3 ml/min/1.73m2 respectively. The limits of agreement for eGFR,

pceGFR and iceGFR were -51 to 20, -41 to 31 and -27 to 21 ml/min/1.73m2 respectively. The CCC (95% CI) of the of the three estimated GFR measures was 0.56 (0.41 - 0.72), 0.64 (0.49 - 0.80) and 0.84 (0.75 - 0.92) for eGFR, pceGFR and iceGFR respectively. The iceGFR CCC was significantly different from the other two GFR CCC estimates (p<.0001) which did not differ from each other (p=0.12). ***Conclusion:*** Compared to eGFR, pceGFR had an improved accuracy but similar imprecision and concordance. iceGFR outperformed eGFR and pceGFR with improvements in bias, precision and concordance. iceGFR shows promise for serial renal function monitoring in environments with limited access to GFR measurement. ***References:*** 1.Holness, J.L., Brink, A., Davids, M.R. et al. ^{123}I-MIBG SPECT-CT Quantification outperforming Curie score in the evaluation of neuroblastoma metastasis and response assessment

***B. Cui*[1],** *B. Ding*[1], *Z. Zhao*[2], *H. Zhang*[1], *G. Shao*[3];
[1]*Department of Nuclear Medicine, Jiangning Hospital, Nanjing Medical University, Nanjing, CHINA,* [2]*Department of Nuclear Medicine, Nanjing First Hospital, Nanjing Medical University, Nanjing, CHINA,* [3]*Department of Nuclear Medicine, Nanjing First Hospital, Nanjing Medical University, Nanjing, CHINA.*

Aim/Introduction: Neuroblastoma is the most common extracranial solid tumor in children with poor prognosis. Iodine 123 labeled meta-iodobenzylguanidine ([123I]MIBG) scan with SPECT/CT imaging is the standard nuclear imaging technique with Curie score as main index which mainly based on the number or size of MIBG-avid lesions. The aim of this study was to assess the diagnostic threshold, response evaluation value of quantitative 123I-MIBG SPECT/CT imaging and compared with Curie score in a prospective series of Neuroblastoma patients. ***Materials and Methods:*** 23 participants (mean age 4.0 ± 3.5 years, 6 cases of low and high risk group, 11 cases with 96 metastatic lesions after treatment, 6 cases repeated [123I]MIBG imaging after treatment) with history of neuroblastoma were enrolled in this study. All children underwent [123I]MIBG planar imaging and Quantitative SPECT/CT imaging using GE Discovery 670 pro. Normal organ uptake (SUVmean), lesion uptake (SUVmax) and tumour-to-muscle ratio (T/M) were measured. Whole body tumor activity or tumor burden (%ID) based on ROI were compared with Curie scores to evaluate therapeutic effect. Lesion-by-lesion analysis was performed to compare detection ratios (DR) between [123I]MIBG planar imaging and SPECT/CT quantitative imaging. MRI, bone marrow puncture or/and 68Ga-DOTA-TATE PET-CT, 6 months follow up were used as gold standard. ***Results:*** [123I]MIBG distribution (SUVmax: g/ml) in normal organs such as bone, bone marrow, muscle, liver, left ventricle wall, blood pool in the mediastinum and adrenals was (0.35±0.21), (0.49±0.32), (0.25±0.178), (5.2±3.9), (4.1±2.6), (0.42±0.26), (1.45±1.2). [123I]MIBG uptake (SUVmax) by metastatic lesions in bone, bone marrow, liver and lymph node ranging from 1.5 to 37. Tumor uptake of [123I]MIBG (SUVmax: 0.6±0.3) in low risk group was significantly less than that in high risk group (SUVmax: 6.3±3.2). The mean DR with [123I]MIBG planar imaging based on visual analysis, semiquantitative analysis (T/M) was significantly lower than SPECT/CT quantitative imaging when tumor uptake threshold(SUVmax: g/ml) was set at 1.0. (60.0% ±16.7% vs. 95.2%±1.5%; p = 0.027). Lesion-by-lesion analysis revealed tumor uptake decrease of [123I]MIBG (60.1% ±35.6) in 23 lesions and increase (1.5 to 4 fold) in 7 lesions after treatment. Whole body tumor uptake (%ID) of [123I]MIBG in all metastatic lesions decreased significantly after treatment while there is no significant Curies scores changes in 4 patients. ***Conclusion:*** 123I-MIBG SPECT-CT Quantification can offer one objective threshold for neuroblastoma metastasis detection, whole body tumor burden assessment and maybe useful to reveal tumor heterogeneity during treatment.

EPS-041

Using whole body low dose PET/CT to assess the lean body mass in a cachexia patient cohort

***I. Burvenich*[1,2],** *G. O'Keefe*[3,4], *S. Gong*[2,3], *S. Lee*[1,3,4], *C. Senko*[1,2,3], *S. Pillai*[3], *R. Fogliaro*[3], *T. Chen*[3], *K. Pathmaraj*[1], *Z. Cao*[1,2], *L. Osellame*[1,2], *N. Hoogenraad*[1,2], *A. Scott*[1,3,4];
[1]*Olivia Newton-John Cancer Research Institute, Heidelberg, AUSTRALIA,* [2]*School of Cancer Medicine, La Trobe University, Bundoora, AUSTRALIA,* [3]*Department of Molecular Imaging and Therapy, Austin Health, Heidelberg, AUSTRALIA,* [4]*Department of Medicine, University of Melbourne, Melbourne, AUSTRALIA.*

Aim/Introduction: The monitoring of lean body mass is an important indicator in the determination of possible cachexia in patients. Diagnostic CT measurements have utilized the L3 skeletal muscle content from regional abdomen/pelvis as an indicator of lean body mass. With the availability of whole-body CT from 18F-FDG PET/CT scans, there exists the possibility to determine a whole-body assessment of lean body mass. This study assesses the accuracy of whole-body low dose CT determination of lean body mass compared to L3 skeletal muscle determination against the DEXA gold standard. ***Materials and Methods:*** A cohort of 28 patients being investigated for cachexia were acquired. Scans from DEXA, diagnostic CT and low dose CT (from 18F-FDG PET/CT) were compiled. L3 vertebral muscle content was assessed using a muscle window [-20, 150] established from previous studies. The low dose CT scans were assessed for fat content using a fat window of [-250, -50] from which the Fat:Whole-body ratio is calculated. The lean body mass ratio is then calculated as Lean Body Mass:Whole body ratio = 1 - Fat:Whole body ratio. ***Results:*** A regression of the PET/CT low dose determined lean mass ratio versus the DEXA determined lean mass ratio yields a correlation coefficient of 0.94. The corresponding vertebral lean mass determination yields a poorer correlation coefficient of 0.73. ***Conclusion:*** Whole-body low dose CT acquired as part of the whole-body 18F-FDG PET/CT procedure allows for an estimate of the lean body mass. This important information can assist with diagnosis of cachexia in patients with cancer.

EPS-042

Correlation of standard uptake values (SUV) and net influx rate (Ki) in healthy organs from whole-body FDG PET/MRI scan

S. Kvernby, *A. Brandt, H. Ahlström, J. Kullberg, J. Eriksson, M. Lubberink;*
Uppsala University, Uppsala, SWEDEN.

Aim/Introduction: Dynamic positron emission tomography (PET) can be performed for accurate quantification of the net influx rate, Ki, but it involves long imaging times and mathematical modelling of the PET data. The semi-quantitative metric, standard uptake value (SUV) is simple, widely used and requires only a short static PET acquisition. For a more accurate SUV metric, especially for obese patients, the SUL can be used, which is similar to SUV but normalized to lean body mass instead of the total body weight. The SUV/SUL has demonstrated a good correlation to the Ki value in different tumors, which enables the use of this simplified metric

instead of the more practically demanding metric Ki for many applications. The aim of this study was to investigate the correlation of Ki and SUV/SUL in healthy organs from whole-body FDG scans in an integrated PET/MRI scanner. ***Materials and Methods:*** Twenty-three non-diabetic obese subjects were included in the study. They underwent a ten-minute dynamic PET scan covering the heart starting with injection of 3 MBq/kg FDG, followed by five repeated whole-body PET/MRI scans (5x10 bed positions, 30 s/bed position). A whole body pixelwise Patlak analysis was performed for calculation of Ki. For calculation of SUV/SUL, data from the fifth whole body PET acquisition (approx. 60 min p.i.) was used. Lean body mass was calculated from whole-body fat/water MRI images and was used for calculation of SUL. Mean values were obtained from spherical representative regions of interest in brain, heart, skeletal muscle and liver. Correlation between SUV/SUL and Ki in the healthy organs was investigated. ***Results:*** There was a good to moderate correlation between SUV/SUL and Ki in the healthy organs. The best correlation was found in the skeletal muscle (SUV: r2=0.81; SUL: r2=0.79) followed by the brain (SUV: r2=0.68; SUL: r2=0.65), and the heart (SUV: r2=0.65; SUL: r2=0.56). The correlation in the liver was lower (SUV: r2=0.35; SUL: r2=0.33), probably due to the small range of Ki values in the liver. The SUV was significantly higher ($p<0.001$) than the SUL-value in all organs. ***Conclusion:*** The standard uptake value (SUV) demonstrated a good correlation with the net influx rate Ki in skeletal muscle and a moderate correlation in the brain and the heart, indicating that SUV can be interpreted as a measure of glucose metabolism also in these healthy organs. In this study population, the SUV and the SUL values demonstrated similar correlation with Ki.

[^{225}Ac]Ac-DOTA-mCAIX to eliminate CAIX-expressing hypoxic cancer cells
S. Wenker[1], *J. Bussink[1], D. Lobeek[1], S. Kleinendorst[1], D. Boreel[1], G. Tamborino[2], M. Konijnenberg[1,2], J. Molkenboer-Kuenen[1], G. Franssen[1], H. Peters[1], S. van Lith[1], S. Heskamp[1];*
[1]RadboudUMC, Nijmegen, NETHERLANDS,
[2]Erasmus MC, Rotterdam, NETHERLANDS.

Aim/Introduction: Tumor hypoxia, low level of oxygen, is associated with a poor prognosis. Hypoxic tumor cells a.o. suppress the immune system and induce resistance to immunotherapy. A promising treatment strategy to kill hypoxic cancer cells is the use of alpha-emitting radionuclides, since they cause irreversible DNA damage and cell death independent of tissue oxygenation. Under chronic hypoxia, tumor cells can upregulate membrane expression of carbonic anhydrase IX (CAIX). We aim to eliminate these CAIX-expressing hypoxic cancer cells using an actinium-225 labeled anti-CAIX monocloncal antibody (mAb), thereby increasing the potential of immune checkpoint inhibition to induce long-term anti-tumor efficacy. ***Materials and Methods:*** A mAb binding to murine and human CAIX (clone MSC3) was functionalized with SCN-DOTA and radiolabeled with indium-111 (111In-mCAIX) or actinium-225 (225Ac-mCAIX). C57Bl/6J mice with subcutaneous B16F10-OVA tumors (containing hypoxic CAIX-positive tumor

regions (1)), were co-injected with 13 kBq 225Ac-mCAIX and 1 MBq 111In-mCAIX. Tracer distribution was determined at 168h post injection with ex vivo gamma counting of indium-111 and intratumoral co-localization with CAIX was determined with autoradiograpy and immunohistochemistry. In the therapy study, mice with B16F10-OVA tumors were injected with 15 kBq 225Ac-mCAIX (radiation dose determined on longtidunal SPECT imaging) with or without anti-CTLA-4 and anti-PD1 (200 ug each at 1, 4, 6, 10, 13 and 16 days post tracer injection). Tumor growth, body weight and survival were followed over time until a tumor volume >2000 mm3 or a humane end point were reached. Statistics were performed on the median survival using the Mantel-Cox test. ***Results:*** 111In-mCAIX and 225Ac-mCAIX were labeled with >95% radiochemical purity. In vivo biodistribution showed high tumor uptake (18.0 ± 1.3 %ID/g), leading to excellent tumor-to-muscle ratios (69.3 ± 27.3) and tumor-to-blood ratios (17.7 ± 15.5). Analysis of tumor sections demonstrated that the 225Ac and 111In-derived radiosignal colocalized with CAIX expression, suggesting CAIX-specific tumor uptake. Furthermore, in the CAIX positive areas of these tumors, γH2AX staining suggests therapeutic effect of 225Ac-mCAIX. In the therapy experiment, the 225Ac-mCAIX group showed a signficantantly improved survival compared with the PBS control ($p = 0.0032$). Furthermore, survival of the 225Ac-mCAIX plus anti-CTLA-4/PD-1 group was significantly better than the PBS control ($p= 0.0019$) and anti-CTLA-4/PD-1 ($p = 0.0031$). Body weight was comparable between the groups. ***Conclusion:*** These results show the potential of 225Ac-mCAIX, especially in combination with anti-CTLA-4/PD-1, to treat hypoxic tumors. In ongoing experiments, the radiobiological and immunological effects of 225Ac-mCAIX are investigated. ***References:*** (1)Boreel 2023 Mol Pharm,20.

OP-142

^{225}Ac-FL-020 is a novel PSMA-targeting radionuclide drug conjugate with promising in vivo anti-tumor activity

J. Zhang[1], *J. Yang[1], F. Liu[1], N. C. L. Wong[1], K. T. Thrane[2], M. W. Hallund[2], R. V. Grønlund[2];*
[1]Full-Life Technologies, Shanghai, CHINA, [2]Minerva Imaging ApS, Ølstykke, DENMARK.

Aim/Introduction: Despite significant developments over the last few decades, metastatic castration-resistant prostate cancer (mCRPC) remains incurable. Prostate specific membrane antigen (PSMA) expression directly correlates with androgen independence, metastasis, and disease progression. PSMA is well-established as a radioligand target for the diagnosis and treatment of mCRPC. Lutetium-177 (177Lu) vipivotide tetraxetan was approved in 2022 for the treatment of progressive PSMA-positive mCRPC. However, only 30% of patients achieved a radiological response in the registrational trial together with a grade 1/2 xerostomia in around 39% of patients. The alpha emitter Actinium-225 (225Ac) is expected to offer significant advantages over beta-emitting 177Lu due to its higher tumor cell killing potency through double-strand DNA breaks and shorter tissue penetration depth. This profile supports the development of 225Ac based radiotherapies. We leveraged our proprietary platform to develop 225Ac-FL-020, a next-generation 225Ac-based PSMA radionuclide drug conjugate (RDC). ***Materials and Methods:*** Binding affinity against PSMA and internalization of the 177Lu-labeled FL-020 was evaluated in PSMA-expressing LNCaP cells. The biodistribution profile of FL-020 was characterized by SPECT/CT imaging and ex vivo biodistribution assays using Indium-111 (111In)-FL-020 and 177Lu-FL-020 in LNCaP tumor-bearing nude mice, respectively. Anti-tumor activity of 225Ac-FL-020 was evaluated in the LNCaP xenograft model and directly compared with 225Ac-PSMA-617. ***Results:*** 177Lu-FL-020 bound to LNCaP cells with a KD value of 29.1 nM. Uptake and internalization of 177Lu-FL-020 by LNCaP cells was time- and PSMA expression-dependent. Off-target screening showed that <50% inhibition of binding or activity was observed by FL-020 at 10 μM against 85 targets including receptors, ion channels, enzymes, and transporters, indicating the high selectivity of FL-020. Meanwhile, 111In-FL-020 and 177Lu-FL-020 displayed promising in vivo distribution profiles with high and sustained tumor uptake and fast systemic clearance. Furthermore, 225Ac-FL-020 exhibited enhanced anti-tumor activity compared with 225Ac-PSMA-617 at the same dose level (10 KBq/mouse) in the LNCaP xenograft model with a favorable safety profile as indicated by body weight and hematological parameters. A mechanistic study was also conducted in 225Ac-FL-020-treated LNCaP tumor samples where DNA double-strand breaks and tumor cell apoptosis were observed, confirming the mechanism of action of alpha emitters. ***Conclusion:*** These results collectively demonstrate that 225Ac-FL-020 is a potent and selective PSMA-targeting RDC with superior anti-tumor activity and a favorable safety profile. A Phase 1 study will be started in 2024 to evaluate the safety, tolerability, and anti-tumor activity of 225Ac-FL-020 in patients with mCRPC.

OP-143

Targeted Alpha Therapy of Prostate Cancer with Actinium-225-labeled Novel Dansylated Amino Acid Derived PSMA-Targeted Radioconjugate ^{225}Ac-LNC1011

T. Zhao, *X. Wee, Q. Hu, X. Wen, V. Jakobsson, X. Chen, J. Zhang; National University of Singapore, Singapore, SINGAPORE.*

Aim/Introduction: Prostate-specific membrane antigen (PSMA) radioligand therapy (PRLT) has become a promising option for treating metastatic castration-resistant prostate cancer (mCRPC). Recently, albumin binders, such as p-iodophenyl, Evans blue, and ibuprofen-modified PSMA radioligands with prolonged blood circulation, have been developed to improve tumour uptake and therapeutic effectiveness. Herein, we report a new PSMA-targeted ligand incorporating dansylated phenylalanine as an optimised albumin binder (denoted as LNC1011) to balance blood circulation while preserving tumour retention. We evaluated the tumour uptake, pharmacokinetics, biodistribution and preliminary efficacy of 225Ac-LNC1011 in the PSMA-positive PC3 PIP model. Alpha emitter 225Ac was chosen for its higher linear energy and stronger tumour penetration over beta emitter 177Lu. ***Materials and Methods:*** Radiolabelling of 225Ac was conducted by mixing 0.5 ml of precursor (5 mg/ml) with 0.3 ml 0.25M NaOAc, added to 0.05 M metal-free HCl with solid 225Ac(NO3)3 salt (45 mins, 100oC), performed on the IPhase automated synthesis module. PSMA-targeting specificity was investigated using saturation binding assay and cellular uptake in PC-3 and PSMA-positive PC-3 PIP cell lines. Radioligands' distribution and tumour uptake were evaluated using single-photon emission computed tomography (SPECT/CT) imaging with 37 MBq of 177Lu-LNC1011. The ex vivo biodistribution study was performed in healthy mice intravenously injected with 18.5 kBq 225Ac-LNC1011. Therapeutic studies were conducted in the PC-3 PIP xenograft mice model with 3.7, 9.25, and 18.5 kBq of the tracer (n = 6/group). ***Results:*** 225Ac-LNC1011 was successfully synthesised, radiolabelled with > 97% radiochemical purity, and analysed at 24 h post-production. Cell uptake and binding assay showed increased uptake of 225Ac-LNC1011 (0.37 kBq/well) up to 8 h in PC-3 PIP cells, effectively blocked by unlabelled PSMA-617. SPECT/CT biodistribution imaging of 177Lu-

LNC1011 showed a rapid tumour uptake at 0.5 h post-injection and peaked (125.8 ± 12.3 %ID/g) at four h post-injection, which persisted high up to 72 h with excellent tumour-to-background contrast. Biodistribution in healthy BALB/c mice showed the highest kidney uptake (16.5 ± 2.0 %ID/g at one h p.i.) but quickly washed out after four h. Our therapy results demonstrated a noteworthy inhibition of tumour growth after a single dose of 9.25 kBq 225Ac-LNC1011, and 6/6 achieved complete remission (CR) in the 18.5 kBq group. ***Conclusion:*** LNC1011, characterised by a favourable improvement in tumour uptake and rapid clearance from background organs, is a promising candidate for PRLT and should be clinically evaluated. Targeted alpha therapy holds great promise to enhance its therapeutic effect.

OP-144

PARP-targeted alpha therapy for treatment of PARPi-resistant ovarian cancer with dosimetric modelling

***C. Ihewulezi*[1],** *H. Lee*[1], *V. Onecha*[2], *D. Suarez-Garcia*[3], *J. Bosque*[2], *F. Simpkins*[1], *A. Bertolet*[2], *S. Gitto*[1], *D. Pryma*[1];
[1]*University of Pennsylvania, Philadelphia, PA, UNITED STATES OF AMERICA,* [2]*Harvard Medical School, Boston, MA, UNITED STATES OF AMERICA,* [3]*Universidad de Sevilla, Sevilla, SPAIN.*

Aim/Introduction: Despite chemotherapy and PARP inhibitor (PARPi) regimens, most BRCA1/2 mutant (BRCA1/2mut) epithelial ovarian cancers (EOC) recur, prompting the need for novel therapies. PARPi bind to active PARP-1 overexpressed in BRCA1/2mut cells. Astatine-211-Parathanatrace ([211At]PTT), an alpha-emitting radiopharmaceutical therapy analogue of rucaparib, binds to DNA-bound PARP-1 to induce lethal double-stranded DNA breaks. We investigated [211At]PTT as a novel therapy for EOC. ***Materials and Methods:*** [211At]PTT was synthesized and assessed for pharmacokinetics and cytotoxicity in 16 human EOC cell lines with varying sensitivity to PARPi. For saturation binding, cells were treated for 1 hour to reach equilibrium. For cytotoxicity, cells were treated with [211At]PTT or unlabeled 211At for 1 or 72 hours followed by bioluminescent assay. Maximum specific binding (Bmax), equilibrium dissociation constant (Kd), and half maximal effective concentration (EC50) were calculated. Monte Carlo micro-dosimetry was performed with TOol for PArticle Simulation (TOPAS) to model dynamic evolution of radioisotopes in the nucleus, the decay, and binding interactions of radioligands and cell-specific receptors as a function of time. ***Results:*** Compared to 211At, [211At]PTT had a 30-fold greater efficacy. Comparing EOC OVCAR8 cells with endogenous PARP1 expression and OVCAR8-PARP1ko cells, [211At]PTT activity was dependent on PARP-1 expression (EC50 0.0079 vs. 0.027 MBq/ml). EC50 was determined in isogenic-matched BRCA2mut PARPi-sensitive and -resistant PEO1 and BRCA2 reversion PEO4 (0.002-0.008), BRCA1mut and BRCA1 restored UWB (0.0021-0.0024), and BRCA2mut and PARPi-resistant JHOS4 cells (0.11- 0.63). Cytotoxicity was similar between PARPi-sensitive and -resistant cells (P=0.86). BRCA1/2WT and CCNE amplified cells had variable sensitivity (0.01-0.8) within concentrations that are safely administered in vivo. The number of [211At]PTT binding sites per cell (Bmax) ranged from 6.31x105 to 2.14x106 and the binding affinity 2.0-11.4 (Kd). EC50 values significantly correlated to binding affinity (r=0.69, P=0.009), whereas no correlation was observed with Bmax. ***Conclusion:*** [211At]PTT cytotoxicity is largely independent of PARPi-sensitivity and more dependent on PARPi binding affinity and line-specific radiation sensitivity, supported by simulated dosimetry results. This suggests PTT may overcome PARPi-resistance. Overall, this study highlights a novel role for radiopharmaceutical therapy in PARPi-resistant BRCA1/2mut EOC. Future work will investigate the mechanistic underpinnings governing sensitivity to predict suitable candidates for therapy.

OP-145

Biodistribution and contribution of in vivo generated daughter radionuclides to the antitumour efficacy of ^{225}Ac-PSMA-Trillium

***S. Zitzmann-Kolbe*[1],** *M. Große*[1], *F. Suurs*[2], *A. Papple*[2], *I. Moen*[2], *H. Nguyen*[1], *U. B. Hagemann*[1], *C. Schatz*[1];
[1]*Bayer AG, Berlin, GERMANY,* [2]*Bayer AS, Oslo, NORWAY.*

Aim/Introduction: Prostate-specific membrane antigen (PSMA) is upregulated in prostate cancer. 225Ac-PSMA-Trillium is a targeted alpha therapy (TAT), which consists of a high-affinity PSMA binder linked to a macropa chelator for stable complexation of the alpha-emitting radionuclide actinium-225. To reduce dose-limiting side effects, 225Ac-PSMA-Trillium has a customised albumin-binding moiety, which prolongs plasma residence, improves tumour uptake, and reduces salivary gland uptake. However, the clearance of the in vivo generated daughter radionuclides of actinium-225 is unknown. Here, we investigated the antitumour efficacy and biodistribution of 225Ac-PSMA-Trillium, and the redistribution of the daughters of actinium-225, bismuth-213 (t1/2 = 45.6 min) and francium-221 (t1/2 = 4.8 min), after 225Ac-PSMA-Trillium treatment in vivo. Astatine-117 (t1/2 = 32.3 ms) and polonium-213 (t1/2 = 3.4 µs) could not be investigated due to short half-lives. ***Materials and Methods:*** The biodistribution of 225Ac-PSMA-Trillium was evaluated using the subcutaneous LNCaP human prostate cancer xenograft model in SCID mice. The mice were treated with a single i.v. injection of 225Ac-PSMA-Trillium (1 MBq/kg with 375 kBq/nmol) and sacrificed either 15 min or 1, 3, 24, 48, 72, 96, 168, 240, or 336 hours post injection. Organs were measured immediately or 24 hours after sacrifice using a germanium detector and a gamma counter. The anti-tumour efficacy of 225Ac-PSMA-Trillium was investigated in the subcutaneous LNCaP xenograft (150 or 300 kBq/kg) and KUCaP-1 patient-derived xenograft (250 kBq/kg) models. ***Results:*** 225Ac-PSMA-Trillium exhibited fast and homogenous tumour penetration within 15 minutes post injection, and good tumour accumulation (~23 %ID/g), peaking 168-240 hours post injection, which were reflected by a prolonged residence time in the blood with clearance after 48 hours. In addition, 225Ac-PSMA-Trillium showed robust in vivo antitumour efficacy in both the androgen-dependent LNCaP and androgen-independent KUCaP-1 models. Actinium-225 decaying in the tumour generated bismuth-213 and francium-221, which were retained within the tumour. However, minor fractions of the bismuth-213 generated in the blood were redistributed into the kidneys. Redistribution of francium-221 from the blood was observed in the kidneys, small intestine and salivary glands. This was reflected by a change of total absorbed dose from 0.94 (calculated without daughter redistribution) to 2.39 Gy. ***Conclusion:*** 225Ac-PSMA-Trillium demonstrates a relatively slow pharmacokinetics profile and marked tumour uptake, which is consistent with its albumin-binding properties. Bismuth-213 and francium-221, the alpha-emitting daughter radionuclides of actinium-225, are predominantly retained in the tumour. Daughter radionuclides generated in the blood were more readily redistributed to the kidneys, salivary glands, or other organs.

OP-146

From Theory to Clinical Application: Understanding Ac-225 radiochemistry through [^{225}Ac]Ac-DOTA-TATE

E. Hooijman, *J. R. de Jong, E. de Blois;*
Erasmus MC, Rotterdam, NETHERLANDS.

Aim/Introduction: Since interest in the treatment with Ac-225-labeled peptides is growing in the field of nuclear medicine, optimal labelling conditions and quality control (QC) of such radiopharmaceuticals is of great importance. Consequently, this research aims to define reaction parameters essential for optimal labeling and robust quality control of Ac-225-labeled radiopharmaceuticals, exemplified by [225Ac]Ac-DOTA-TATE. ***Materials and Methods:*** Determination of the quality of the different Ac-225 sources was performed by evaluating the radionuclidic purity with HP-Ge-detector and quantification of metal-ions (ingrowth) using UPLC-analysis at different time points (1-4 weeks after dissolving). [225Ac]Ac-DOTA-TATE was labelled under standardized conditions (90kBq/nmol, 0.035M ascorbate, pH=4) as a reference. The radiochemical yield (RCY) was monitored according to previous work [1]. For radiolabeling the parameters such as: pH of labelling, molar activity, (90kBq/nmol-540kBq/nmol) and labelling volume (0.1-10mL), buffering (0.015-1M TRIS (pH=9), 0.015-1M Na-Ac (pH=5)) and quenchers (0.035M, pH=8.5) ascorbic acid, cysteine, vanilin and L-methionine) were tested. The radiochemical purity (RCP) is based upon indirect measurement approach [1]. The HPLC-method was optimized and different parameters such as: gradient slopes, recovery/carry-over methods and volume/fraction was tested. Other characteristics like microwave heating and storage conditions like as dry-ice and -20oC were monitored on HPLC (t0, t4 and t24h). ***Results:*** Three different Ac-225 sources were tested and contained different amounts (<5%) of metal impurities (Fe, Zn, Cu); however, all sources were suitable for radiolabeling, up to 2 weeks after dilution. The standardized radiolabeling of DOTA-TATE with Ac-225 was performed successfully, resulting in a RCY>99% and RCP >90% up to 24h. 20 minutes 90oC resulted high incorporation, longer heating times showed no improvement. A positive effect on stability could be observed when buffering with 0.015M TRIS, using ascorbate (0.035M,pH=5.8) and ethanol (10%v/v). The HPLC-method as published previously showed a good separation profile for [225Ac]Ac-DOTA-TATE, varying the slope and concentration of the mobile phases showed no improvement. It has to be noted that for optimal recovery and carry over, in depth analysis and modifications to the HPLC-system and column, including injection parameters, are required. When the molar activity and labelling volume was decreased, a reduced RCY was obtained, furthermore, increased stability was observed when stored on dry-ice or by -20°C. ***Conclusion:*** This research underlines the importance of validating the different radiolabeling conditions for alpha-radionuclides such as Ac-225, as well as the appropriate quality control for implementation towards the clinic. ***References:*** Hooijman et al. 2024.

OP-147

Long-acting ^{225}Ac-ART-101 for targeted alpha therapy of advanced CRPC

R. Hernandez, *M. Idrissou, A. Pinchuk, C. Ferreira, L. Lambert, A. Carston, E. Aluicio-Sarduy, H. Comas Rojas, J. Engle;*
University of Wisconsin-Madison, Madison, WI, UNITED STATES OF AMERICA.

Aim/Introduction: Despite the undeniable clinical activity of PSMA-based targeted alpha therapy in castration-resistant prostate cancer (CRPC), PSMA-617 as a delivery vehicle for 225Ac has several disadvantages, such as fast kinetics, poor tumor retention, and significant off-target toxicity to salivary glands. Therefore, novel agents designed with optimal pharmacokinetics and tumor retention for long-lived 225Ac and reduced salivary gland uptake are needed to realize the full curative potential of targeted alpha therapy in mCRPC. ***Materials and Methods:*** To improve upon the pharmacokinetics of PSMA-617 we synthesized a next-generation PSMA-targeted radiopharmaceutical ((1-carboxy-5-(18-(4-(2-(4,7,10-tris(carboxymethyl)-1,4,7,10-tetraazacyclodo-decan-1-yl)acetamido)phenyl)octa-decanamido)pentyl)carbamoyl)-glutamic acid (ART-101; MW:1063). Longitudinal PET/CT imaging and ex vivo biodistribution compared the pharmacokinetic, tumor-targeting, and biodistribution of 86Y-ART-101 and 86Y-PSMA-617 in two immunocompromised mouse models of prostate cancer, LNCaP and PC3-PIP. The efficacy of therapeutic 225Ac-ART-101 was tested in groups of mice bearing PC3-PIP or LNCaP xenografts (n=5) receiving a single IV injection of saline, 225Ac-ART-101 20-80 kBq (~0.5-2 µCi), or 225Ac-PSMA-617 40-80 kBq (~1-2 µCi). Toxicity evaluations included overall health assessments, CBC, CMP, and normal tissue histology in naïve ICR mice. ***Results:*** PET/CT imaging studies showed rapid 86Y-PSMA-617 tumor uptake in PSMA-expressing tumor xenografts, peaking at 4.0 ± 0.2 percent injected activity per gram of tissue (%IA/g) at 4 hours post-injection (p.i.), but poor retention with only 2.9 ± 0.5 %IA/g remaining 24 h p.i. of the radioligand. Conversely, 86Y-ART-101 showed significantly higher (P<0.01) peak tumor uptake (8.9 ± 1.7 %IA/g at 24 h p.i) and prolonged tumor retention (7.9 ± 1.1 %IA/g at 72 h p.i.) resulting in markedly enhanced tumor exposure for 86Y-ART-101 compared to 86Y-PSMA-617. Given this prolonged tumor retention, ART-101 radiolabeled to 225Ac delivered significant absorbed doses to prostate tumors. Consistent with the literature, treatment with 225Ac-PSMA-617 40 kBq resulted in marked tumor growth inhibition and significant (P < 0.0001) survival advantage compared to controls in both LNCaP and PC3-PIP models. Similarly, treatment with 225Ac-ART-101 at either injected activity, 20 or 40 kBq, led to significant tumor regression and prolongation in mouse survival. Median overall survival was 43, 84, 92, and 92 days for control, 225Ac-PSMA-617 (40 kBq), 225Ac-ART-101 (20 kBq), and 225Ac-ART-101 (40 kBq), respectively. Toxicology data indicated a favorable safety profile of 225Ac-ART-101 at relevant human equivalent injected activity levels. ***Conclusion:*** In conclusion, ART-101 showed significantly improved blood kinetics, enhanced tumor uptake, prolonged retention, and primarily hepatic clearance, translating into an improved therapeutic efficacy of 225Ac-ART-101 in murine models of mCRPC.

OP-148

Absorbed dose estimation of [^{211}At]PSMA-5 using a novel semiconductor imaging system in a preclinical study

T. Watabe[1], *S. Takeda[2], K. Kaneda-Nakashima[1], M. Katsuragawa[2], A. Yagishita[2], Y. Shirakami[1], Y. Kadonaga[1], K. Ooe[1], A. Toyoshima[1], H. Haba[3], J. Cardinale[4], F. L. Giesel[4], K. Fukase[1], T. Takahashi[2], N. Tomiyama[1];*
[1]Osaka University, Suita, JAPAN, [2]The University of Tokyo, Tokyo, JAPAN, [3]RIKEN, Wako, JAPAN, [4]University Hospital Duessldorf, Duessldorf, GERMANY.

Aim/Introduction: Astatine (211At) is an alpha-particle-emitting radionuclide that can be produced using a cyclotron with a natural bismuth target. The 211At-labeled prostate-specific membrane antigen (PSMA) compound ([211At]

PSMA-5) demonstrated excellent tumor growth suppression in a xenograft model (Watabe T, et al. Eur J Nucl Med Mol Imaging. 2023). This study aimed to compare the therapeutic effects of [211At]PSMA-5 with the absorbed dose, as estimated using a novel semiconductor imaging system. ***Materials and Methods:*** Tumor xenograft models were established by subcutaneous implantation of human prostate cancer cells (LNCaP) in NOD/SCID mice. [211At]PSMA-5 solutions were intravenously administered into mice and divided into four groups: 0.4 MBq, 0.1 MBq, 0.04 MBq, and a vehicle control group (each with n=4). Whole-body images were acquired at 1, 4 and 21h after administration using the XCam-CdTe planar imaging system (iMAGINE-X, Tokyo, Japan), which is equipped with a cadmium telluride semiconductor detector and a tungsten collimator. Scan durations were set as 10 min for each scan (n=2 for each group). Absorbed doses were estimated using the trapezoidal method according to the previous study (Watabe T, et al, J Nucl Med. 2019). Mice were monitored for 35 days to evaluate relative tumor sizes compared to baseline sizes at the time of administration by caliper measurement. ***Results:*** [211At] PSMA-5 images revealed high tumor retention (19.8 ± 5.8, 28.0 ± 9.3, and 38.6 ± 13.2 %ID/g at 1, 4, and 21 h, respectively) and significant uptake in the kidneys, indicative of PSMA expression in the proximal tubule. Tumor growth was significantly inhibited in a dose-dependent manner. Relative tumor sizes were 0.95 ± 0.12 for 0.4 MBq, 1.86 ± 0.18 for 0.1 MBq, 3.98 ± 0.15 for 0.04 MBq, and 5.77 ± 0.35 for the control group, respectively ($p<0.05$ by Dunnett test). Absorbed doses were estimated as 3.16 ± 1.14 Gy for 0.4 MBq, 1.89 ± 0.45 Gy for 0.1 MBq, and 0.63 ± 0.17 Gy for 0.04 MBq. A significant negative correlation was observed between relative tumor size and absorbed dose ($r=-0.825$ and $p<0.05$ by Spearman's correlation). ***Conclusion:*** This study demonstrated a dose-dependent therapeutic effect of [211At]PSMA-5 in the LNCaP xenograft model, with feasible estimation of absorbed doses using a novel semiconductor imaging system. [211At] PSMA-5 is expected to be a next-generation targeted alpha therapy against prostate cancer with the sustainable production using a cyclotron. ***References:*** Watabe T, et al. Eur J Nucl Med Mol Imaging. 2023 Feb;50(3):849-858.

OP-149

Lanatoside C enhanced the At-211 therapy in poorly differentiated thyroid cancers through restoring NIS

S. Sinha, *K. Devasena, B. Kim, K. Song, I. Lim;*
Korea Institute of Radiological and Medical Sciences, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: The treatment for poorly differentiated thyroid cancer (PDTC) is challenging due to insufficient sodium iodide symporters (NIS) which makes it refractory to conventional radioactive iodine (RAI) therapy. The objective of study was to investigate whether lanatoside C improved the 211At alpha therapy in poorly differentiated thyroid cancers through restoring NIS. We have also showed the In-Vitro comparison of alpha and beta therapy efficacies after redifferentiation. . ***Materials and Methods:*** A poorly differentiated papillary thyroid carcinoma cell line BHP10-3SCP with RET/PTC rearrangement was chosen for executing the experiments. Firstly, cytotoxicity test was performed for comparing the toxicities of 211At alone and in combination with lanatoside C (1μM). Clonogenic survival of BHP10-3SCp cell line exposed to lanatoside C (50μM) for 48 h followed by treatment with 3.7KBq/100μl of 211At (211At+Lan) for 6 h was monitored for 10 days. Restoration of NIS protein and mRNA was confirmed by western blot and PCR respectively. Furthermore, to compare double strand DNA damage by 211At and 131I was confirmed by confocal imaging of γH2AX.Statistical significance was tested using Mann Whitney test and Kruskal Wallis test. ***Results:*** Cytotoxicity test results showed significantly lowest viability in combination group of 211At+Lan (16.7±14.0%) vs Control (98.4±2.4%) vs lanatoside C only (88±3.5) vs 211At only (50.8±21.2%) ($p= 0.0003$). Total percentage of colonies survived in 211At treated cells after exposure of lanatoside C for 48h was 21.1% whereas in Control it was 100%; in only lanatoside C, 72.8%; in 211At, 48.3% ($p=0.001$). The NIS protein expression was found to be 1.8±0.3 fold more than control ($p=0.03$) in 50μM lanatoside C treated cells for 48h. The mRNA NIS expression was found to be increased by 124±62 ($p=0.01$) fold for 50μM lanatoside C in comparison to control. The maximum relative intensity of γH2AX for 211At treated cells after lanatoside C pre-treatment for 48h was found to be 3.5-fold more than that of non-treated cells whereas in case of 131I it was 1.8-fold. ***Conclusion:*** Our study indicates that lanatoside C can enhance 211At therapy due to restoration of Sodium Iodide Symporters in poorly differentiated thyroid cancers. Additionally, 211At being an alpha emitter is more effective than 131I for therapeutic purposes. However, further investigations are necessitated for in vivo evaluation and clinical application.

Understanding Time-Activity Curve and Time-Integrated Activity Variations in Radiopharmaceutical Therapy: Experience from the TACTIC AAPM Grand Challenge 2023

O. Ivashchenko[1], *J. O'Doherty[2], D. Hardiansyah[3], E. Grassi[4], J. Tran-Gia[5], J. W. T. Heemskerk[6], E. Hippelainen[7], M. Sandström[8], M. Cremonesi[9], G. Glatting[10];*
[1]University Medical Center Groningen, Groningen, NETHERLANDS, [2]Siemens Medical Solutions, Malvern, PA, UNITED STATES OF AMERICA, [3]Universitas Indonesia, Depok, INDONESIA, [4]Azienda USL-IRCCS di Reggio Emilia, Reggio Emilia, ITALY, [5]University Hospital, Würzburg, GERMANY, [6]Leiden University Medical Center, Leiden, NETHERLANDS, [7]University of Helsinki and Helsinki University Hospital, Helsinki, FINLAND, [8]Uppsala University, Uppsala, SWEDEN, [9]European Institute of Oncology, Milan, ITALY, [10]Ulm University, Ulm, GERMANY.

Aim/Introduction: The process of determining time-activity curves (TACs) for radiopharmaceutical therapy (RPT) relies heavily on user- and site-specific steps, impacting time-integrated activity (TIA) and, effectively, absorbed dose calculations. Despite TIA's clinical significance, there is no consensus on data processing methods nor an understanding of how user-dependent TAC calculation affects personalized RPT dosimetry. In 2023, the TACTIC AAPM Grand Challenge was created to address these challenges. This work presents results and insights from the challenge. ***Materials and Methods:*** Launched in January 2023, the TACTIC challenge consisted of three phases: warm-up (P0),

individual patient-based TAC fitting (P1), and population-based TAC fitting (P2). Participants were provided with pre-processed synthetic biokinetic data of [177Lu]Lu-PSMA-617 (kidney, blood, and tumor) and tasked with modeling the TAC and calculating TIA values for each target organ. Additionally, participants submitted information about the TAC type and parameters used for fit optimization. The best-performing team in P1 and P2 was determined by the lowest total root mean squared error (RMSE) error over the organs. ***Results:*** A total of 132 individuals from over 30 countries registered for the challenge, representing a diverse mix of highly experienced dosimetry groups, industry professionals, and newcomers to RPT dosimetry. Among them, 73 participants requested data, of which 35 (P0), 35 (P1) and 28 (P2) submitted their results. Across the three phases, 13 different fit functions were utilized, with varying advanced model selection criteria and levels of uncertainty incorporation. Notably, the bi-exponential function was most prevalent, utilized in 51% (P1) and 32% (P2) of submissions, while the least square objective function was the primary choice for 40% of submissions (P1). Despite the challenge's nature, only a minority of participants—6 in P1 and 8 in P2—incorporated uncertainty budgets into their TIAC calculations. Population-based information was utilized in only 7 submissions during P2. Interestingly, no correlations were found between choice of fit function, objective function, uncertainty incorporation, or population information use and participants' performance. Winners in each phase employed diverse models and objective functions. However, the top-performing participants consistently integrated uncertainty information when selecting the most suitable TAC model. A decrease in some participants' performance from P1 to P2 when including uncertainty or population-based information suggests that more guidance and training is needed to use them effectively. ***Conclusion:*** The TACTIC challenge results offer insights into global TAC modeling practices, revealing significant variations in result quality. This underscores the importance of education in TAC fitting methodologies.

OP-151

More is not always better: Dosimetry imaging schemes with two versus three timepoints

J. Gustafsson[1], *J. Taprogge[2], K. Sjögreen Gleisner[1];*
[1]Lund University, Lund, SWEDEN, [2]Royal Marsden NHSFT, Sutton, UNITED KINGDOM.

Aim/Introduction: The aim was to compare radionuclide-therapy dosimetry for [177Lu]Lu-DOTA-TATE based on two or three imaging timepoints with respect to error variability. Previously (1), a formula was presented for the standard deviation (SD) of the relative error in time-integrated activity-concentration (TIAC) as function of imaging time-points. This study applies the formula for comparison of two versus three timepoints. ***Materials and Methods:*** The previously introduced formula describes the SD in the relative error of the TIAC for a mono-exponential function with a fixed coefficient-of-variation (CV) in estimated activity-concentrations at each imaging time point. A formula for iso-SD-curves was derived for imaging with two time-points. Numerical simulations were performed of TIACs for kidneys and spleen (10000 repetitions), where mean effective half-lives and SDs were obtained from a set of 18 patients (2), assuming log-normal distributions of the biological decay-constant and errors in estimated activity-concentrations. Activity-concentration CVs of 5% and 10%, respectively, were studied. Three different three-timepoint schemes were considered: (a) 24 h, 48 h, 72 h; (b) 24 h, 72 h, 96 h; and (c) 24 h, 96 h, 168 h. 465 two-timepoint schemes were simulated with imaging times ranging from 5 h to 165 h in steps of 5 h, with restriction that timepoints were separated by at least 12 h. The fraction of two-timepoint schemes with a lower TIAC SD than for the three-timepoint schemes were determined. Results from numerical simulations were compared with theoretical predictions from the iso-SD-curve formula. ***Results:*** Mean effective half-lives (CVs) of kidneys and spleens were 55 h (17%) and 76 h (22%), respectively. For kidneys and the activity-concentration CV of 5%, three-time point scheme (a) yielded a higher SD than the two-timepoint schemes in 63% of the cases, and 94% of these schemes were correctly classified by the iso-SD-expression. Corresponding results for (b) and (c) were 10% and 90%; and 0% and 100% respectively. For spleen, corresponding results for (a), (b), and (c) were 77% and 98%; 48% and 97 %; and 0% and 100%. Results were similar when increasing the activity-concentration CV to 10%. ***Conclusion:*** The dispersion of relative errors in time-integrated activity-concentration can be described by a simple analytical formula that agrees well with numerical simulations. Two-timepoint imaging schedules with one early and one late time-point can be more accurate than schemes with three early timepoints. ***References:*** 1. Gustafsson and Taprogge, Submitted manuscript 2., Stenvall et al., 10.1186/s13550-022-00947-2.

OP-152

Machine Learning- Data-Driven Time-Integrated Activity Estimation for [^{177}Lu]Lu-PSMA-I&T Therapy in Prostate Cancer

A. Adinegoro[1], *S. Siregar[1], D. Hardiansyah[1], G. Glatting[2,3];*
[1]Medical Physics and Biophysics, Physics Department, Faculty of Mathematics and Natural Sciences, Universitas Indonesia, Depok, INDONESIA, [2]Department of Nuclear Medicine, Ulm University, Ulm, GERMANY, [3]Medical Radiation Physics, Department of Nuclear Medicine, Ulm University, Ulm, GERMANY.

Aim/Introduction: The commonly used method for Time-Integrated Activity (TIA) estimation is the fitting of biokinetic data with a mono-exponential function [1]. However, the mono-exponential fitting method often does not provide an adequate TIA estimation. Addressing these challenges, we proposed an estimation of the kidney's TIA for [177Lu]Lu-PSMA-I&T using the Machine Learning algorithm by the Partial Least Squares Regression (ML-PLSR) method. PLSR is used to estimate TIA by reducing dimensionality and handling multicollinearity among predictors, thereby improving the accuracy and reliability of predictions. ***Materials and Methods:*** Biokinetic data of [177Lu]Lu-PSMA-I&T in the kidneys of 1000 patients was simulated using the PBPK model [2] with injected activity of 7.3 GBq. A total of 500 patients were used for each training and testing of the ML-PLSR method with 20-fold cross-validation. Time-activity data was collected at 3, 24, 48, 72, and 168 h post-injection. Physiological parameters of the PBPK model in adult humans were simulated for log-normal parameter distributions using a random number generator. Reference TIAs (rTIAs) were calculated from the simulation using the PBPK model and the physiological parameters. Various combinations of biokinetic dataset sizes (3 to 5 time points) and physiological parameters PP (age, weight and height) were trained with the ML-PLSR model, and corresponding estimated TIA (eTIA-ML-PLSR) were calculated for each combination. Individual mono-exponential function (m-EF) fitting was used to calculate the estimated TIA (eTIA-mono). The performance of ML-PLSR was tested using relative deviation (RD) and root-mean-squared error (RMSE) between eTIA-ML-PLSR and rTIA; m-EF was similarly evaluated by eTIA-mono and rTIA. ML-PLSR method disregards intra-patient variability, instead representing

inter-patient variability through physiological parameters across different individuals. ***Results:*** The ML-PLSR method using the 3-time points dataset at 24, 48, and 168 h post-injection and PP (RD=(3.6±2.7)%, RMSE=4.5%) showed similar performance with ML-PLSR method using 5-time points dataset and PP (RD=(3.6±2.6)%, RMSE=4.5%). ML-PLSR method outperformed the m-EF method based on the performance measure of m-EF of (RD=(5.3±3.3)%, RMSE=6.3%). ML-PLSR Analysis identified the 24 and 48 h time points as critical for estimating TIA. ***Conclusion:*** The ML-PLSR method shows promising results in determining the TIA value of [177Lu]Lu-PSMA-I&T. This method offers a robust alternative for TIA prediction in clinical environments where extensive data collection is challenging. In addition, the ML-PLSR method outperforms the frequently used m-EF method for our population and radiopharmaceutical. ***References:*** [1] Uribe C et al., J Nucl. Med, 62(12):36S-47S, 2021. OP-153

Time-Integrated Activity Estimation of [^{177}Lu]Lu-PSMA-617 Using Single-Time-Point Data and a Machine Learning Models

A. Wicaksono[1], *S. Siregar[1], J. Jabar[2], D. Hardiansyah[1], G. Glatting[3,4];*
[1]Medical Physics and Biophysics, Physics Department, Faculty of Mathematics and Natural Sciences, Universitas Indonesia, Depok, INDONESIA, [2]Nuclear and Biophysics, Physics Department, Faculty of Mathematics and Natural Sciences, Institut Teknologi Bandung, Bandung, INDONESIA, [3]Department of Nuclear Medicine, Ulm University, Ulm, GERMANY, [4]Medical Radiation Physics, Department of Nuclear Medicine, Ulm University, Ulm, GERMANY.

Aim/Introduction: Individual estimation of time-integrated activity (TIA) is highly desirable in molecular radiotherapy. However, as individual TIA estimation is lengthy and complex, it is challenging to apply in clinical practice. This study aims to evaluate the accuracy of individual TIA estimation in [177Lu]Lu-PSMA-617 radioligand therapy using single-time-point (STP) data and ML models. ***Materials and Methods:*** Biokinetic data of [177Lu]Lu-PSMA-617 radiopharmaceutical (RP) in kidneys were simulated at five different time points TP (TP1=1.8h, TP2=18.7h, TP3=42.6h, TP4=66.2h, TP5=160.3h) using a published non-linear mixed effects (NLME) model [1], considering interindividual variability while omitting intraindividual variability. The biodistribution of the RP was simulated by generating 5,500 virtual patient kinetics, with 5,000 allocated for ML model training and 500 for evaluation. Reference TIAs (rTIAs) were calculated for evaluation based on the analytical solution suggested by the literature [1]. Linear Support Vector Regression (L-SVR), K-nearest neighbour (KNN), and decision tree (DT) ML models were trained to generate estimated TIA (eTIA) with STP data at various TP through multi-stage testing. ML models and TPs were evaluated based on the lowest relative deviation (RD) and root mean square error (RMSE) between eTIA and rTIA. Based on the STP method proposed by Hänscheid et al. [2], the TIA (hTIA), RD, and RMSE were also analysed. ***Results:*** The RD and RMSE of ML with L-SVR, KNN, and DT were similar in each investigated TP, e.g. at TP2, the RD of the models were (14±12)%, (14±12)%, and (14±12)%. TP3 was identified as the best TP for STP TIA estimation in all ML models, with RDs of L-SVR, KNN, and DT of (9.5±8.5)%, (9.8±8.6)%, and (9.8±8.4)%. L-SVR ML and TP3 STP was identified to have the lowest RD and RMSE of 9.5 ±8.5% and 12.7%. ML STP with L-SVR at TP3 outperforms the STP method [2] based on the RD and RMSE of hTIA of (16.0±9.9) and 18.8%. ***Conclusion:*** The result of this study suggests that applying ML in nuclear medicine can potentially improve STP dosimetry. Further investigation and model validation, especially with measured biokinetic data, are needed to verify and investigate the performance of the ML model so it can be applied in routine clinical practice. ***References:*** [1] Hardiansyah et al., J. OP-154

Time-Integrated Activity Calculation for Benign Thyroid Disease using Single-Time-Point Data and Non-Linear Mixed-Effects Modelling

D. Hardiansyah[1], *A. Riana[1], H. Hänscheid[2], M. Lassmann[2], G. Glatting[3];*
[1]Universitas Indonesia, Depok, INDONESIA, [2]University Hospital Würzburg, Würzburg, GERMANY, [3]Ulm University, Ulm, GERMANY.

Aim/Introduction: This study aimed to evaluate the accuracy of time-integrated activity (TIA) estimation using single-time-point (STP) data with NLME modelling and population-based model selection (PBMS) in 73 patients with benign thyroid disease. Additionally, we conducted a comparative analysis to assess the accuracy of the STP approach employing the PBMS-NLME methodology against the STP approaches in the EANM dosimetry guideline (EJNMMI, 2013). ***Materials and Methods:*** Biokinetic data of 131I in benign thyroid diseases (Graves' disease, toxic nodular goitre, non-toxic goitre) were obtained from seventy-three patients with uptake measurements 2, 6, 24, 48, and 96 (n=53) or 120 (n=20) hours after oral capsule administration of 131I. PBMS with different parameterisations of sum-of-exponentials (SOE) functions, i.e., two to nine parameters, were employed for the analysis. The best SOE function to describe the biokinetic data was determined through a goodness-of-fit assessment and the Akaike weight, which indicates the likelihood of a function accurately representing the data. The best SOE function was then used for conducting single-time-point (STP) dosimetry at different time points (sTIAs). In addition, TIAs (hTIAs) were calculated from STP data according to the EANM guideline, assuming a fixed half-life of 5.5 d for the measurements after 24 and 48 hours. The accuracy of the computed sTIAs and hTIAs was assessed by comparing them with the reference TIAs (rTIAs) obtained from fitting all time points using the best model. This comparison involved calculating relative deviations (RDs) and root-mean-square errors (RMSEs). The total number of patients with absolute RDs of sTIAs and hTIAs higher than 5% (RD5) was also analyzed. ***Results:*** The SOE function with four adjustable parameters was selected as fit function most supported by the data based on the goodness-of-fit test with an Akaike weight of approximately 100%. The mean±standard deviation of RD (RMSE, RD5) of STP dosimetry with the best SOE function for 2, 6, 24, 48, 96, and 120 hours post-administration were 19%±44% (48.0%,58), 12%±34% (35.9%,46), 8%±27% (28.1%,41), 7%±19% (20.8%,38), 4%±8% (8.5%,13), and 2%±4% (4.5%,5), respectively. The mean±standard deviation of RD (RMSE, RD5) of STP dosimetry according to the guideline for 24, 48, 96, and 120 hours post-administration were -2%±26% (26.3%,61), -0%±19% (19.3%,60), 0%±8% (8.2%,28) and 0%±5% (5.0%,9), respectively. ***Conclusion:*** STP dosimetry using NLME modelling generally reduces the number of RD5 deviations compared to the guideline and, in combination with a late measurement, leads to accurate TIAC values in 131I benign thyroid therapy.

OP-155

Outcome-Driven Assessment of Single-Time Point Dosimetry for ^{177}Lu-PSMA-617RPT

J. Hu, *AITT, R. Seifert, S. Xue, C. Ferreira, A. Afshar-Ormieh, A. Rominger, K. Shi;*
Department of Nuclear Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, Swi, Bern, SWITZERLAND.

Aim/Introduction: Personalized dosimetry-based treatment planning emphasizes the sue of Multiple-Time-Point Dosimetry (MTPD) to tailoring the applied dose to tumor and organs at risk. However, challenges persist in clinical implementation, necessitating a simplified approach that retains the ability to assess therapy outcomes effectively. In this study, we applied both Single-Time-Point Dosimetry (STPD) and MTPD for 177Lu-PSMA-617 Radiopharmaceutical Therapy (RPT). Analyses were performed in comparing dosimetry methods and evaluating their effectiveness in predicting therapy responses and toxicity indicators. ***Materials and Methods:*** In this retrospective study, we analyzed data from 81 cycles involving 21 patients diagnosed with metastatic castration-resistant prostate cancer (mCRPC) who received multiple cycles of 177Lu-PSMA-617 RPT. Comprehensive quantitative SPECT/CT-based dosimetry measurements are conducted with varying time points, specifically at 2-4 hours post-injection and at least two additional time points within the 1-9 days window. Using a voxel dosimetry module and advanced organ segmentation, organ-wise MTPDose and STPDose were computed, STPDose were generated by Hanscheid method, and quality control by bi-exponential decay fitting model. Therapy outcomes were evaluated including PSA response, overall survival (OS), and relevant toxicity assessment. ***Results:*** The optimal time-points were determined based on minimal RMSE, with Day 1 p.i. identified for organs at risk and Day 3 p.i. for whole-body-tumors, when compared with MTPDose. Significant differences in MTPDose and STPDose of Day 1-3 p.i. were observed among subgroups based on PSA response rates ($p<0.001$). Specifically, in the 3rd- 6th treatment cycles, both MTPDose (3rdcycle HR = 1.18, 4thcycle HR = 1.17, 5thcycle HR = 2.09, and 6thcycle HR = 2.74; all $p < 0.05$) and STPDose (3rdcycle HR = 1.16, 4thcycle HR = 1.10, 5thcycle HR = 1.89, and 6thcycle HR = 1.08; all $p < 0.05$) of whole-body tumors were identified as significant predictors of overall survival using univariate Cox regression analysis. Furthermore, both MTPDose and STPDose demonstrated higher values with increasing hematotoxicity grade ($p<0.001$). ***Conclusion:*** Our findings validate the comparability of STPD with the referenced MTPD, highlighting the clinical feasibility of streamlined dosimetry techniques to facilitate personalized treatment planning and monitoring therapeutic outcomes.

OP-156

Population-Based Model Selection with Nonlinear Mixed-Effects Model (PBMS-NLME) for Renal Dosimetry in [^{177}Lu]Lu-PSMA-617 Therapy using Inter-Occasional and Inter-Individual Variability

I. Budiansah[1], *D. Hardiansyah[1], S. A. Pawiro[1], S. M. B. Peters[2], M. W. Konijnenberg[3,2], G. Glatting[4];*
[1]Medical Physics and Biophysics, Physics Department, Faculty of Mathematics and Natural Sciences, Universitas Indonesia, Depok, INDONESIA, [2]Department of Medical Imaging, Radboud University Medical Centre, 9101, 6500 HB, Nijmegen, NETHERLANDS, [3]Department of Radiology and Nuclear Medicine, Erasmus Medical Centre, Rotterdam, NETHERLANDS, [4]Medical Radiation Physics, Department of Nuclear Medicine, Ulm University, Ulm, GERMANY.

Aim/Introduction: This study aims to optimise the time-integrated activity (TIA) estimation in kidneys by using population-based model selection with non-linear mixed-effects modelling (PBMS-NLME), inter-occasional variability (IOV), and inter-individual variability (IIV) in two cycles of [177Lu]Lu-PSMA-617 therapy. ***Materials and Methods:*** Renal biokinetic data was gathered from a cohort of ten prostate cancer patients who underwent two cycles of therapy utilising [177Lu]Lu-PSMA-617. SPECT/CT scans were performed at 1, 24, 48, 72, and 168 hours post injection. Sums of exponential functions (SOEFs) with up to seven parameters were fitted to the biokinetic data using NLME modelling. Variability due to the treatment cycle and kidneys' site/position (left/right) was described in the model by taking into account the IOV and IIV in the structural model. The PBMS-NLME was done based on the goodness-of-fit criteria and the Akaike weight value to select the SOEF most supported by the data. The performance of the best-fit function integrating IOV and IIV in this study was compared to the best-fit function from the PBMS-NLME method in the literature for [177Lu]Lu-PSMA-617 (Hardiansyah et al. JNM 2024). The performance of the models was evaluated using the relative deviation (RD) between the TIA from the best SOEF in this study and the TIA from the best SOEF in the literature for [177Lu]Lu-PSMA-617, i.e. f6c=A1e-(λ1+λphys)t+A2e-(λ2+λphys)t-A3e-(λ3+λphys)t-(A1+A2-A3)e-(λbc+λphys)t ***Results:*** The SOEF with five parameters f5a=A1e-(λ1+λphys)t+A2e-(λ2+λphys)t-(A1+A2)e-(λ3+λphys)t considering the IOV and IIV was selected as the best-fit SOEF with an Akaike weight of 92%. The RD between the TIA from the best SOEF in this study and the TIA using the literature function for the first and second cycles were -0.2 [-4.1,2.7]% and -0.3 [-5.8,9.4]%, respectively. ***Conclusion:*** Integrating the IOV and IIV into the PBMS-NLME model is beneficial to improve the accuracy of the estimated kidney TIAs in [177Lu]Lu-PSMA-617 therapy, as evidenced by the Akaike weight of 92%. ***References:*** D. Hardiansyah, E. Yousefzadeh-Nowshahr, F. Kind, A. J. Beer, J. Ruf, G. Glatting, and M. Mix, "Single-Time-Point Renal Dosimetry Using Nonlinear Mixed-Effects Modeling and Population-Based Model Selection in [177Lu]Lu-PSMA-617 Therapy," Journal of Nuclear Medicine, Feb. 2024.

OP-157

Single-time-point dosimetry for tumour lesions during [^{177}Lu]Lu-PSMA-617 therapy using non-linear mixed-effects modeling

D. Hardiansyah[1], *E. Yousefzadeh-Nowshahr[2], F. Kind[3], A. J. Beer[2], J. Ruf[4], M. Mix[3], G. Glatting[2];*
[1]Universitas Indonesia, Depok, INDONESIA, [2]Ulm University, Ulm, GERMANY, [3]University of Freiburg, Freiburg, GERMANY, [4]Klinikum Karlsruhe, Karlsruhe, GERMANY.

Aim/Introduction: The study aimed to calculate the accuracy of tumour lesion dosimetry in [177Lu]Lu-PSMA-617 therapy using single-time-point (STP) imaging data from SPECT/CT, non-linear mixed-effects (NLME) modelling, and the population-based model selection (PBMS) method in a population of 52 patients. ***Materials and Methods:*** Time-activity per volume data for [177Lu]Lu-PSMA-617 in lesions were collected using SPECT/CT at: TP1=(1.8±0.8) h, TP2=(18.7±0.9) h, TP3=(42.6±1.0) h, TP4=(66.3±0.9) h, and TP5=(158.8±22.8) h post-injection. Ten sum-of-exponentials (SOE) functions were fitted to the time-activity per volume data. A PBMS method was employed based on goodness-of-fit tests and Akaike weights. The optimal function derived from the PBMS method and data from all time points was utilised to compute the reference time-integrated activities

per volume (rTIAVs). The parameters of this optimal function were fitted to the STP data for each patient, and these adjusted parameters were then employed to calculate the STP TIAVs (sTIAVs). Additionally, STP dosimetry was conducted using the method outlined by Hänscheid et al. (JNM,2018) to determine the TIAVs (hTIAVs). The accuracy of the computed sTIAVs and hTIAVs was assessed by evaluating the mean and standard deviations (SDs) of relative deviations (RDs), the root-mean-square errors (RMSEs) of the RDs, and the mean absolute errors (MAEs). ***Results:*** The function with four parameters was selected as the best-fit function from PBMS. For STP dosimetry, a solitary SPECT/CT measurement at TP4 exhibited a mean deviation of (0±21)% and a median deviation of 0.6%. The RMSEs for deviations in sTIAVs at TP1, TP2, TP3, TP4, and TP5 were 78%, 30%, 20%, 21%, and 20%, respectively. The RMSE values for deviations in hTIAVs at TP1, TP2, TP3, TP4, and TP5 were 96%, 62%, 33%, 21%, and 28%, respectively. The mean absolute errors (MAEs) of STP TIAVs at TP1, TP2, TP3, TP4, and TP5 were 2.4 %h/mL, 1.5 %h/mL, 1.1 %h/mL, 0.7 %h/mL, and 0.7 %h/mL, respectively. Conversely, the MAEs for hTIAs at TP1, TP2, TP3, TP4, and TP5 were 6.9 %h/mL, 4.6 %h/mL, 2.2 %h/mL, 1.1 %h/mL, and 1.1 %h/mL, respectively. The proportion of deviations less than 10% at T4 was 32/52 (62%) for sTIAVs and 20/52 (38%) for hTIAVs. ***Conclusion:*** Our findings indicate that, a single SPECT/CT measurement at 3 d post-injection could be used to predict tumour lesion TIAVs in [177Lu]Lu-PSMA-617 therapy through NLME modelling. This STP approach outperforms the STP method proposed by Hänscheid et al. for the investigated radiopharmaceutical and patient population.

OP-158

Accuracy of personalised single time point dosimetry for bone marrow and liver dosimetry in Yttrium-90-Anti CD66 radioimmunotherapy

A. Nautiyal[1], *G. Lewis[1], K. Orchard[1], F. Wilson[2], M. Guy[1], S. Michopoulou[1];*
[1]University Hospital Southampton, Southampton, UNITED KINGDOM, [2]Telix Pharmaceuticals Limited, London, UNITED KINGDOM.

Aim/Introduction: [90Y]-Anti-CD66 radioimmunotherapy (RIT) is a promising treatment for multiple myeloma and leukaemia. By performing patient-specific dosimetry, the therapeutic dose can be precisely tailored to minimise organ toxicity and maximise treatment efficacy. Our study aimed to evaluate and compare different approaches to estimating absorbed dose from a single time point (STP) imaging in clinical practice in terms of accuracy and effort. ***Materials and Methods:*** Whole-body SPECT/CT was acquired from 28 patients at 24h, 72h, and 96h after administration of [111In]-Anti-CD66 (0.18 ± 0.01GBq) as a surrogate to [90Y]-Anti-CD66 (2.4 ± 0.5GBq). The absorbed dose was estimated using STP methods (M1-M4) and compared against the reference multi-time point (MTP) dosimetry method (M0). The population mean effective half-life (Teff) was used for calculation in bone marrow (BM) (47.35 ±4.30h) and liver(69.84 ±11.55h). M1: The time-integrated activity (TIA) of 24h imaging time point was estimated by a mathematical approximation of measured activity with monoexponential decay function based on Mean Teff; M2: TIA was calculated using the ratio of activity at measurement time and a decay constant; M3: TIA was calculated as a product of measurement time and activity and the factor of 2/0.693, M4: TIA was estimated using an in-house function based on the product of measured time, activity and a ratio of Teff and time and constant The resulting time-integrated activity from these methods is multiplied with organ-based S-value to estimate the dose. ***Results:*** The measured BM and liver absorbed dose (mGy/MBq) was 5.76 ±1.54 and 3.11 ±2.40 (M1); 5.7 ±1.47 and 3.1 ±2.54(M2); 5.68 ±1.54 and 3.08 ±2.34(M3); 6.07 ±1.6 and 3.36 ±2.64(M4); 5.95 ±1.73 and 2.91 ±1.84(M0), respectively. Using STP methods for BM had -2.52 ±6.96%(M1), -2.79 ±10.20%(M2), -2.50 ±6.96%(M3) and 2.67 ±7.06%(M4) difference against M0, while 2.32±12.12%(M1), 1.40 ±16.33%(M2), 2.36±12.12%(M3) and 9.87±12.27%(M4) in liver. In BM, none of the patients have an error of more than 20% with M1 and M3, whereas 3.57% have an error of more than 20% with M2 and M4 in the liver. The percentage of patients with an error of more than 20 % in the liver was lowest (14.29%) with M1 and M3. ***Conclusion:*** STP dosimetry obtained with the M1 for [90Y]-Anti-CD66 RIT using SPECT/CT at 24h led to the lowest error and provided high accuracy in dose estimation. Implementing this finding can reduce patient and department burden and increase dosimetry adoption.

Fibroblast Activation Protein targeted Imaging Outperforms FDG-PET/CT in Malignant Mesothelioma: Prospective Single-Center Observational Trial

L. Kessler, *K. Pabst, M. Metzenmacher, B. Schaarschmidt, F. Schwaning, M. Nader, J. Siveke, M. Schuler, S. Boeluekbas, L. Umtlu, D. Theegarten, M. Stuschke, W. P. Fendler, K. Herrmann, H. Hautzel;*
University Hospital Essen, Essen, GERMANY.

Aim/Introduction: Mesothelioma is a rare tumor entity mostly affecting the pleura and is associated with overall poor prognosis. On molecular level, various mesothelioma subtypes have shown expression of fibroblast-activation-protein (FAP) in tumor cells and carcinoma-associated fibroblasts, suggesting FAP as a potential target for imaging and therapy. Therefore, the novel radiolabeled FAP-inhibitors (FAPI) are of interest for future theranostic approaches. The FAPI-PET observational trial (NCT04571086) explores Ga-68-FAPI PET imaging in cancer patients and here we present preliminary data on Ga-68-FAPI in patients with malignant mesothelioma. ***Materials and Methods:*** From April 2020 till August 2023 forty-one patients underwent Ga-68 FAPI-PET imaging, contrast-enhanced CT (Ce-CT), and F-18-FDG PET. The primary aim was to correlate Ga-68-FAPI-PET uptake (SUVmax and SUVpeak) with histopathological FAP expression by spearmen correlation. Secondary objectives included detection rate (rate of PET positive results) and sensitivity (SE), specificity (SP), positive/negative predictive values (PPV/NPV) and accuracy (ACC) compared to F-18-FDG PET validated by histopathology or a compound reference standard (histopathology, alternative imaging or follow-up imaging). Two blinded readers reported Datasets. ***Results:*** A significant moderate correlation was observed between FAPI SUVmax and SUVpeak values and histopathological FAP expression (SUVmax r = 0.49, p = 0.04; SUVpeak r = 0.51, p = 0.03). Overall Ga-68-FAPI showed very good diagnostic

performance (SE 98%, SP 81%, PPV 88% and NPV 97%). Compared to F-18-FDG sensitivity was similar on both per-patient (100.0% vs. 97.3%) and per-region (98.0% vs. 95.9%) basis. Notably, Ga-68-FAPI exhibited higher SP (81.1% vs. 36.8%) and PPV (87.5% vs. 66.2%) in per-region analysis, indicating superior performance. Main reason for this discrepancy were a higher number of false positive regions on F-18-FDG (FAPI, N = 7 vs. FDG, N = 31). ***Conclusion:*** This study validates the correlation between Ga-68-FAPI uptake and histopathological FAP expression in mesothelioma patients. Furthermore, it demonstrates superior detection rate and diagnostic performance compared to F-18--FDG. These findings highlight the potential of Ga-68-FAPI as a valuable diagnostic tool in clinical practice.

OP-160

^{18}F-FDG-PET/CT atypical response patterns to immunotherapy in non-small cell lung cancer patients: long term prognosis assessment and clinical management proposal.

M. Masse, *D. Chardin, P. Tricarico, V. Ferrari, N. Martin, J. Otto, J. Darcourt, V. Comte, O. Humbert;*
Centre Antoine Lacassagne, Nice, FRANCE.

Aim/Introduction: Determine the long-term prognosis of immune-related response profiles (pseudoprogression and dissociated response), not covered by conventional PERCIST criteria, in patients with non-small-cell lung cancer (NSCLC) treated with immune checkpoint inhibitors (ICPIs). ***Materials and Methods:*** 109 patients were prospectively included and underwent 18F-FDG-PET/CT at baseline, after 7 weeks (PETinterim1), and 3 months (PETinterim2) of treatment. On PETinterim1, tumor response was assessed using standard PERCIST criteria. In case of PERCIST progression at this time-point, the study design provided for continued immunotherapy for 6 more weeks allowing to refine the response patterns considering PETinterim2 results: pseudo-progression (PsPD) if response was observed on PETinterim2; confirmed progressive metabolic disease (cPMD) in case of confirmed progression and dissociated response (DR) in case of coexistence of responding and non-responding lesions. Patients were followed up for at least 12 months. ***Results:*** Median follow-up was 21 months. At PETinterim1, PERCIST progression was observed in 60% (66/109) of patients and ICPI was continued in 59/66. At the subsequent PETinterim2: 14% of patients showed PsPD, 11% DR, 35% cPMD, and 28% had a sustained metabolic response. Median overall survival (OS) and progression-free-survival (PFS) did not differ between PsPD and DR (27 vs 29 months, p=1.0; 17 vs 12 months, p=0.2, respectively). The OS and PFS of PsPD/DR patients were significantly better than those with cPMD (29 vs 9 months, p<0.02; 16 vs 2 months, p<0.001), but worse than those with sustained metabolic response (p<0.001). This 3-group prognostic stratification enabled better identification of true progressors, outperforming the prognostic value of standard PERCIST criteria (p=0.03). ***Conclusion:*** These results are in favor of introducing new criteria that consider atypical response patterns to ICPIs (DR and PsPD) after initial metabolic progression. They refine the prognostic stratification of the usual PERCIST criteria and support a "wait and see" strategy after early PET assessment.

OP-161

Head-to-head comparison of the dual heterobivalent tracer [^{68}Ga]Ga-FAPI-RGD and the cyclic RGD homodimer [^{68}Ga]Ga-PRGD2 for PET imaging of lung carcinoma

R. Wang[1], *J. Xiang[1], J. Wang[1], X. Peng[1], N. Liang[1], X. Chen[2], Z. Zhu[1], J. Zhang[2];*
[1]Peking Union Medical College (PUMC) Hospital, Beijing, CHINA, [2]National University of Singapore, Singapore, SINGAPORE.

Aim/Introduction: Radiolabeled fibroblast activation protein inhibitor (FAPI) and RGD molecules have been investigated for imaging FAP and integrin αvβ3 receptor expression in various tumor types. However, the difference between heterodimers and homodimers has never been compared. In this study, we evaluated the [68Ga]Ga labeled heterodimer [68Ga]Ga-FAPI-RGD and the cyclic RGD homodimer [68Ga]Ga-PRGD2 for the first time in patients with lung neoplasms to compare their clinical performance. ***Materials and Methods:*** This prospective study was approved by the Peking Union Medical College Hospital ethics committee (IRB protocol I-22PJ249) and registered at ClinicalTrials.gov (NCT05543954). All patients provided written informed consent to receive both the [68Ga]Ga-FAPI-RGD and [68Ga]Ga-PRGD2 PET/CT within 1 week. Patients with suspected primary or metastatic lung carcinomas were recruited. All patients underwent [68Ga]Ga-FAPI-RGD PET/CT scan at 85.8 ± 24.0 min and [68Ga]Ga-PRGD2 PET/CT scan at 59.9 ± 10.3 min after intravenous injection. The peripheral normal tissue was considered as background for calculation. The SUVmax was calculated for further analysis. Histopathological findings were used for final diagnostic determinations of all primary tumors. ***Results:*** Twenty-four patients were enrolled in this study (10 men and 14 women; mean ± age SD, 63 ± 9.8 years). All patients tolerated the examination well and no significant adverse events related to the study were reported in any of the patients. There were 22 patients with lung adenocarcinomas and 2 patients with squamous cell lung carcinomas. [68Ga]Ga-FAPI-RGD showed much higher SUVmax (6.02 ± 4.08 vs. 2.81 ± 1.79, $p < 0.001$) than [68Ga]Ga-PRGD2. Compared with [68Ga]Ga-PRGD2, [68Ga]Ga-FAPI-RGD detected 4 more primary lesions (20/24 vs. 16/24). [68Ga]Ga-FAPI-RGD PET/CT also detected more metastases than [68Ga]Ga-PRGD2 PET/CT in 6/8 patients (172 vs. 98 lesions) and showed a higher SUVmax (7.78 ± 2.84 vs. 3.97 ± 1.06, $p < 0.001$). ***Conclusion:*** This pilot study demonstrated the first clinical application of two dimer tracers in lung cancer. [68Ga]Ga-FAPI-RGD showed better performance than [68Ga]Ga-PRGD2, resulting in higher tracer uptake, higher tumor detection rate and improved detection of metastases. Further investigation of the differences between the heterodimer and homodimer tracers in larger clinical trials is warranted.

First experience with [^{195m}Pt]cisplatin imaging in lung cancer patients

D. Hoogenkamp[1], *B. J. de Wit - van der Veen[1], K. van der Schilden[2], J. S. A. Belderbos[1], M. M. Rossi[1], N. H. Hendrikse[3], W. V. Vogel[1], E. A. Aalbersberg[1];*
[1]Netherlands Cancer Institute, Amsterdam, NETHERLANDS, [2]NRG, Nuclear Research and consultancy Group, Petten, NETHERLANDS, [3]Erasmus MC, Rotterdam, NETHERLANDS.

Aim/Introduction: Cisplatin as a combination therapy with radiotherapy has proven to be effective in treatment of non-small cell lung cancer (NSCLC) patients. However, treatment with this platinum-based chemotherapy shows heterogeneous response

and there is a risk of nephrotoxicity. Radiolabeled [195mPt] cisplatin has been developed as an imaging tool to determine the biodistribution of cisplatin in vivo and aid in patient selection. The aim of this phase I study was to determine the (radiation) safety, biodistribution, and image quality of [195mPt]cisplatin SPECT/CT scans in NSCLC patients. ***Materials and Methods:*** [195mPt] cisplatin was produced under good manufacturing practice (GMP) with a radiochemical purity of ≥95%. Patients with locally advanced NSCLC received 24 daily fractions radiotherapy with concurrent low-dose cisplatin 1-2 hours before each fraction were included in this study. In the second or third week of treatment 100 MBq [195mPt]cisplatin was given. Planar imaging and SPECT/CT scans were acquired at 1.5, 48, 120, and 168 hours after injection. Image quality was determined by visual inspection. Automated full organ segmentations were made in 3DSlicer (TotalSegmentator), and organ specific activities time-activity curves were generated by fitting mono-exponential curves. Effective and absorbed doses for [195mPt]cisplatin were obtained with S-values from IDAC-Dose 2.1. Any toxicity CTCAE >2 was scored as severe toxicity. ***Results:*** In total, six patients were included (66 years ±4.5, 3/6 male) with an average primary tumor size of 5.2 cm (range 3.0-7.6 cm). Patients received 100.9 ± 3.3 MBq [195mPt]cisplatin at a radioactivity concentration of 11.1 ± 4.9 MBq/ml. No adverse events of grade 3 or higher were observed in any patient. The liver received highest mean [195mPt]cisplatin concentrations with 4.2 ± 0.2 kBq/ml at T=1.5 hours, followed by the kidneys at 3.8 ± 0.8 kBq/ml at T=1.5 hours. The liver and kidneys also showed highest absorbed doses with 48.6 ±7.9 mGy and 38.4 ±7.2 mGy respectively. A mean effective dose of 14.8 mSv ± 1.5 (0.15 ± 0.02 mSv/MBq) was received. Mean tumor to blood ratio was 1.0 ± 0.05, but [195mPt]cisplatin still showed to be suitable for imaging. ***Conclusion:*** [195mPt]Cisplatin is safe to use for imaging in patients with NSCLC, with a mean effective dose of 14.8 mSv ± 1.5 (0.15 ± 0.02 mSv/MBq). The image quality of [195mPt]cisplatin was suitable for imaging, although the tumor uptake was similar to that of blood.

OP-163

Prognostic value of fully-automatic Metabolic Tumor Volume calculation for patients with metastatic lung cancer treated with immunotherapy

O. Humbert[1], *P. Tricarico[1], C. Cheze-Le-Rest[2], T. Pace-Loscos[1], V. Ferrari[1], G. Lamazou[3], R. El Jurdi[3], E. Schalck[3];*
[1]Antoine Lacassagne Cancer Center, Nice, FRANCE, [2]CHU, Poitiers, FRANCE, [3]EuraNova, Marseille, FRANCE.

Aim/Introduction: Total Metabolic Tumor Volume (tMTV), assessed by 18FDG PET, is an effective biomarker to estimate tumor burden, and has demonstrated strong prognostic value for non-small cell lung cancer (NSCLC) patients treated with Immune Checkpoint Inhibitors (ICPI). However, tMTV requires manual delineation of all lesions, which limits its adoption in clinical practice. We aimed to assess the prognostic value of automatic tMTV, using a deep learning (DL) model previously trained for this specific task. ***Materials and Methods:*** Patients with metastatic NSCLC were retrospectively included in two different universitary hospitals (Nice and Poitiers, France). 18FDG PET scans were performed before the start of ICPI in monotherapy (PETbaseline) and 6-8 weeks later (PETinterim1). Tumor response was assessed using PERCIST criteria. tMTV was automatically calculated on both time-points using a 3D U-Net model (Dice Score=0.73) initially trained on 700 other multicentric PET/CT studies manually segmented by 4 nuclear physicians. Median follow-up was 45.2 (39.8-NR) months. Uni- and multivariate cox regressions were performed to identify factors associated with 12-months overall survival (OS) and 6-months progression-free survival (PFS), using tMTV thresholds independently determined in a previous publication (DOI: 0.1136/jitc-2023-007628). ***Results:*** 87 patients were included (Nice=26; Poitiers=61). Median OS was 15 [8.7-22.5] months. Mean tMTV was 99±117 mL at PETbaseline, and 109±225 mL at PETinterim1. At baseline, patients with high tMTV (threshold=50mL) had both decreased 12-months OS (HR= 4.2[2-8.6]; p<0.0001) and 6-months PFS (HR= 3.8[2-7.4]; p<0.0001). At PETinterim1, patients with high tMTV (threshold=57mL) had also decreased 12-months OS (HR= 3.3[1.5-7.3]; p=0.003) and 6-months PFS (HR= 6.9[3.1-15]; p<0.0001); According to PERCIST criteria, 55.6% of patients (35/87) had progressive disease on PETinterim1. Patients with PERCIST progression had lower 12-months OS (HR= 2.6 [1.2-5.7]; p=0.01) and 6-months PFS (HR= 5.1 [2.2-12]; p<0.001). Baseline tMTV and PERCIST criteria were independent prognostic factors for 12-months OS (p= 0.0003 and 0.05, respectively) and 6-months PFS (p= 0.0003 and 0.0006, respectively). A score combining these 2 parameters strongly improved the prognostic stratification of patients, with a 12-months OS of 100% in the low-risk group, 49% in the intermediate-risk group and 34% in the high-risk group (p<0.0001). ***Conclusion:*** The fully automatic calculation of tMTV, using a dedicated DL model, is a strong prognostic marker for NSCLC patients treated with ICPI, both before and early after treatment initiation. PERCIST and baseline tMTV are independant prognostic markers and can be combined to achieve a more accurate prognostic stratification of patients.

OP-164

Correlation of PET Imaging with the Somatostatin Receptor Antagonist ^{68}Ga-SSO120 with Immunohistochemistry and Survival for Theranostics of SCLC

D. Kersting[1], *I. Mavroeidi[2], A. Romanowicz[1], T. Haake[3], J. Wienker[4], M. Metzenmacher[2], K. Darwiche[4], F. Oezkan[4], S. Bölükbas[5], M. Stuschke[6], L. Umutlu[7], M. Opitz[7], M. Nader[1], R. Hamacher[2], J. Siveke[2], J. Winantea[4], W. P. Fendler[1], M. Wiesweg[2], W. E. E. Eberhardt[2], K. Herrmann[1], D. Theegarten[3], M. Schuler[2], H. Hautzel[1];*

Aim/Introduction: Positron Emission Tomography (PET) using the somatostatin receptor 2 (SSTR2)-antagonist satoreotide trizoxetan (68Ga-SSO120) is a novel promising imaging modality for small-cell lung cancer (SCLC), which holds potential for theranostic applications. Here, we correlate tumour uptake in 68Ga-SSO120 PET with SSTR2 expression in immunohistochemistry (IHC). Moreover, we analyse the prognostic value of SSTR2 expression

at initial staging of patients with SCLC in comparison with other established metrices. ***Materials and Methods:*** We screened our institutional database for patients with SCLC who underwent 68Ga-SSO120 PET/CT during initial diagnostic workup. Mean±standard deviation administered activity and uptake time were 141.8±29.0 MBq and 64±16 min. If available within ±2 weeks before/after 68Ga-SSO120 PET, 18F-FDG PET/CT was considered for comparison. Lesion volumes, SUVmax/SUVmean/SUVpeak and corresponding tumour-to-liver ratios (TLR) were estimated. TLG and MTV were calculated from 18F-FDG PET. SSTR2 expression in IHC was evaluated on a 4-level scale and correlated with 68Ga-SSO120 SUVmax and TLRpeak on a lesion level. PET uptake values, IHC SSTR2 score, and clinical parameters were analysed for association with overall survival (OS) and time to treatment failure (TTF) by univariate and multivariate Cox regression (cut-off values identified on data for best separation). ***Results:*** We included 54 patients (median age 65 years, 30 female/24 male, 21 M0/33 M1 according to TNM classification). In 43 patients with available tumour tissue, hottest lesion SUVmax and TLRpeak showed a good significant correlation with SSTR2-expression in IHC (ANOVA $p<0.001$, Spearman's rho 0.86 and 0.81, both $p<0.001$). High SSTR2 expression in IHC, 68Ga-SSO120 SUVmax and TLRpeak of the hottest lesion per patient, whole-body TLRmean, MTV, TLG, M status, and serum LDH were significantly associated with poorer TTF/OS in univariate analysis. In separate multivariate Cox regression (including sex, age, M stage, and LDH) higher hottest-lesion TLRpeak was significantly associated with shorter OS (HR=0.26, 95%CI: 0.08-0.84, p=0.02) and SSTR2 expression in IHC with significantly shorter TTF (HR=0.24, 95%CI: 0.08-0.71, p=0.001) and OS (HR=0.22, 95%CI: 0.06-0.84, p=0.03). In total, 12 patients (22.2%) showed low (<1), 21 (38.9%) intermediate (≥1 but <2), 14 (25.9%) high (≥2 but <5), and 7 (13.0%) very high (≥5) whole-body mean TLRmean. ***Conclusion:*** SSTR2 expression assessed by 68Ga-SSO120 PET and by IHC showed a good correlation and SSTR2 was associated with poorer survival. More than 75% of patients exhibited higher whole-body 68Ga-SSO120 tumour uptake than liver uptake and almost 40% high or very high uptake, indicating the theranostic potential in combination with 177Lu-SSO110 radioligand therapy.

OP-165

Prognostic Value of Tumor Dissemination (Dmax) Derived from Basal ^{18}F-FDG PET/CT in Patients With Non-Small Cell Lung Cancer

S. Pellegrino[1], *R. Fonti[1], R. Morra[2], A. Servetto[2], R. Bianco[2], S. Del Vecchio[1];*
[1]Department of Advanced Biomedical Sciences, University Federico II, Naples, ITALY, [2]Department of Clinical Medicine and Surgery, University Federico II, Naples, ITALY.

Aim/Introduction: The aim of the present study was to test whether a parameter reflecting tumor dissemination (Dmax), derived from basal 18F-FDG PET/CT, may predict clinical outcome in patients with advanced non-small cell lung cancer (NSCLC). ***Materials and Methods:*** Seventy-eight patients (55 men, 23 women) with stage III and IV NSCLC who had undergone whole-body 18F-FDG PET/CT scan at diagnosis were included in the study. Imaging parameters including SUVmax, SUVmean, MTV and TLG of primary lung tumors along with total MTV (MTVTOT) and whole-body TLG (TLGWB) of all malignant lesions were determined by using an automated contouring program setting an absolute threshold for SUV at 2.5. Moreover, the largest distance between two ^{18}F-FDG avid lesions (Dmax) in each patient was measured. Univariate and multivariate analyses of clinical and imaging variables were performed using Cox proportional hazards regression whereas Kaplan-Meier method and log-rank tests were used for survival analysis. ***Results:*** A total of 441 lesions were analyzed including 78 primary tumors, 174 metastatic lymph nodes and 189 distant metastases. In primary tumors, average values of SUVmax, SUVmean, MTV and TLG were 11.80 ± 5.73, 5.37 ± 2.09, 60.61 ± 102.57 mL and 340.36 ± 558.40 g, respectively, whereas mean values of MTVTOT, TLGWB and Dmax were 155.90 ± 176.94 ml, 851.08 ± 1032.17 g and 29.98 ± 20.98 cm, respectively. Univariate analysis was performed including age, gender, histology, stage, MTVTOT, TLGWB, Dmax and imaging parameters derived from 78 primary lung tumors. Overall survival (OS) was predicted by MTVTOT (p=0.0145), TLGWB (p=0.0518), Dmax (p=0.0031) and stage (p=0.0130). Then, these predictive variables along with age were included in multivariate analysis and only Dmax was retained in the model ($\chi2=7.3130$, p=0.0068). By Kaplan-Meier method and log-rank test, patients with Dmax ≤ 8.8 cm had significantly better OS as compared to patients with Dmax > 8.8 cm ($\chi2=5.8673$, p=0.0154). ***Conclusion:*** Dmax by reflecting tumor dissemination can predict overall survival in NSCLC patients.

OP-166

Assessment of 68-Gallium-Fibroblast Activation Protein Inhibitor (FAPI) PET/CT and ^{18}F-Fluorodeoxyglucose (FDG) PET/CT in Non-Small Cell Lung Cancer: A Comparative Analysis

S. Sathoo, *D. Halanaik, R. Manju, S. Pradeep, V. Madivanane;*
Jawaharlal Institute of Postgraduate Medical Education & Research, Puducherry, INDIA.

Aim/Introduction: Lung cancer presents a significant global health burden, necessitating accurate staging for effective management. While ^{18}F-FDG PET-CT has been a cornerstone in staging, the emergence of 68Ga-FAPI PET-CT offers a promising alternative due to its distinct targeting of cancer-associated fibroblasts. This study aims to compare ^{18}F-FDG PET/CT and 68Ga-FAPI PET/CT in evaluating Non-small cell lung cancer (NSCLC). ***Materials and Methods:*** This single-centre study recruited 21 newly diagnosed treatment-naive NSCLC patients. All the participants underwent 68Ga-FAPI and ^{18}F-FDG PET/CT imaging within one week for baseline staging. Primary lesions, lymph nodes and distant metastases were assessed and compared between the two tracers. Semi-quantitative parameters like Standardised Uptake Value Maximum (SUVmax) based on body surface area and Tumour-to-Background Ratio (TBRmax) were measured and analysed using Paired T-tests. The tumours were staged using the 8th edition of TNM classification of lung cancers. ***Results:*** Among the participants (mean age 57.3 ± 10 years; 13 males, 8 females), 68Ga-FAPI PET/CT identified more metastases in lymph nodes (80 vs 69), bone (142 vs 128), liver (7 vs 5), pleura (19 vs 13), lung (36 vs 31), and brain (1 vs 0) compared to ^{18}F-FDG PET/CT. Additionally, 68Ga-FAPI demonstrated higher SUVmax in primary lesions (4.7±1.6 vs 3.7±1.4, p=0.002) as well as lymph nodes (3.2±1.3 vs 2.2±1.2, $p<0.001$), skeletal (3.7±1.7 vs 2.1±0.9, $p<0.001$), liver (5.3±2.5 vs 2.5±0.6, p=0.04), pleural (2.1±0.9 vs 1.3±0.7, $p<0.001$), and adrenal (3.3±1 vs 2.2±0.5, p=0.009) metastases. The TBRmax was significantly higher in 68Ga-FAPI scans across all these lesions ($p<0.05$). 68Ga-FAPI improved metastasis visualisation in bone, brain, and liver compared to ^{18}F-FDG due to reduced background uptake. No statistically significant differences were found in the SUVmax (2.0±1.0 vs 1.8±0.9, p=0.054) and TBRmax (3.8±2.1 vs 3.3±1.7, p=0.052) of lung metastases. The 68Ga-FAPI PET/CT scan resulted in the upstaging of the N stage in three patients

and, in two cases, led to an upstaging of the overall TNM stage. ***Conclusion:*** 68Ga-FAPI PET/CT outperforms ^{18}F-FDG PET/CT in detecting metastatic lesions in lymph nodes, bone, liver, pleura, lung, and brain in non-small cell lung cancer (NSCLC) patients. With higher SUVmax and enhanced tumour-to-background ratio, 68Ga-FAPI may refine NSCLC staging and offer therapeutic potential for metastatic cancers. Furthermore, the on-site generation of Gallium-68 streamlines radiotracer availability for 68Ga-FAPI PET/CT imaging, while its minimal patient preparation requirements improve accessibility and flexibility in clinical settings.

Aim/Introduction: To evaluate T&N-staging diagnostic performances of [68Ga]Ga-FAPI-46(FAPI) and ^{18}F-FDG PET/CT(FDG) in a suspected/confirmed lung cancer(LC) surgical cohort. ***Materials and Methods:*** Patients were enrolled in a prospective monocentric trial (EudraCT:2021-006570-23) to perform PET/CT with investigational FAPI, in addition to conventional-staging-flow-chart (including FDG). For the current purpose, only surgical patients were included. PET scans were interpreted by at least three readers (expert in oncological/non-FDG-PET imaging). Visual-positivity-criteria was defined for T&N as uptake higher than mediastinal-blood-pool (MBP) (excluding physiological/paraphysiological). Agreement(%) between FAPI/FDG and histopathology was assessed by TNM-StagingAJCC8thEdition. PET-semiquantitative-parameters were measured for T&N: SUVmax, target-to-background-ratios (TBRs:SUVmaxLesion/SUVmeanBackground) using MBP, liver(L) and pulmonary-parenchyma(P) as backgrounds.FAPI-PET/CT visual and semiquantitative performances (ROC-AUC for SUVmax and TBRs) were analyzed per-patient and per-T&N-regions, compared to FDG-PET/CT, with surgical-histopathology as standard-of-truth. ***Results:*** 63 FAPI were performed out of 64 patients enrolled (26May22-30Nov23). 50/63 patients underwent surgery and were included (mean age:72y[45-87];M:F=33:17). Agreement(%) with histopathological-T&N-StagingAJCC8thEdition (FAPIvsFDG) was: T-66% vs 58%, N-80.4% vs 71.7%. When T&N were dichotomized (0vs1) agreement(%) increased respectively to T-80% vs 80%, N-80.4% vs 73.9%. The results of patients/region-based analyses are presented.Analyses T-per-patient (n=50), Visual (FAPIvsFDG): TN 4 vs 3, FN 2 vs 7, TP 42 vs 37, FP 2 vs 3; sensitivity 95% vs 84%, specificity 67% vs 50%, PPV 95% vs 93%, NPV 67% vs 30%, accuracy 92% vs 80%.Analyses T-per-region (n=59), Visual (FAPIvsFDG): sensitivity 79% vs 66%, specificity 67% vs 50%, PPV 95% vs 92%, NPV 27% vs 14%, accuracy 78% vs 64%. 6/59 resulted benign: 1 actinomyces and 1 granulomatous abscesses (concordant FDG&FAPI-FP), 4 inflammatory nodules (1 FDG-FP/FAPI-TN and 3 concordant-TN); 53/59 resulted malignant: 37 adenocarcinomas (9 concordant FDG&FAPI-FN, predominantly lepidic and in 1 case mucinous; 6 FDG-FN/FAPI-TP; 22 concordant FDG&FAPI-TP-the majority acinar),13 SCC (1 concordant FDG&FAPI-FN; 1 FDG-FN/FAPI-TP; 11 concordant FDG&FAPI-TP), 1 carcinoid (concordant FDG&FAPI-FN).PET-indexes performed similarly, slightly in favour of FAPI, although not significantly different (FAPIvsFDG): SUVmax-AUC=0.65(cut-off=1.3, accuracy=0.85) vs 0.48(12;0.80), TBR-L-AUC=0.62(0.9;0.8) vs 0.47(4.8;0.8), TBR-MBP-AUC=0.61(2.3;0.71) vs 0.50(7.4;0.81), TBR-P-AUC=0.59(6.5;0.66) vs 0.54(3.8;0.73). Analyses N-per-patient (n=46; 34 pN0 and12 pN+:8pN1, 4pN2); Visual (FAPIvsFDG): TN 31 vs 26, FN 6 vs 4, TP 6 vs 8, FP 3 vs 8; sensitivity 50% vs 67%, specificity 91% vs 76%, PPV 67% vs 50%, NPV 84% vs 87%, accuracy 80% vs 74%. ***Conclusion:*** In a suspected/confirmed LC surgical cohort, diagnostic performances for T&Nstaging were slightly in favour of FAPI in all cases (except for N-sensitivity, which remains suboptimal). Further analyses are ongoing (non-surgical-cohort, N-per-region and FAP-expression-IHC).

TROP Session: Thyroid Committee: Radioiodine Therapy in Bengin and Malignant Thyroid Disease: An Evergreen Treatment

OP-168

The effect of radioiodine therapy I-131 in patients with non-toxic nodular goitre

S. Abdelrazek, *P. Szumowski, J. Mysliwiec, W. Madra, I. Sulima; Medical University of Bialystok, Bialystok, POLAND.*

Aim/Introduction: Simple goitre is defined as the enlargement of the thyroid gland, in the absence of autoimmune thyroid disease, malignancy, or inflammation, still constitutes a major diagnostic and therapeutic challenge. Radioiodine therapy (RAIT) is non-invasive, safe and cost effective method of therapy for reduction of goitre. There is no consensus regarding the optimum treatment of benign non-toxic goitre. Randomised studies have shown that levothyroxine has poor evidence of efficacy and is inferior to radioiodine therapy regarding goitre reduction. The aim of our study was to evaluate the short term efficacy of radioiodine therapy to reduce thyroid volume with minimal risk of hypothyroidism in patients with non-toxic nodular goitre. ***Materials and Methods:*** We treated 980 patients, aged 20-90 years; (76%) of the studied groups were female and (24%) male; the mean radioiodine uptake (RAIU) was 39% and thyroid volume ranged between 44-170ml. Qualification of these patients were based on normal levels of serum fT4, TSH and characteristic appearance on thyroid scans and ultrasound. Malignant changes were excluded in all suspected nodules by fine needle aspiration biopsy. The activity dose was calculated by the use of Marinelli's formula and ranged between 200 -800 MBq. The mean absorbed dose was 199.4 ± 23.8 Gy, and was proportional to thyroid volume. Thyroid ultrasonography, and thyroid scan with RAIU at 24hours was done before and after 12 months of RAIT. Follow up control for the evaluation of fT4, TSH was done every 6 weeks. ***Results:*** After 12 months of radioiodine therapy a mean thyroid volume reduction of 48% was achieved. Approximately half of the effect is obtained within the first 3 months. Euthyroidism persist in 92% of patients, and hypothyroidism develop in 8% of patients. All patients were highly satisfied; with improvement in

obstructive symptoms and exercise tolerance in the majority of patients ***Conclusion:*** Radioiodine is non-invasive, safe and cost effective method of therapy for reduction of the goiter volume and should not be restricted to elderly patients, or to patients with high operative risk, but should be used as first choice in every patient with non toxic nodular goitre with thyroid volume > 40 ml especially in patients with special profession. Surgery should be reserved as first choice if malignancy is suspected. The reduction of thyroid volume with low percent of hypothyroidism, were due to well accurate measurement of administered activity, relatively high effective half-life, & well-organised follow up.

OP-169

Analysis of parameters associated with Graves' disease relapse in patients treated with radioiodine

L. Urso[1,2], *V. Lombardo[1,2], S. Ceron[3], L. Manco[4], F. Borgia[1,2], C. Cittanti[1,2], L. Uccelli[1,2], E. Tonini[4], M. Verrienti[5], M. R. Ambrosio[5], A. Turra[4], M. C. Zatelli[5], M. Bartolomei[2];*
[1]Department of Translational Medicine, University of Ferrara, Ferrara, ITALY, [2]Nuclear Medicine Unit, Onco-Hematology Department, University Hospital of Ferrara, Ferrara, ITALY, [3]University of Ferrara, Ferrara, ITALY, [4]Medical Physics Unit, University Hospital of Ferrara, Ferrara, ITALY, [5]Department of Medical Sciences, University of Ferrara, Ferrara, ITALY.

Aim/Introduction: Graves' disease (GD) is the most frequent cause of hyperthyroidism due to functional upregulation of the whole gland by autoimmune stimulation. Radioiodine treatment (RAI) is an effective therapeutic option for GD patients allowing a definitive resolution of hyperthyroidism in ~75-85% of patients. Aim of this work is to analyse the parameters associated to GD relapse in patients treated with RAI. ***Materials and Methods:*** GD patients treated with dosimetrically determined activities of 131I between 2010 and 2022 with a minimum follow-up of 2 years were retrieved. Clinical parameters (including gender, age at RAI, FT4 and Thyrotropin Receptor Antibodies (TSHrAb) values at diagnosis, thyroid volume at ultrasound (US) within a month from RAI, 24h uptake of 131I, GREAT score and orbitopathy) were collected. RAI was performed by a dosimetric approach with gamma probe (Capintec Inc.) and the administered activity was calculated to achieve 300Gy to the gland, considering the 24h uptake and thyroid volume according to US. The evidence of GD relapse, defined as clinical and biochemical evidence of hyperthyroidism after RAI, was considered as outcome at multivariate analysis and one-way ANOVA test. ***Results:*** 73 GD patients (16 males and 57 females; median age 55±12 years) treated with RAI were collected. The administered doses of 131I ranged between 256 and 592 MBq (median 333±88.8 MBq). After a mean follow-up of 6.2±3.7 years, 12 patients (16.4%) showed GD relapse. The mean intercurrent time between RAI and relapse was 12±16.6 months. At multivariate analysis, patients with relapsed GD demonstrated significantly higher mean 24h uptake (82.4±10.6% vs 63.1±16.6%; p=0.003), thyroid volume at US (24.7±12.6 ml vs 17.4±9.1 ml; p=0.02) and GREAT score (4±2 vs 2.5±1.7; p=0.01) as compared to non-relapsing patients. Moreover, one-way ANOVA confirmed statistically significant difference in 24h uptake (F=[14.45]; p=0.003), thyroid volume at US (F=[5.28]; p=0.02) and GREAT score (F=[7.00]; p=0.01) among the 2 groups. ***Conclusion:*** our cohort of GD patients treated with RAI confirms the efficacy of this therapeutic approach that allowed a definitive resolution of hyperthyroidism in 83.6% of cases. Patients who showed GD relapse - as expected - were those with the largest thyroid volumes. Surprisingly, we found significantly higher values of 24h thyroid uptake in relapsed patients, leading us to conclude that in glands that are very avid for iodine, predictive dosimetry using gamma probe may sometimes underestimate the 131I activity needed for an effective treatment. These findings deserve confirmation in larger cohorts.

OP-170

The efficacy of radioiodine therapy in patients with toxic adenoma in subclinical hyperthyroidism

S. Abdelrazek, *J. Mysliwiec, P. Szumowski, W. Madra;*
Medical University of Bialystok, Bialystok, POLAND,

Aim/Introduction: Subclinical hyperthyroidism (SCH) is a state of increased thyroid function with few or no clinical definitive signs or symptoms of hyperthyroidism, characterized by a subnormal serum TSH level, with normal serum levels of free thyroxine (FT4), triiodothyronine (TT3) and/or free triiodothyronine (FT3). The prevalence of endogenous SCH varies considerably, between 0.6 and 16% . SCH is associated with increased risk of coronary heart disease mortality, incident atrial fibrillation, heart failure, fractures and all-cause mortality in patients with serum TSH levels < 0.1 mIU/l (grade 2 SCH). The risk of progression to overt hyperthyroidism (OHT) varies between studies 1-15% / year. The aim of our study was to assess the influence of radioiodine (131I) therapy on the achievement of euthyroidism, prevention of adverse effects on the cardiovascular and prevent evolvement to overt hyperthyroidism. ***Materials and Methods:*** We treated 1950 patients with toxic adenoma (TA) referred to our department during the last 10 years, aged 20-85 years; 88% of them were females and 12% males;. Some of the patients were treated with antithyroid drugs for 1-3 months before radioiodine therapy (120 patients). Malignant changes were excluded in all nodules by fine-needle aspiration biopsy. All the patients had serum TSH levels <0.1 mU/l (grade 2 SCH) and effective T-half was more than 3 days at the time of treatment. The activity dose was calculated by the use of Marinelli's formula and ranged between 200 and 800 MBq. The absorbed dose (Gy) ranged between 180 and 300, and was proportional to thyroid volume. Follow-up control was done every 8 weeks. ***Results:*** Euthyroidism achieved in 99% of patient and 1% of patients develop hypothyroidism. One patients develops Graves' disease and received second dose of radioiodine therapy. In all of the patients, the symptoms and signs of subclinical hyperthyroidism disappeared (palpitation, tachycardia, atrial fibrillation, exercise tolerance improved, the blood pressure normalised and the quality of life improved). ***Conclusion:*** The achievement of euthyroidism and the remission of the symptoms and signs of subclinical hyperthyroidism, were due to good diagnosis, well preparation of the patients; accurate measurement of administered activity, effective half-life, and well-organised follow-up. We recommend early treatment of subclinical hyperthyroidism, and long period of follow-up to evaluate the long-term effect of radioiodine therapy.

OP-171

Autonomously Functioning Thyroid Nodules (AFTN): comparison between use of Radioactive iodine 131I (RAI) in combination with Percutaneous Microwave Thermoablation (PMWT) and Percutaneous Microwave Thermoablation (PMWT) alone.

B. Criscuoli[1], *F. Salvatori[2], C. Manni[1], C. Mincarelli[2], S. Alborino[2], F. Capoccetti[1];*
[1]Nuclear Medicine Unit, Macerata Hospital, AST Macerata, Italy, Macerata, ITALY, [2]Interventional Radiology Unit, Macerata Hospital, AST Macerata, Italy, Macerata, ITALY.

Aim/Introduction: In AFTN, RAI is the first-line therapy choice in most of patients,surgery rarely is necessary. Minimally invasive US-guided techniques (RFA,Laser,recently MWT)have become increasingly available in benign thyroid nodular disease, whereas useful in AFTN is debated. Purpose to compare effictiveness and safety of combined RAI/PMWT and PMWT alone in AFTN. ***Materials and Methods:*** From May 2021,25 patients with AFTN(13 F,12 M;aged 51-84;mean 65) divided as follows:GroupA (9/25)received RAI and subsequently PMWTGroupB (16/25) treated with PMWT alone 3/16 of GroupB was moved to PMWT alone after evidence of high dosimetric-previsional RAI activity due to high AFTN volume. Inclusion criteria: clinically symptomatic or laboratory functional-thyroid overactivity,compressive symptoms, cosmetic concerns, solid nodule ≥20%,≥ 2 cm diameter,"hot nodule"target on Thyroid-Scintiscan with99mTc-Pertecnetate;2FNA cytology pathologically-confirmed benign(TIR2sec ITC CS 2014).Group A: mean RAI-activity adminstered after dosimetry (300 Gy target)471,88 MBq of 131 I (range 113-1395),after clinical revaluation,restore of euthyroidsm/persistence of symptoms and/or nodular target the patients move to PMWT,within 3months.GroupA e GroupB: US-guided PMWTA was carry-out under local anesthesia through Microwave antenna: 10-15Wx10-15 minutes.7-10 days after PWTA thyroid-hormon levels was remeasured.Follow-up scheduled at 1,6,12 months through: clinical/thyroid physical examination,rating symptomatology with Compressive Score(CS on a 10cm visual-analog scale),Aesthetic Score (AS from 1-no palpable to 4 palpable/visible in all positions),thyroid-hormone serum levels,US to record Volume of AFTN(V-AFTN) and volume reduction rate%(VRR).Functional therapeutic success defined as restoration of euthyroidism and volumetric therapeutic success as volume reduction ≥50 % ***Results:*** GroupA: no peri-procedural major complications occurred after PMWT 7/9 restore euthyrodism 2/9 hypothyroidism after-RAI.GroupB: 4/16(25%) showed transient increase of hormone levels strictly supervised in ¾ and 1/4 develop 10 days after PMWT atrial fibrillation pharmacologically reverted; in 6 months all the patients restore baseline hormone levels.From baseline to 12 mth follow-up:GroupA: CS from 2,8 to 1,7,AS from 3,4 to 2,1;mean vAFTN from 22,0 mL (range 93-2,8 mL)to 8,8 mL (range 54-0,24 mL)VRR mean of 72,5 %(range 41,9-95%)Functional and volumetric success: 82 and 91 %GroupB: CS from 4,5 to 1,8,AS from 3,4 to 2,5;a mean vAFTN from 32,5 mL(range 216-3 mL)to 18,6 mL(range 160-0,61 mL)VRR mean of 58,93 %(range 30,41-89,75%) Functional and volumetric success: 100 and 75 % ***Conclusion:*** Use of combined RAI/PMWT demonstrated safety, high-successful rate,obtaining restore of euthroidsm and nodule-shrinkin.We underline that in several cases,mainly for large AFTN,should be primarily proposed PWMT with a satisfying security profile too. We encurage a personalized treatment approach,based to every singol centre capability. ***References:*** Giovannella Eur J Nucl Med Mol Imaging.2024.

OP-172

Delaying Initial Radioiodine Therapy Does Affect Response in Intermediate Risk Differentiated Thyroid Cancer in Latin-American Population

S. Medina-Ornelas;
Ángeles Lindavista, Mexico City, MEXICO.

Aim/Introduction: the optimal time of initiating radioactive iodine (RAI) therapy for differentiated thyroid cancer (DTC) patients is controversial. we investigate the relationship between the timing of initiating RAI and the clinical response based on dynamic stratification risk in intermediate-risk DTC patients in the Mexican population ***Materials and Methods:*** we evaluated 132 patients with intermediate-risk DTC who received a dose of RAI to 100-150 mCi and were retrospectively reviewed. the patients were divided into 2 groups agreeable initial therapy (between total thyroidectomy and initial RAI), called time interval therapy (TIT): Group A: TIT < 6 months (n=69), and Group B: TI ≥ 6 months (n=63). Six and twelve months after RAI, we followed up with these patients and evaluated the therapy response with neck ultrasound, whole-body scan SPECT/CT, and measures of thyroglobulin and antibodies anti-thyroglobulin. According to the therapy stratification system, the therapy responses to RAI were assessed as either excellent response (ER), biochemical incomplete response (BIR), indeterminate response (IR) or structural incomplete response (SIR) at every follow-up. We conducted a univariate and multivariate analysis to determine different factors associated with different responses. A $p < 0.05$ was considered to be statistically significant. ***Results:*** Group A had significantly lower BIR rates (14.2 vs 38.2 and 4.7 vs 39.5, all P<0.05, respectively) and higher ER rates (72.8 vs 34.1 and 86.2 vs 44.2, all P<0.05, respectively) than group B during dynamic follow-ups. By univariate and multivariate analyses, prolonged TIT (HR: 5.66, 95%CI: 1.811-22.018, P=0.003), histology aggressive (HR: 7.98, 95%CI: 3.022-21.567, P=0.002), nodal extension (HR: 5.66, 95%CI: 1.199-14.257, P=0.005) were manifested to be independent risk factors for IR, SIR and BIR. Doses of 150 mCi were statically significant in patients with more than two risk factors for higher rates of ER (p=0.0045) ***Conclusion:*** early treatment with RAI is associated with greater biochemical response, and ER. Delayed initial RAI (≥6 months after thyroidectomy) is associated with poor response and poor outcome. Doses of 150 mCi had better response in patients with more than two risk factors.

Predicting post-treatment persistent/metastatic disease by ^{131}I whole-body scintigraphy in patients with differentiated thyroid cancer

F. Volpe[1], *R. Megna[2], C. Nappi[1], E. Zampella[1], V. Gaudieri[1], L. Piscopo[1], E. Di Donna[1], M. Petretta[3], A. Cuocolo[1], M. Klain[1];*
[1]Department of Advanced Biomedical Sciences, University Federico II, Naples, Italy, Napoli, ITALY, [2]Institute of Biostructure and Bioimaging, National Research Council, Naples, Italy, Napoli, ITALY, [3]Scientific Institute for Research, Hospitalization and Healthcare SYNLAB SDN, Naples, Italy., Napoli, ITALY.

Aim/Introduction: In patients with differentiated thyroid cancer (DTC), undergoing 131I therapy after surgery, post-treatment whole-body scintigraphy (WBS) is the method of choice to identify iodine avid local or distant metastasis. A model for predicting persistent/metastatic DTC after surgery based on post-treatment WBS results was developed using a decision tree (DT) algorithm (1). We sought to externally validate this prediction model in a cohort of Italian patients and to compare the obtained results with a further developed internal model. ***Materials and Methods:*** Data were collected from 1994 to 2021 in patients with DTC referred to the Federico II University Hospital of Naples for 131I therapy after surgery. Age, sex, histology, T stage, N stage, risk classes, remnant estimation, thyroid-stimulating hormone, and thyroglobulin (Tg) levels were identified as potential predictors of post-therapy WBS results. For external validation, the variables N stage and Tg cut-off values of 7.1, 23.3, and 35.0 ng/mL were put into the DT model previously developed using the same software package. For constructing the internal model, potential predictors were selected by metrics obtained with DT analysis as well as by multivariable logistic regression analysis using the10-

fold-cross-validation method. ***Results:*** The study population included 836 patients (78% women, age 44±15 years). A total of 99 (12%) patients had positive post-therapy WBS. Among these latter patients, 35 (4%) had positive N stage. In the entire cohort, mean Tg levels were 121±933 ng/mL. We obtained a DT with the first ramification due to Tg cut-off at 35.0 ng/mL. For patients with Tg values below this cut-off, N stage determined a second and last split. No further ramification was found for patients with Tg above 35.0 ng/mL. The area under receiver operating characteristic (ROC) curve for predicting positive post-therapy WBS was 58% (95% confidence interval, CI, 53-62%), and positive and negative predictive values were 0.52 and 0.99. The best internal model was obtained with Tg levels, T stage, N stage, and administered 131I activities as significant covariates at multivariable logistic regression. The area under ROC curve for predicting positive WBS was 75% (95% CI 68-81%), and positive and negative predictive values were 0.90 (95% CI 0.88-0.92 and 0.68-0.99). ***Conclusion:*** In our cohort, the previously proposed DT model, considering only N stage and Tg levels, has a limited value for predicting post-therapy 131I WBS findings. The internal model also including T stage and administered 131I activities demonstrates a higher predictive value. ***References:*** 1)https://doi.org/10.1007/s00259-023-06239-8.

OP-174

Factors Affecting Survival and Prognosis in Bone Metastatic Differentiated Thyroid Cancer

E. Cansu Çay, *G. Uçmak, B. B. Demirel;*
Ankara Dr. Abdurrahman Yurtaslan Oncology Training and Research Hospital, Ankara, TÜRKIYE.

Aim/Introduction: Bone metastases (BM) occur in 2-13% of patients with differentiated thyroid carcinoma (DTC). BM is the second most common site of distant metastasis after the lung. Multimodal treatment approaches with radioiodine therapy(RAI) are important for disease control. In our study, we aimed to investigate the factors affecting prognosis and survival in the diagnosis-follow-up processes in patients with BM-DTC. ***Materials and Methods:*** Sixty two patients with BM-DTC who were followed up and treated in our clinic between 1990 and 2024 were included in the study.Demographic and clinico-pathologic characteristics of the patients are summarized in Table 1. Biochemical findings during the follow-up period, RAI doses and processes, surgery and radiotherapy (RT) due to BM, use of tyrosine kinase inhibitors (TKI) and bisphosphonate, and follow-up results were recorded. The impact of clinical, pathologic and treatment practices on survival was evaluated using Kaplan-Meier and Cox Regression analysis. ***Results:*** The mean age at diagnosis was 52.6±11.2 years (17M, 45F). BM was present in 49 patients(79%) at diagnosis time. During the follow-up period, 15(24.2%) patients had a single BM, while 47(75.8%) patients had multiple BM.All patients received RAI treatment at least once. Surgical treatment (metastasectomy) was performed in 38(61.2%) and RT in 47(75.8%) patients. The median total RAI dose was 1000(540-1285) mCi. The median number of RAI treatments was 4(1-7). One patient with BM-DTK was cured with RT and RAI treatment and one patient was cured after metastasectomy and RAI treatment. Progression-free survival (PFS) was 102 months (95% CI 76.7-127.3) and overall survival (OS) was 111 months (95% CI 79.2-142.7).When the effect of disease characteristics on mortality and progression was investigated; age, BM at diagnosis, number of BM, postoperative Thyroglobulin (Tg) value were found to be effective on progression and mortality ($p<0.05$). Mortality was found to increase with age and according to ROC analysis, age >53 years was statistically significant in affecting OS. In addition, mortality was found to increase with postoperative Tg, and according to ROC analysis, Tg>36.4 ng/mL was statistically significant in affecting OS.The 5-year PFS was 54%, 10-year PFS 35% and 15-year PFS 30%. In addition, 5-year OS was 57%, 10-year OS was 44% and 15-year OS was 33%. ***Conclusion:*** As a result of the single-center long-term follow-up data; it is thought that long survival times can be achieved with a personalized dynamic approach and treatment at the time of diagnosis and during the follow-up period.

OP-175

Predictors of Disease Recurrence Following Radioactive Iodine Therapy in Pediatric Well-Differentiated Thyroid Cancer

A. Kiliçaslan[1], *B. Cagdas[1], M. N. Azili[2], N. C. M. Gülaldi[1];*
[1]University of Health Sciences, Ankara Bilkent City Hospital, Department of Nuclear Medicine, Ankara, TÜRKIYE, [2]Ankara Yildirim Beyazit University, Ankara Bilkent City Hospital, Department of Pediatric Surgery, Ankara, TÜRKIYE.

Aim/Introduction: This study aimed to investigate the relationship between age, gender, tumor size, radioactive iodine dose, multifocality, metastasis status, and histopathological types in patients with recurrence after 131I (RAI) treatment in childhood well-differentiated thyroid cancer. ***Materials and Methods:*** 36 patients (30F, 6M, 4-18 years) who underwent bilateral total thyroidectomy for well-differentiated thyroid cancer, and who received RAI after surgery were included in the study. All patients were classified as low-, intermediate- and high-risk based on post-operative histopathology, tumor size, multifocality, metastatic lymph node status, stimulated thyroglobulin and anti-thyroglobulin values before RAI, and neck USG. Patients over 40 kg were given RAI doses determined by the empirical method applied to adults according to risk assessment. Patients under 40 kg, 30-50 MBq/kg for ablation in the low-risk group, 51-100 MBq/kg for adjuvant treatment in the intermediate-risk group, and 101-200 MBq/kg for neo-adjuvant treatment in the high-risk group. 18F-FDG PET/CT scan was performed for the high-risk group before RAI. Tg, anti-Tg, TSH values, and neck USG were followed up at least 8 months after RAI, and treatment efficacy was evaluated. ***Results:*** 2 follicular carcinoma (FC), 1 NIFT-P, 18 papillary thyroid carcinoma (PTC), 6 PTC-FC, 8 PTC-microcarcinoma and 1 PTC-microcarcinoma-NIFT-P histopathology were treated with RAI. 14 patients had multifocal foci. Recurrent disease was detected in 6 patients in the post-RAI period. Linear regression analysis showed that Tg and Anti-Tg level elevations in the pre-RAI period after total thyroidectomy predicted disease recurrence and formed a connection model (Tg R2:0.120 $p=0.052$, Anti-Tg R2:0.099 $p<0.05$). The correlation between tumor diameter, number of metastatic lymph nodes, post-RAI Tg, Anti-Tg, and TSH values was evaluated with Spearman's rho correlation test in all groups which were found to be homogeneously distributed. Tumor diameter was significantly correlated with Tg positivity and recurrence in the post-RAI period and central and lateral neck lymph node dissection was significantly correlated with the number of metastatic lymph nodes ($p<0.05$). Histopathological poor variant type or multifocal disease was insufficient to predict recurrence. ***Conclusion:*** In the risk classification of RAI treatment planned after total thyroidectomy in well-differentiated thyroid cancer in the pediatric group, histopathological tumour diameter formed a positive model in predicting recurrence. We suggest higher empirical radioiodine doses in this group. In addition, routine application of central lymph node dissection is important for

preventing local and lateral lymph node recurrences and should be taken into account for risk stratification before RAI treatment.

OP-176

Pediatric Papillary Thyroid Carcinoma: 14 Years Of Clinical Experience

D. Silva[1], *M. Lopes-Pinto[2], S. Ribeiro[3], I. Próspero[1], D. Barbosa[1], N. Vasconcelos[1], J. C. Ferro[1], R. Ferreira[1], S. F. Castro[1], G. Ferreira[1], L. Violante[1], J. P. Teixeira[1], H. Duarte[1], F. Leite[1], I. L. Sampaio[1];*
[1]Instituto Português de Oncologia do Porto Francisco Gentil, Porto, PORTUGAL, [2]Unidade Local de Saúde de Santa Maria, Lisboa, PORTUGAL, [3]Unidade Local de Saúde de São João, Porto, PORTUGAL.

Aim/Introduction: Differentiated thyroid carcinoma (DTC) is rare in children (<1% of tumors), representing 2% of all DTC cases, and has an excellent prognosis. Nevertheless, it's usually diagnosed at more advanced stages, and associated with higher recurrence rates compared to adults. Among risk factors, we find radiation exposure, thyroid nodules and autoimmune thyroiditis, other autoimmune diseases, and family history. This study presents clinical features and outcomes over 14 years of experience with Papillary Thyroid Carcinoma (PTC) in children. ***Materials and Methods:*** Retrospective analysis of pediatric patients with PTC treated in an oncologic institution between 2010 and 2023. ***Results:*** Thirty-five patients were included in this study, 27 of whom were female, with a mean age of 15 years at the time of diagnosis [10-17]. Nineteen patients had at least one risk factor (mostly family history), 11 children presented symptoms leading to diagnosis (mainly cervical mass) and 4 patients had previous thyroid pathology (hypothyroidism and goiter). Regarding staging, 18 tumors were classified as T1, eight T2, eight T3, and one T4. Ten patients presented lymph node involvement. Seven patients underwent surgical conservative treatment (hemithyroidectomy), and 28 patients were submitted to total thyroidectomy, complemented by lymph node dissection in 7 cases. After surgery, 12 patients remained in surveillance, all of them classified as ATA low risk, and 23 underwent radioactive iodine therapy (RAI). The majority received only 1 treatment [1-5] and mean activity administered per cycle was 3.5 GBq [1.8 - 6.1]. Eight patients reported mild symptoms after RAI, most commonly nausea, effectively managed with antiemetics. Four patients (20%) in the RAI group were upstaged, due to pulmonary metastasis detection at post-therapy scintigraphy. The average follow-up time for the group (n=35) was 8 years [1-14]. According to medical records, there were no medium/long-term side effects until this date. All patients remain alive, with three presenting persistent but stable disease (1 cervical, 1 pulmonary, and 1 elevated Tg without structural evidence of disease, after 2, 5, and 4 RAI cycles, respectively). ***Conclusion:*** In comparison to adults, children have higher recurrence rates and longer follow-up time. This study confirms excellent survival in pediatric PTC and reinforces RAI's role in remnant ablation, treatment, and disease upstaging in post-therapeutic scintigraphy. Metastatic pulmonary unknown disease was detected in 4 patients, 3 cured with RAI. RAI treatment was effective in the majority of patients, with no recurrence case registered to date, while maintaining a very favorable toxicity profile.

The diagnosis of inflammatory cardiac diseases:the role of ^{18}F-FDG PET/MRI compared to pet and MRI alone

L. Burroni1, *G. Argalia[1], M. Fogante[2], F. M. Fringuelli[1], G. Biscontini[1], P. E. Pirani[2], A. Palucci[1], C. Romagnolo[1], N. Schicchi[3], C. Cottignoli[1], G. Argalia[2];*
[1]Nuclear Medicine, Ancona, ITALY, [2]Maternal-Child-Senological-Cardiological Radiology and Outpatient Ultrasound, Department of Radiological Sciences, Ancona, ITALY, [3]Cardiovascular Radiological Diagnostics, Department of Radiological Sciences, Ancona, ITALY.

Aim/Introduction: PET/MRI is an emerging multimodality technique allowing the synchronous acquisition of MRI anatomical and functional data and PET metabolic activity, with excellent spatial correlation. Our aim was to evaluate the added value of integrated 18F-FDG-PET/MRI systems, compared with MRI and PET performed separately, in the diagnosis of inflammatory cardiac diseases. ***Materials and Methods:*** We retrospectively enrolled all consecutive patients who underwent 18F-FDG-PET/MRI at our department for clinical suspicion of myocarditis or endocarditis and with an inconclusive echocardiography from September 2022 to January 2024. Exclusion criteria included patients with electrical devices and valve prostheses deemed unsafe for 3Tesla MRI, claustrophobic patients, pregnant women, and patients with pre-exam glucose concentration >200 mg/dL. Before the examination, all patients must follow a carbohydrate-free fat-rich diet, which is necessary to suppress the physiological myocardial 18F-FDG

uptake. 18F-FDG-PET/MRI scans were performed with a hybrid PET/MRI tomograph enabling simultaneous acquisition of PET and 3Tesla-MRI images. Contrast-agent was injected intravenously. MRI and PET images were initially evaluated separately by the Radiologist and the Nuclear Medicine physician and then PET/MRI analysis was performed with a multidisciplinary approach. ***Results:*** Overall, 20 patients were included, 9 with suspected myocarditis and 11 with suspected endocarditis. In patients with suspected myocarditis MRI was negative in 2/9 and inconclusive in 7/9. PET was negative for active inflammation in 9/9. The review of the hybrid PET/MRI images confirmed the absence of ongoing inflammation, suggesting an old inflammatory process in the MRI imaging, reclassifying 7/9 (78%) cases. In patients with suspected endocarditis MRI was positive in 1/11 and inconclusive in 10/11. PET was positive in 4/11 although was limited to assess anatomic extent and functional information, negative in 6/11 and inconclusive in 1/11. The review of hybrid PET/MRI images was useful in 10/11 (90.9%) cases, especially to locate the uptake area (foci of active inflammation), determine their extent, and evaluate their repercussion on valvular and ventricular function. ***Conclusion:*** Synchronous acquisition of 18F-FDG-PET and MRI with hybrid PET/MRI tomograph provides added value compared to MRI and PET alone in patients with inflammatory cardiac diseases. In particular, PET confirms/excludes the presence of foci of active inflammation in cases of inconclusive MRI, and MRI provides anatomical/functional information in cases of positive/inconclusive PET.

EPS-044

A comparison of simultaneous ^{18}F-FGD PET/MRI with conventional MRI in the diagnosis and assessing treatment response in patients with spondylodiscitis

***R. Aleksyniene*[1]**, *M. Reichkendler[1,2], H. H. Johannesen[1], P. Gideon[1], M. Gheshlaghi[1], D. Podlekareva[3], Å. B. Andersen[1], S. Heidari[1], T. L. Andersen[1], S. D. Nielsen[1], B. M. Fischer[1]; [1]Rigshospitalet, Copenhagen, DENMARK, [2]Zealand University Hospital, Køge, DENMARK, [3]Copenhagen University Hospital - Bispebjerg and Frederiksberg, Copenhagen, DENMARK.*

Aim/Introduction: The aim was to evaluate the additive diagnostic value of ^{18}F-FDG PET/MRI compared to MRI of the spine in diagnosing spondylodiscitis and its complications, as well as early and late assessment of response to antibiotic therapy. ***Materials and Methods:*** In this prospective single-center study, 13 (thirteen) patients admitted to Rigshospitalet, Copenhagen with culture verified and/or imaging suspected spondylodiscitis were included between February 2019 and January 2024. Routinely, patients with clinical suspect spinal infection underwent a contrast enhanced MRI of the entire spinal column around the time of admission to verify the diagnosis. In this study, all patients additionally underwent concomitant ^{18}F-FDG PET/MRI scheduled for three time points: at the earliest possible time point after admission (baseline), after approx. 2 weeks of intravenous antibiotic therapy (early follow up) and late follow up at 4-6 months after termination of antibiotics. Board certified specialists reported the stand-alone MRI and concomitant PET/MRI independently while blinded to other scan results. ***Results:*** All 13 patients underwent a baseline scan. 9 patients underwent the baseline and early follow up scan and 6 patients were investigated at all three time points. On the baseline scan spinal infection with or without complications was shown in 11 patients on PET/MRI and in 10 cases on MRI. Discrepancy between the modalities was reported in 2 cases which influenced clinical management: in one patient spondylodiscitis was not diagnosed on MRI due to metal artefacts from aorta stent and in the second case the result was equivocal on MRI due to sacrum fracture and surrounding edema where spondylodiscitis was excluded on PET/MRI. In further 5 cases spondylodiscitis was diagnosed on both modalities but minor additional changes were shown on PET/MRI in 4 cases and in one case on MR. These did not influence treatment regime. On both the early and late follow-up time points, additional PET was helpful in two cases showing metabolic response in the morphological unchanged areas on MRI. Concomitant infection was not found on PET/MRI in any case. ***Conclusion:*** PET/MRI may be helpful in equivocal or selected cases in diagnosing spondylodiscitis and assessing treatment response, but this modality has not yet been recommended in daily clinical practice. Further investigation to demonstrate a clear benefit is needed. ***References:*** PET/MR Imaging in Musculoskeletal Precision Imaging - Third wave after X-Ray andMR. Hancin EC et al. Early experience with hybrid $^{[18F]}$-FDG PET/MRI for identification of musculoskeletal pain generators

***J. Mostert*[1]**, *E. H. G. Oei[1], M. Ananta[1], G. S. R. Muradin[1], F. J. M. P. Huygen[1], C. C. de Vos[1], P. K. Bos[1], S. Biswal[2], R. A. van der Heijden[1,2]; [1]Erasmus MC, Rotterdam, NETHERLANDS, [2]University of Wisconsin-Madison, Madison, WI, UNITED STATES OF AMERICA.*

Aim/Introduction: Chronic pain is the most common reason for patients to seek medical care. However, up to 79% of patients believe their pain is inadequately treated. This treatment failure is partly due to our inability to accurately identify pain generators with conventional anatomical imaging. Hybrid imaging with ^{18}F-FDG PET/MRI visualizes both structural changes and tissue metabolism, which is potentially more sensitive for identifying inflammation in the context of pain. This study describes our early experience with $^{[18]}$F-FDG PET/MRI in two patient groups often presenting with musculoskeletal pain of unknown origin: chronic low back pain (LBP) or persistent pain after total hip replacement (THR). ***Materials and Methods:*** Patients aged 18-75 years with chronic LBP or hip pain after THR with unknown origin were referred by their physician. Study participants were randomized in either the control arm comprising of standard clinical care or the intervention arm consisting of $^{[18]}$F-FDG PET/MRI. Potential pain generators were identified by increased FDG uptake on PET and/or structural abnormalities on MRI. Findings were discussed with the referring physicians and changes in clinical management and patient outcomes were recorded. ***Results:*** 27 patients were included, 15 LBP and 12 with pain after THR. Thirteen patients were randomized to the PET/MRI group. PET-MRI provided new diagnostic insights in 12 patients (86%), which led to multiple changes in clinical management including targeted treatment and subsequent symptom relief in a subset of patients. Low Back Pain Increased FDG uptake (SUVmax 1.0-3.6) corresponding with the pain location was seen in 5 patients (83%), leading to targeted treatment in four patients. In the control group, none of the patients underwent additional diagnostic imaging and only three patients (33%) underwent nerve root injection. Pain after Total Hip Replacement Abnormal FDG uptake (SUVmax 1.0-6.4) corresponding with the pain location was seen in all 7 THR patients (100%). Additional diagnostic imaging or procedures were performed in 6 patients, and THR revision in two patients. Two control group patients (40%) underwent additional diagnostic imaging not leading to new insights. One participant underwent THR revision. ***Conclusion:*** In our early experience, $^{[18]}$F-FDG PET/MRI can reveal previously unidentified pain generators in patients with chronic LBP or persistent pain after THR, leading

to changes in clinical management including targeted treatment with favorable outcome in a subset of patients. Future evaluation in a larger cohort will further determine the added value of [18] F-FDG PET/MRI in terms of patient outcomes.

EPS-046

Aortitis as Predictor of Aortic Dilatation in Giant Cell Arteritis

R. Durmo[1], *C. Marvisi[1], K. Guggenberger[2], C. Ricordi[1], R. Werner[2], G. Besutti[1], R. Fari[1], M. Fröhlich[2], L. Spaggiari[1], P. Pattacini[1], C. Salvarani[1], M. Schmalzing[2], A. Versari[1], F. Muratore[1], T. Bley[2];*
[1]AUSL-IRCCS of Reggio Emilia, Reggio Emilia, ITALY,
[2]University Hospital Wuerzburg, Wuerzburg, GERMANY.

Aim/Introduction: Aortic dilation has been reported both in the early and late course of GCA, and patients with GCA who develop aortic dilation have an increased mortality. This retrospective study aimed to assess aortic inflammation and identify predictors of aortic dilatation in a longitudinally monitored cohort of patients with newly diagnosed GCA. ***Materials and Methods:*** This was a retrospective study on prospectively collected data of consecutive patients diagnosed with GCA in two European centers (Reggio Emilia/Italy and Wurzburg/Germany). Patients with a new diagnosis of GCA confirmed by temporal artery biopsy or imaging, who underwent PET/CT or MRI or CT at diagnosis and after at least 6 months of follow-up were included. Aortitis was determined by increased FDG uptake (visual score ≥ 2) on PET/CT or wall thickening on CT or MRI. Aortic dilation was defined by specific diameter thresholds. ***Results:*** A total of 157 patients were included. At diagnosis, 43 (27.4%) patients underwent aortic MRI, and 114 (72.6%) PET/CT. Aortitis was present in 92 (58.6%) patients, and aortic dilation in 31 (19.7%). Aortitis was present in 70.3% of PET/CT and 32.6% of MRI, p<0.0001, and aortic dilation in 22.7% and 14% respectively, p=0.420. At univariate logistic regression analysis, significant predictors of baseline aortic dilation were male sex [OR 5.37 (95% CI 2.33 to 12.40)], fever [OR 2.02 (95% CI 0.90 to 4.55)], hypercholesterolemia [OR 0.35 (95% CI 0.13 to 0.90)], and aortitis [OR 2.56 (95% CI 1.02 to 6.42)]. At multivariate analysis, predictors of aortic dilation were aortitis [OR 3.65 (95% CI 1.25 to 10.71)] and male sex [OR 8.33 (95% CI 3.13 to 22.18)]. There was a significant increase in aortic diameters between the first and last imaging [mean change (95% CI) 1.1 (0.6 to 1.6) mm at the ascending aorta, p<0.0001; 0.9 (0.6 to 1.2) mm at the aortic arch, p<0.0001; 0.9 (0.4 to 1.4) mm at the descending aorta, p<0.0001; 0.2 (-0,003 to 0.4) mm at the suprarenal aorta, p=0.099]. At follow-up imaging, 12 (9.8%) patients developed a new aortic aneurysm. Cox proportional hazards regression analysis did not show a significantly higher risk for incident aortic aneurysms in patients with baseline aortitis (sex- and age-adjusted HR 1.65 (95% CI 0.59 to 5.62). ***Conclusion:*** Aortitis and aortic dilation were common findings in patients with newly diagnosed GCA, and baseline aortitis was associated with higher aortic diameters.

EPS-047

[18F]FDG-PET/CT in Giant Cell Arteritis. Which vascular segmental quantitative parameter is most useful?

M. Velasco Nuño[1], *A. Fernández-León[1], P. Moya Alvarado[2], P. Stefaneli[1], M. Calls Calahorro[1], H. Sang Park[2], A. Barros-Membrilla[3], G. Guzmán Prudencio[1], V. Camacho[1], J. Duch[1], C. Soldevila-Lozano[1], S. Castejón Echevarne[1], B. Magallares Lopez[2], I. Castellví Barranco[2], H. Codes Mendez[2], H. Corominas Macias[2], A. Flotats[1];*
[1]Nuclear Medicine Department, Hospital de la Santa Creu i Sant Pau, Barcelona, SPAIN, [2]Rheumatology and Systemic Autoimmune Diseases Department, Hospital de la Santa Creu i Sant Pau, Barcelona, SPAIN, [3]Aorta Pathology Unit, Cardiology Service, Hospital de la Santa Creu i Sant Pau, Barcelona, SPAIN.

Aim/Introduction: To analyze the diagnostic performance of several quantification methods of [^{18}F]FDG-PET/CT in the assessment of vasculitis secondary to giant cell arteritis (GCA) in different vascular segments, as well as to determine the most frequently affected segment. ***Materials and Methods:*** Retrospective study of 48 patients with GCA (according to ACR/EULAR 2022 criteria), who had a [^{18}F]FDG-PET/CT. Visual assessment (concentric and homogeneous hypermetabolism in the vascular wall was considered positive) and quantitative evaluation of SUVmax and its normalization to target-to-background ratio (TBR) of liver (TBR-H) and superior vena cava blood pool (TBR-SVC) in 10 vascular segments were performed: aortic root (AR), ascending aorta (AscA), aortic arch (AA), thoracic descending aorta (TDA), suprarenal aorta (SRA), infrarenal aorta (IRA), common iliac arteries (right: RCIA and left: LCIA), and common carotids arteries (right: RCCA and left: LCCA). The area under the curve (AUC), cut-off point, sensitivity (Sen), and specificity (Spe) of the 10 quantified vascular segments were calculated using ROC curves. ***Results:*** 28 patients (58%) had a positive study by visual assessment. The frequency of affected segments was: AA 25, TDA 24, AscA 23, SRA 21, AR 20, IRA 18, RCCA and RCIA 12, and LCCA and LCIA 10. In 7/10 segments, TBR-H was the parameter with the highest AUC, with AR being the segment with the highest diagnostic accuracy (AUC: 0.914, cut-off: 0.96, Sen: 80%, and Spe: 96%). TBR-SVCn was superior in IRA and RCIA. SUVmax was the parameter with the lowest AUC in 9/10 segments. The mean and cut-off range for SUVmax, TBR-H, and TBR-SVC were 2.93 (2.52-3.44), 0.91 (0.85-0.96), and 1.48 (1.31-1.65), respectively. ***Conclusion:*** Quantification of [^{18}F]FDG-PET/CT using TBR-H showed a higher diagnostic performance than using TBR-SVC or SUVmax, consequently, it could be used as a supportive tool for the visual assessment of vasculitis secondary to GCA. The aortic arch was the most frequently affected segment.

EPS-048

Clinical usefulness and diagnostic performance of ^{18}F-FDG PET/CT in IgG4-related disease

I. Martínez-Rodríguez, *Á. Gutiérrez-González, J. Jiménez-Bonilla, A. Sánchez-Salmón, N. Martínez-Amador, F. Gómez-de la Fuente, B. Lucas-Velázquez, M. De Arcocha-Torres, V. Mendi-Barcina, A. Bota-Bota, M. Pombo-López, A. García-Ruiz, F. Rodríguez-Izquierdo, N. Carvalho-Duarte, M. Botanch-Domingo, L. Cabrera-Portillo, R. Quirce;*
Nuclear Medicine Service. Marqués de Valdecilla University Hospital. Molecular Imaging Group (IDIVAL). University of Cantabria, Santander, SPAIN.

Aim/Introduction: IgG4-related disease (IgG4-RD) is characterized by plasma cell infiltration, tissue fibrosis, and elevation of serum IgG4 that can affect practically all organs, showing frequently non-specific symptoms that makes its diagnosis difficult. Our objective was to evaluate the clinical usefulness and diagnostic performance of ^{18}F-FDG PET/CT (PET/CT) in the detection of inflammatory activity in patients with suspicion or diagnosis of IgG4-RD. ***Materials and Methods:*** This retrospective study included 31 consecutive patients (25 women, age: 55±14, 25-87 years) with clinical suspicion (27 patients) or known IgG4-RD (4 patients) referred for ^{18}F-FDG PET/CT for diagnosis or assessment of inflammatory activity. A visual analysis of images was performed. Findings were considered positive when there were areas of hypermetabolism suggesting inflammatory process. The definitive diagnosis was established by histological analysis (16

patients) and/or clinical/biochemical criteria (15 patients). ***Results:*** PET/CT was positive in 17/31 patients (54.8%). The final diagnosis was IgG4-RD (true positive result) in 12/17 patients (70.6%), 6 with histological confirmation. A multi-organ involvement was observed in 7 of them, being the organs more frequently involved the thoracic aorta (8 patients), the lymphatic nodes (4) and the salivary/lacrimal glands (3). Other affected organs were the orbit, thyroid, pancreas, lung, and pleura. In 1 of these patients a metastatic lymph node involvement for a previous cervical cancer was also detected. In 5/17 patients with a positive PET/CT (29.4%) the final diagnosis was a non IgG4-RD condition (false positive): pancreatitis, pancreatitis plus lung cancer, interstitial pneumonia, panniculitis, and cutaneous B-cell lymphoma (4 with histological confirmation). PET/CT was negative in 14/31 patients (45.2%). The result was true negative in 13 (being the final diagnosis other benign conditions in 9, lymphoma in 1, and ovarian carcinoma metastasis in 1) and false negative in 1 (IgG4-RD confirmed by bronchial biopsy). The accuracy, sensitivity, specificity, positive and negative predictive value were 80.7%, 92.3%, 72.2%, 70.6% and 92.9%, respectively. In 8 patients a follow-up PET/CT was performed. In 4 patients with clinical/biochemical worsening PET/CT showed increased inflammatory activity, and in 4 patients with good clinical response PET/CT confirmed a decrease in inflammatory activity. ***Conclusion:*** ^{18}F-FDG PET/CT showed a good accuracy to confirm or exclude the presence of IgG4-RD, helping in the differential diagnosis with other pathologies with similar clinical course, with a high negative predictive value. PET/CT was also very useful as a guide for biopsy, and for the evaluation of the extend of the disease and treatment response.

EPS-049

Dynamic Whole-Body FDG PET for Evaluation of Vasculitis and Polymyalgia Rheumatica

B. Sah[1,2], *L. Husmann[1], F. Kotasidis[3], A. Maurer[1], M. Huellner[1];*
[1]Department Nuclear Medicine, University Hospital Zurich and University of Zurich, Switzerland, Zurich, SWITZERLAND, [2]Department of Diagnostic, Interventional, and Pediatric Radiology, Inselspital, University of Bern, Switzerland, Bern, SWITZERLAND, [3]GE Healthcare, Waukesha, WI, UNITED STATES OF AMERICA.

Aim/Introduction: Vasculitis and polymyalgia rheumatica (PMR) are autoimmune diseases which frequently overlap within rheumatic inflammatory conditions. Static FDG-PET has been demonstrated to be an accurate imaging method in the diagnostic workup (DOI: 10.2967/jnumed.122.265016). This study investigated the value of a dynamic whole-body acquisition of F^{18}-Fluorodeoxyglucose-positron-emission-tomography (PET) in comparison to state-of-the-art static PET parameters. ***Materials and Methods:*** Following Institutional Ethics Committee approval and informed consent, a total of 39 patients with suspected vasculitis or PMR were prospectively enrolled in this single-center study. Dynamic whole-body PET images were obtained with a conventional PET scanner using a multi-bed multi-pass dynamic whole-body acquisition approach (dPET). Patients underwent imaging prior to start of treatment. Activity was injected on the scanner bed, and a single bed over the heart was acquired simultaneously (10 minutes), followed by 11 whole-body dynamic frames (46 minutes, 5 beds, 50 seconds/bed), followed by a static acquisition at 60 minutes postinjection (1.5 minutes/bed). Reconstructed images, together with an aortic input function (IF), were used to generate MR-FDG images based on traditional Patlak (11 frames, full IF). MR-FDG image data sets of dynamic acquisition and SUV image data sets of static acquisition were reviewed. In case of pathologic FDG uptake, VOIs were placed in vessel walls and joints for quantitation. The target-to-background ratio (TBR) was defined as the ratio of measured uptake in VOIs of pathologic vessel walls or joints (maximum values), to VOIs in blood pool (in vasculitis), or to VOIs in physiologic muscles (in PMR) (mean values). ***Results:*** 16 patients showed pathologic FDG uptake, 11 patients were diagnosed with vasculitis, and 11 patients with polymyalgia rheumatica (six patients both diagnosis). TBR of dPET in vasculitis (MR-FDG_max_vessel_wall / MR-FDG_mean_blood_pool) was 44.4 (range 3.4-127), and TBR of static PET (SUVmax_vessel_wall / SUVmean_blood_pool) was 2.1 (range 1.2-3.1). TBR of dPET in PMR (MR-FDG_max_joint / MR-FDG_mean_muscle) was 10.2 (range 4.1-23.8), and TBR of static PET (SUVmax_joint / SUVmean_muscle) was 6.6 (range 2.1-14.7). The difference of TBR of dPET and static PET was significant in both diseases (TBR dPET vs. TBR static PET p=0.005, and p=0.005 respectively). ***Conclusion:*** The detectability of vasculitis and of PMR was significantly better in the dPET images. Patlak graphical analysis allows separating metabolized FDG from unmetabolized tracer in the blood pool and tissue. Dynamic PET may thus have the potential to increase sensitivity in detection of vasculitis and PMR. ***References:*** Role_of_^{18}F-FDG_PET/CT_in_Large_Vessel_Vasculitis_and_Polymyalgia_Rheumatica, JNM 2023 (DOI: 10.2967/jnumed.122.265016).

EPS-050

Diagnostic performance of digital [18F]FDG PET-CT in patients with suspected vasculitis. Experience in a tertiary center.

A. Peña Fuentes, *R. Nuñez-Muñoz, I. Vinagre Pérez, M. Astudillo Sarmiento, J. Lavilla, G. Portilla Quattrociocchi, I. Fernández Tercero;*
Hospital Universitario de Cruces, Bilbao, SPAIN.

Aim/Introduction: To assess the diagnostic performance of digital tomography [18F]FDG PET-CT in patients with suspected first episode of vasculitis. ***Materials and Methods:*** We retrospectively enrolled 41 patients with clinical and/ or radiological suspected vasculitis who underwent [18F]FDG-PET-CT at our department from February 2022 to January 2023 (17 men, 24 women; median age: 74 years; 15 with previous diagnosis of polymyalgia rheumatica [PMR]). Patients previously diagnosed of vasculitis were excluded. To interpretate PET findings, we used the Meller visual score as recommended by EANM guidelines in the assessment of vasculitis, considering a Meller score 2 and 3 as PET positive. Final diagnosis for large vessel vasculitis (LVV) was established using the 2022 ACR/EULAR Vasculitis Classification Criteria, and clinical-analytical and imaging criteria for other types of vasculitis. The minimum time of follow-up was 1 year, in which we collected clinical-analytical and imaging information to verify evolution. ***Results:*** 12 of the 41 patients had a positive [18F]FDG PET-CT, 9 (75%) of which were finally considered vasculitis: 5 as LVV, 2 as solitary infectious aortitis and 2 isolated temporal arteritis. 3/12 did not obtain a final diagnosis. All 12 patients were treated with corticosteroids, showing clinical improvement, except one of the solitary infectious aortitis. Of the 29 patients with negative [18F] FDG PET-CT, only 3 (10%) met ACR/EULAR vasculitis criteria and were diagnosed and treated as LVV with improvement. Of the remaining 26, the majority were also treated with corticosteroids without significant clinical improvement. 17 of the 41 patients in this study had radiological imaging (CT with contrast and/or temporal ultrasound) with findings compatible with vasculitis. 10/17 (59%) did not present pathological uptake in [18F]FDG PET-CT and none were considered as vasculitis. Of the 15 patients with a previous diagnosis of PMR or with symptoms of arthralgia,

93% presented a PMR pattern on [18F]FDG PET-CT. ***Conclusion:*** [18F] FDG PET-CT is useful in the diagnosis of vasculitis as well as in the assessment of associated PMR. Negative [18F]FDG PET-CT makes the presence of vasculitis highly unlikely. [18F]FDG PET-CT appears superior to radiological imaging for the detection of vasculitis.

EPS-051

Role and diagnostic performance of [18F]FDG PET/CT in patients with suspected ventricular assist device infection.Experience in a dedicated cardiac PET/CT center

J. Diaz-Moreno[1], *B. Hervás-Sanz[1], L. Gràcia-Sánchez[1], I. Sánchez-Rodríguez[1], P. Notta-González[1], M. Pudis[1], C. Martínez-Ramos[1], V. Carrero-Vásquez[1], J. Robles-Barba[1], C. Díez-López[2], J. González-Costello[2], L. Herrador-Galindo[2], F. Escrihuela-Vidal[3], N. Sabé-Fernández[3], I. Grau[3], D. Ortiz-Berbel[4], K. Osorio-Higa[4], D. Plaza-González[5], M. Cortés-Romera[1];*
[1]Nuclear Medicine-PET (IDI) Department, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, Barcelona, SPAIN, [2]Cardiology Department, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, Barcelona, SPAIN, [3]Infectious Disease Department, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, Barcelona, SPAIN, [4]Cardiovascular Surgery Department, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, Barcelona, SPAIN, [5]Quality Department, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, Barcelona, SPAIN.

Aim/Introduction: The implantation of ventricular assist devices (VAD) has increased exponentially over time as a bridge or destination therapy. One of the most common complications is infections of the VAD. The aim of this work is to assess the role and diagnostic performance of PET/CT with [18F]FDG in patients carrying VAD with suspected underlying infectious processes. ***Materials and Methods:*** Retrospective study of 11 patients (p) carrying VAD assessed by PET/CT with [18F]FDG with suspected infection between July 2018 and March 2024. Demographic variables, baseline pathology, VAD purpose and PET/CT findings were analyzed. Diagnostic yield values were calculated between concordance of PET/CT diagnosis and definitive diagnosis agreed by consensus in the scientific committee. ***Results:*** 11p with a total of 20 scans were analyzed, 6 men, 4 women and 1 transgender woman. Mean age 60 years [31-77], 3p with dilated cardiomyopathy and 8p ischemic. 5p were VAD carriers as destination therapy and 6p as bridge therapy. In 12/20 PET/CT scans the findings were suggestive of infection (10 in the extrathoracic tract, 1 in the ventricular device and 1 in the intra/extrathoracic tract), with a definitive diagnosis of infection. In 1/20 PET/CT scan the findings were not conclusive of infection, nevertheless a diagnosis of probable infection was decided in committee. 7/20 PET/CT scans were not suggestive of infection and infectious involvement of the VAD was ruled out; these patients had respiratory, skin and bone infections. The sensitivity of the [18F]FDG-PET/CT was 92% [78-100], specificity and PPV was 100%, NPV 88% [65-100]. The median SUVmax of patients with extrathoracic infection (cutaneous entry and subcutaneous tract) was 2.8 g/ml vs. 1.83 g/ml in relation to the rest of patients without infection. The SUVmax in intrathoracic infections was 4.33 g/ml vs. 3.6 g/ml in the rest of the patients without infection. ***Conclusion:*** The [18F]FDG PET/CT is a useful noninvasive method for detecting VAD-related infection or raising other differential diagnoses. The [18F]FDG PET/CT has an optimal diagnostic performance for diagnosing VAD infection, with a therapeutic benefit for patients and has an important role in clinical and therapeutic decision making in complex patients.

EPS-052

New post-INVEAT era: contribution of ^{18}F-FDG PET/CT in the study of infective endocarditis. Our experience.

M. Moreno-Caballero, *E. Moratalla-Aranda, G. Sabatel-Hernández, J. Venero-Chaparro, M. Gallego-Márquez, D. Becerra-García;*
Hospital Universitario San Cecilio, Granada, SPAIN.

Aim/Introduction: The Next Generation EU funds, channeled in Spain through the INVEAT plan (spanish acronym for "investment in high technology") have allowed the renewal and/or expansion of diagnostic equipment in many hospitals. In the study of infective endocarditis (IE) [18F] FDG-PET/CT has recently been included within the major diagnostic criteria defined by the European Society of Cardiology (SEC). Our objective is to describe the experience obtained in this field after the recent acquisition of a digital PET/CT. ***Materials and Methods:*** All patients referred to our Service for suspected IE between July 2023 and March 2024 for whole body [18F] FDG-PET/CT, with specific protocol for myocardial FDG suppression. Among the variables included were age, sex, qualitative and quantitative assessment of the test, incidental findings and discordances with the ultrasound study. Finally, the diagnostic validity was analyzed considering the final diagnostic decision agreed upon by the multidisciplinary endocarditis committee as the Gold Standard. ***Results:*** Twenty-nine patients were included, 12 women (41.4%) and 17 men (58.6%), mean age 72.06 (35-89). Regarding clinical suspicion of IE, 13 were on native valves, 9 prosthetic and 7 on implantable medical devices. The test was considered negative in 17 patients, positive in 9, discarding 3 due to inadequate myocardial suppression. Of the studies with positive results, FDG distribution was focal in 44.4%, heterogeneous in 55.6%, mean SULmax value of 3.79 (2.98-4.51). The most frequent microorganism isolated in blood cultures was S. Aureus (3), followed by S. Gallolyticus-Pasteurianus (2). In addition to the cardiac evaluation, the test showed embolisms or septic processes in 5 patients: liver (1), lung (1), spleen (1), spondylodiscitis (2). The validity of the study compared with the defined Gold Standard showed values of S 100%, E 94%, PPV 89% and NPV 100%. Regarding the ultrasound study, the [18F] FDG-PET/CT was able to clarify the diagnosis in three equivocal cases and modify it in seven, four with positive ultrasound and three negative for IE. In addition to the objective of the study, a patient was identified with an intestinal hypermetabolic lesion compatible with colorectal neoplasia, subsequently confirmed by colonoscopy. ***Conclusion:*** Our preliminary results with [18F] FDG-PET/CT, possible thanks to the INVEAT plan, corroborate the important role of this diagnostic technique in the study of IE, acknowledged by recent guideline updates. ***References:*** Delgado V et al. ESC Guidelines for the management of endocarditis 2023;44(39):3948-4042. https://doi.org/10.1093/eurheartj/ehad19.

EPS-053

Assessing the prognostic potential of ^{18}F-FDG PET/CT in acute spinal cord: a pilot investigation.

T. Nazerani-Zemann[1], *E. Kalcher[2], P. Puchwein[2];*
[1]Division of Nuclear Medicine, Department of Radiology, Medical University of Graz, Graz, AUSTRIA, [2]Department of Orthopaedics and Trauma, Graz, AUSTRIA.

Aim/Introduction: Utilizing magnetic resonance imaging (MRI) as the gold standard for evaluating soft tissue injuries, particularly spinal cord lesions, is a conventional approach. However, patients experiencing acute traumatic spinal injuries often require stabilization through surgical intervention involving

the placement of paramagnetic metallic implants. Unfortunately, these implants introduce artifacts that significantly compromise MRI image quality, impeding accurate prognostic assessment. Hence, we sought alternative methods for evaluating spinal cord damage. Our aim was to establish a correlation between glucose metabolism and the functional neurology of patients with spinal cord trauma. While similar studies have been conducted on animal models, particularly rats, demonstrating promising outcomes, we aimed to ascertain if glucose metabolism rates at the lesion site and adjacent areas correlate with neurological function in human subjects. This endeavor holds potential for facilitating comparative analyses of therapeutic strategies and interventions. ***Materials and Methods:*** Our cohort study comprised patients with acute trauma-induced spinal cord injuries, manifesting motor or sensory deficits, who underwent surgical intervention at our institution. We assessed their neurological status using the ASIA Impairment Scale shortly postoperatively, typically within 3-5 days. Subsequently, we performed FDG-PET scans to evaluate glucose metabolism rates at the injury site, as well as cranially and caudally. Follow-up examinations, including repeat FDG-PET scans, were scheduled six months post-surgery. Data analysis focused on correlating glucose metabolism with functional neurology. ***Results:*** Initially intended for ten patients, our pilot study encountered challenges in follow-up due to patient limitations. Consequently, we revised our primary objective to assess the correlation between FDG PET-CT findings and baseline functional neurology. Nine acutely injured patients were included, exhibiting varying degrees of neurological impairment. Our interim analysis revealed a significant correlation between mean standardized uptake value (SUV) and neurological impairment. Follow-up assessments of three patients at six months post-surgery demonstrated improved neurological function, corroborated by changes in SUV. ***Conclusion:*** This study represents the first endeavor to establish a correlation between FDG PET-CT findings and functional neurology in acute spinal cord injury patients. Our preliminary findings support the utility of FDG PET-CT as a predictive tool for assessing functional neurology shortly postoperatively. Ongoing data collection and analysis, particularly at the six-month follow-up, will further validate our results. Future investigations should explore the efficacy of different rehabilitation strategies to optimize patient outcome.

EPS-054

Detectability of spinal inflammatory lesions in [18F]FDG PET images of patients with chronic pain - pilot study with synthetic lesions

J. Mostert[1], *R. A. van der Heijden[1,2], M. Segbers[1], E. H. G. Oei[1], G. Kotek[1];*
[1]Erasmus MC, Rotterdam, NETHERLANDS, [2]University of Wisconsin-Madison, Madison, WI, UNITED STATES OF AMERICA.

Aim/Introduction: [18F]FDG PET is a sensitive method to detect metabolically hyperactive lesions in spinal nervous tissues, joints, or bony structures as potential cause of back pain. However, these spinal inflammatory lesions can be difficult to detect given the low level of increased uptake compared to the physiological uptake in the adjacent bone marrow. Automated lesion detection tools could improve assessment by pinpointing potential lesions that show statistically significant increased uptake compared to normal background activity. This study aims to establish a detectability threshold of synthetically inserted lesions in [18F] FDG PET through statistical methods that can inform our future automated lesion detection tool. ***Materials and Methods:*** Three [18F]FDG PET/MRI images without apparent pathological spinal uptake were retrospectively selected through expert consensus. Regions of interest (ROIs) for synthetic lesions were manually drawn in the lumbar spinal canal and a lumbar nerve root, with corresponding ROIs at a subsequent spinal level and the contralateral nerve root as internal reference. Synthetic lesion sinograms were simulated with a range of uniform activity levels (250, 500, 750, 1000, 1250, 1500 Bq/mL), taking into account scanner characteristics, scatter, and attenuation.1 The synthetic sinograms were added to the original sinogram, and PET images were reconstructed from the combined sinograms with EARL2 reconstruction parameters. Standardized Uptake Values (SUV) were calculated and maximum values (SUVmax) were extracted from the ROIs. Differences in SUV distribution between the inserted lesions and the lesion-free image, as well as the internal reference, were tested using one-sided Kolmogorov-Smirnov tests. ***Results:*** SUVmax on lesion-free images ranged from 0.70 to 1.40 in the spinal canal and 1.17 to 1.55 in the nerve root. For the synthetic spinal canal lesions, SUV distribution was significantly different from the lesion-free image in all patients when lesion activity was >500 Bq/mL, corresponding to a mean SUVmax increase of 0.16. For the nerve root the minimum detectable lesion activity was 1000 Bq/mL (mean SUVmax 0.31). Comparison to the internal reference showed statistical differences across all patients for lesions >1000 Bq/mL in the spinal canal and >1500 Bq/mL in nerve roots, corresponding to mean SUVmax increases of 0.47 and 0.51 respectively. ***Conclusion:*** Small increases in [18F] FDG uptake in spinal canal and nerve root lesions are detectable when compared to an internal reference, provided the exact lesion location is known. Future work should include a larger cohort and assess other lesion characteristics and their variability. ***References:*** 1. Wangerin et al. (2017). J Med Imaging.

EPS-055

Usefulness of ^{18}FDG-PET/CT in the management of febrile neutropenia: a retrospective cohort from a tertiaryuniversity

K. Velasquez[1], *B. Rodriguez[2], P. Soares[1], I. Garrido[1], A. Grajeda[1], L. Santamaria[1], I. Obedkova[1], C. Pradere[1], L. Quiroz[1], A. Fernandez[1];*
[1]Hospital Puerta de Hierro, Majadahonda, SPAIN, [2]Hospital Universitario Puerta de Hierro, Majadahonda, SPAIN.

Aim/Introduction: Febrile neutropenia (FN) is a complication of hematologic malignancy therapy. Early diagnosis would allow optimization of antimicrobials. 18F-FDG-PET-CT may aid in the diagnosis of invasive infections, identify occult infection sites, and help evaluate response to treatment. However, evidence regarding this topic is scarce. ***Materials and Methods:*** We retrospectively analyzed the patients with hematologic malignancies and FN, who underwent 18F-FDG-PET-CT in our university hospital, and compared the results with those obtained from conventional imaging. ***Results:*** 24 patients with FN underwent 18F-FDG-PET-CT, 92% of which also had also been subjected to conventional CT imaging. In 5/24 episodes (21%), the fever was of infectious etiology, either bacterial (2), fungical (2) or parasitic (1). When compared to conventional imaging, 18F-FDG-PET-CT had an added value in 20 cases (83%): it diagnosed a new site of infection in 4 patients (17%), excluded infection in 16 (67%), and helped modify antimicrobials in 16 (67%). Antimicrobials were discontinued in 10 (41.6%). ***Conclusion:*** Available data suggests that ^{18}F-FDG-PET-CT is useful in the management of FN, especially in the diagnosis of unknown infectious foci and in the adjustment of antimicrobial treatment.

EPS-056

Hypermetabolism of Axillary Lymph Nodes Following COVID-19 Vaccination: A Longitudinal Follow-up and Comparison of Vaccines Utilizing Different Technologies

M. Chiang, *C. Lu, P. Kuo;*
National Taiwan University Hospital, Taipei, TAIWAN.

Aim/Introduction: In the wake of the COVID-19 pandemic, various vaccine technologies such as virus vectors, mRNA, and spike proteins were developed and deployed globally. An increase in hypermetabolism of axillary lymph nodes (HLN) was observed in 18Ffluorodeoxyglucose (FDG) positron emission tomography (PET)/computed tomography (CT), typically used to detect tumors or metastases. This study aims to compare the characteristics of HLN associated with different vaccine technologies. ***Materials and Methods:*** This retrospective single-center study enrolled adult patients (aged ≥18) who had received a COVID-19 vaccination prior to undergoing FDG PET/CT scans between July 2021 and February 2024. A total of 668 patients vaccinated with ChAdOx1 nCoV-19, mRNA-1273, or MVC-COV1901 were included in the analysis. Clinical data, including age, gender, vaccination date, dosage, vaccine type, vaccination site, and the time elapsed between the latest vaccination and the FDG PET/CT scan, were reviewed through April 2024. Metabolic avidity was quantified using SUVmax on FDG PET/CT scans, with values exceeding 1.5 times those of the contralateral axillary node or deltoid muscle considered significant. Statistical analysis involved independent t-tests, Kaplan-Meier analysis, and Spearman's rank correlation coefficient to examine characteristics across different vaccine technologies. ***Results:*** The incidence of HLN was significantly higher in the mRNA vaccine group (26.7%) compared to the virus vector group (19.0%, p=0.03) and was significantly greater in the virus vector group compared to the spike protein vaccine group (19.0% vs. 3.8%, p<0.01). There were no significant differences in the incidence of active deltoid muscle, SUVmax of active axillary lymph nodes, or SUVmax of active deltoid muscle across the three groups. A negative correlation was found between SUVmax and the time interval from vaccination to FDG PET/CT scan (Spearman's coefficient: -0.25, p<0.01). ***Conclusion:*** mRNA vaccines showed the highest incidence of HLN hypermetabolism, followed by virus vector vaccines, while spike protein vaccines had the lowest incidence. There was a notable negative correlation between metabolic avidity and the time elapsed since vaccination, suggesting a decrease in metabolic response over time.

EPS-057

Increased Splenic Accumulation after COVID-19 Vaccination: Is It Specific to mRNA Vaccination or the Reflection of Systemic Inflammation?

K. Nakatani[1,2], *K. Yoshino[2], T. Kumazawa[2], S. Nakamura[1], T. Koyama[2];*
[1]Dept. of Diagnostic Imaging and Nuclear Medicine, Graduate School of Medicine, Kyoto University, Kyoto, JAPAN, [2]Dept. of Diagnostic Radiology, Kurashiki Central Hospital, Kurashiki, JAPAN.

Aim/Introduction: It is important to discuss the safety of mRNA vaccines, which have rapidly spread worldwide as a countermeasure against the COVID-19 pandemic, as relatively strong adverse reactions have been reported compared with conventional vaccines. On FDG-PET/CT imaging, axillary lymph node accumulation has been studied as a local response, while systemic changes have occasionally been reported. This study aimed to investigate a group that developed splenic accumulation after COVID-19 vaccination and to characterize its significance by examining differences from the others. ***Materials and Methods:*** Inclusion criteria were those who underwent FDG-PET/CT between 02/2021 and 11/2022 and whose COVID-19 vaccination history, including information on the month of vaccination, was verifiable. Exclusion criteria were those with definite tumor involvement on axillary nodes. They were divided into three groups: within 1 month, 1-2 months, and >2 months of vaccination, and the frequency of increased splenic accumulation was investigated in each group, excluding the cases with splenic tumor involvement. Location, size, number, and visual scores (following the Deauville five-point scale), and SUVmax of lymph nodes with FDG accumulation were compared between those with and without splenic accumulation. ***Results:*** The vaccination history was confirmed in 1115 patients, and after excluding 59 patients with axillary involvement, the study population consisted of 1056 patients (F:M = 466:590, mean age: 71±11). Reactive splenic uptake was observed in 9 of 451 patients within 1 month of vaccination, while 2 of 280 were present at 1-2 months and none of 325 at >2 months. In contrast, five patients within 1 month of vaccination showed splenic involvement, one at 1-2 months, and four at >2 months, and they were excluded. In the group within 1 month of vaccination, the proportion of lymph node accumulation between the 9 patients with reactive splenic uptake and the remaining 437 patients was 100%:41% in axillary, 67%:23% in subpectoral, 56%:11% in subclavian, and 22%:3% in supraclavicular nodes. The mean node diameter was 5.7±1.7mm:3.4±1.6mm. The percentage of cases with ≥6 lymph node accumulation was 56%:9%. The percentage of cases with visual score≥4 was 56%:12%. All were significantly higher in the splenic uptake group. The mean SUVmax of measurable axillary nodes was 4.5±3.3: 2.5±1.5. One patient with splenic uptake at 1-2 months of vaccination had large vessel vasculitis. ***Conclusion:*** Splenic accumulation after vaccination correlated with the findings in regional nodes, suggesting that it may reflect systemic inflammation rather than being specific to COVID-19 vaccination.

EPS-058

To assess the clinical utility of Gallium68 Citrate PET imaging modality in comparison to other imaging studies for routine management of spinal TB

J. Hephzibah;
Christian Medical College Vellore, Vellore, INDIA.

Aim/Introduction: Aim: To study clinical utility of Gallium68 Citrate PET imaging modality in response assessment of spinal TB. ***Materials and Methods:*** Patients with proven spine TB based on history, physical examination, laboratory results, radiological evidence of infection and identification of pathogens at site of infection were recruited for study after an informed consent. Patients underwent 68Ga citrate PETCT and scans were interpreted visually by two independent Nuclear Medicine Physicians. Uptake on scan was correlated clinically and were followed up with a second scan after treatment with ATT/debridement for response assessment. ***Results:*** Thirty-five patients with TB spine had baseline Ga68 citrate PET-CT. • 25 showed avid spinal lesions and corresponding CT showed features of infective spondylodiscitis. • Ten showed non-avid spine lesions with corresponding CT images showing infective spondylodiscitis. 4/10 showed avid extra-osseous lesions: Two showed avid lung nodules with mediastinal nodes Two showed foci of muscle uptake (iliacus and

psoas). 15/35 had follow up Ga68 citrate PET CT imaging after 9-12 months of ATT. • Negative on baseline (6/15): All were negative on follow up imaging • Positive on baseline (9/15) Avid spine lesions (7): Six showed good clinical response and resolution of uptake on follow up imaging. One regression of uptake of spine lesion in follow up compared to the baseline study with good clinical response. Avid extra-osseous lesions (2): Two with avid lung and muscle lesions on baseline showed resolution of uptake on follow up imaging. ***Conclusion:*** On follow up, absence of uptake in those with baseline avid lesions correlated well with good clinical improvement at end of ATT treatment. Hence Ga-68 citrate PET CT may be a robust marker of therapeutic response and can be used as a guide for clinicians in deciding the cessation/ continuation of ATT in dubious cases ***References:*** 1. [^{99m}Tc]Tc-HMPAO-labeled autologous leukocyte scintigraphy in Ukrainian patients injured on the war front

A. Olmedo Chiva[1], *M. Calderón Calvente[1], N. Canchumanya Huatuco[1], V. Aina Monterde[1], C. Lorente Fonrodona[1], M. Falgás Lacueva[1], L. Del Barco Díez Canseco[1], M. Rodero Roldán[2], C. Riola Parada[1], M. Álvarez Ruiz[1], M. Sangrós Sahún[1], P. Navarro Beltrán[1], M. de la Cueva Barrao[1];*
[1]Hospital Universitario Miguel Servet, Zaragoza, SPAIN, [2]Hospital General de la Defensa de Zaragoza, Zaragoza, SPAIN.

Aim/Introduction: Despite the limited sample size, [99mTc]Tc-HMPAO-labeled autologous leukocyte scintigraphy proves to be valuable in guiding therapeutic decisions for extremity infections in Ukrainian patients evacuated from the war front. ***Materials and Methods:*** A retrospective analysis was conducted on requests for collaboration to perform [99mTc]Tc-HMPAO-labeled autologous leukocyte scintigraphy in Ukrainian patients treated at the HGDZ for traumatic or prosthetic wound infections in the extremities. Subsequently, the results of [99mTc]Tc-HMPAO-labeled autologous leukocyte scintigraphy were compared with microbiological cultures, and their impact on therapeutic decision-making was evaluated. ***Results:*** Between February 2022, the onset of the Russian invasion of Ukraine, and February 2024, 94 Ukrainian patients were evacuated to the HGDZ for treatment of war-related wounds, presenting potential infections. Eight [99mTc]Tc-HMPAO-labeled autologous leukocyte scintigraphies were performed in patients with clinical suspicion of active infection, aiming to confirm or exclude infection before therapeutic surgical intervention or to optimize antibiotic therapy duration. All scintigraphies (100%) showed findings consistent with an active infectious process. Subsequent cultures were performed in all cases, yielding true positive results in seven cases (87.5%). Identified pathogens included Klebsiella pneumoniae, Klebsiella pneumoniae ESBL, Pseudomonas aeruginosa, extensively drug-resistant (XDR) methicillin-resistant Staphylococcus aureus, Finegoldia, or Serratia marcescens. The scintigraphic findings influenced therapeutic management in 7 out of 8 cases (87.5%), confirming the presence of active infection, with one false positive result observed. ***Conclusion:*** Despite the limited sample size, [99mTc]Tc-HMPAO-labeled autologous leukocytescintigraphy proves to be valuable in guiding therapeutic decisions for extremity infections in Ukrainian patients evacuated from the war front.

EPS-060

Intra and inter-rater variability of white blood cell scintigraphy of hip and knee prosthetic infections

R. Manta[1], *G. Campagna[2], C. Lauri[2], R. Ottaviani[2], E. Woff[1], A. Signore[2];*
[1]Institut Jules Bordet, Hôpital Universitaire de Bruxelles, Bruxelles, BELGIUM, [2]Sant'Andrea Hospital, Rome, ITALY.

Aim/Introduction: White blood cell scintigraphy plays a major role in the diagnostic approach to periprosthetic infections (1). Despite the procedure has been well standardized by the publication of several guidelines, the interpretation of this technique may be susceptible to intra-and inter-observer variability. Thus, we aimed to assess the reproducibility of interpretation between different nuclear medicine physicians (inter-variability) and by the same physician (intra-variability). ***Materials and Methods:*** 99mTc-WBC scintigraphy of 59 patients with suspected hip or knee prosthesis infection were retrospectively analyzed by three nuclear medicine physicians, blinded to all patient data. Each WBC study was assessed twice by each reader with a minimum 48h-hour interval between the first and second reading, both visually (positive vs. negative) and, in case of doubt, semi-quantitatively according to guidelines of the European Association of Nuclear Medicine (EANM)(2) by drawing an irregular ROI over the suspected infectious lesion and coping it to the normal contralateral bone. The mean counts per ROIs were used to calculate lesion-to-reference tissue (L/R) ratios for both delayed and late images. An increase in L/R over time (L/Rlate > L/Rdelayed) of at least 20% was considered as indicative of infection. Agreement between readers and between readings was assessed by Gwet's AC1 coefficient. Reading time for each scan was compared between the three readers in both the first and the second reading, by using Generalized Linear Mixed Model. ***Results:*** An excellent agreement was found among all three readers 0.94 for first reading and 0.95 for second reading. Both inter- and intra-variability showed values ≥ 0.90. Eighteen cases were unanimously identified as doubtful by all three readers. Subsequent semiquantitative analysis demonstrated 100% agreement on the results for these cases, indicating consistent drawing of similar ROIs and outcomes among all readers. ***Conclusion:*** Intra- and inter-rater variability studies, such as the present study, contribute to the assessment and improvement of the reliability of nuclear medicine imaging techniques. ***References:*** 1. Radiolabelling of leucocytes with ^{18}[F]fluoro-désoxy-glucose ($^{[18F]}$FDG) for infectious disease imaging

***J. Costes*[1],** *C. H. Kamani*[2], *M. Panchaud*[2], *M. Meyer*[3], *M. Nicod Lalonde*[2], *K. Casagrande*[1], *J. Delage*[1], *N. Schaefer*[2], *J. O. Prior*[2], *F. Sadeghipour*[4];
[1]*Radiopharmacy Unit, Department of Pharmacy, Lausanne University Hospital and University of Lausanne, Lausanne, SWITZERLAND,* [2]*Department of Nuclear Medicine, Lausanne University Hospital and University of Lausanne, Lausanne, SWITZERLAND,* [3]*Department of Nuclear Medicine, Bordeaux University Hospital and University of Bordeaux, Bordeaux, FRANCE,* [4]*Department of Pharmacy, Lausanne University Hospital and University of Lausanne, Lausanne, SWITZERLAND.*

Aim/Introduction: Radiolabelled autologous white blood cells (WBC) scintigraphy with 99mTc-HMPAO is the gold standard for accurate infections diagnosis. However, the sensitivity can be low for several localizations. Labelling WBC with $^{[18F]}$FDG may be an alternative, combining the excellent sensitivity of PET/CT with the high specificity of WBC-radiolabelling. We aim to investigate the feasibility and safety of $^{[18F]}$FDG-labelled WBC in patients with suspected infectious disease. ***Materials and Methods:*** In total 7 males (67±8 years) with suspected cardiovascular, osteoarticular or soft tissue infections were included and 80-120mL blood were collected from each participant. WBC were isolated and labelled with 800±150MBq of $^{[18F]}$FDG for 20min. Dosimetry measurement of operators (whole body+extremities) was performed during the labelling process. Participants underwent whole-body PET/CT at 2h and 3h post administration of 259±40 MBq of $^{[18F]}$FDG-labelled WBC. PET images were analysed visually and comparison of FDG uptake was performed between suspected lesions and healthy organs. Viability of FDG-labelled WBC, radiolabelling efficacy, stability and operator dose were assessed. ***Results:*** The mean labelling duration was 3.0 ± 0.5 h. Radiolabelling yield and efficiency were found lower with diabetic compared to non-diabetic patients with 62±22% vs 85±5% and 67±24% vs 91±5%. Cell viability was 99±1%. Stability at 2h and 3h after end of labelling was 85±6% and 80±4%. Mean operator dosimetry was 40±12µSv for whole body and 69±26µSv for extremities. 9 (70 %) lesions were found to be true positive, 2 (15 %) true negative and 2 false negative (15%), mostly located in bone. We found higher $^{[18F]}$FDG-labelled WBC in infectious lesions than healthy organs, although they were lower than the reticuloendothelial system (liver, spleen, bone marrow). There was no significant myocardial FDG uptake despite the absence of a dietary preparation. ***Conclusion:*** $^{[18F]}$FDG-labelled WBC offer very good diagnosis performances with limitation when localized in the axial skeleton and the reticuloendothelial system. The labelling procedure ensures high efficacy, strong reproducibility, and operators' radioprotection. Dosimetry can be improved with suitable equipment and radioprotection during the labelling steps. Further analysis of kinetic of $^{[18F]}$FDG-labelled WBC uptake in greater patient numbers and clinical scenarios will be needed.

EPS-062

Quantitative^{99m}Tc-HMPAO WBC SPECT/CT to diagnose Musculoskeletal Infections

***L. Jonghi-Lavarini*[1],** *C. Bianchi*[2], *E. Balduzzi*[2], *C. Landoni*[1], *P. A. Erba*[1];
[1]*University Milano-Bicocca, Milano, ITALY,* [2]*ASST Ospedale Papa Giovanni XXIII, Bergamo, ITALY.*

Aim/Introduction: In this prospective study, we report our initial experience on the first 15 patients (4 women, 11 men; median age 59 yrs ± 13.4, range 28-77 yrs) who underwent labelled 99mTc-HMPAO WBC scintigraphy for suspected musculoskeletal infection (2 total hip arthroplasties, 8 total knee arthroplasties, 1 spine device infection, 2 ankle-leg OM). ***Materials and Methods:*** Comprehensive clinical and laboratory assessments (blood counts and ESR/CRP), and 3-phase bone scans, were performed on all patients. Medical history reviews were conducted, with emphasis on recent antimicrobial use. Radiolabelling of autologous WBC with 99mTc-HMPAO was performed in accordance with EANM guidelines, with labelling efficiency >60% and administered activity between 408-705 MBq. Images were acquired at 1 hour (early images, whole-body and planar images), at 4 hours (delayed images), and at 24 hours (late images, planar and SPECT/CT images) according to EANM guidelines. Planar images were acquired with decay-corrected acquisition protocol, whereas for semiquantiative SPECT/CT images we used Siemens Symbia Pro.specta and xSPECT Quant™. The studies were classified as (a) "negative for infection" if stable, decreased or no uptake was observed in delayed and late planar images, and (b) "positive for infection" when at least one focus of abnormal uptake showed increase in radioactivity or size from delayed to late planar images. For semiquantitative analysis, ROIs were drawn over suspected infection areas and copied to normal reference tissue. Mean counts per pixel in ROIs from delayed and late images were recorded to calculate target/background (T/B) ratios. Stable or decreasing T/B ratios indicated a negative scan for infection, while a 20% increase in T/B ratios over time indicated a positive result. For SPECT/CT semiquantitative assessment, SUV values (KBq/ml) in the ROI semiautomatically drawn over suspected infection areas (20% threshold) were used to assess time-dependent changes in absolute uptake, using different values of ΔSUV. ***Results:*** Patients presented negative (n=3) or mild ESR/PCR elevation (n=6) and positive 3-phase bone scan for loosening with associated signs of inflammation in all cases. Semiquantitative analysis of planar and SPECT/CT images showed high concordance in all cases except one patient with a chronic infection, showing positive semiquantitative planar image and negative semiquantitative SPECT/CT. ***Conclusion:*** If confirmed in large series, the use of semiquantitive SPECT/CT will provide reliable quantification and anatomical definition of infection extent, better discriminating between pathological foci and physiological uptake. Furthermore, SPECT/CT offers methodological advantages over planar imaging, including heightened reproducibility and diminished susceptibility to operator influence.

EPS-063

Molecular imaging of acute radiation-induced esophagitis using PET/CT by targeting C-X-C-chemokine-receptor-type-4

J. Pei, *J. Yu, J. Liu;
Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan, CHINA.*

Aim/Introduction: Acute radiation-induced esophagitis (ARIE) is a common side effect and dose-limiting factor of radiotherapy for thoracic tumors and we currently lack established means for the early detection of ARIE. Increased expression of C-X-C-chemokine-receptor-type-4 (CXCR4) was observed in ARIE mice model, suggesting that CXCR4 may serve as a potential biomarker of ARIE. The hypothesis is that non-invasive imaging of 18F labeled polypeptide (QHY-04) targeting CXCR4 enables early detection of ARIE. ***Materials and Methods:*** An ARIE model was constructed using a high-dose single radiotherapy. Small

animal Magnetic Resonance Imaging (MRI) was conducted on day 3, 5, 7 and 15 after radiotherapy. ARIE animals were scanned with [18F]AlF-NOTA-QHY-04 PET/CT and [18F] FDG PET/CT at various time-points post radiotherapy. Dynamic, in vivo blocking study, RNA sequencing analysis, flow cytometry and histopathological studies were performed on the day of peak uptake. Changes of esophageal [18F]AlF-NOTA-QHY-04 uptake were analyzed before and during RT in patients with thoracic tumors. ***Results:*** Enhanced signal intensity of the esophagus and surrounding tissues was observed in ARIE mice compared with normal mice by MRI. Pathological manifestations of radiation induced esophagitis including congestion of blood vessels, detachment of the esophageal epithelium and layer distortion due to necrosis was confirmed by H&E staining. RNA sequencing analysis identified CXCR4 as a potential target of ARIE and significant up-regulation of CXCR4 in the ARIE mice was verified by immunofluorescence staining. Significantly increased [18F]AlF-NOTA-QHY-04 uptake in the irradiated esophagus in comparison with normal esophagus was observed on day 5 post radiotherapy while no obvious [18F] FDG uptake was shown on day 4 to day 8 post radiotherapy. Simultaneously injection with an excess of non-radiolabeled precursor significantly blocked esophagus uptake. The feasibility of [18F]AlF-NOTA-QHY-04 PET/CT imaging for detecting ARIE was further verified in a rat model of ARIE. Immune cell infiltration and flow cytometry identified CXCR4 positive neutrophils and monocytes as the major source of the radiotracer detected by PET. Esophageal uptakes were significantly increased in patients with thoracic tumors after RT compared with esophageal [18F]AlF-NOTA-QHY-04 uptakes before radiotherapy. ***Conclusion:*** [18F]AlF-NOTA-QHY-04 PET/CT can detect ARIE non-invasively and earlier than [18F] FDG PET/CT in experimental animal models. Clinical studies verified its feasibility, suggesting the clinical potential of [18F]AlF-NOTA-QHY-04 as a PET/CT tracer for early monitoring of ARIE.

Gamifying diagnostics for pediatric patients: the DIVING (Diagnostic ImmersiVe ImagING) project

***M. De Summa*[1],** *S. Spinosa[1], A. Mattiassi[2], F. Sorrentino[3], A. Pascale[3], M. Capasso[4], S. Annunziata[5], A. Giordano[6];*
[1]Medipass S.p.A. - Ergèa Group. Integrative Service PET/CT - Radiopharmacy, Fondazione Policlinico Universitario A. Gemelli IRCCS, Roma, Italy, Rome, ITALY, [2]Game Science Research Center, IMT School for Advanced Studies Lucca, Italy, Rome, ITALY, [3]Immensive s.r.l.s., Caserta, ITALY, [4]Università degli Studi della Campania "Vanvitelli" - Dipartimento di Architettura e Disegno Industriale, Caserta, ITALY, [5]Nuclear Medicine Unit, GSTeP Radiopharmacy, Department of Diagnostic Imaging, Oncological Radiotherapy and Hematology, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy, Rome, ITALY, [6]Nuclear Medicine Unit, Department of Diagnostic Imaging, Oncological Radiotherapy and Hematology, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy, Rome, ITALY.

Aim/Introduction: The PET-CT diagnostic workflow for pediatric patients is characterized by significant stress and anxiety associated with medical diagnostics, resulting in low compliance during the exams. The DIVING (Diagnostic ImmersiVe ImagiNG) project introduces gamification into the diagnostic workflow to address such issues. This innovative approach hypothesizes that integrating game mechanics into the workflow of medical procedures can significantly improve compliance and maintain diagnostic performance reducing the doses of radiopharmaceuticals. ***Materials and Methods:*** The project introduces a customized Virtual Reality game themed around underwater exploration, delivered to pediatric patients (ages 5-14) during biodistribution of the radiopharmaceutical, a downtime phase of the diagnostic process. This allows divertion of the attention from the medical procedure and engagement of the children, together with their caretakers, in an immersive narrative. Additionally, the narrative is integrated in the rest of the diagnostic workflow, in order to create an immersive and coherent experience from the beginning to the end of the workflow. Most importantly, the game mechanics allow the patient to become acquainted with the PET-CT scan experience and to learn how to stand still in association with specific sounds of the game environments that are later played inside the scanner. ***Results:*** The study evaluates the psychological and clinical impact of gamification on patient experience and compliance, utilizing a pre- and post-intervention survey methodology and comparing results with a control group not exposed to the gamification approach. Expected results include significant decrease in anxiety levels among participants, with improved patient cooperation and reduced motion artifacts during scans. Crucially, the gamified approach is expected to reduction in radiopharmaceutical dosage. ***Conclusion:*** Finally, we expect enhanced satisfaction with the diagnostic process and an improvement in the overall hospital experience for pediatric patients and their caretakers. The paper illustrates preliminar findings on a small group of participants. ***References:*** Schneider, S. M., Kisby, C. K., & Flint, E. P. (2011). Implementation of a Cardiac PETMRI Training Programme to Meet the Demands of Emergent Hybrid Imaging

S. Kinsella, *S. Jeljeli, G. Testanera;*
King's College London at GSTT Trust, London, UNITED KINGDOM.

Aim/Introduction: In 2015, a PETMRI scanner was installed at our KCL PET Centre in St Thomas' Hospital. Its primary focus was research imaging in oncology and neurology. In recent years, the use of PETMRI in cardiac research trials has increased in our department. An interest in exploring and developing the use of PETMRI in evaluating patients with cardiac sarcoidosis, amyloidosis and inflammatory diseases, including potential clinical

applications, has gained precedence. Combining this specialty with hybrid imaging adds a layer of complexity that requires the advanced training of staff to provide high quality images, inciting the need to establish a suitable training programme for technologists/ radiographers. The aim was to identify and manage the challenges cardiac MRI presents to the technologist/ radiographer in the PETMRI environment. Establish and implement a training programme for technologists/ radiographers to gain the skills and confidence needed to perform cardiac PETMRI research scans efficiently and competently. ***Materials and Methods:*** In coordinating with the KCL Cardiac MRI service within our trust, learning objectives were identified and a regular rotation of PETMRI staff with senior cardiac MRI radiographers was established. Weekly routine training sessions involved reviewing cardiac anatomy, sequence planning, identifying image artifacts/ resolutions, understanding ECG gating and its role in image acquisition, managing patient noncompliance (i.e. poor breathe hold) and proper patient preparation. Technologists/ radiographers would be evaluated and signed off as competent on their training checklist by a senior radiographer before progressing to cardiac scanning in the PETMRI department. The images for subsequent PETMRI research scans were reviewed by an NM physician and cardiac radiologist and graded for quality. Patient feedback surveys were collected to evaluate patient experience for comfort, efficiency and quality of care received during the procedure. ***Results:*** Two PETMRI technologists/ radiographers have completed the training through the implementation of this programme. Approximately 83 patients across 3 cardiac PETMRI research trials have been successfully scanned. Image quality was assessed by NM physicians and cardiac radiologists as adequate/ optimal and patient feedback surveys were positive for their overall experience. ***Conclusion:*** Though challenging, the investment made to establish a specialised training programme for PETMRI has been successful thereby enabling technologists/ radiographers to gain the skillsets necessary to support the current demands of the service. This undertaking has created a pathway for PETMRI technologists/ radiographers to provide all facets of cardiac PETMRI from radiopharmaceutical administration to cardiac scanning and processing.

OP-183

Diagnostic value of [18F]FDG-PET/CT versus CT-TAP in patients with serious non-specific symptoms and signs of cancer (NSSC): A retrospective study

S. Nissum[1], *R. B. Grønnemose[2], S. Nadaraja[1], P. S. Hansen[2], S. Hess[1], P. Thye-Rønn[2];*
[1]Department of Nuclear Medicine, Odense University Hospital, Odense, DENMARK, [2]Diagnostic Centre, Svendborg Hospital, Odense University Hospital, Odense, DENMARK.

Aim/Introduction: To ensure fast-track cancer workup, 25 organ-specific Cancer Patient Pathways (CPP) have been established in Denmark. If a patient presents with serious non-specific symptoms and signs of cancer (NSSC) that does not indicate a specific type of cancer, they can be referred to the non organ-specific NSSC-CPP. Most NSSC-CPP patients undergo a CT scan of the thorax, abdomen, and pelvis (CT-TAP) while some patients undergo an [18F] FDG-PET/CT. Previous studies found [18F]FDG-PET/CT to have higher sensitivity and specificity for identifying cancer compared to CT-TAP (Lebech et al., 2017). This study aims to clarify the diagnostic value of [18F]FDG-PET/CT compared to CT-TAP as a diagnostic tool for diagnosing patients exhibiting NSSC. ***Materials and Methods:*** This retrospective cohort study included all NSSC-CPP patients referred to the Diagnostic Centre in Svendborg in 2022. Scans performed during the patient's investigational course at the Diagnostic Centre or up to 12 weeks prior were included while scans performed after were excluded. We scored the imaging reports of the included patients receiving a scan on how likely the patient was to have a malignant diagnosis based on scan results using a 4-point scale: 1 represented scans with no abnormal findings whereas 2-4 was scans with abnormal findings deemed benign, possible, or probable to represent cancer, respectively. The reference standard was the patients' follow-up diagnosis after six months, which in most cases of cancer were biopsy-verified. Scans scored as 1 or 2 were interpreted as benign while scans scored 3 or 4 were considered malignant. Data and clinical final diagnosis were used to calculate sensitivity, specificity, accuracy, positive and negative predictive values (PPV, NPV). ***Results:*** A total of 995 patients were included who underwent either one or both scans. In total, 1,038 scans were included, 118 [18F]FDG-PET/CT and 920 CT-TAP. Cancer prevalence was 31% for patients undergoing [18F]FDG-PET/CT and 16% for patients undergoing CT-TAP. Sensitivity, specificity, accuracy, PPV and NPV of [18F]FDG-PET/CT were 92%, 72%, 78%, 60%, and 95%, respectively. For CT-TAP, sensitivity, specificity, accuracy, PPV and NPV were 76%, 87%, 85%, 53%, and 95%, respectively. ***Conclusion:*** [18F]FDG-PET/CT had a higher sensitivity and PPV than CT-TAP, whereas CT-TAP had higher specificity and accuracy. NPV were comparable. The study is still ongoing, and further investigation is in progress. ***References:*** Lebech et al. 2017. Journal af Nuclear Medicine, 58(7), 1058-1064.

OP-184

Extravasation of Radiopharmaceuticals in Nuclear Medicine - incidence, causes and reporting events

R. Chagas, *G. Pitts;*
Derriford Hospital, Plymouth, UNITED KINGDOM.

Aim/Introduction: Evaluate the occurrence of radiopharmaceutical extravasation in Nuclear Medicine, identify possible risk factors and frequency of events reported. ***Materials and Methods:*** Initial retrospective visual analysis of 722 Bone studies (3 FOV SPECT) between January and June 2023 and respective reports. Extravasation cases were classified into 4 different groups based on severity. Patient demographics (age, weight and gender) and injection methods (cannula/ butterfly, site of injection and injecting technologist) were evaluated. Findings and contributing factors discussed with team. Extravasation audit for Bone studies repeated between January and June 2024. Extravasation with cannula were evaluated on Myocardial Perfusion studies (MPS). ***Results:*** In the initial analysis, extravasation was found in 9.7% (n=68) of patients, of which 41% were administered via a cannula, and only 17% were mentioned on the report. Of the 68 patients, only 12% had severe extravasations affecting image quality. Patient demographics (age, weight and gender) do not appear to influence extravasation rates. After findings were discussed, incidence of extravasation in Bone scans was reduced and no extravasation on MPS was found. This is an ongoing study and results may change. ***Conclusion:*** Our results are consistent with other published investigations. A similar study carried out at the University of Alberta reports an extravasation rate of 15%-20% (McIntosh & Abele , 2016). A review of four studies involving 2613 patients reports an average frequency of extravasation of 17% (Martin et al., 2021). However, this data is not consistent with reported extravasation rates for chemotherapy (0.09%) or IV Contrast (0.24%). This can be explained due to the different criteria used to describe extravasation in other

modalities. The reduction of extravasation in Bone scan may be explained by increased awareness of the problem, which may lead to better technique. No extravasation events in MPS lead us to believe the poor results with cannulas in Bone Scans may be due to poor technique or longer intervals between cannulation and administration, although the difference in volumes administered make to comparisons difficult. ***References:*** McIntosh, C., & Abele , J. OP-185

Lung Ventilation and Perfusion scanning using ^{68}Galligas and ^{68}Gallium-MAA - a new application for PET/CT?

M. Coelho, *M. Nader, P. Fragoso Costa, K. Herrmann, H. Hautzel; University Hospital Essen, University Duisburg - Essen, Essen, GERMANY.*

Aim/Introduction: 68Galligas and 68Ga-labeled macroaggregated albumin (MAA) are potential tracers for lung Ventilation and Perfusion (V/P) positron emission tomography (PET) imaging and could display an advantage over conventional V/P imaging in terms of sensitivity and specificity [1,2,3]. Our study aims to reproduce published protocols in order to check reproducibility, analyse the practice and verify advantages and disadvantages in patient care. ***Materials and Methods:*** Our study included a total of 30 patients from whom 5 patients underwent ventilation with 68Galligas and perfusion with 68Ga-MAA. To prepare the 68Ga-MAA kit, we used 68Ga solution from a 68Ge/68Ga Generator which was buffered to a pH of 4. This was always controlled with chromatographic paper. For MAA we used the Pulmocis kit (Curium Deutschland GmbH, Berlin, Deutschland). For optimal reaction, the reagent was mixed and heated for 20 min at 75°C with subsequent thin layer chromatography quality control [2]. Ventilation imaging was performed with 68Ga using the Technegas© generator. An additional protective wall was used due to lead shielding designed for 140 keV from 99mTc inappropriate for 511 keV. In addition, the distance between technician and generator was kept as far as possible. 25 ± 7 MBq of 68Ga-MAA were used for perfusion and 31 ± 7 MBq of 68Galligas were used for ventilation. A thoracic PET with low-dose CT was subsequently acquired. ***Results:*** The quality controls for 68Ga-MAA were within the specified reference range. Due to the low pH value, local pain at the injection site was regularly reported, which briefly disappeared within 10 to 20 seconds after rinsing with 20 ml of 0.9% NaCl solution. At a maximum of 8 minutes, the scan time was significantly shorter than for comparable V/P SPECT/CT with higher image quality. ***Conclusion:*** The 68Ga-marked V/P PET/CT achieves shorter examination times with the possibility of treating more patients and a higher spatial resolution compared to V/P SPECT/CT with the same reliability in terms of quality controls. The disadvantages are the time-consuming kit preparation, the quality control that must be carried out for each individual kit synthesis and, in 68Galligas production, the limited radiation protection of the generator, which requires additional radiation protection measures. ***References:*** 1. Diagnostic Performance of $^{[18F]}$Fluorocholine PET/CT as a First-Line Procedure in Localizing Parathyroid Adenomas Verified By Histopathology

M. Rode, *H. Reilev Moeller, L. Lange Oestergaard, P. Holdgaard; Lillebaelt Hospital, University Hospital of Southern Denmark, Vejle, DENMARK.*

Aim/Introduction: Accurate localization of potential parathyroid adenomas is crucial prior to surgery. Previous methods have included [99mTc]-sestamibi and [99mTc]-pertechnetate scintigraphy with a detection rate range of 61 - 88 %. Recently a novel imaging technique using $^{[18F]}$fluorocholine PET/CT (FCH) have emerged, and the first findings in the literature indicates improved diagnostic accuracy. Previously, FCH would be second-line after a negative scintigraphy and/or ultrasound. The aim of this study was to evaluate the diagnostic performance of FCH PET/CT when used as a first-step procedure in localizing parathyroid adenomas in patients with biochemically indicated hyperparathyroidism. ***Materials and Methods:*** Patients received 2.5 MBq/kg FCH followed by image acquisition 35 minutes post injection. Imaging was performed on a LSO PET/CT scanner with time-of-flight of 214 ps., 128-slice CT (CarekV on, 120 kV, 110 quality-reference mAs). The scan ranged from the lower mandibula to below aortic arch, thus including most common sites of normal and ectopic parathyroid gland locations. Acquisition time were according to patient BMI, with an acquisition time of 10 min for patients with a Body-Mass-Index (BMI)<30 and 15 min at BMI>30. The nuclear physicians assessed all images for presence of possible adenomas, including size and location relative to the thyroid gland on a 10-regions-map shared between the nuclear physicians and the surgeons. Diagnostic performance was based on detection rates determined by comparing the nuclear imaging results with histopathological findings. ***Results:*** Over a six-month period, 40 patients underwent FCH as a first-line procedure. FCH identified a potential parathyroid adenoma in 33 patients (82.5%). Compared with surgery and histopathology verification the FCH correctly diagnosed 32 parathyroid adenoma, resulting in a per-patient detection rate of 97.0 %. Thirty-four potential adenomas were detected by FCH, one of these was false positive, resulting in a per-lesion localisation rate of 97.1 %. The seven patients with a negative FCH did not undergo surgery, thus calculating sensitivity and specificity is not possible. ***Conclusion:*** Applying $^{[18F]}$fluorocholine PET/CT as a first-line imaging procedure provides a very high histopathology confirmed detection rate in correctly locating parathyroid adenomas. The FCH's higher detection rate improves the surgical planning, reduces the potential number of bilateral neck explorations, thus reducing potential side effects to surgery.

OP-187

Do alterations in surgical borders of glioblastoma correlate with overall survival time? a [^{11}C]Methionine PET, diffusion MRI, and perfusion MRI study

C. Van Der Weijden, *B. R. J. van Dijken, R. H. Enting, R. J. H. Borra, H. Jeltema, E. F. J. de Vries, A. van der Hoorn; UMCG, Groningen, NETHERLANDS.*

Aim/Introduction: Glioblastomas (GBMs) are highly aggressive brain tumors with a median survival of only 15-months despite extensive treatment including surgery and chemoradiotherapy.

Recurrence near the surgical site is typical due to tumor cells that evade detection and develop treatment-resistance. Hence tissue alterations in the surgical borders, might predict tumor-recurrence. Conventional MRI has not yet shown to display alterations in the surgical border predictive for tumor growth. Advanced imaging techniques like perfusion-MRI and amino-acid PET, including [^{11}C]methionine-PET, might better indicate tumor activity and proliferation. Therefore, this prospective study evaluates the predictive power of imaging parameters from diffusion-weighted-imaging (DWI), intravoxel-incoherent-motion (IVIM), dynamic-susceptibility-contrast (DSC), and [^{11}C]methionine-PET and overall survival times post-surgery. ***Materials and Methods:*** Twenty-one patients with post-surgery GBM were included in the study. For 16 subjects, the overall-survival-time was available. Thirteen subjects underwent [^{11}C]methionine-PET, all 21 received DWI, 9 received DWI suitable for IVIM, 17 underwent DSC MRI, and 13. Regions of interest (ROIs) with a distance of 0 to 5 mm, 5 to 10 mm, and 10 to 15 mm distance from the edge of the surgical cavity were drawn. In addition, a whole-brain normal appearing white matter region (NAWM) and a sphere with a 10 mm radius contralateral to surgical cavity NAWM where drawn as control regions. The various parameters extracted from DWI, IVIM, DSC, and PET were correlated with overall survival time using a Spearman rank-order correlation coefficient. ***Results:*** Uptake of the PET-tracer [^{11}C]methionine in whole-brain NAWM, expressed as SUVmean, was positively correlated with the overall survival time (r=0.745, p=0.008, N=11), whereas the DWI parameter b1000 of the whole brain NAWM was negatively correlated with overall survival time (r=-0.497, p=0.050, N=16). The IVIM-parameters D*, measured 5-10 mm from the surgical cavity (r=-0.786, p=0.036, N=7) and D, measured 0-5 mm from the surgical cavity (r=0.821, p=0.023, N=7) were significantly negatively correlated with overall survival time. Other parameters either derived from [^{11}C]methionine PET, DWI, IVIM, or DSC were not significantly correlated with overall survival time. ***Conclusion:*** More aggressive tumor left behind after surgery as indicated by [^{11}C]methionine-PET and D*, representing metabolism and high blood flow respectively, thus correlated with poorer survival. In contrast high cellularity represented with D indicated better overall survival, which might hint to a mechanism of better response to radiotherapy as e.g. higher cell density as resulting in more cell divisions and thus better radiosensitivity and treatment response. Further research should help to understand these mechanism.

OP-188

The influence of a saline-flush after administration of Rubidium-82 on myocardial blood flow measurements using PET in a propensity matched cohort

M. de Rue[1,2], *E. S. Bos[1,2], A. G. Tegelaar-Kuiper[1], J. A. van Dalen[1], B. N. Vendel[1], J. D. van Dijk[1], E. D. Ekkelenkamp[1];*
[1]Isala Hospital, Zwolle, NETHERLANDS,
[2]Hanzehogeschool, Groningen, NETHERLANDS.

Aim/Introduction: When performing myocardial perfusion PET imaging using Rubidium-82 (Rb-82), the method of infusion may impact scan outcomes. The influence of a saline-flush after administration of Rb-82 on improving image quality was demonstrated previously. Flushing the remaining activity out of the tubing results in increased activity delivered to the heart1. However, the impact of a flush on quantitative myocardial blood flow (MBF) is unknown. We aimed to study the influence of a saline-flush after administration of Rb-82 on the rest and stress myocardial blood flow (MBF) and myocardial flow reserve (MFR). ***Materials and Methods:*** We retrospectively included 288 consecutive patients who underwent rest and regadenoson-induced stress Rb-82 PET; 150 patients received a saline flush after administration of 740 MBq Rb-82, in both rest and stress; the other 138 patients did not. To ensure comparability of these nonrandomized groups, a propensity score matching (PSM) was carried out, ensuring balance between groups on the following covariates2: age, gender, body mass index, aspirin use, beta-blocker use, statin use, diabetes mellitus, history of myocardial ischemia. The recorded rest and stress MBF and MFR (defined by the ratio of stress to rest MBF) for the myocardium as a whole (global) and the vascular territories (LAD, LCX, RCA) were compared between both groups using an independent sample t-test. ***Results:*** PSM resulted in two matched groups of 138 patients. Mean global MBF was 1.01 (unflushed) vs 1.12 ml/g/min (flushed) (p=0.20) in rest and 2.17 vs 2.34 ml/g/min (p=0.053) in stress. Rest MBF in the LAD was 1.06 vs 1.16 ml/g/min (p=0.024) and in stress 2.21 vs 2.40 ml/g/min (p=0.036). Rest MBF in the LCX was 1.05 vs 1.18 ml/g/min (p=0.008) and in stress 2.20 vs 2.38 ml/g/min (p=0.040). Rest MBF in the RCA was 1.04 vs 1.13 ml/g/min (p=0.055) and in stress 2.34 vs 2.49 ml/g/min (p=0.16). Moreover, MFR did not differ between flushed and unflushed; global MFR was 2.21 vs 2.21 (p=0.98) and for the territories: LAD 2.16 vs 2.17 (p=0.94), LCX 2.17 vs 2.12 (p=0.54), RCA 2.32 vs 2.35 (p=0.68). ***Conclusion:*** Groups were well matched, allowing comparison. A saline-flush after Rb-82 elution results in a marginal, yet significant increase of MBF in rest (global, LAD and LCX) and stress (LAD and LCX), while not affecting MFR values. Consistency in the application of flushing is recommended. Furthermore, MFR may be the preferred parameter to use in Rb-82 PET myocardial perfusion imaging. ***References:*** 1Renaud. https://doi.org/10.1007/s12350-018-1261-4 2Farhad. https://doi.org/10.1093/ehjci/jet068.

^{68}Ga-PSMA vs. ^{18}F-PSMA: Technical and metabolic differences

T. Oliveira Hackl, *P. Durmaz, A. Nagy, B. Beyer, J. Sailer, P. Peloschek, M. Hoffmann;*
Radiology Center, Vienna, AUSTRIA.

Aim/Introduction: PSMA provides a promising target for prostate cancer specific imaging. A range of PSMA-based radiotracers is available today that can be based on SPECT or PET radioactive labels. Our retrospective study compares the technical approach and diagnostic performance of 68Ga-PSMA versus 18F-PSMA-PET/CT in patients with PCa. ***Materials and Methods:*** From December 2018 to January 2024, 313 patients were examined for prostate cancer primary staging or follow up (restaging). In the majority of patients (n = 293) 18F-PSMA PET/CT was performed. In 20 patients 68Ga-PSMA was used. The inclusion criteria for the performance of a PSMA PET/CT was performed for staging in biopsy proven prostate cancer prior to (local) therapy or clinical suspicion of recurrence with detectable/rising PSA levels during or following therapy. The decision for 18F-PSMA or 68Ga-PSMA was based on availability. 68Ga-PSMA PET/CTs were performed 60 minutes after administration of 2.2 MBq/kg. 20 mg furosemide were given 20-30 minutes after tracer application. 18F-PSMA-PET/CT was performed not earlier than 2 hours after injection of 4.4 MBq/kg. ***Results:*** PSMA imaging at our institution was, due to availability, performed with 18F-PSMA. Later on, 68Ga-PSMA was available for our institution and we started using both according to daily availability. Studies reporting 18F-PSMA and 68Ga-PSMA show no outstanding advantage of either method, yet there are differences in imaging procedure as well as biodistribution. 68Ga-PSMA has a short half-life, of 68 min, limiting the capacity of

examination, when there is no generator 68Ge-68Ga supply at the place. Therefore, in most cases, in-house production is required. 18F-PSMA may overcome the limitations of the short half-life from 68Ga-PSMA, with a half-life of 110 minutes. Both tracers can be purchased as compounds. The biodistribution of the two tracers is different. The low urinary tracer excretion of 18F-PSMA may offer an advantage over 68Ga-PSMA in terms of evaluation of the primary tumor or local tumor recurrence and iliacal lymph node involvement.Some studies report that 18F-PSMA shows more unspecific focal bone uptake.The choice between 68Ga-PSMA and 18F-PSMA is not influenced by significant differences in the rate of detection, while it is mainly influenced by availability. For this reason, technical as well as medical staff has to be familiar with the differences in imaging protocols and biodistribution. ***Conclusion:*** For enhancing the flexibility of our institution to provide prostate cancer imaging, on short notice, it was crucial to become experienced in performing PSMA-PET/CT with all available PSMA-compounds.

Improving the pharmacokinetics of FAP radiopharmaceuticals - insights from a dose escalation study

A. Bilinska[1], *E. Pilatis[1], E. Menéndez[1], M. Marcel[2], E. Moon[2], T. Läppchen[1], F. Rösch[2], A. Rominger[1], E. Gourni[1];*
[1]Department of Nuclear Medicine, Inselspital, Bern University Hospital, Bern, SWITZERLAND, [2]Department of Chemistry—TRIGA site, Johannes Gutenberg University of Mainz, Germany, Mainz, GERMANY.

Aim/Introduction: Utilizing FAP (Fibroblast Activation Protein) radiopharmaceuticals for pan-cancer targeting stands as a groundbreaking cancer management strategy. Despite their great promise, challenges persist, like elevated blood pool uptake, a common characteristic of FAP-based radiotracers. The main objective of this study is to explore the impact of the administered mass of five radiotracers (monomers and dimers) on their overall pharmacokinetic performance, shedding light on crucial factors influencing their efficacy. ***Materials and Methods:*** DOTA.SA.FAPi, DATA5m.SA.FAPi, DOTAGA.(SA.FAPi)2, DOTAGA.Glu(FAPi)2 and DO3A.Glu.(FAPi)2 were labelled with gallium-68. In a dose-escalation study in PC3 xenografts, the administered mass of all radiotracers was gradually raised from 10 to 1500 pmol, followed by biodistribution and PET/CT imaging at 1 h p.i.. The selectivity towards FAP, PREP, and DDP4, along with their stability in vivo, was examined by biodistribution and metabolite analysis, respectively, in different cohorts of mice. FAP expression in mouse blood and various organs was confirmed through RNA extraction followed by qPCR analysis. ***Results:*** The administered mass of the radiotracers appeared to have a significant impact on blood retention and tumor uptake. By increasing the mass from 10 pmol to the respective optimal dose, blood uptake could be reduced by a factor of 5 to 8. The optimal administered mass ranged from 350 to 600 pmol, resulting in peak tumor uptake between 12 and 19 %IA/g. For example for [68Ga]Ga-DOTAGA.Glu(FAPi)2: blood uptake was 25.8±3.2%IA/g and 3.2±0.5%IA/g, while tumor uptake was 12.5±1.7%IA/g and 16.5±2.3%IA/g at 10 and 600 pmol of injected radiotracer mass, respectively. Further increasing the injected mass of the radiotracers to 1000 to 1500 pmol resulted in a substantial alteration of the pharmacokinetic behavior of the radiotracers. Biodistribution studies validated the in vivo selectivity of all radiotracers towards FAP, even in the presence of PREP and DPP4 inhibitors. All radiotracers also demonstrated remarkable stability in vivo. Metabolite analysis of blood samples taken 10 min p.i., showed a single radioactive peak on HPLC, corresponding to the reference compound. qPCR detected expression of FAP in the bloodstream, along with the simultaneous presence of both murine and human FAP within PC3-tumors. ***Conclusion:*** Our extensive dose escalation study of monomeric and dimeric FAP radiotracers, revealed the critical importance of administering the correct mass for their effectiveness. Despite FAP's presence in the bloodstream, achieving optimal injected mass correlates directly with improved in vivo performance. This systematic investigation offers valuable insights for optimizing the diagnostic and therapeutic efficacy of FAP radiopharmaceuticals.

OP-206
Heterodimerization of Fibroblast-Activation Protein α (FAP) radiotracers as a novel strategy to increase residence time in FAP$^+$ tumors

T. Bailly, *J. Millul, M. Fani;*
University Hospital Basel, Division of Radiopharmaceutical Chemistry, Basel, SWITZERLAND.

Aim/Introduction: Radioligands based on small-molecule FAP inhibitors (e.g. FAPI-46) suffer from insufficient tumor residence time. Homodimerization of small-molecule inhibitors or cyclic peptides (e.g FAP2286) are two efficient strategies to alleviate this issue (1). We aimed to investigate whether a combination of both, i.e. heterobivalency (e.g. FAPI-46 and FAP2286 assembled in a single molecule) is a valuable alternative and if it can further improve the tumor residence time. Based on a click-chemistry platform (2), we developed three heterobivalent ligands containing spacers of increasing lengths: TB28, TB32, TB33. The best ligand was compared to TB60, its small-molecule FAPI homodimer based on the same chemical platform. ***Materials and Methods:*** The derivatives were synthesized following established procedures. They were all functionalized with DOTA and labeled with Lu-177. Their lipophilicity and stability was evaluated. Cellular uptake and distribution were determined in HT1080.hFAP cells up to 4h at 37°C. SPECT/CT images were acquired in HT1080.hFAP and HT1080.wt dual-xenografted mouse model at 4h p.i. Ex vivo biodistribution was performed from 4 up to 120h p.i.. ***Results:*** All radioligands were obtained with radiochemical purities >95%. The spacer length improved hydrophilicity (log D = -1.1±0.1, -1.5±0.1 and -2.2±0.2 for the [177Lu]Lu-TB28, [177Lu]Lu-TB32 and [177Lu]Lu-TB33, respectively). The heterodimer with the longer spacer showed the highest cellular uptake (62% for [177Lu]Lu-TB33 vs. 46% and 39% for [177Lu]Lu-TB32 and [177Lu]

Lu-TB28, respectively). All radioligands visualized FAP+ tumors in SPECT/CT images. In line with the hydrophilicity, [177Lu]Lu-TB28 accumulated mainly in the liver (16.8±5.6%IA/g at 4h p.i)., while [177Lu]Lu-TB33 in the kidneys (19.4±3.6%IA/g at 4h p.i.). The tumor uptake was comparable for all radioligands at 4h p.i. (9-10%IA/g). However, [177Lu]Lu-TB33 showed a persistent tumor uptake at 24h, and the slowest washout 72h p.i. (56% of the uptake at 4h p.i. remained in the tumor). All other heterodimers were washed out faster (15-31% of the uptake at 4h p.i. remained in the tumor). Between the heterodimer [177Lu]Lu-TB33 and its homodimer [177Lu]Lu-TB60, there was a significant difference in the tumor retention, with [177Lu]Lu-TB33 remaining by 46% in the tumor against 11% for [177Lu]Lu-TB60 at 120h p.i.. ***Conclusion:*** Heterobivalent radioligands combining FAPI-46 and FAP2286 binding moieties constitutes a promising approach for increasing radiation dose of FAP+ tumors. In comparison to the homodimerisation, heterobivalency showed advantages regarding tumor residence time. ***References:*** 1. Millul et al. Eur.J.Nucl.Med.Mol.Imaging. 2023;50:3050-3061. 2. OP-207

Development of Multivalent OncoFAP Derivatives for the Tumor-Targeted Delivery of Theranostic Radionuclides

A. Galbiati[1], *M. Bocci[1], S. Gervasoni[2], D. Ravazza[1], E. Prodi[1], J. Mock[1], G. Malloci[2], E. Gilardoni[1], D. Neri[3], S. Cazzamalli[1];*
[1]Philochem AG, Otelfingen, SWITZERLAND, [2]University of Cagliari, Cagliari, ITALY, [3]Swiss Federal Institute of Technology, Zurich, SWITZERLAND.

Aim/Introduction: Fibroblast Activation Protein is abundantly expressed in the stroma of most solid tumors. Radiolabelled FAP ligands are routinely used for the detection of various cancers. We recently described OncoFAP, a small organic FAP ligand with rapid accumulation in tumors and low uptake in healthy tissues[1]. To unleash their full therapeutic potential, FAP-targeting compounds must remain at the tumor site for days after administration. Here, we describe the development of OncoFAP-multimers with single-digit picomolar affinity and improved tumor residence time. In addition, we demonstrated that the combination with the clinical-stage immunocytokine L19-IL2 strongly potentiates OncoFAP-based RLTs. ***Materials and Methods:*** In-silico analysis of the FAP structure revealed a wide and deep pocket with distinct hotspots where extra OncoFAP-headpieces bind. In vitro characterization was performed using recombinant FAP and transfected FAP-expressing cell lines. The tumor-targeting properties and therapeutic efficacy of the novel OncoFAP derivatives were investigated in biodistribution and therapy studies, alone and in combination with L19-IL2. The mechanism of action of this combination was studied thanks to proteomic analysis. ***Results:*** As compared to the monovalent counterpart, TriOncoFAP (IC50 = 13pM, also called OncoFAP-23) and TetraOncoFAP (IC50 = 2.4pM) showed a ~43-fold and ~235-fold enhanced inhibitory activity, respectively. 177Lu-TriOncoFAP emerged for its superior biodistribution profile, presenting a very high and prolonged uptake in target lesions at all tested time-points (e.g., 16%ID/g at 96h), with a favorable tumor-to-organ ratio. When compared to 177Lu-FAP-2286, the most advanced FAP-targeted RLT in clinical development, 177Lu-TriOncoFAP exhibited a ~2.7-fold higher overall uptake in tumors, with a ~1.8-fold lower kidney uptake. Despite its superior tumor accumulation, 177Lu-TetraOncoFAP presents some uptake in liver and kidney. Higher-order multimers presented worse in vitro and in vivo performances due to increased steric hindrance. 177Lu-TriOncoFAP exhibited a dose-dependent anticancer activity, with potent efficacy already at 5 MBq/mouse. The combination with L19-IL2 resulted in complete tumor eradication in all treated animals. Proteomic analyses revealed a potent synergistic effect for the combination modality, describing an enhanced activation of the host immune system directed against the tumor mass. ***Conclusion:*** The data presented in this work strongly supports the clinical development of 177Lu-TriOncoFAP. We are launching a Phase I clinical trial to define the 177Lu-TriOncoFAP maximum tolerated dose, evaluating its safety profile, and collecting preliminary signs of efficacy. The compound will be given as single agent or in combination with L19-IL2 in patients with multiple types of FAP-positive tumors. ***References:*** [1] Millul et al., PNAS, 118:e2101852118.

Development and evaluation of covalent binding FAPIs for tumor theranostics

L. Feng[1], *W. Hu[1], J. Wang[1], C. Zheng[1], M. Li[1], Y. Shi[2], S. Liang[2], X. Lan[1], D. Jiang[1];*
[1]Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA, [2]GrandPharma (China) Co. Ltd, Wuhan, CHINA.

Aim/Introduction: As an unnatural amino acid, fluorosulfate-l-tyrosine (FSY) could bond with specific amino acids (His, Lys, and Tyr) covalently in physiochemical environments[1]. The aim of this study was to evaluate the FSY-modifed FAPI (FMF) tracers for their tumor retention and potential effectiveness of targeted radiotherapy in animals. ***Materials and Methods:*** Ga-68 and Lu-177 radiolabeling of a series of FSY-modified FAPI tracers was carried out. The radiochemical purity (RCP) and radiochemical yield (RCY) of the tracers was examined by high performance liquid chromatography and instant thin layer chromatography. Subsequently, PET/CT imaging and SPECT/CT imaging was conducted in U87MG tumor-bearing mice. Therapeutic experiments were performed on the most promising molecules (FMF-06), with Lu-177 radiolabeled FAPI-04 as a control. ***Results:*** The FAPI tracers were successfully modified with FSY and labeled with gallium-68 and lutetium-177. RCY was tested to be 36.77-98.42%, and RCP was over 95%. PET/CT images demonstrated significant tumor uptake with a tumor-to-organ ratio more than 15.0. For the molecule FMF-06, the tumor uptake was measured at 21.50 ± 6.02 %ID/g at 0.5 h postinjection (p.i.) and maintained stable at 21.67 ± 4.33 %ID/g at 2 h p.i., 11-18 fold to that of FAPI-04. SPECT/CT images suggested that [177Lu]Lu-FMF-06 mainly retained at the tumor sites for over 8 h, and other organs such as the gall bladder and large intestine. Treatment experiments showed significant tumor inhibition after one injection of 1 mCi of [177Lu]Lu-FMF-06, compared to 1 mCi [177Lu]Lu-FAPI-04 ($P < 0.001$, ****). Kaplan-Meier analysis suggested that the survival rate of group treated with 1 mCi [177Lu]Lu-FMF-06 was 85%, while all other groups at a survival rate of less than 50% within 20 days. ***Conclusion:*** FSY-modification strategy on FAPI tracers can significantly prolong their tumor uptake and retention, which further exhibited excellent tumor suppression after Lu-177 labeling upon one injection. ***References:*** Wang N, Yang B, Fu C, et al. Genetically Encoding Fluorosulfate-l-tyrosine To React with Lysine, Histidine, and Tyrosine via SuFEx in Proteins in Vivo[J]. Journal of the American Chemical Society, 2018, 140(15): 4995-4999.

Novel FAPi dimers labeled via tetrazine ligation

M. Martin1, *U. M. Battisti[1], S. Matiussi[2], F. Elvas[3], A. Miranda[3], V. Shalgunov[1,4], S. Stotz[2], T. K. Gustavsson[2], N. B. Pedersen[2], L. A. Vázquez[2], C. B. M. Poulie[1], A. I. Jensen[1], M. M. Herth[1,2,4];*
[1]TetraKit Technologies ApS, Copenhagen, DENMARK, [2]Department of Drug Design and Pharmacology, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, DENMARK, [3]Molecular Imaging and Radiology (MIRA), Faculty of Medicine and Health Sciences, University of Antwerp, Antwerp, BELGIUM, [4]Department of Clinical Physiology, Nuclear Medicine & PET, Rigshospitalet, Copenhagen, DENMARK.

Aim/Introduction: Despite the success of diagnostic radiotracers targeting the pan-tumor target fibroblast activation protein (FAP) in many different cancer types, the translation into therapeutic counterparts remains a challenge. In contrast to monomeric FAP inhibitor (FAPi) radiotracers, FAPi dimers with two FAPi targeting vectors demonstrate prolonged tumor retention leading to high tumor doses and promising results in first clinical applications. Current therapeutic FAP-targeting compounds are chelator-based and can thus only be labeled with radiometals. We have developed a technological platform that enables fast tetrazine ligation using the new trans-cyclooctene T4CO to yield only one isomer selectively. This was linked to a FAPi dimer targeting vector and enables easy labeling with various radiohalogens (18F, 123/131I, 211At) alongside radiometals. Thus, the new compounds DUAL FAPi-5, -6 and -7 imply a broad theranostic application. Especially 131I-DUAL FAPi will enable a cost-effective radioligand therapy (RLT) that can keep up with the strongly increasing demands for FAP-RLT in the future. ***Materials and Methods:*** DUAL FAPi-5/6/7 were radiolabeled with 68Ga (60-75°C for 5-10min) in NH4OAc buffer (pH=4.0) and radiochemical conversion and purity was determined via radio-TLC and radio-HPLC. The logD7.4 values were determined via shake-flask method. The excretion profile was investigated by 68Ga-µPET in naïve rats for 90min. The compounds were labeled with 111In under similar conditions and investigated via SPECT and ex vivo biodistribution in U87-MG tumor-bearing mice up to 72h p.i. ***Results:*** [68Ga]Ga-DUAL FAPi-5/6/7 were labeled with high RCC>90% (20-30 GBq/µmol), decay-corrected RCY=70-75% and RCP>97%. 68Ga-µPET showed predominantly renal excretion with fast kidney-washout for the DUAL FAPi compounds. Labeling of [111In]In-DUAL FAPi-5 and -7 gave RCC>90% after 30min (6.6-10 GBq/µmol, RCP>95%, RCY=85-90%). LogD7.4<−3 was determined for all compounds. 111In-µSPECT and biodistribution showed rapid and high tumor uptake 1h p.i. (9.67 ± 0.73 and 8.13±0.96 %ID/g) which was mostly retained after 24h (5.81 ± 3.42 and 8.46 ± 0.26%ID/g) for both compounds. Initial DUAL FAPi liver and kidney uptake was washed out largely after 4h p.i. and accumulation in other healthy organs was low. 131I-DUAL FAPi synthesis is ongoing and preliminary results show RCC=81±9% (n=4) for the 131I-tetrazine labeling which is then clicked to DUAL FAPi. ***Conclusion:*** The novel DUAL FAPi derivatives show high tumor uptake and retention while having faster and predominantly renal excretion that will be beneficial for future therapeutic applications with 131I and 211At. Preclinical studies of 131I-DUAL FAPi using U87-MG xenografts to investigate therapeutic response will start soon.

OP-210

Design, Synthesis and Biological Activity Study of a Novel Trimeric FAPI Diagnosic and Therapeutic Integrated Probe

L. Bai, *H. Cheng, S. Song;*
Department of Nuclear Medicine, Cancer Hospital of Fudan University, Shanghai, CHINA.

Aim/Introduction: To address the current situation of excessive in vivo metabolism of fibroblast activation protein (FAP) inhibitor (FAPI) nuclide probes, we designed and synthesized radio-labelled FAPI trimeric riboprobe [68Ga/177Lu]-FAPI-Trimer, harnessing the polyvalency effect of multimerization in order to enhance tumor uptake and retention, with novel structure and proprietary intellectual property rights. ***Materials and Methods:*** The stable 68Ga/177Lu labelling conditions were explored, the basic properties of the probe were tested by stability and lipid-water partition coefficients, and the specific uptake was verified by in vitro cytological experiments. Human FAP was stably transfected into the human fibrosarcoma cell line HT-1080 using a lentivirus. CDX models were constructed and imaged in PET/CT and SPECT/CT, respectively, and the in vivo distribution and metabolism were explored by biodistribution and blood clarity experiments. ***Results:*** PET/CT imaging of 68Ga-labelled FAPI-Trimer showed stable uptake values at 1-4h on the HT-1080-FAP CDX model with increasing target/native ratios (7.47±1.34 %ID/g, 1 hour after injection; 8.17±1.56 %ID/g, 4 hours after injection), and SPECT/CT imaging of 177Lu-labelled FAPI-Trimer showed stable tumor retention 72-120h after injection. Currently, 177Lu therapeutic experiments are underway, and there has been a significant inhibition of tumor growth in the administered group. ***Conclusion:*** Our FAPI-trimer structure showed higher intra-tumoral uptake compared to monomers such as FAPI-04, significantly prolonged blood clearance half-life and increased radiopharmaceutical tumor retention. These results suggest that [68Ga/177Lu]-FAPI-Trimer has the potential to be a promising tracer for FAP-targeted therapy in the future, and its anti-tumor effect needs to be further research results.

OP-211

[^{68}Ga]Ga/[^{177}Lu]Lu-AAZTA-NI-FAPI-04: a new improved FAP-targeting agent containing nitroimidazole moiety for diagnosis and radiotherapy

Y. Luo[1], *W. Jin[1], H. Hong[1], Y. Huang[1], L. Yan[1], R. Wang[1], J. Qiao[1], L. Zhu[1], H. Kung[2];*
[1]Key Laboratory of Radiopharmaceuticals, Ministry of Education, College of Chemistry, Beijing Normal University, Beijing, CHINA, [2]Department of Radiology, University of Pennsylvania, Philadelphia, PA, UNITED STATES OF AMERICA.

Aim/Introduction: Fibroblast activation protein (FAP) is an attractive target for diagnosis and therapy of cancer. Promising results have been reported for FAP-targeting agents, i.e., [68Ga]Ga-DOTA-FAPI-04, in tumor imaging. But enhancing tumor uptake and retention remains desirable for improvement of clinical applications. In this study, a new ligand, AAZTA-NI-FAPI-04, 1, was developed by incorporating a 2-nitroimidazole (NI) moiety into the core structure of FAPI-04 and utilizing AAZTA as the chelator for [68Ga]Ga(III) or [177Lu]Lu(III). ***Materials and Methods:*** Compound 1 was synthesized and labeled with either [68Ga]Ga(III) or [177Lu]Lu(III). The radiochemical purity (RCP) and in vitro stability of [68Ga]Ga/[177Lu]Lu-1 were determined by radio-HPLC and radio-TLC. In vitro cell uptake studies and competitive binding assays were conducted using HT1080-FAP positive cells. PET/CT imaging and biodistribution studies were performed in mice model bearing U87MG tumor. ***Results:*** [68Ga]Ga-1 and [177Lu]Lu-1 were efficiently labeled under mild conditions (RCP > 95%), and they remained stable in saline and mouse serum for over 120 minutes

and 6 days, respectively. The FAP binding affinity of compound 1 was comparable to that of DOTA-FAPI-04 (IC50, 7.38 vs 3.94 nM). [68Ga]Ga-1 demonstrated higher specific cellular uptake (19.59 ± 0.37 vs 3.18 ± 0.33 %ID/(7 × 105 cells)) and internalization (18.32 ± 0.33 vs 2.81 ± 0.31 %ID/(7 × 105 cells)) as compared to [68Ga]Ga-DOTA-FAPI-04 at 60 min. [177Lu]Lu-1 exhibited similar uptake at 60 min, with values of 29.76 ± 2.01 vs 18.66 ± 0.56 and 26.91 ± 0.88 vs 15.09 ± 0.22 %ID/(8 × 105 cells), respectively. PET/CT imaging with [68Ga]Ga-1 surprisingly revealed higher specific tumor uptake and prolonged retention with rapid clearance from normal tissues resulting in an improved tumor-to-muscle ratio compared to [68Ga]Ga-FAPI-04 (4.40 vs 3.98 and 14.7 vs 4.42 at 60 min and 120 min, respectively). Biodistribution studies further confirmed the superior tumor uptake of [68Ga]Ga-1 over [68Ga]Ga-DOTA-FAPI-04, with respective values of 29.0 vs 6.15 and 27.6 vs 5.72 %ID/g at 60 and 120 min post-injection, respectively. Similarly, [177Lu]Lu-1 exhibited higher tumor uptake compared to [177Lu]Lu-DOTA-FAPI-04 (29.0 vs 17.9 and 28.3 vs 20.5 %ID/g at 60 and 120 min post-injection, respectively). ***Conclusion:*** New FAP-targeting agents, [68Ga]Ga/[177Lu]Lu-1, were prepared and evaluated. By incorporating the 2-nitroimidazole (NI) moiety, [68Ga]Ga/[177Lu]Lu-1 exhibited enhanced tumor uptake and prolonged retention compared to [68Ga]Ga/[177Lu]Lu-DOTA-FAPI-04. Initial experiments suggest that [68Ga]Ga/[177Lu]Lu-1 is a promising FAP-targeting agent. Further human studies are warranted to validate the surprisingly high tumor targeting.

OP-212

Development and evaluation of novel cancer theranostic radiopharmaceutical by targeting FAP

B. Yang, *Y. Gai, J. Hu, X. Zhang, M. Li, Y. Zhang, R. An, X. Lan; Dept of Nuclear Medicine and PET center,Union Hospital,Tongji Medical College,HUST, wuhan, CHINA.*

Aim/Introduction: Fibroblast activation protein (FAP) is a type II transmembrane serine protease with dipeptidyl peptidase and endopeptidase activity, closely related to tumor growth, invasion, metastasis, and prognosis. It selectively overexpresses on the membrane of cancer associated fibroblasts (CAFs) in various epithelial derived malignant tumor stroma, making it an ideal tumor stroma target. Various FAP inhibitors based on quinolines have been developed, but their retention time in tumors is relatively short and not ideal for radioactive therapy. This study utilized an albumin-binding strategy to modify the UAMC1110 framework with high affinity for FAP, improving its pharmacokinetics and pharmacodynamics to enhance tumor targeting and prolong tumor retention. ***Materials and Methods:*** The precursors (HX and HX-AB) were synthesized by adding functional chemical groups (small organic ligands, linkers, albumin binder) and were labeled with 68Ga and 177Lu, respectively. The stability study, partition coefficient and serum albumin-binding property were determined. A series of cell assays was performed to identify the binding affinity and FAP specificity in vitro. PET imaging, SPECT imaging, and biodistribution studies were performed to evaluate the pharmacokinetics in HT-1080-FAP xenograft mice models. The cancer treatment efficacy of 177Lu-HX-AB were evaluated in HT-1080-FAP xenograft mice. ***Results:*** All radiopharmaceuticals were successfully prepared with high purity and stability. 177Lu-HX-AB was stable in PBS (pH 7.4) and saline for at least 96 h. They exhibit excellent stability in vitro, with high protein binding rate and good water solubility. The 68Ga-HX and 68Ga-HX-AB exhibited high FAP-binding affinity and specificity both in vitro and in vivo. Compared with the precursor HX, PET imaging, SPECT imaging, and biodistribution studies of the precursor HX-AB demonstrated their remarkably enhanced tumor accumulation and retention. In radioligand therapy studies, remarkable tumor suppression was observed with the 177Lu-HX-AB in HT-1080-FAP xenograft mice. ***Conclusion:*** An albumin binder-conjugated FAPI radiopharmaceuticals have been developed and evaluated in vitro and in vivo. Significantly improved tumor uptake and retention were observed, compared with the HX without albumin binder. The favorable in vivo pharmacokinetics and excellent treatment efficacy, make it a promising radiopharmaceutical for theranostic applications.

Impact of fitting technique and number of SPECT-CT time points in Renal Dosimetry Post ^{177}Lu-DOTATATE Therapy

B. Driscoll[1], *R. Wong[1], A. Shessel[1], D. Laidley[2], S. Myrehaug[3], R. Juergens[4], T. Farncombe[4], K. Zukotynski[5], R. Stodilka[6], J. Beauregard[7], U. Metser[1], P. Veit-Haibach[1], A. Hendler[1], S. Ezzat[1], K. Lajkosz[1], J. Gabrys[1], O. Levine[4], R. Mohan[1], A. Mesci[1],* I. Yeung[1]; *[1]University Health Network, Toronto, ON, CANADA, [2]London Health Sciences Center, London, ON, CANADA, [3]Odette Cancer Centre, Toronto, ON, CANADA, [4]Juravinski Cancer Centre, Hamilton, ON, CANADA, [5]McMaster University, Hamilton, ON, CANADA, [6]London Health Sciences Centre, London, ON, CANADA, [7]Cancer Research Centre and Department of Radiology and Nuclear Medicine, Université Laval, Laval, QC, CANADA.*

Aim/Introduction: In the multi-institution prospective single arm OZM-067 177Lu-DOTATATE trial (NCT02743741), 68GaDOTATATE positive patients receive 4 cycles of therapy with individualized dosimetry as assessed using SPECT-CT. This study investigates the impact of fitting algorithm and number of SPECT-CT time point scans post treatment administration. ***Materials and Methods:*** All patients receive an initial dose of 7.4GBq with subsequent dose per cycle (maximum 11.1GBq) based on renal dose tolerance of 23Gy. Dosimetry calculations are based on quantitative SPECT-CT acquired at 4, 24 and 72 hours post injection. A 3-parameter bi-exponential (3PBE) function is fitted as the reference fit to the three points and the area under this curve is used for dose calculation. Other fitting algorithms are compared to this reference fit, namely, mono-exponential (ME), linear fitting from 0 to 24 hours followed by mono-exponential (LME), simplified bi-exponential (2PBE) using only 2 time points (4 and 72 hour only) and single time point (STP) calculation by Hanscheid(2018). ***Results:*** 173 patients were accrued to the study from 4 sites between Aug 2016 & June 2021. 129 patients completed all 4 cycles of treatment and 90 patients completed all 12 SPECT-CT sessions (3 sessions x 4 cycles). Comparing the two mono-exponential results to the 3PBE, the ME model produces absorbed dose values on average 0.60±0.77Gy (13.5±16.5%) higher with a Pearson correlation (ρ) of 0.939, while the LME model resulted in absorbed dose values 0.11±0.53Gy (2.7±13.0%) higher and ρ=0.959. Removing the 24-hour SPECT-CT resulted in a 0.026±0.52Gy (1.0±13.5%) reduction

in calculated absorbed dose (ρ=0.957). This difference was higher when comparing 3PBE to STP where the dose reduction was 0.37±0.50Gy (8.9±11.1%) (ρ=0.964). Using the 2PBE and STP to prescribe the injected activity of subsequent cycles results in an average under treatment of only 0.6±4.0% for 2PBE and 3.4±6.0% for STP with very high correlation of ρ=0.983 and ρ=0.963 respectively. In the case of the 2PBE fit only 3/90 patients received an injected activity in excess of 10% different from the 3PBE while 11/90 patients were outside that window for the STP model. ***Conclusion:*** Removing the 24-hour time point has only a slight impact on injected activity and absorbed dose estimates to the kidneys. One time point dosimetry provided reasonable results with high correlation (r=0.963) with modest bias (8.9 ± 10.7 per cycle 3.4 ± 6.0% overall). The 2 time point BE model can help facilitate wider adoption of internal dosimetry in PRRT treatment protocols.

OP-214

Towards an international audit system for personalised theranostics: Results from a European comparison exercise of dosimetry software

A. Denis-Bacelar[1], *T. MRTDosimetry Collaboration[2], N. Calvert[3], J. Tipping[3], A. F. Fenwick[1], K. M. Ferreira[1], A. P. Robinson[1];*
[1]National Physical Laboratory, Teddington, UNITED KINGDOM, [2]EURAMET EMPIR, Funding Programme, UNITED KINGDOM, [3]The Christie NHS Foundation Trust, Manchester, UNITED KINGDOM.

Aim/Introduction: Despite the introduction of legislation requiring individually planned treatments according to the radiation absorbed doses delivered, its implementation remains challenging; partly due to the wide range of dosimetry methods available and the lack of a robust methodology to validate dosimetry software. The aim of this study was to perform a comparison exercise of commercial and research dosimetry software using a reference imaging dataset to assess the accuracy, variability and uncertainties at each step of the dosimetry workflow. ***Materials and Methods:*** Each participating site was provided with: (i) a Standardised Operating Procedure, (ii) two reference imaging datasets comprised of reconstructed SPECT/CT scans (D1: 1, 4, 24, 40, 72 h; D2: 1, 24, 40, 72, 144 h) of a 3D printed anthropomorphic phantom with a tumour (TU), liver (LV), spleen (SP), kidneys (KB) (left (KL) and right (KR) kidneys, sub-divided into medulla (KLM, KRM) and cortex (KLC, KRC), filled according to a clinically realistic biokinetic model for 177Lu-DOTATATE [2]; and (iii) a dedicated reporting template adapted from the IAEA Radiotracer Biodistribution Template (RaBiT). Participants were asked to report details on their workflows, and results on the volume, activity, cumulated activity, fitting parameters of the time-activity curve, time integrated activity coefficient and absorbed dose to each region, amongst other parameters. Uncertainty analysis was performed centrally [3]. ***Results:*** 23 submissions (D1=12, D2=11) from 10 sites were received. Preliminary results show a large variability in absorbed doses calculated for each organ (KB: 21%; KL: 18%; KR: 19%; KLC 29%; KLM: 34%; KRC: 34%; KRM: 23%; LI: 62%; SP: 73%; TU: 42%), and significant deviations from the true absorbed doses (KB: -21%; KL: -15%; KR: -19%; KLC: -14%; KLM: 66%; KRC: -33%; KRM: 68%; LI: 22%; SP: 56%; TU: -11%). Major parameters affecting the results include the delineation method and time-activity curve fitting. No statistically significant differences were observed between D1 and D2, or between voxel and organ-based methods. The uncertainty analysis identified software bugs including misuse of DICOM tags that resulted in an underestimation of calculated absorbed doses in a software package. ***Conclusion:*** The results highlight the need to establish robust international quality assurance system using traceable reference datasets to audit and validate dosimetry software for post-therapy verification and personalised theranostics treatment planning. ***References:*** [1] Robinson et al. 3D Printing of Anthropomorphic Phantoms with Non-uniform Activity Distributions for the Evaluation of Quantitative SPECT

L. Jessen, *J. Gustafsson, M. Ljungberg, K. Sjögreen Gleisner;*
Medical Radiation Physics, Lund, SWEDEN.

Aim/Introduction: SPECT-based activity quantification of 177Lu is challenging for small, non-uniform, and irregularly shaped objects. Our aims were to 3D-print anthropomorphic phantom inserts that mimic these difficulties in SPECT images and use them to assess accuracy in estimation of activity-concentration based on experimental measurements and Monte Carlo simulations. ***Materials and Methods:*** Two kidney and five tumour inserts were 3D-printed. For kidneys, non-uniform activity distributions were constructed with a grid-based technique that utilized the limited spatial resolution of SPECT, results in an apparently lower mean-activity concentration (Ac) in a region. The kidneys were designed based on XCAT phantom templates, and the tumours on patient 68Ga-PET-images. Kidneys encompassed cortex, medulla and renal pelvis. The medulla was printed using the grid technique resulting in a lower mean Ac for that region with a total encompassing volume of 126 mL and 136 mL. The tumours were kept hollow to result in a uniform activity distribution with volumes between 3 mL to 15 mL. Phantoms were filled with a 177Lu solution and SPECT images acquired. The Ac in each insert was determined from reconstructed SPECT images by manual delineation of the whole objects. The estimated Ac was compared with the reference Ac and presented as a recovery for each phantom. To validate the grid-based technique, Monte Carlo simulations of the true activity distribution in the kidneys were performed. The simulated SPECT images were compared with the physical measurements both qualitatively and quantitatively. ***Results:*** Recoveries were 85% and 91% for the kidneys and 48%, 69%, 54%, 68% and 72% for the 5 tumours. Measured and simulated SPECT images showed agreement in activity distribution and quantitative profiles, thus confirming the grid-based technique for mimicking non-uniform activity distributions. ***Conclusion:*** 3D-printed grid-based techniques facilitate the production of non-uniform anthropomorphic phantoms that are easy to prepare as they can be filled from a single stock-solution. The phantoms provide clinically realistic and relevant images for the evaluation of quantitative SPECT and are currently used as a method for comparison and validation of activity quantification in a clinical multicentre study.

OP-216

Uncertainty estimations for activity measurements with medical radionuclide calibrators using ^{99m}Tc and ^{18}F

O. Sipilä[1], *V. Sundell[1], T. Ihalainen[1], E. Hippeläinen[1], J. Jaatela[1], P. Toroi[2];*
[1]HUS Diagnostic Center, Helsinki University Hospital and University of Helsinki, Helsinki, FINLAND, [2]STUK- Radiation and Nuclear Safety Authority, Vantaa, FINLAND.

Aim/Introduction: As a pilot study for the national AKKA-project concerning traceable calibration of medical radionuclide calibrators, uncertainties of routine 99mTc and 18F activity measurements were estimated utilizing a secondary standard radionuclide calibrator. ***Materials and Methods:*** Standard uncertainties (k=1) related to three scenarios for 99mTc and 18F were considered: 1) Geometry specific traceable calibration coefficients would be determined and utilized for each syringe and volume applied in daily practice. 2) One traceable calibration coefficient for one reference geometry would be determined and utilized, and potential deviations related to all other geometries would be included in the uncertainty estimation. 3) Only manufacturer given coefficients for a radionuclide calibrator would be used and all deviations were considered in the uncertainty estimations. Altogether six radionuclide calibrators were included in the estimations. Traceable calibration coefficients were transferred to these calibrators using a 10 ml reference vial with active solution of 2 - 8 g for 99mTc and 4 - 5 g for 18F. Also, a selection of clinically utilized syringes with different volumes was measured. Several factors were included in the uncertainty estimation: calibration coefficients, repeatability, long term stability, linearity and accuracy of display, decay correction and volumes (weights). To minimize dependence on individual measuring sessions, the final uncertainty results were computed by taking into account the worst estimates found for these individual factors for the six calibrators included. In addition, the uncertainties were also computed assuming the linearity to be 5%, which is commonly used as an acceptance criterium. ***Results:*** With measured linearities for the six calibrators, the uncertainties were 3% for both 99mTc and 18F in scenario 1, 4% (99mTc) and 3% (18F) in scenario 2, and 9% (99mTc) and 6% (18F) in scenario 3. When assuming linearity of 5%, the corresponding uncertainties were 4% for both 99mTc and 18F in scenario 1, 5% (99mTc) and 4% (18F) in scenario 2, and 10% (99mTc) and 6% (18F) in scenario 3. These uncertainties were estimated for a selection of geometries and must be updated when introducing e.g. new syringes in clinical use. ***Conclusion:*** As expected, scenario 3 had the largest uncertainties. Scenario 1 would give optimal calibration but is impractical. Also, a vast selection of calibration coefficients could be an error source in clinical work. Scenario 2 with radionuclide calibrator specific calibration coefficients for 99mTc and 18F produced acceptable standard uncertainties of ≤ 5% and would also be applicable in clinical routine.

OP-217

Towards metrologically traceable activity measurements in clinical setting - including ^{15}Oand automatic PET dispensing/infusion systems

H. Gröhn[1], *P. Toroi[2], T. Ollikainen[3], T. Laitinen[1], M. Hakulinen[1]; [1]Kuopio University Hospital, Kuopio, FINLAND, [2]Radiation and Nuclear Safety Authority of Finland, Helsinki, FINLAND, [3]North Carelian Central Hospital, Joensuu, FINLAND.*

Aim/Introduction: The requirement of metrological traceability for activity measurements performed with radionuclide calibrators in clinically used measurement geometries is challenging to fulfill. One approach is to use Secondary Standard Calibrator (SSC). However, the use of SSC in every nuclear medicine center is not practical and the use of local reference radionuclide calibrator calibrated against SSC is an attractive option.The aim of the study was to measure accuracy of radionuclide calibrators for wide range of clinically relevant radionuclides and geometries using SSC as reference. In addition, feasibility to transfer metrological traceability to local reference radionuclide calibrator was evaluated. ***Materials and Methods:*** Accuracy of activity measurements was defined for the following isotopes: 99mTc, 123I, 131I, 223Ra, 90Y, 18F, 177Lu and 15O, for 12 radionuclide calibrators from two hospitals, by comparing the displayed activity to reference value defined based on the SSC measurements, and calculating their relative difference. Measurements were performed in vial and syringe geometry, 18F was also measured in the geometry of automatic PET dispensing/infusion system and 131I was measured in capsule geometry. The measured activities covered clinically used activity range, from 3MBq to 3.7GBq. Metrological traceability was maintained in all measurement geometries by using activity measured in standardized geometry with SSC, mass of the sample and calculated activity concentration. ***Results:*** Preliminary results are reported. For 15O the difference between the reference value and measured activity was within 2%.Relative difference for 18F activities measured in automatic PET dispensing/infusion systems were <1.6% and <3.2%, for 1ml and 3ml measurement volumes. For all radionuclide calibrators corresponding relative difference for 18F in vial and syringe geometry was -1.4-3.1% and 4.2-5.8%. Relative difference for 99mTcm was less than 3% and less than 1.0% in vial and syringe geometry, respectively. In 177Lu measurements, the relative difference was 4.6-6.2% and -3.4-2.3% for vial and syringe geometry, respectively. For 90Y the relative difference was between 6% and 7% in vial geometry and for 131I capsules within 2.3%.The use of local reference radionuclide calibrator values as baseline provided similar results. ***Conclusion:*** All differences were well below required expanded uncertainty level of 10% (95% confidence level). Metrological traceability was maintained on all measurement geometries, including previously challenging 15O and automatic PET dispensing/infusion systems. The use of calibrated local reference radionuclide calibrator is feasible option for providing metrological traceability for activity measurements. One local calibrated reference meter can be used to calibrate other radionuclide calibrators in nearby hospitals.

OP-218

Uncertainty Estimation for Dosimetry from SPECT Image Reconstructions

L. Polson[1], *S. Kurkowska[2], P. Esquinas[3], C. Uribe[4], A. Rahmim[1]; [1]University of British Columbia, Vancouver, BC, CANADA, [2]Department of Nuclear Medicine, Szczecin, POLAND, [3]BC Cancer Research Institute, Vancouver, BC, CANADA, [4]University of British Columbia, BC Cancer Research Institute, BC, CANADA.*

Aim/Introduction: A variety of uncertainties exist in patient dose estimation, arising from tasks such as volume delineation, calibration source measurement, and time activity curve fitting. A source of uncertainty typically not accounted for in dosimetry procedures is the uncertainty of reconstructed counts in SPECT images due to Poisson noise in the projection data. We present an iterative reconstruction algorithm to estimate this uncertainty on measured counts within segmented volumes in clinical SPECT images. ***Materials and Methods:*** The algorithm for uncertainty estimation is a modification of a previous algorithm (Qi, 2003) and works for any linear preconditioned gradient ascent algorithm (such as OSEM); it is implemented in the open-source python library PyTomography and is presently validated on Tc99m Jaszczak phantom data (i) simulated via SIMIND and (ii) acquired on a Siemens Symbia T2. The simulated SIMIND Monte Carlo Tc99m Jaszczak phantom contained 6 spheres of radii 0.47 cm, 0.8 cm, 0.95 cm, 1.27 cm, 1.59 cm, and 1.9 cm with activity concentration 1.46 MBq / mL and with a cold background at 1/10th the activity. 4000 separate noise realizations of this data (5 s per projection) were reconstructed in PyTomography (OSEM

10it/8ss) to estimate the true count variance. The real data consisted of a Jaszczak phantom with sphere sizes of 0.635 cm, 0.710 cm, 0.970 cm, 1.110 cm, 1.825 cm, and 2.875 cm filled at a 8:1 source to background ratio. 56 scans (5s / projection) were acquired and rebinned into 70 separate realizations to account for activity decay and yield a 160 kBq/mL activity concentration per realization. ***Results:*** For the simulated data, the estimated uncertainties from the reconstruction of a single noise realization were 6.39%, 1.78%, 1.19%, 0.68%, 0.47%, and 0.34%, while the actual variation in counts in the 6 respective spheres from the 4000 realizations were 6.34+/-0.26%, 1.74+/-0.07%, 1.26+/-0.05%, 0.66+/-0.03%, 0.46+/-0.02%, and 0.35+/-0.01%. For the real data, the estimated uncertainties from a single realization were 22.45%, 15.36%, 7.24%, 3.95%, 2.00%, and 0.68%, while the actual variation in counts from the 70 realizations were 22.27+/-1.89%, 16.45+/-1.40%, 6.81+/-0.58%, 4.53+/-0.39%, 2.05+/-0.17%, and 0.62+/-0.05% ***Conclusion:*** A technique for uncertainty estimation from SPECT reconstructions was developed and validated on Monte Carlo and real Tc99m phantom data. The uncertainties obtained using this technique may be valuable for estimation of patient dose in dosimetry protocols. ***References:*** Qi, Jinyi. "A unified noise analysis for iterative image estimation." Physics in medicine and biology vol. 48,21 (2003): 3505-19. doi:10.1088/0031-9155/48/21/004.

OP-219

Determination of calibration factors for ^{177}Lu in digital 3D and conventional dual-head SPECT/CT systems over a wide range of activities

L. Kääriä[1], *A. Saikkonen[1], M. Seppänen[2], T. Noponen[1];*
[1]Department of Clinical Physiology, Nuclear Medicine, Turku PET Centre and Medical Physics, Turku University Hospital and Wellbeing Services County of Southwest Finland and University of Turku, Turku, FINLAND, [2]Department of Clinical Physiology, Nuclear Medicine, and Turku PET Centre, Turku University Hospital and Wellbeing Services County of Southwest Finland and University of Turku, Turku, FINLAND.

Aim/Introduction: PSMA-directed radioligand therapies (PSMA-RLT) utilizing 177Lu have been increasingly used in clinics. These treatments usually require post-therapy imaging for dosimetry purposes, which can be conducted a couple of hours and one-week after the treatment. However, given the significant variance in remaining activities in patients at these time points, it becomes essential to assess whether the existing activity level influences the calibration factor of the systems. In this study, we determined the calibration factors for 177Lu in conventional dual-head analog and digital CZT 3D ring-design general-purpose whole-body SPECT/CT systems. Additionally, we evaluated whether these calibration factors remain constant across the range of activity levels. ***Materials and Methods:*** A cylindrical phantom containing 3.70-3.75 GBq of 177Lu was used in the calibration measurements. The phantom was imaged multiple times as the activity decayed, until reaching near-complete depletion. The acquisition protocols were standardized between the systems. The duration of the imaging time in both systems were 20 minutes. The digital 3D SPECT/CT system was capable of detecting both main photon peaks (113 and 208 keV) of 177Lu while 208 keV peak was measured with the conventional SPECT/CT system. The activity and the activity concentration of the phantom were determined for every acquisition. The data were reconstructed in both systems using a basic iterative OSEM algorithm with 6-20 iterations, 6-15 subsets and CT attenuation correction. The total counts were determined with a commercial nuclear medicine processing software using a cylindrical 2001.2 cm3 VOI (with 140 mm in diameter and 130 mm in height). The acquisition times used in the calculation of the calibration factors were determined from the image header. ***Results:*** The mean calibration factor for the conventional SPECT/CT system was 5.74±0.18 cps/MBq and for the ring-design system for 113 and 208 keV peaks 69.79±1.68 cps/MBq (range 67.69-72.45 cps/MBq) and 71.64±2.44 cps/MBq (range 64.61-75.38 cps/MBq), respectively. The calibration factor remained stable from 3700 to 16 MBq in 208 keV peak and from 3700 to 140 MBq in 113 keV peak in the digital 3D SPECT/CT and in the conventional SPECT/CT from 3700 to 24 MBq. The reconstructed sensitivity was 12 times better in the digital 3D than in conventional SPECT/CT system. ***Conclusion:*** The calibration factors remain stable in the clinically used activity range of 177Lu therapies. The digital 3D SPECT/CT system demonstrates a sensitivity enhancement of 12-fold compared to conventional gamma-camera technology, providing a substantial advancement in SPECT/CT imaging capabilities.

OP-220

Automated determination of optimal post-reconstruction filter parameters for EARL accreditation

D. Schmidt, *D. Völkl, E. Rathsmann, S. Böhner, D. Hellwig;*
Universitätsklinikum Regensburg, Regensburg, GERMANY.

Aim/Introduction: Standardized image generation and inter-laboratory standardization are necessary not only for advanced patient care and support for clinical research, but also for consistent image quality as essential to the advancement of artificial intelligence in nuclear medicine. Accreditation programs such as EARL play an important role in promoting quality assurance within nuclear medicine and ensuring the consistency of measurements. This, in turn, facilitates the development of valuable training datasets for deep learning applications. Here, we present a novel tool that fully automates the optimization of PET/CT reconstruction parameters of PET or SPECT phantoms to meet the quantitative criteria for EARL accreditation. ***Materials and Methods:*** The program uses the Python programming language. Initially, PET or SPECT images in DICOM format are imported and SUV-scaled. Using Lie thresholding, the hot spheres are automatically detected and segmented. The recovery coefficients (RCs) for the maximum and mean activity levels within the spheres are determined. With the aid of a scoring function, the variation of FWHM values for the convolution of the phantom images by a Gaussian filter allows for optimal adjustment of the recovery coefficients within the limits of the EARL accreditation requirements. The optimal FWHM can then be applied for post-reconstruction filtering in the routine acquisition protocol for EARL-compliant PET or SPECT image generation. The tool was evaluated in our former PET phantom measurements for the EARL qualification. ***Results:*** The deviation of the VOI segmentation between our tool and commercial ones is approximately 5%. The tool demonstrates robust convergence and good results with deviations of about 10% from the RCs ideally expected for EARL accreditation what was always within the confidence intervals of EARL. The time needed to determine optimal reconstruction parameters is reduced compared to manually varying parameters at the scanner console.Due to the Lie thresholding algorithm, which requires no prior knowledge of the geometries to be segmented, the program can be quickly adapted to additional geometries (such as more and or larger spheres for example for Lu-177 accreditation) and measurement methods (including quantitative SPECT/CT) as well. ***Conclusion:*** By using the

program, the quality assurance process for EARL accreditation is facilitated. This way, the acceptance and spread of such crucial standardization initiatives can be increased. We can suggest the integration of our tool into the EARL portal so that each EARL site can see whether and with which convolution parameter the EARL specifications are met before final image upload.

OP-221

New Total-Body and Long-axial Field-of-view PET Scanner Quality Control and Quality Assurance Protocol Developed at UC Davis

B. A. Spencer[1], *R. Bayerlein[1], N. Omidvari[1], E. Shanina[1], K. J. Chung[1], B. Mehadji[1], C. Mingels[1,2], E. Berg[1], E. M. Revilla[1], Y. G. Abdelhafez[1], Y. Zhu[1], S. Li[1], J. P. Schmall[1,3], M. Nguyen[1], Z. Xie[1], E. J. Li[1], E. K. Leung[1,3], Y. Wang[1], G. Wang[1], E. Roncali[1], T. Jones[1], S. R. Cherry[1], L. Nardo[1], R. D. Badawi[1];*
[1]University California Davis, Sacramento, CA, UNITED STATES OF AMERICA, [2]Inselspital, Bern University Hospital, University of Bern, Bern, SWITZERLAND, [3]UIH America Inc., Houston, TX, UNITED STATES OF AMERICA.

Aim/Introduction: With their increasing adoption in routine clinical care and a variety of research applications, total-body (TB) and long-axial field-of-view (LAFOV) PET/CT scanners play a key role in high-performance nuclear medicine imaging. With this work we aimed to develop a new generalizable protocol for a stringent and robust quality control (QC) and assurance (QA) on the uEXPLORER TB PET scanner at UC Davis. ***Materials and Methods:*** In total we scanned more than 2,000 participants across 30 different research studies utilizing a broad range of radiotracers (e.g. $^{[18F]}$-Fluorodeoxyglucose, [68Ga]Ga-DOTATATE, $^{[18F]}$Fluciclovine, [^{11}C]-Butanol, [89Zr]-Df-Crefmirlimab) and a therapeutic agent ([90Y]-microspheres) over a 15,000-fold activity range with TB PET over the past 5 years. This work led to a stringent QC and QA protocol. ***Results:*** A. Daily detector check: A 1-minute blank scan can provide a measurement of the average LYSO detector background count-rates of the scanner. This allows a fast and efficient method of daily QC and long-term monitoring of scanner performance.B. Weekly quantification check: A uniform 68Ge cylinder can be utilized to assesses temporal quantitative accuracy as a standardized QC procedure. Acquisitions of this phantom at ≥3 axial locations across the AFOV can check quantification across the AFOV.C. Dose calibrator cross-calibration: A uniform 18F-filled phantom gives the cross-calibration factor; tracking this calibration factor over time provides an assessment of long-term temporal stability.D. Sensitivity monitoring: Measuring scanner sensitivity periodically using a line source which is longer than the scanner AFOV provides a standardized evaluation of long-term scanner performance. E. Time-of-flight QA: Acquisitions of a line source positioned axially off-center can provide an estimate of TOF calibration accuracy and could reveal detector abnormalities that may cause TOF misalignment. This QA assessment can be applied to the line source acquisitions of subsection D or performed as needed.F. Stringent quantitative accuracy and image quality monitoring: Imaging multiple NEMA image quality phantoms spanning the AFOV provides a quantitative investigation of the entire AFOV. Acquisition of this phantom data across a wide range of activity levels (e.g. from 555 to 0.5 MBq) ensures a full and thorough assessment of quantitative accuracy and image quality. ***Conclusion:*** We found that our proposed protocol ensured thorough examination of TB or LAFOV PET scanner performance and stability. We recommend this protocol be implemented on any TB or LAFOV PET scanner to facilitate reliable clinical healthcare and research.

^{99m}Tc-MIP-1404 SPECT/CT is promising in the detection of local lymph node metastases in subjects with newly diagnosed, high-risk prostate cancer

S. Malaspina[1], *M. Seppänen[2], T. Noponen[3], M. Anttinen[4], L. Eklund[4], T. Tommila[4], K. Timonen[5], J. Raiko[1], J. Kemppainen[1], J. Schildt[6], L. Nummelin[1], M. Högerman[7], I. Rinta-Kiikka[8], J. Ronkainen[8], E. Saukko[9], I. Kohonen[9], P. Boström[4], O. Ettala[4];*
[1]Turku PET Centre, University of Turku and Turku University Hospital, Turku, FINLAND, [2]Department Nuclear Medicine and Turku PET Centre, University of Turku and Turku University Hospital, Turku, FINLAND, [3]Department of Medical Physics and Nuclear Medicine, University of Turku and Turku University Hospital, Turku, FINLAND, [4]Department of Urology, University of Turku and Turku University Hospital, Turku, FINLAND, [5]Department of Clinical Physiology and Nuclear Medicine, Central Hospital of Central Finland, Jyväskylä, FINLAND, [6]Department of Clinical Physiology and Nuclear Medicine, University of Helsinki and Helsinki University Hospital, Helsinki, FINLAND, [7]Department of Biostatistics, University of Turku, Turku, FINLAND, [8]Department of Radiology, Tampere University and Tampere University Hospital, Tampere, FINLAND, [9]Department of Diagnostic Radiology, University of Turku and Turku University Hospital, Turku, FINLAND.

Aim/Introduction: Staging at the time of diagnosis is crucial in the care of prostate cancer patients. It is established that prostate-specific membrane antigen (PSMA) PET/CT is more sensitive in detecting metastases compared to bone scintigraphy (BS) and contrast-enhanced computed tomography (CE-CT). Since not all units have access to PSMA PET/CT due to high costs and tracer availability, 99mTc-MIP-1404, a novel PSMA-targeted SPECT radiopharmaceutical, could broaden the access to PSMA imaging. The aim of this study is to prospectively compare the diagnostic performance of 99mTc-MIP-1404 SPECT/CT to conventional imaging in primary staging setting. ***Materials and Methods:*** PROSTAMIP is an ongoing investigator-initiated randomised prospective single-institution Phase III trial conducted in Turku University Hospital (EUDRA-CT 2021-000486-33; NCT06219746). It is designed to demonstrate the superiority of 99mTc-MIP-1404 SPECT/CT (PSMA arm) over CE-CT (control arm) in the detection of local lymph node metastases. Based on the proPSMA study, it was anticipated that local lymph node metastases are found in 9% and 20% of cases in the control arm and the PSMA arm, respectively (1). Using a two-sided alpha of 0.05, a beta of 0.20, and a dropout rate of 5%, a total of 320 subjects with newly diagnosed, high-risk prostate cancer (Gleason ≥4+4, PSA ≥20 and/ or cT≥3a) are randomised 1:1 into the control arm and the PSMA arm. ***Results:*** Here, we report the results of a pre-planned interim analysis conducted in December 2023. The first 100 subjects (control arm n=50, PSMA arm n=50) had a mean(SD) age of 71(8) years and a median(IQR) PSA of 14(29) ng/ml. The majority presented with an ISUP grade group 4 or 5 cancer; 22(22%), 56(56%), respectively, and clinical T3-stage or higher cancer; 54(54%).In the control arm, CE-CT detected 20 local lymph node metastases with a median

(IQR) diameter of 12 (10-13) mm in 10 (20%) subjects. In the PSMA arm, 99mTc-MIP-1404 SPECT/CT detected 48 local lymph node metastases with a median (IQR) diameter of 8.0 (6.0-11) mm in 20 (40%) subjects. ***Conclusion:*** Interim results indicate that 99mTc-MIP-1404 SPECT/CT detects more subjects with local lymph node metastases compared to CE-CT. ***References:*** 1. Prostate-specific membrane antigen PET-CT in patients with high-risk prostate cancer before curative-intent surgery or radiotherapy (proPSMA): a prospective, randomised, multicentre study. Lancet (London, England). 2020;395(10231).

OP-223

Diagnostic Accuracy of Fully Hybrid PET/MRI with [^{68}Ga] Ga-PSMA-11 and [^{68}Ga]Ga-RM2 for Primary Prostate Cancer Characterization: Results from a Prospective Phase II Clinical Trial

S. Ghezzo[1,2], *P. Mapelli[1,2], A. Samanes Gajate[2], G. Brembilla[1,3], V. Cucchiara[4,5], C. Bezzi[1,2], I. Neri[2], M. Freschi[6], A. Briganti[1,4,5], F. De Cobelli[1,3], A. Chiti[1,2], P. Scifo[2], M. Picchio[1,2];*
[1]Vita-Salute San Raffaele University, Milan, ITALY, [2]Department of Nuclear Medicine, IRCCS San Raffaele Scientific Institute, Milan, ITALY, [3]Department of Radiology, IRCCS San Raffaele Scientific Institute, Milan, ITALY, [4]Department of Urology, IRCCS San Raffaele Scientific Institute, Milan, ITALY, [5]Division of Experimental Oncology, URI, Urological Research Institute, Milan, ITALY, [6]Department of Pathology, IRCCS San Raffaele Scientific Institute, Milan, ITALY.

Aim/Introduction: The primary goal of this study consisted in the head-to-head comparison of the diagnostic accuracy of [68Ga]Ga-PSMA-11 PET, [68Ga]Ga-RM2 PET, and multiparametric (mp)MRI for the preoperative characterization of primary prostate cancer (PCa). ***Materials and Methods:*** Forty-two men with biopsy-proven high-risk PCa (median PSA: 6.66 ng/mL) were enrolled in this prospective phase II clinical trial (EudraCT: 2018-001034-18). All patients underwent [68Ga]Ga-PSMA-11 PET/MRI, with mpMRI, and 36/42 also underwent [68Ga]Ga-RM2 PET/MRI within a median of two days (range: 2 - 16 days). Twenty-five patients underwent radical prostatectomy and extended lymphadenectomy (ePLND), while only 23/36 patients examined with [68Ga]Ga-RM2 PET/MRI underwent surgery. Two Nuclear Medicine physicians reviewed all PET examinations and mpMRI was interpreted by a radiologist using PI-RADS v2 criteria. Histopathological samples gathered at biopsy were used to validate intraprostatic findings, while the histopathological assessment of lymph nodes after ePLND was used as ground truth for regional lymph nodes involvement. Patient level sensitivity was used as primary endpoint for the diagnostic accuracy of imaging modalities at the intraprostatic level, while overall accuracy, sensitivity, specificity, positive predicted value (PPV) and negative predictive value (NPV), along with their 95% CI, were used to evaluate imaging performance for the detection of regional lymph nodes involvement. ***Results:*** [68Ga]Ga-PSMA-11 PET and mpMRI identified at least one intraprostatic cancer lesion in all patients , while [68Ga]Ga-RM2 PET was positive in 33/36 patients. [68Ga]Ga-PSMA-11 PET showed regional lymph nodes involvement in 5/25 patients, 3 confirmed by histology. Five out of 25 patients were also positive at mpMRI for N staging (2 true positives). [68Ga]Ga-RM2 PET identified 2/23 patients with lymph nodes involvement that were later confirmed as true positives by histology. The pathological assessment of the resected lymph nodes showed 5/25, 6/25, and 4/23 false negative findings for [68Ga]Ga-PSMA-11 PET, mpMRI, and [68Ga]Ga-RM2 PET, respectively. Detailed results for N staging in Table 1. ***Conclusion:*** All imaging modalities showed high sensitivity for the localization of primary PCa. [68Ga]Ga-PSMA-11 PET was the most sensitive modality for the identification of pathologic pelvic lymph nodes, while [68Ga]Ga-RM2 PET showed the highest specificity in this setting.

OP-224

^{18}F-Flotufolastat PET/MR in suspicious prostate cancer: correlation with histopathological biopsy-results

I. Rauscher[1], *N. Gabler[1], S. Kirchhoff[1], M. Heck[2], M. Eiber[1];*
[1]Department of Nuclear Medicine, Technical University of Munich, Klinikum rechts der Isar, Munich, GERMANY, [2]Department of Urology, Technical University of Munich, Klinikum rechts der Isar, Munich, GERMANY.

Aim/Introduction: Several studies have proven that prostate-specific membrane antigen (PSMA) positron emission tomography/magnetic resonance imaging (PET/MRI) exceeds the results of solo use of multiparametric (mp) MRI in the primary detection of prostate cancer (PC). Therefore, the aim of this retrospective study was to determine the detection efficacy of 18F-flotufolastat (formerly 18F-rhPSMA-7.3) PET/MRI using the recently introduced PRIMARY score for PET assessment of tumour lesions in correlation to results from biopsy. ***Materials and Methods:*** In total, 72 patients (median pre-scan PSA 10.1 ng/mL) undergoing clinically indicated 18F-flotufolastat PET/MRI were included. 18F-Flotufolastat PET and MR-images of the prostate were read independently using the PRIMARY and MR-PIRADS score. Imaging scores on patient-basis were compared to transperineal biopsy results (clinically significant (cs) PC ISUP ≥ 2) performed at a median time interval of 42 days (range 10-265 days) after PET. Diagnostic performance parameters were calculated and ROC-analyses were performed on a patient-basis. ***Results:*** In total, 20 (27.8%) patients were recorded as csPC. Sensitivity, specificity, PPV and NPV were 85.0%, 82.7%, 65.4% and 93.5% for PRIMARY score and 85.0%, 50.0%, 39.5% and 90.0% for MR-PIRADS score, respectively. Using combined PET and MRI, sensitivity, specificity, PPV and NPV were 95.0%, 42.3%, 38.8%, 95.7%, respectively. ROC analysis revealed an AUC of 0.86 (95% CI 0.76-0.93), 0.74 (95% CI 0.62-0.84) and 0.80 (95% CI 0.69-0.89) for PRIMARY score, Pi-RADS-score and combined PET/MRI score, respectively. The comparison of PRIMARY and Pi-RADS to PET/MRI ROC-curves did not reach significance (p=0.14 vs. 0.18) whereas the comparison between both scores was statistically significant (p=0.08). ***Conclusion:*** The PRIMARY score for detecting biopsy-proven primary PC lesions on 18F-flotufolastat PET outperformed sole mpMR imaging using Pi-RADS score showing higher diagnostic performance parameters. Thus, the PRIMARY score should be considered when interpreting intraprostatic PSMA PET images.

OP-225

Pre-operative detection of extraprostatic tumor extension in patients with primary prostate cancer undergoing [68Ga]Ga-PSMA PET/MRI: A post-hoc machine learning analysis of the RAPID trial

J. Ning, *C. Spielvogel, K. Kluge, D. Haberl, G. Wasinger, L. Papp, B. Grubmüller, S. F. Shariat, L. Kenner, M. Hacker, A. Haug, S. Rasul;*
Christian Doppler Lab for Applied Metabolomics, Vienna, AUSTRIA.

Aim/Introduction: Radical prostatectomy (RP) is widely used as an initial treatment for patients with localized prostate cancer (PCa), of which nerve-sparing surgery patterns are highly recommended to preserve quality of life. However, the precise

pretreatment identification of extraprostatic extension (EPE) is still a huge challenge, often resulting in less than optimal treatment strategies. Machine learning (ML) is emerging as a beneficial tool for improving preoperative EPE detection by integrating various types of data non-invasively or minimally invasively. ***Materials and Methods:*** A post-hoc analysis of the cohort from a prospective clinical trial (NCT02659527) was conducted, which included 131 patients undergoing [68Ga]Ga-PSMA-11 PET/MRI from 2014 to 2019. We gathered comprehensive preoperative data, such as PET-derived features, blood-based markers, histology-derived parameters, and patient demographics. We developed ML models using both non-invasively and invasively acquired features to detect EPE, and compared these models against traditional PET imaging analysis. 100-fold Montre Carlo cross-validation was used to ensure the robustness of ML models. ***Results:*** The cohort comprised 77 patients, 44 of whom (57%) had EPE confirmed by postoperative analysis. The ML models outperformed conventional PET imaging, with the explainable boosting machine (EBM) model reaching an AUC of 0.88. Additionally, the ML model incorporating invasive features showed enhanced predictive accuracy for EPE compared to conventional visual assessments (AUC 0.88 vs. 0.71, p=0.02), while the difference in AUCs between the ML model with non-invasive features and visual assessments was not statistically significant (AUC 0.83 vs. 0.71, p=0.34). ***Conclusion:*** Employing explainable ML models that utilize routinely collected clinical data can significantly enhance the detection of EPE in patients with PCa before surgery, potentially leading to more precise clinical staging, informed treatment decisions, and improved outcomes for patients. ***References:*** 1. OP-226

Focal unspecific bone uptake on [18F]PSMA1007 PET: evaluation analog PROMISE criteria and validation via PET/CT follow-up

J. Benecke, *E. Calderón Ochoa, M. Reimold, C. la Fougère, J. Vogel;*
Nuclear Medicine and Clinical Molecular Imaging, Department of Radiology, University Hospital of Tuebingen, Tuebingen, GERMANY.

Aim/Introduction: Focal unspecific bone uptake (UBU) is commonly observed in [18F]PSMA1007 PET/CT, a trend that is escalating with the adoption of advanced digital PET systems and whole-body PET/CT-scanners. Nevertheless, the clinical significance of these findings remains elusive, contributing to uncertainty in many cases, potentially leading to over- or undertreatment of patients. ***Materials and Methods:*** 99 patients (age 69±7 years) with histologically confirmed prostate cancer underwent [18F]PSMA1007 PET/CT for staging with a standardized protocol (3 MBq/kg; 70±14 min p.i.). The prevalence of UBU (defined using miPSMA-score analogous PROMISE criteria) and bone metastases was assessed and correlated with various imaging and clinical parameters such as serum PSA and Gleason score. Subsequently, all patients underwent a follow-up [18F] PSMA1007 PET/CT after 13.0 ± 7.2 months to ascertain the nature of the UBUs. ***Results:*** On initial PET/CT, 230 lesions in 56 patients were classified as UBU (without presence of bone metastasis). 19 patients had bone metastases, while 24 patients had no focal bone uptake. The UBU distribution by site was as follows: ribs 50%, spine 30%, pelvis 15%, and other sites 5%. There were no significant differences in age, Gleason score, injected tracer dose, uptake time, or mean uptake in the spleen and parotid gland between patients with and without UBU. However, serum PSA were significantly higher in both patients with UBU ($p = 0.027$) and patients with bone metastases ($p = 0.014$) compared to patients without focal bone uptake. Mean blood pool uptake was lower in the prevalence of UBU ($p < 0.001$). Follow-up evaluation showed no change in miPSMA-score and CT appearance in 43 patients, regression of miPSMA (without systemic treatment) in 6 cases, and new bone metastases in 7 patients (13%). Patient-specific analysis indicated that 4 bone metastases were newly formed, while 3 initially appeared as UBU. Among patients without focal uptake on initial PET/CT, 4 patients developed osseous metastases on follow-up (17%). ***Conclusion:*** Our study underscores the lack of significant differences between patients with or without UBU concerning various imaging and clinical parameters. Furthermore, only a small fraction of the detected UBUs turned out to be metastases over time (5%). This proportion is lower than the likelihood of developing new osseous metastases, which also appears to be independent of the presence of UBU. Therefore, our data suggest that the presence of UBU, analogous to the PROMISE criteria, does not influence the development of osseous metastases over time.

OP-227

PSMA based Indocyanine Green for Image-Guided Enhanced Tumor Theranostics

J. Hou, *M. Zhou, S. Hu;*
Xiangya Hospital, Central South University, Changsha, CHINA.

Aim/Introduction: We have developed a new nuclear-fluorescence molecular probe based on PSMA and evaluate the ability of this probe to guide prostate cancer (PCa) targeted resection in real-time, objectively, with high sensitivity, and specificity; simultaneously to evaluate whether 177Lu-XY-PSMA-ICG can improve the tumor uptake and therapeutic efficacy of PCa, as well as its toxic side effects. ***Materials and Methods:*** The in vitro PSMA-targeting efficiency of XY-PSMA-ICG, the reference PSMA-617, and their corresponding 68Ga- counterparts were determined in PC3-PIP cells via competitive binding assays (IC50) and dual-tracer radioligand and fluorescence internalization studies. Biodistribution and small-animal PET imaging studies were performed in PC3 and PC3-PIP xenograft-bearing mice, respectively, and complemented by intraoperative far-red fluorescence imaging. Radioligand therapy studies were conducted to systematically assess the therapeutic effect of 177Lu-XY-PSMA-ICG. ***Results:*** No obvious abnormalities were observed through the H&E-stained section of organs after injection of 120mg/kg XY-PSMA-ICG. XY-PSMA-ICG showed high binding affinity (IC50 = 5.871 nM) to PSMA in vitro, which was comparable with that of PSMA-617 (IC50 = 27.49 nM). 68Ca- XY-PSMA-ICG demonstrated excellent uptake in PSMA-positive cells in vitro, with more than 50% internalization at 2 h for each PSMA-positive cell line with uptake correlating to PSMA expression levels. Tumor uptake of 68Ga-XY-PSMA-ICG was higher than 68Ga-PSMA-617 in 1h , 2h, and 4h , but there was no statistically different (all $P>0.05$). XY-PSMA-ICG obviously aggregated in the tumor site of the mouse model, and its fluorescence intensity was stable within 24 h. Meanwhile, compared with the treatment of saline or 7.4 MBq of 177Lu-XY-PSMA-ICG, the groups treated

with 18.5 MBq or 29.6 MBq of 177Lu-XY-PSMA-ICG, respectively, showed remarkable suppression of tumor growth. 177Lu-XY-PSMA-ICG with high specific activity induced superior tumor growth inhibition without subacute hematologic toxicity, the same as the groups of 177Lu-PSMA-617. ***Conclusion:*** We present a novel XY-PSMA-ICG ligand, which showed excellent radiolabeling characteristics, high selectivity towards PSMA receptors in vitro, and favorable tumor accumulation in PSMA positive PC3-PIP tumor-bearing mice. These characteristics make XY-PSMA-ICG have the potential to become an integrated probe for prostate cancer diagnosis and treatment, and pave the way for its further development and clinical application. ***References:*** 1. Comparison of PSMA-PET/CT and Whole-Body MRI for Staging and Restaging in Prostate Cancer Patients: a Prospective Single-Centre Study

E. Greco[1], *L. Bianchi[2], C. Gaudiano[3], B. Corcioni[3], L. Spinozzi[4], C. Catanzaro[4], C. Mignogna[4], B. Renzetti[5], A. Cattabriga[3], R. Schiavina[2,4], E. Brunocilla[2,4], C. Mosconi[3,5], P. Castellucci[6], S. Fanti[1,6], A. Farolfi[6];*
[1]Nuclear Medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY, [2]Division of Urology, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY, [3]Department of Radiology, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY, [4]Division of Urology, Alma Mater Studiorum University of Bologna, Bologna, ITALY, [5]Department of Radiology, Alma Mater Studiorum University of Bologna, Bologna, ITALY, [6]Nuclear Medicine, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.

Aim/Introduction: PSMA-PET and Whole-body MRI (wbMRI) are accurate techniques for local PCa staging and to identify distant bone, lymph node, and visceral metastases. Despite wbMRI efficacy, a lack of robust recommendations for its integration into routine clinical practice still remains. This study aims to compare the diagnostic performance of PSMA-PET-CT and wbMRI in detecting PCa localizations in two patient groups: those with high-risk PCa (staging) eligible for radical treatment and those experiencing biochemical recurrence (BCR) following radical therapies. ***Materials and Methods:*** Prospective single-centre study enrolling PCa patients undergoing both PSMA-PET-CT and wbMRI within a 2-month timeframe for staging or BCR. No PCa treatments were allowed between PSMA-PET and wbMRI. Independent readers reviewed the images: 2 nuclear medicine physicians for PET images and 2 radiologists for wbMRI. The concordance of both techniques in assessing local or residual disease (T-Tr), local (N) and distant (M1a) lymph node, bone (M1b) and visceral (M1c) metastasis was evaluated using Cohen's kappa. In patients subsequently treated with radical prostatectomy (RP), sensibility, specificity, positive predictive value (PPV), negative predictive value (NPV) and accuracy of PSMA-PET and wbMRI were compared, using histopathology as gold standard. ***Results:*** A total of 62 patients were enrolled (median age 70 years): 41/62 (66%) newly diagnosed PCa and 21/62 (34%) BCR. PSMA-PET and wbMRI were performed within a median timeframe of 18 days (IQR 8-29). Overall, PSMA-PET was positive for PCa in 46/62 (74%) patients and wbMRI in 46/62 (74%). PSMA-PET up-staged and down-staged in 5% (3/62) and in 5% (3/62) respectively if compared to wbMRI. The concordance between PSMA-PET-CT and wbMRI for T-Tr, N, M1a, and M1b was 0.84, 0.88, 0.86 and 0.44, respectively (Cohen's kappa). Among the staging cohort, 23/41 (56%) patients underwent subsequent RP. In those patients, PSMA-PET and wbMRI sensitivity for local disease (T) was 96% vs 100% while PPV 100% vs 100%. Furthermore, for pelvic nodes involvement (N) sensitivity was 44% vs 44%, specificity 100% vs 93%, PPV 100% vs 80%, NPV 74% vs 72% and accuracy 78% vs 74%. ***Conclusion:*** Although based on a limited sample size, both PSMA-PET and wbMRI demonstrated high agreement in detecting local disease (T and N) and distant lymph nodes involvement (M1a), while a partial agreement was observed for bone disease. Notably, wbMRI outperformed PSMA-PET-CT for local disease detection, whereas PSMA-PET-CT was superior in nodal metastasis detection showing high specificity, PPV, NPV and accuracy.

OP-229

Comparative whole-body multi-parametric [^{68}Ga]Ga-PSMA-11 and [^{18F}]PSMA-1007 PET/CT: a randomised and prospective intra-individual comparison of tracer dynamics

I. Alberts[1], *H. Sari[2], C. Mingels[2], A. Afshar-Oromieh[2], A. Rominger[2];*
[1]BC Cancer, Vancouver, BC, CANADA,
[2]Inselspital, Bern, SWITZERLAND.

Aim/Introduction: This sub-study compares intra-individual [18F] PSMA-1007 and [68Ga]Ga-PSMA-11 for healthy organs and target lesions to see if parametric analysis might reveal insights into in vivo radiopharmaceutical behaviour and in the characterisation of malignant tissues. ***Materials and Methods:*** 10 patients with biochemically recurrent prostate cancer underwent both [68Ga]Ga-PSMA-11 (PSMA-11) or [18F]PSMA-1007 (PSMA-1007) PET/CT in randomised order as part of planned sub-analysis of a prospective comparative imaging trial (NCT05079828); trial entry and exclusion criteria are as previously published. Dynamic scans were acquired from 0 to 60 minutes using a long-axial field-of-view PET/CT with static imaging performed at 2h p.i. Healthy tissue and lesion segmentation was performed by a board certified nuclear medicine physician using 40% iso-contour where appropriate. Following model selection, data were fitted using a reversible two-tissue compartment (2TC) model. Non-specific activity at ganglia and foci of unspecific bone uptake (UBU) were also included. Values were compared using paired t-tests. ***Results:*** Preliminary analysis of the target lesions showed no statistically significant differences in tracer delivery (K1) for any tissue type or organ. Faster (non-significant) binding was observed for K3 for PSMA-11, but also with faster K4, suggesting reversible kinetics. For PSMA-1007 K4 was very low for all lesion types, in-keeping with irreversible kinetics. For all lesions, including UBU, no significant differences were seen for the specific distribution volume (Vs) suggesting that non-specific binding is not the cause of the higher frequency of UBU seen in PSMA-1007 or of ganglia in PSMA-11. For net influx Ki statistical significance was reached for nodal ganglia and borderline higher net influx for local recurrence (p=0.08) for PSMA-11. ***Conclusion:*** Parametric analysis showed no clear differences between specific (e.g. bone metastases) and non-specific (e.g. UBU) findings. Differences in kinetics were seem with reversible kinetics for PSMA-11 and irreversible kinetics for PSMA-1006 with a statistically significant higher net-influx Ki for ganglia in PSMA-11. ***References:*** Alberts I, Bütikofer L, Rominger A, Afshar-Oromieh A (2022) A randomised, prospective and head-to-head comparison of [68Ga]Ga-PSMA-11 and [18F]PSMA-1007 for

the detection of recurrent prostate cancer in PSMA-ligand PET/CT—Protocol design and rationale. PLoS ONE 17(7): e0270269. https://doi.org/10.1371/journal.pone.0270269.

Context-Level Machine Learning to Improve the Identification of Lymph Node and Bone Metastases in Prostate Cancer Patients Using F^{18}-PSMA-1007-PET

R. J. Poelarends[1], *J. A. van Dalen*[2], *J. D. van Dijk*[3], *B. N. Vendel*[3], *H. Stevens*[3];
[1]*University of Twente, Enschede, NETHERLANDS,* [2]*Department of Medical Physics, Isala, Zwolle, NETHERLANDS,* [3]*Department of Nuclear Medicine, Isala, Zwolle, NETHERLANDS.*

Aim/Introduction: Advanced imaging techniques, such as prostate-specific membrane antigen (PSMA)-PET/CT, have improved the detection of primary tumours and metastases in prostate cancer. However, interpreting F^{18}-PSMA-1007 PET/CT scans can be challenging due to the occurrence of aspecific uptake in lymph nodes and bones. Machine learning has proven its suitability to use a large number of features to model complex non-linear relations leading to accurate diagnosis. Our aim was to develop a machine learning method that includes context-level features to better identify lymph node and bone metastases in prostate cancer patients using F^{18}-PSMA-1007 PET. ***Materials and Methods:*** We retrospectively included 110 patients who underwent F^{18}-PSMA-1007 PET/CT, in whom focal uptake was observed by visual evaluation in bone structures (n=290) and lymph nodes (n=273). These uptakes were labelled as either malignant or non-malignant by two experienced nuclear medicine physicians using all available imaging and clinical data and the interpretation of these data at multidisciplinary meetings, as reference. Three machine learning models: Random Forest, Decision Tree, and K-Nearest Neighbors, were trained and evaluated across two levels of features. The first level incorporates basic uptake-specific features, such as SUVmax, the anatomical location of the focal uptake, and the tissue type of the location (bone/lymph node). The second level includes context-level features as well. This method uses, for example, the SUVmax of the primary tumour and the number of uptake regions in bone and lymph nodes to identify a specific metastatic bone lesion and/or lymph node. The diagnostic performance of the models was evaluated using the area under the curve (AUC), specificity, and sensitivity. ***Results:*** The Random Forest (RF) model outperformed the Decision Tree and K-Nearest Neighbors models in at least two of the evaluation metrics ($p<0.001$), for both the basic and context-level approach. The RF-model using context-level features outperformed the RF-basic model in terms of the AUC (0.91 vs 0.96, $p<0.001$), specificity (0.79 vs 0.86, $p<0.001$), and sensitivity (0.85 vs 0.91, $p<0.001$). ***Conclusion:*** We successfully developed a classifier to identify lymph node and bone metastases in prostate cancer patients using F-18-PSMA-1007 PET. The results underscore the potential of leveraging context-level information in machine learning methods to improve identification of metastases, potentially leading to improved diagnosis and ultimately a better treatment strategy for the patient.

Role of the Fibroblast Activation Protein as biomarker of fibrotic lung diseases: interim analysis of a prospective exploratory multi-cohort study

A. Deleu[1], *Z. Wimana*[1], *S. Vercauteren*[1], *S. Lacroix*[1], *C. Marin*[1], *B. Vanderlinden*[1], *A. Arçay Öztürk*[1], *P. Lavis*[1], *L. Taraji*[1], *B. Lesire*[1], *S. De Bontridder*[1], *P. Flamen*[1], *B. Bondue*[1,2];
[1]*Hôpital Universitaire de Bruxelles (H.U.B.), Brussels (Anderlecht), BELGIUM,* [2]*European Reference Network for Rare Pulmonary Diseases (ERN-LUNG), Frankfurt, GERMANY.*

Aim/Introduction: Pulmonary fibrosis entails a spectrum of different clinical entities characterized by irreversible destruction of the alveolar wall, leading eventually to respiratory failure.(1) Despite the development of antifibrotic treatments, overall survival rates remain low and good predictive and prognostic biomarkers are lacking.(2) The aim of this study is to evaluate the value of the fibroblast activation protein (FAP) as a biomarker of fibrotic lung diseases with FAPI PET/CT as noninvasive measurement tool. ***Materials and Methods:*** This is a prospective exploratory multi-cohort study including patients with idiopathic and non-idiopathic progressive pulmonary fibrosis. FAP was measured in blood samples and bronchoalveolar lavage (BAL) specimens of patients starting a treatment or suffering a disease exacerbation. A [18F]FAPI-74 or [68Ga]FAPI-46 PET/CT was performed at different time points. Quantitative PET parameters were compared before and during treatment. Finally, uptake values were compared to the clinical evolution of the patient in terms of pulmonary function tests. ***Results:*** At the time of the interim analysis, 28 patients underwent a baseline FAPI PET/CT which was repeated after treatment initiation in 21 of these patients. A significant negative correlation was found between the SUVmean value and the forced vital capacity (FVC) and diffusing capacity (DL) of the lungs at baseline ($r = -0,47$; $p=0,04$ and $r=-0.52$; $p=0.02$ respectively). SUVmean values were significantly higher in patients suffering from a disease exacerbation compared to patients with stable disease ($p = 0.002$). No significant differences of PET uptake values were detected between the scans at baseline versus at 3 months post-antifibrotic treatment. However, when correlated to the clinical evolution of the patient, a significant strong negative correlation was found between the change in SUVmean and the change in DL after 3 months of antifibrotic treatment (n=8; $r=-0.87$; $p=0.005$). ***Conclusion:*** Preliminary results point out that FAPI PET/CT can be used as a noninvasive tool to monitor disease activity in different clinical entities of the pulmonary fibrosis spectrum, given the correlation of PET uptake values with the lung function of the patient. Further inclusion and follow-up of patients is ongoing to evaluate if PET parameters at baseline can separate progressors vs non progressors, and thus to confirm the prognostic value of FAPI PET/CT. ***References:*** 1. OP-232

A Head-to-Head Comparison of [^{68}Ga]Ga-FAPI-04 PET/CT and 2-[^{18F}]FDG PET/CT in Patients with Idiopathic Pulmonary Fibrosis

J. Wang, *R. Wang, X. Peng, J. Xiang, Z. Zhu;*
Peking Union Medical College Hospital, Chinese Academy of Medical Science and Peking Union Medical College, Beijing, CHINA.

Aim/Introduction: Pulmonary fibrosis represents the terminal stage of a group of lung diseases characterized by extensive proliferation of fibroblasts, significant accumulation of extracellular matrix, accompanied by inflammatory damage, and structural tissue destruction. Activated fibroblasts play a pivotal role in the pathogenesis and progression of pulmonary fibrosis. The aim of this article is to explore the value of [68Ga]Ga-FAPI-04 PET/CT in assessing the inflammatory activity status of pulmonary fibrosis and compare it with the clinical PET gold standard 2-[^{18F}]FDG PET/CT, offering a novel approach for evaluating the active status of pulmonary fibrosis and post-treatment efficacy assessment. ***Materials and Methods:*** Twenty-two patients diagnosed with pulmonary fibrosis, with approval from the Ethics Committee of Peking Union Medical College Hospital and informed consent, underwent [68Ga]Ga-FAPI-04 and 2-[^{18F}]FDG PET/CT scans within a week. Dynamic imaging at 1 hour post-injection was performed for the initial five patients with [68Ga]Ga-FAPI-04 PET/CT. All patients received anti-fibrotic treatment, and [68Ga]Ga-FAPI-04 PET/CT follow-up was conducted 3-6 months after treatment. Semi-quantitative analysis was conducted, measuring the mean standardized uptake value (SUV), maximum SUV (SUVmax), and tumor metabolic volume parameters (MTV), comparing the uptake patterns of the two imaging agents within pulmonary fibrotic lesions, and integrating high-resolution CT scans and pulmonary function results for analysis. ***Results:*** Dynamic imaging of the initial five patients revealed that the optimal imaging time for [68Ga]Ga-FAPI-04 PET/CT in pulmonary fibrotic disease was 15-20 minutes post-injection. Significant differences were observed in uptake values between [68Ga]Ga-FAPI-04 and 2-[^{18F}]FDG PET/CT ($P < 0.0001$). Comparing the correlation with HRCT and pulmonary function parameters, the [68Ga]Ga-FAPI-04 PET/CT detection of fibrotic lesion SUVmax exhibited a positive correlation with the FVC pulmonary function parameter ($r = 0.61$, $p < 0.05$), while the 2-[^{18F}]FDG PET/CT detection of fibrotic lesion SUVmax showed a notable correlation with FVC ($r = 0.22$, $p = 0.05$). Among the fifteen follow-up patients, eight showed decreased FAPI PET uptake post-treatment, five exhibited marginal changes in FAPI uptake post-treatment compared to pre-treatment, and two displayed a notable increase in FAPI uptake compared to pre-treatment. For 2-[^{18F}]FDG PET, twelve patients showed minimal changes pre- and post-treatment, while three patients exhibited increased 2-[^{18F}]FDG uptake during the follow-up compared to pre-treatment. ***Conclusion:*** Compared to 2-[^{18F}]FDG PET/CT, [68Ga]Ga-FAPI-04 PET/CT provides a more comprehensive reflection of the active status of pulmonary fibrosis and allows for a better assessment of treatment efficacy.

OP-233

Anatomical pattern of entheseal and synovial fibroblast activation in psoriasis patients and its risk for developing psoriatic arthritis

A. Atzinger[1], *G. Corte[2], T. Selahattin-Alp[2], R. Noversa de Sousa[3], M. Yalcin Mutlu[2], V. Schönau[2], M. G. Raimondo[2], A. Kleyer[4], T. Kuwert[1], A. Ramming[2], D. Simon[4], M. Sticherling[5], C. Schmidkonz[6], G. Schett[2], F. Fagni[2];*
[1]Department of Nuclear Medicine, Erlangen, GERMANY, [2]Department of Internal Medicine, Deutsches Zentrum für Immuntherapie, Erlangen, GERMANY, [3]Department of Internal Medicine, Deutsches Zentrum für Immuntherapie/Servico de Medicina Interna, Hospital Pedro Hispano, Erlangen/Matosinhos, GERMANY, [4]Department of Internal Medicine, Deutsches Zentrum für Immuntherapie/Department of Rheumatology and Clinical Immunology, Charité-Universitätsmedizin, Erlangen/Berlin, GERMANY, [5]Department of Dermatology, Deutsches Zentrum für Immuntherapie, Erlangen, GERMANY, [6]Department of Nuclear Medicine/Institut for Medical Engineering, Technical University of Applied Sciences Amberg-Weiden, Erlangen/Weiden, GERMANY.

Aim/Introduction: To assess the presence and anatomical distribution of activated fibroblasts in the joints and entheses of high-risk psoriasis patients and to test how fibroblast activation visualized by 68Ga-FAPI-04-PET/CT correlates with clinical tenderness, musculoskeletal ultrasound findings and progression to PsA. ***Materials and Methods:*** We conducted a prospective cohort study in patients with psoriasis and arthralgia who underwent clinical and ultrasound evaluation and whole-body PET/CT imaging with 68Gallium-labeled Fibroblast Activation Protein Inhibitor (68Ga-FAPI)-04. 68Ga-FAPI-04 uptake at synovial and entheseal sites was assessed by maximal standardized uptake values (SUVmax) and PET/CT Joint Index (JI); logistic regression models were used to investigate its correlation with clinical and ultrasound findings. Survival analyses were performed on patients with at least 6 months of follow-up. ***Results:*** Thirty-six psoriasis patients were enrolled. 68Ga-FAPI-04 uptake was found in 318 (7.9%) joints and 369 (7.3%) entheses in 29 (80.6%) participants, with a mean SUVmax (SD) of 3.2 (1.8) for joints and 2.9 (1.6) for entheses. Large joints and the lower limbs were predominantly affected. A significant positive relationship was found between 68Ga-FAPI-04-PET/CT signal intensity and the 68 tender joint count (SUVmax: $p < 0.001$; PET/CT-JI: $p < 0.001$) and tender entheses count (SUVmax: $p < 0.001$; PET/CT-JI: $p = 0.002$). No correlations were found with ultrasound findings (SUVmax: $p = 0.969$; PET/CT-JI: $p = 0.720$). Patients with relevant synovio-entheseal 68Ga-FAPI-04 uptake showed a statistically significant higher risk of developing PsA ($p = 0.02$), independent of ultrasound findings ***Conclusion:*** Patients with Psoriasis presenting with arthralgias show localized signs of resident tissue activation in joints and entheses, which are associated with higher risk of developing PsA.

OP-234

68Ga-FAPI PET/CT for non-invasive characterization of ulcerative colitis and Crohn´s disease

M. Röhrich[1,2], *J. Debus[2], J. Brandt[3], R. Ehehalt[3], M. Lang[2], U. Haberkorn[2];*
[1]University hospital Mainz, Mainz, GERMANY, [2]University hospital Heidelberg, Heidelberg, GERMANY, [3]Gastroenterology Outpatient Clinic, Heidelberg, GERMANY.

Aim/Introduction: Inflammatory Bowel Disease (IBD), represents a spectrum of chronic inflammatory conditions of the gastrointestinal tract (GIT) including ulcerative colitis (UC) and Crohn´s disease (CD). Management of IBD necessitate the use of various diagnostic modalities to assess disease activity, extent, and complications. Positron Emission Tomography (PET) imaging utilizing fibroblast activation protein inhibitor (FAPI) has emerged as a promising tool for detecting activated fibroblasts. Given the role of fibroblast activation and tissue remodeling in the pathophysiology of IBD, we aimed to explore the potential of FAPI-PET for IBD. ***Materials and Methods:*** PET/CT (1 h post injection) with 68Gallium-labelled Fibroblast Activated Protein

Inhibitors (68Ga-FAPI-PET/CT) were applied in 19 consecutive patients with pathologically confirmed IBD and a gender- and age-matched control group of 11 patients without IBD. Volumes of interest (VOIs) of standardized healthy GIT structures and visually FAPI-avid GIT-lesions were delineated using an isocontour tool. Uptake parameters (SUVmax and SUVmean) were extracted and analyzed with regard to differences between IBD entities and IBD disease activity status of patients (based on coloscopy findings and clinical parameters). ***Results:*** 11 patients had UC, 7 CD and 1 colitis indeterminata. CD patients showed a tendency towards increased uptake in the healthy appearing ileum compared to UC patients and controls. The uptake of the other physiological gastrointestinal structures did not show significant differences between IBD patients and the control group. Visually discernable FAPI-avid lesions of IBD patients showed overall high FAPI-uptake (SUVmax: 5.0 +/- 2.6, SUVmean: 2.6 +/- 1.1). Lesions of CD patients showed higher uptake (SUVmax 5.4 +/- 3.4; SUVmean 2,7 +/- 1.6) than those of UC patients (SUVmax 3.9 +/- 3.6; SUVmean 2.3 +/- 1.7). With respect to localization, ileum lesions showed markedly increased uptake in CD patients (SUVmax 6.9 +/- 3.7; SUVmean 3.5 +/- 1.7) compared to UC patients (SUVmax 2.0 +/- 0; SUVmean 1.2 +/- 0) and similarly colon lesions (CD: SUVmax 6.3 +/- 1.6; SUVmean 2.7 +/- 0.5; UC: SUVmax 3.7 +/- 2.0; SUVmean 2.1 +/- 0.9). Lesions of patients with active IBD showed higher uptake (SUVmax 5.2 +/-2.5; SUVmean 2.7 +/- 1.1). than lesions of patients with clinically inactive disease (SUVmax 3.0 +/- 1.6; SUVmean 1.6 +/- 0.8). ***Conclusion:*** Our findings suggest a potential role for FAPI-PET as a new imaging tool for assessing inflammatory activity in both UC and CD. Further research involving larger cohorts is warranted to validate the clinical value of FAPI-PET in IBD.

OP-235

Assessing Crohn's Disease with^{68}Ga-FAPI-04 PET/CT:in comparison with^{18}F-FDGPET/CT

Q. Pan, *H. Xu, Y. Luo;*
Chinese Academy of Medical Sciences and Peking Union Medical College Hospital, Beijing, CHINA.

Aim/Introduction: Crohn's Disease (CD) is a chronic granulomatous inflammatory disease involving gastrointestinal tract .We performed a prospective cohort study to compare the diagnostic performance of 68Ga-FAPI-04 and 18F-FDG PET/CT, as well as their correlation with disease activity of CD. ***Materials and Methods:*** Seventeen CD patients were included. Gold standard was defined as the gastrointestinal lesion showing positivity on at least two of the diagnostic methods (endoscopy, CTE, ultrasound or PET/CT) was considered as true positive lesion. Quantitative measurement of gastrointestinal lesions was measured as metabolic intestinal lesions volume (MIVFDG for 18F-FDG and MIVFAPI for 68Ga-FAPI-04) and total intestinal lesions uptake (TIUFDG for 18F-FDG and TIUFAPI for 68Ga-FAPI-04). ***Results:*** PET/CT diagnostic performance The sensitivity and specificity of 68Ga-FAPI-04 were 90.0% and 93.0%, while those of 18F-FDG were 85.0% and 88.4% (Table 1). In ROC curves, the AUC and 95% confidence interval (CI) for the detection of affected segments with 68Ga-FAPI-04 and 18F-FDG PET/CT were 0.92 (CI, 0.83-0.97, P<0.001) and 0.87 (CI, 0.78-0.93, P<0.001), respectively. 68Ga-FAPI-04 PET/CT showed slightly better diagnostic performance compared with 18F-FDG(P =0.043). Comparison of the uptake between different types of lesions Among all the affected segments, 22/40 of them were stricture/fistula lesions and 18/40 were non-stricture/fistula lesions. The SUVmax of 68Ga-FAPI in stricture/fistula lesions were significantly higher than those in non-stricture/fistula lesions (10.9±6.7 vs 5.0±3.5, P=0.0002). The same result was also observed in the SUVmax of 18F-FDG (stricture/fistula vs non-stricture/fistula lesions: 9.5±4.9 vs 5.3±1.8, P=0.0016). There were 8 patients received medicine therapy before PET/CT scan, and the remaining 9 patients were without pre-therapy. The SUVmax of 68Ga-FAPI-04 showed no difference between patients with and without pre-therapy (12.1±9.7 vs12.2±4.7, P=0.541). The SUVmax of 18F-FDG was higher in patients without pre-therapy than those with (11.8±3.9 vs 8.6±6.0), but this difference was not statistically significant(P=0.075). Correlations of PET/CT with other biomarkers TIUFAPI and MIVFAPI were significantly correlated with CRP (P=0.045 and P=0.016), and MIVFAPI significantly correlated with simple endoscopic score for CD (SES-CD) (P=0.036). Only TIUFDG and MIVFDG were significantly correlated with SES-CD (P=0.04 and P=0.04). Other biomarkers including ESR, CDAI and simplified CDAI was not correlated with any semiquantitative indexes of PET/CT (P>0.05). None of the semiquantitative parameters in 68Ga-FAPI-04 and 18F-FDG PET/CT showed difference between low disease activity and moderate to high activity groups (P>0.05). ***Conclusion:*** 68Ga-FAPI-04 PET/CT showed slightly better diagnostic performance compared with 18F-FDG.

OP-236

Comparative Assessment of Ga 68 FAPI PET/CT and F^{18} FDG PET/CT in Takayasu Arteritis: Insights into Inflammatory Disease Activity

R. Maurya[1], *V. Singh[2], M. Ora[1], S. Gambhir[1];*
[1]Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, INDIA, [2]All India Institute of Medical Science , Rishikesh, Rishikesh, INDIA.

Aim/Introduction: Takayasu Arteritis (TA) a rare inflammatory disorder affecting large arteries, presenting with nonspecific symptoms and potential arterial occlusion. Molecular imaging advancements promise in improving the detection and management of Large Vessel vasculitis. F^{18} FDG PET/CT commonly used for evaluating inflammatory conditions, including arterial inflammation. However, its lack of specificity and limited utility in monitoring clinical response has led to interest in novel PET radiotracers targeting immune cells. Fibroblast activation protein (FAP) Alpha, expressed on activated fibroblasts, plays a role in various pathological processes. FAPI, a small molecule inhibitor selectively binding to FAP-alpha and labelled with a radioactive isotope, has shown promise in diagnosing and monitoring inflammatory diseases. This study evaluates Ga 68 FAPI PET/CT's role in assessing TA activity, comparing it with standard techniques. ***Materials and Methods:*** The study involved examination of 20 patients, focusing on demographic information and medical history. F^{18} FDG PET/CT scans done, followed by Ga68 FAPI PET/CT scans within a week for comparison, adhering to the same scan protocol. SUV max of the affected vessels was gathered from both scans. The Wilcoxon signed-rank test was applied to analyze the SUV max from both scans using SPSS software. ***Results:*** The mean age of the patients was 30 years. 15 patients (75%) were female. 8 (40%) patients had disease activity on FDG PET/CT, whereas 15 (75%) patients had vascular uptake on FAPI /PET/CT. We evaluated 9 major arteries in all the patients. 24 out of 180 arteries (13%) showed inflammatory activity on FDG. 35 arteries (19.4%) had uptake on FAPI. The mean SUV max on FDG PET/CT was 3.23 (range: 2.4-4.5, standard deviation [SD]: 0.68), while on FAPI PET/CT, it was 3.44 (range: 1.5-7.88, SD: 1.76). Compared to FDG, FAPI detected arterial involvement in 11 arteries and had 40 % higher SUV max. 12 patients had no disease activity on the F^{18}

FDG PET/CT. 8 (58.8%) showed ongoing fibrosis on FAPI PET/CT, indicating a significant difference (p-value: 0.016). ***Conclusion:*** F^{18} FDG PET/CT is TA's standard of care functional imaging. This study highlighted the superiority of Ga 68 FAPI PET/CT over F^{18} FDG PET/CT in identifying vascular involvement in Takayasu Arteritis. Higher uptake with lower background FAPI uptake results in the detection of more vessels on FAPI. Ongoing fibrosis on FAPI PET was observed in a few patients without inflammatory activity on FDG PET. This phenomenon needs evaluation in prospective studies to assess long-term outcomes.

OP-237

Distinct uptake of ^{68}Ga-FAPI and ^{18}F-FDG in the two subtypes of IgG4-related disease

S. liu, *H. Zhang, Q. Pan, Y. Luo;*
Peking Union Medical College Hospital, Beijing, CHINA.

Aim/Introduction: IImmunoglobulin G4-related disease (IgG4-RD) is a highly heterogeneous autoimmune disease. Recently, two subtypes of IgG4-RD, proliferative type and fibrotic type were defined according to patients' clinicopathological characteristics. As we previously found significant 68Ga-FAPI uptake in IgG4-RD, which might be related to the pathogenesis of fibrosis, we further wonder if there is different manifestation of 68Ga-FAPI and 18F-FDG uptake in these two subtypes of IgG4-RD. ***Materials and Methods:*** We retrospectively selected treatment-naïve newly diagnosed patients with IgG4-RD in our prospectively recruited cohort from March 2019 to February 2024. Patients were classified into proliferative type or fibrotic type according to the involved organs. The SUVs of IgG4-RD lesions were measured and blood pool was regarded as background (TBR=lesion SUVmax/blood pool SUVmax). To compare the 68Ga-FAPI and 18F-FDG uptake in the two subtypes, PET index of certain involved organ was defined as the quotient of the SUVmax or TBR of 68Ga-FAPI and 18F-FDG in the lesion; and PET index of an individual patient were calculated as a sum of PET indexes of the involved organ. ***Results:*** Thirty-six patients with newly diagnosed IgG4-RD were included (28 proliferative subtype, 8 fibrotic subtype). Serum IgG4 levels in proliferative subtype patients was significantly higher than that in fibrotic subtype (Table). When comparing 68Ga-FAPI and ^{18}F-FDG uptake in different involved organs, the SUVmax and TBR of 68Ga-FAPI of the lesions in the pancreas, bile duct/liver, submandibular gland were significantly higher than the SUVmax and TBR in ^{18}F-FDG PET/CT ($p<0.005$). The PET index of pancreato-biliary disease was significantly higher than that of head-and-neck disease or fibrosis/aortitis (3.42±2.07 vs. 1.81±1.11 vs. 1.72±1.02, p=0.01[index calculated by SUVmax]; 5.40±2.89 vs. 2.94±1.77 vs. 2.54±1.54, p=.018 [index calculated by TBR]). When comparing the SUVmax and TBR of the hottest lesions in proliferative subtype and fibrotic subtype, the two groups of patients showed similar ^{18}F-FDG uptake, however proliferative subtype showed significantly higher uptake of 68Ga-FAPI than fibrotic subtype (Table). Furthermore, the PET index of proliferative subtype was also significantly higher than the index in fibrotic subtype (p=0.005, Table), suggesting a more dominant uptake of 68Ga-FAPI in proliferative subtype of IgG4-RD than the fibrotic subtype. ***Conclusion:*** The proliferative subtype of IgG4-RD showed a more dominant uptake of 68Ga-FAPI than the fibrotic subtype, suggesting more activation of fibroblasts in proliferative subtype of IgG4-RD.

Aim/Introduction: Long COVID has emerged as a major healthcare problem. Although many pathophysiological pathways have been proposed, a comprehensive mechanism of disease remains to be elucidated. Supposed pathophysiology includes persistent low-grade inflammation and microthrombosis, leading to fibroblast activation and ongoing tissue remodeling. Molecular imaging with [68Ga]FAPI (which binds to fibroblast activation protein (FAP)) PET allows for whole body assessment of in vivo fibroblast activation. The objective of this study was to explore lung FAP activity in former critical COVID-19 patients with persistent dyspnea complaints. ***Materials and Methods:*** A prospective observational study (NCT05981885) was conducted in patients with self-reported complaints of dyspnea more than 3 months after hospital discharge for confirmed SARS-CoV-2 infection requiring mechanical ventilation or high-flow nasal oxygen therapy. Each subject underwent a PET/CT and HRCT on a Biograph Vision or Vision Quadra after i.v. administering of 200 MBq [68Ga]FAPI-46. For quantification lungs and muscle were automatically segmented using TotalSegmentator. To measure the diffuse (homogeneous, non-focal) lung uptake, elevated [68Ga]FAPI uptake areas were extracted using <50% isocontour. Mean standardize uptake value corrected for lean body mass (SUL) was collected. Muscle [68Ga]FAPI uptake was measured in the paravertebral muscles. HRCT was analyzed visually for the presence of ground glass opacities (GGO). Fifteen age- and sex-matched subjects without pulmonary pathology, recruited from two other centers using similar settings, scanned for oncological reasons, were used as controls. An independent samples T-test was used for group comparison. The correlation between clinical markers and [68Ga]FAPI was explored using Pearson's or Spearman's test.

Results: Eighteen long COVID patients were included: 10 males (56%), mean age 61 years (±SD 8), BMI of 36 kg/m2 (mean ±SD 9). Scans were performed at a median of 30 months (IQR 7.5 - 34.3) after hospital discharge. Patients with long COVID showed increased pulmonary uptake of [68Ga]FAPI, with a mean (±SD) SULmean of 1.2 (0.4) compared to 0.7 (0.3) (p = <0.001) in controls. The difference remained after blood pool (vena cava inferior) background correction of the whole lung and diffuse uptake (p = <0.001). The presence of GGO (p = 0.07), time after discharge (p = 0.11) and BMI (p = 0.60) did not correlate with lung uptake. Paravertebral muscle [68Ga]FAPI uptake did not differ between long COVID patients and controls (p = 0.12). ***Conclusion:*** Patients with long-term complaints of dyspnea after hospitalization for severe acute COVID showed increased pulmonary FAP expression, suggesting persistent fibroblast activity.

OP-239

^{68}Ga-FAPI-04 PET/CT COVID-19

X. Peng, *R. Wang, J. Wang, J. Xiang, Y. Cai, Z. Zhu;*
Peking Union Medical College Hospital, Beijing, CHINA.

Aim/Introduction: Previous research on the COVID-19 pandemic has proved the severe consequence of pulmonary fibrosis due to SARS-CoV-2 infection. However, there have not yet been adequate methods for assessing progressive pulmonary damage in post-COVID-19 patients. Consistent with idiopathic pulmonary fibrosis (IPF), fibroblast activation and expansion contribute to lung fibrosis in SARS-CoV-2 infection. As a novel imaging modality, 68Ga-fibroblast activation protein inhibitor (FAPI) PET/CT has shown potential benefits in the diagnosis of IPF. Therefore, this pilot study investigated the potential of 68Ga -FAPI PET/CT in detecting post-COVID-19 pulmonary fibrosis. ***Materials and Methods:*** This was a single-center prospective pilot study. 29 patients (15 females; age range 30-86 years) with suspected or proven severe COVID-19 pneumonia were recruited from January 2023 to March 2023. The control group included 10 patients (4 females; age range 31-68 years) who were diagnosed with solid tumors without COVID-19 infection or pathologic pulmonary findings. After providing written informed consent, all participants underwent 68Ga-FAPI-04 PET/CT. During the follow-up period, 3 patients had a second 68Ga-FAPI-04 PET/CT scan to assess fibrosis changes after three months of treatment. Clinical characteristics and PET/CT imaging were collected and analyzed. ***Results:*** The average duration between COVID-19 diagnosis and 68Ga-FAPI-04 PET/CT was 51.8 ± 19.2 days. Overall, COVID-19 patients had intense 68Ga-FAPI uptake in pulmonary regions, which showed statistically a significant difference from control groups (SUVmax 4.83 ± 2.4 vs. 1.41 ± 0.47, p< 0.0001; SUVmean 2.78±1.12 vs. 0.70 ± 0.26, p< 0.0001). Additionally, SUVmean of 68Ga-FAPI uptake positively correlated with HUmean in CT of fibrosis lesions (r=0.5864, p<0.0001). Furthermore, follow-up scans of three patients showed gradual resolution of lung lesions and decreased [68Ga]Ga-FAPI uptake, indicating reversible pulmonary damage with appropriate clinical intervention. ***Conclusion:*** This pilot study demonstrated that 68Ga-FAPI PET/CT, as a non-invasive imaging method, is a promising tool for assessing pulmonary fibrosis after SARS-CoV-2 infection, and may have value in monitoring the treatment response in COVID-19 patients.

Role of $^{[18F]}$ FDG PET/MRI in drug-resistant epileptic patients (preliminary results)

B. Hervás-Sanz[1], *L. Rodríguez-Bel[1], M. Pudis[1], À. Camins-Simón[2], J. X. Sala-Padró[3], M. Falip-Centellas[3], M. Suárez-Piñera[1], J. L. Díaz-Moreno[1], V. A. Carrero-Vásquez[1], A. Bagán-Trejo[1], M. Cortés-Romera[1];*
[1]Nuclear Medicine-PET (IDI) Department, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, SPAIN, [2]Radiodiagnosis Department, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, SPAIN, [3]Neurology Department, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, SPAIN.

Aim/Introduction: The study aimed to analyze the added value of $^{[18F]}$FDG PET/MRI in the localization of the epileptogenic focus (EF) in patients with drug-resistant epilepsy (DRE). ***Materials and Methods:*** Retrospective study of 38 patients (p) with DRE, potential candidates for surgery. These patients underwent the following complementary tests: EEG, MRI, ictal/interictal SPECT, SISCOM, and $^{[18F]}$FDG PET/MRI study for the identification of the EF. The basal PET/MRI studies were performed on SIGNA GE hybrid equipment, 30 minutes after the administration of 148 MBq of $^{[18F]}$FDG. The MRI sequences were 3D Coronal T1, T2 Axial PROPELLER, T2 Coronal FSE Temporal, 3D Axial ASL, and 3D Axial SWAN. A visual assessment of PET/MRI was performed by a nuclear physician and neuroradiologist specialized in epilepsy. PET/MRI was considered positive in patients who showed a focal metabolic alteration on PET images and/or morphological abnormalities on MRI that could correspond to EF. PET/MRI findings were correlated to other complementary studies and with the multidisciplinary board decision. The diagnostic validity of PET/MRI was assessed. ***Results:*** PET/MRI was positive in 13/38p (34%) (7 females; mean age 42 years [17-56]), all of them with metabolic alterations. Ten patients had previous negative MRIs, one had positive MRIs and two did not have previous MRI studies. PET/MRI identified 12 hypometabolic focuses: 3p focal cortical dysplasia (1 previously positive on MRI), 3p mesial temporal sclerosis, 2p focal cortical dysplasia plus mesial temporal sclerosis, 4p nonspecific alterations, and 1 hypermetabolic focus: 1 ganglioglioma. The sensitivity of PET/MRI for diagnosis of EF was 34% (13/38p) compared to the sensitivity of MRI alone which was 28% (10/36p). Therefore, thanks to the use of a hybrid technique (PET/MRI), it was possible to localize the probable cause of the EF in 67% (8/12p) of the patients. Of the 13p with a positive result in $^{[18F]}$ FDG PET/MRI, 10p had concordance with the rest of the complementary studies for the DRE study, which increased the diagnostic confidence. Of these 10p, 6p were candidates for surgery and 4 of them did not meet the criteria for surgery. Three patients are still pending some complementary studies. ***Conclusion:*** PET/MRI improves the diagnostic sensitivity of localizing the EF in DRE. These results have an impact on the clinical and therapeutical management of these patients. The hybrid image assessed together increases the detection capacity of possible EF compared to both techniques (PET and MRI) separately.

OP-241

Assessing Refractory Epilepsy Patients with Dynamic ^{18}F-FDG PET: Insights from Kinetic Analysis.

R. Ferrando[1,2,3], *A. Damian[1,2,3], P. Braga[4,3], A. Gómez[5], A. Bogacz[3], M. Legnani[4,3], M. Pages[4,3], L. Cristino[4,3], P. Duarte[2], A. Fernández[5]; [1]Nuclear Medicine and Molecular Imaging Centre, Clinics Hospital, University of the Republic, Montevideo, URUGUAY, [2]Uruguayan Centre for Molecular Imaging (CUDIM), Montevideo, URUGUAY, [3]Epilepsy Surgery Program, Clinics Hospital, University of the Republic, Montevideo, URUGUAY, [4]Institute of Neurology, Clinics Hospital, University of the Republic, Montevideo, URUGUAY, [5]Department of Signal Processing, Electrical Engineering Institute, Faculty of Engineering, University of the Republic, Montevideo, URUGUAY.*

Aim/Introduction: PET with 18F-FDG is a well-established technique for localizing the epileptogenic zone (EZ) in patients undergoing epilepsy surgery. Typically, image analysis is confined to semi-quantitative strategies, which may not fully exploit the potential of the technique to elucidate specific physiological processes. This study aims to assess the effectiveness of kinetic analysis of dynamic 18F-FDG PET studies compared to conventional quantification methods in identifying characteristic metabolic asymmetries within the EZ. ***Materials and Methods:*** Eight patients (age range 23-52 years, 4 women) underwent prospective evaluation using dynamic interictal PET/CT lasting 60 minutes following intravenous administration of 208 &#177 47 MBq of 18F-FDG. The probable EZ was defined by consensus following comprehensive presurgical evaluation in the institutional Epilepsy Surgery Program. Six patients had temporal lobe epilepsy, and two had extratemporal epilepsies. Three analysis methods were employed: quantification of the area under the curve (AUC) for the complete dynamic PET (60 minutes), AUC of minutes 40-60 post-injection (AUC 40-60), and kinetic analysis using the Patlak method. For Patlak's analysis, proprietary routines developed in Matlab were utilized, incorporating estimation of the input function from dynamic images. The asymmetry index was determined in volumes of interest corresponding to the epileptogenic area compared to the contralateral symmetric region in all cases (2 x [(ipsilateral - contralateral)/(ipsilateral + contralateral)] x 100). The three strategies were compared using Friedman's ANOVA of ranks for repeated measures, with Tukey's test for paired comparison of the groups. ***Results:*** The asymmetry indices obtained were 9.9 &#177 5.1, 11.3 &#177 6.2, and 19.8 &#177 13.5 for AUC, AUC 40-60, and Patlak, respectively (mean ± SD). A significant difference was evident among the different quantification strategies ($p = 0.01$). In paired comparisons, a significant difference was observed between the AUC and Patlak strategies ($p < 0.05$), with the latter demonstrating superior performance in revealing the asymmetry. ***Conclusion:*** Kinetic analysis of dynamic PET with 18F-FDG offers additional insights for identifying metabolic asymmetries in the EZ, potentially enhancing the localization accuracy of the study. These findings suggest the presence of flow-metabolism mismatch in the EZ, with greater emphasis on the metabolic component than on regional cerebral blood flow.

OP-242

[^{11}C]Metoclopramide PET can detect a seizure-induced upregulation of cerebral P-glycoprotein in epilepsy patients

S. Mairinger[1,2], *M. El Biali[1], M. Jackwerth[1], L. Breuil[3], K. Bamminger[2], I. Rausch[4], M. Hacker[2], S. Rodrigo[3], V. Bouilleret[3], M. Zeitlinger[1], M. Bauer[1], E. Pataraia[5], N. Tournier[3], O. Langer[1,2]; [1]Department of Clinical Pharmacology, Medical University of Vienna, Vienna, AUSTRIA, [2]Department of Biomedical Imaging und Image-guided Therapy, Division of Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA, [3]Laboratoire d'Imagerie Biomédicale Multimodale (BIOMAPS), Université Paris-Saclay, CEA, CNRS, Inserm, Service Hospitalier Frédéric Joliot, Orsay, FRANCE, [4]QIMP Team, Center for Medical Physics and Biomedical Engineering, Medical University of Vienna, Vienna, AUSTRIA, [5]Department of Neurology, Medical University of Vienna, Vienna, AUSTRIA.*

Aim/Introduction: There is a critical need for imaging biomarkers for the delineation of epileptic brain tissue in the presurgical evaluation of drug-resistant epilepsy patients. A large body of evidence shows that epileptic seizures lead to an up-regulation of the efflux transporter P-glycoprotein (P-gp) at the blood-brain barrier (BBB). We hypothesized that drug-resistant epileptic foci can be distinguished from healthy or drug-sensitive epileptic tissues based on regional P-gp function at the BBB as a hallmark of drug-resistant epilepsy. PET with radiolabelled P-gp substrates can be used to measure P-gp function at the human BBB, but previously used radiotracers (e.g. (R)-[^{11}C]verapamil) suffered from several limitations (i.e., low brain uptake, brain-penetrant radiolabelled metabolites), which impeded their clinical applicability in epilepsy patients. In this study, we assessed whether a new radiotracer, i.e. [^{11}C]metoclopramide, can overcome these limitations and detect P-gp up-regulation in epilepsy patients. ***Materials and Methods:*** Eight patients with drug-resistant temporal lobe epilepsy (DRE), 5 seizure-free patients with drug-sensitive focal epilepsy (DSE), and 15 healthy subjects underwent brain PET imaging with [^{11}C]metoclopramide on a fully-integrated PET/MRI system. Concurrent with PET, arterial blood sampling was performed to generate a metabolite-corrected arterial plasma input function for kinetic modelling. The choroid plexus was outmasked on the PET images to remove signal contamination from the neighbouring hippocampus. Using a brain region atlas (N30R83), 10 temporal lobe sub-regions were defined and analysed with a 1-tissue-2-rate constant compartmental model to estimate the rate constants for radiotracer transfer from plasma to brain (K1) and from brain to plasma (k2), and the total volume of distribution (VT = K1/k2). ***Results:*** Peripheral metabolism of [^{11}C]metoclopramide was not significantly different between epilepsy patients and healthy subjects. Whole brain uptake of [^{11}C]metoclopramide in epilepsy patients was approximately two times higher than previously reported for (R)-[^{11}C]verapamil (VT: 1.67±0.26 vs. 0.85±0.17 ml/cm3). DRE patients but not DSE patients showed significantly higher [^{11}C]metoclopramide k2 values and a trend towards lower VT values in several temporal lobe sub-regions located ipsilateral to the epileptic focus as compared to healthy subjects (k2: hippocampus: +34%, anterior temporal lobe, medial part: +28%, superior temporal gyrus, posterior part: +21%). ***Conclusion:*** Our data suggest that [^{11}C]metoclopramide can detect seizure-induced P-gp up-regulation in the epileptic brain. The efflux rate constant k2 seems to be the most sensitive parameter to measure increased P-gp function with [^{11}C]metoclopramide. Seizure-induced P-gp up-regulation measured with [^{11}C]metoclopramide PET may help to better delineate drug-resistant epileptic foci during presurgical evaluation.

Metabolic correlates of epileptogenic activity in patients with autoimmune encephalitis (AE): visual and voxel-based approach to brain FDG PET

M. Mangia[1], *A. Di Liberto[2], M. Zotta[1], F. Massa[3], L. Mirandola[4], L. Benedetti[5], S. Raffa[6], G. Rovera[1], G. Morana[7], D. Arnaldi[3,5], P.*

Mattioli[3,5], M. Bauckneht[6], M. Vigliani[8], S. Morbelli[1];
[1]Nuclear Medicine Unit, AOU Città della Salute e della Scienza di Torino, University of Turin, Turin, ITALY, [2]Epilepsy Center, Clinical Neurology, AOU Città della Salute e della Scienza di Torino, University of Turin, Turin, ITALY, [3]Department of Neurosciences, University of Genoa, Genoa, ITALY, [4]Epilepsy Center, ASL Città di Torino, Ospedale San Giovanni Bosco, Turin, ITALY, [5]Clinical Neurology, IRCCS Ospedale Policlinico San Martino, Genoa, ITALY, [6]Nuclear Medicine Unit, IRCCS Ospedale Policlinico San Martino, Genoa, ITALY, [7]Neuroradiology Unit, AOU Città della Salute e della Scienza di Torino, University of Turin, Turin, ITALY, [8]'Rita Levi Montalcini' Department of Neuroscience, University of Turin, Turin, ITALY.

Aim/Introduction: Pathogenesis of epilepsy in patients with AE may be related to a persisting inflammatory process or to the effect of encephalitic-related damage. FDG-PET-related metabolic patterns might help to disclose the pathophysiology of epileptic activity both in the acute phase and at follow-up. There is a lack of studies correlating the topography of hypo/hypermetabolism with the electroclinical manifestations of seizures in AE, even at baseline. We aimed to evaluate the match between baseline hypo and hypermetabolic patterns and the topography of epileptogenic-activity based on clinical and EEG features. ***Materials and Methods:*** Within all AE patients who performed FDG-PET at baseline between 2013 and 2023, we selected patients with clinics and EEG confirming the presence of epileptiform-activity. Availability of MRI imaging and autoantibodies assay was considered mandatory, although seronegative patients with AE confirmed at follow-up were not excluded. The topography of epileptogenic-activity was defined by the referring-neurologist (clinics/EEG) and the cortical/subcortical origin was classified as: 1 limbic; 2. fronto-insular/vegetative (insular) 3. motor cortex (motor), 4. parieto-occipital (posterior) 5. other regions/diffuse alterations. FDG-PET was evaluated visually by a nuclear medicine physician blinded to clinical/EEG features and then with a voxel-based analysis (SPM12). Hypo and hypermetabolic patterns were fitted in the same 5 subgroups. The topographical match between hypo and hypermetabolism pattern and electroclinical features was assessed. ***Results:*** 27 out of 44 patients with AE showed epileptogenic-activity and were included in the present analyses. Based on autoantibodies assay they were classified as: LGI1 n=9, CASPR2 n=3, GAD65 n=2, NMDAR n=4, SOX1 n=1, MA2 n=2, seronegative n=6. MRI was abnormal in 13/27 pt while PET showed metabolic alterations in 27/27 at visual analysis (20/27 concomitant hyper and hypometabolism and 7/27 hypometabolism) and in 24/27 at voxel-based-analysis (23/27 concomitant hyper and hypometabolism; 1/27 hypometabolism only). Electroclinical data classified epileptogenic-activity as limbic n=12, insular n=7, motor n=1, posterior n=4, other/diffuse n=3. Hypermetabolism matched electroclinical topography in 75% of patients at visual analysis and only in 50% at voxel-based analysis. The capability of hypometabolism to locate the onset of the epileptogenic-activity was poor at baseline (only 2 topographical matches with both analysis). ***Conclusion:*** Visual-analysis is more sensitive than voxel-based approach for the detection of AE-typical features in the patients with seizure. The large topographical overlap between hypermetabolism and epileptogenic activity supports the inflammation-related genesis of seizure at baseline. Collection of follow-up FDG-PET is ongoing to disclose the pathophysiological meaning of persistent seizure after AE.

OP-244

Heterogeneity of TSPO-PET Distribution Patterns Among Patients with Temporal Lobe Epilepsy

J. Ge, *Y. Chen, H. Lin, J. Lu, Y. Guan, C. Zuo, X. Wu;*
Huashan Hospital, Fudan University, Shanghai, CHINA.

Aim/Introduction: Localization of epileptic foci using non-invasive methods is crucial in the diagnosis and treatment of epilepsy. Given the recognized role of neuroinflammation in epilepsy development, burgeoning researches has emerged to investigate its potential in identifying neuroinflammation at epileptic foci. This study aimed to reveal the heterogeneous distribution pattern of translocator protein 18 kDa-positron emission tomography (TSPO-PET) among patients with temporal lobe epilepsy (TLE) and investigate clinical factors affecting the outcome of TSPO-PET scans. ***Materials and Methods:*** Twenty-one patients diagnosed with TLE according to the International League against Epilepsy criteria underwent TSPO-PET scans. Detailed documentation of clinical factors such as age at onset, seizure types, frequency, and interval from last seizure to PET scan was conducted. The hemisphere with the clinically-defined epileptic focus was determined using patients' seizure history, video-electroencephalography (VEEG), and magnetic resonance imaging (MRI). Visual evaluation of TSPO-PET scans was performed by three independent imaging physicians, followed by quantitative analysis of brain regional standardized uptake value ratio (SUVR) using the asymmetry index (AI) formula: [(ipsilateral–contralateral) / (ipsilateral+contralateral)] × 200%. TSPO uptake and AI of each brain region were presented as heat maps. Logistic regression analysis was employed to investigate clinical factors associated with TSPO-PET outcomes. ***Results:*** Visual evaluation revealed increased $^{[18F]}$DPA-714 uptake in fifteen patients, with 57.1% (12/21) involving the lateral temporal lobe. The hemisphere with potential epileptic foci, as clinically defined mainly by VEEG and symptoms, was entirely consistent with visual TSPO-PET evaluation. Quantitative analysis with AI showed that 71.4% of patients had at least one brain area with AI exceeding 15%, predominantly in the temporal lobe (57.1%, 12/21), including the hippocampus and parahippocampus (41.7%, 5/12) and amygdala (66.7%, 8/12). A high AI could also be observed outside the temporal lobe, such as in the parietal lobe (9.5%, 2/21) and occipital lobe (23.8%, 5/21). Logistic regression analysis indicated a significant association between TSPO-PET outcome and interval from last seizure to PET scan (P=0.041, OR=11.073), suggesting a higher uptake rate with a shorter interval. Additionally, patients with more frequent seizures tended to have higher uptake, although not statistically significant (P=0.882, OR=1.113). ***Conclusion:*** The majority of TLE patients exhibit higher uptake of $^{[18F]}$DPA-714 in the ipsilateral hemisphere with the clinically-defined epileptic focus, indicating ongoing neuroinflammation. But its distribution patterns may vary among patients. The outcome of TSPO-PET may be influenced by some clinical factors such as interval from last seizure to PET scan and seizure frequency.

OP-245

Subgroups of Metabolic Brain Derangement on FDG PET in Patients with Neuropsychiatric Systemic Lupus Erythematosus

B. Berndorfler[1], *J. M. Warwick[1], A. G. G. Doruyter[1,2], R. Du Toit[1], P. Dupont[3,1];*
[1]Stellenbosch University, Cape Town, SOUTH AFRICA, [2]NuMeRi Node for Infection Imaging, Cape Town, SOUTH AFRICA, [3]KU Leuven Brain Institute, Leuven, BELGIUM.

Aim/Introduction: Neuropsychiatric systemic lupus erythematosus (NPSLE) is the second leading cause of morbidity and mortality in systemic lupus erythematosus (SLE) patients. The pathogenesis of NPSLE is poorly understood and diagnosis is difficult. Advances in neuroimaging show promise, but no patterns specific for the disease have emerged. Exploring the relationships between different metabolic imaging patterns and clinical and laboratory parameters, may lead to improvements in diagnostic accuracy and provide insights into the pathogenesis of NPSLE. ***Materials and Methods:*** Fifty-six patients (n=56) with suspected NPSLE who underwent F^{18} FDG PET-CT at Tygerberg Hospital between December 2016 and January 2023 were screened for inclusion. Seven patients were excluded based on missing data (n=1), not fulfilling the EULAR/ACR classification criteria for SLE (n=4) or absence of NPSLE features on clinical review (n=2). The remaining patients (n=49) exhibited NPSLE features according to the SLEDAI-2K criteria and definitions and were included in the analysis. FDG PET brain DICOMs underwent standard checks for quality before being converted to NIfTI using MRIcroGL and pre-processed in SPM12 (repositioning, warping into standardized MNI space). Using the Brainnetome atlas, mean values in each region were extracted after normalisation for global counts. A hierarchical clustering technique employing Ward's linkage method with an Euclidean distance was performed. Demographic, clinical and laboratory characteristics of the patient clusters were compared using standard statistical tests. ***Results:*** Based on visual analysis an optimal cluster number of 2 was selected, which was supported by the Gap Statistic and the Calinski-Harabasz Index. Comparing imaging features of scans in cluster A (n=23) and cluster B (n=26), scans in the latter group demonstrated significantly higher metabolism in the striata, thalami, midbrain and cerebellum. Patients in cluster B had higher SLEDAI-2K disease activity scores (mean cluster A=19 vs cluster B=28, p=0.001) and were more likely to present with psychosis (p= 0.047) and stroke (p=0.024). Cluster B patients were also more likely to have positive anti-dsDNA and anti-Smith antibodies, as well as higher anti-Smith antibody titres (mean cluster A=31IU/ml vs cluster B=120IU/ml, p=0.031). ***Conclusion:*** Cluster analysis identified a subgroup of NPSLE with common features of hypermetabolism in striata, thalami, midbrain and cerebellum. Patients in this cluster exhibited higher disease activity scores, higher frequencies of several symptoms, and higher levels of certain immune markers. This metabolic pattern may be driven by a common pathological mechanism and could have implications for predicting individual outcomes and prognoses in NPSLE.

OP-246

Towards PET-based Atlas of Resting State Brain Networks: Preliminary Results

D. Steenken[1,2], *I. Yakushev[1];*
[1]Nuclear Medicine Department, Technical University of Munich, Munich, GERMANY, [2]Graduate School of Systemic Neurosciences Ludwig Maximilian University, Munich, GERMANY.

Aim/Introduction: Atlases of resting state networks (RSNs) as based on fMRI data have proven useful in research of brain function. Positron emission tomography with ^{18}F-fluorodeoxyglucose (FDG-PET) is known to capture neural function at rest in a more direct way than BOLD fMRI. Of note, RSNs have been successfully identified in FDG-PET data and utilised for diagnostic purposes. The goal of this study was to build an atlas of RSNs using FDG-PET data. ***Materials and Methods:*** We used data of cognitively healthy subjects from the Alzheimer's Disease Neuroimaging Initiative and local institutional databases. The former was divided into two age- and sex-matched groups: 1) n = 62,73.5±6.13 (mean±SD) years old, 2) n = 61, 73.5, ±6.5 years old. The third group included n = 63 subjects of 56.1±4.1 years old. All PET data were available as one image per subject. Independent component analysis (ICA) was applied in the GIFT toolbox to identify RSNs in each group in a data-driven manner. Herewith, we systematically studied the impact of the mode of spatial normalisation (T1-dependent vs -independent) and intensity scaling method (remove mean subject-wise, remove mean voxel-wise, intensity normalisation and variance normalisation). Main outcomes of interest were the percentage of meaningful independent components (IC) and their replicability across the groups. Replicability was measured with dice coefficient. ***Results:*** Overall, the T1w-dependent pipeline produced a higher percentage of meaningful components (40-60%) than the T1w-independent one (30-50%). The highest percentage of meaningful components was produced by the voxel-wise removal across intensity scaling (40-60%), the lowest with the variance normalisation (0-6,7%). Meaningful components produced with T1w-dependent preprocessing, 30 ICs and voxel-wise mean removal scaling method, demonstrated moderate dice coefficient for visual and cerebellar networks (0.40-0.47), and fair dice coefficient for executive and auditory networks (0.31-0.43) across groups.There were 2 midline networks which have not been described in fMRI studies in this form: a network covering the middle and anterior cingulate cortex and a network in the mesial frontal lobe. ***Conclusion:*** According to our preliminary results, the T1w-dependent preprocessing pipeline and voxel-wise mean removal as intensity scaling method produced the highest number of replicable ICs that can be interpreted in terms of RSNs. Two new midline RSNs deserve further investigations.

OP-247

Individual cerebellar metabolic connectome in patients with MTLE and NTLE associated with surgical prognosis

Y. Tang[1,2], *L. Xiao[1], J. Yang[1], J. Hong[2], J. Hou[1], A. Rominger[2], K. Shi[2], S. Hu[1];*
[1]Xiangya Hospital Central South University, Changsha, CHINA, [2]Department of Nuclear Medicine, Inselspital, Bern University Hospital, Bern, SWITZERLAND.

Aim/Introduction: Patients with mesial temporal lobe epilepsy (MTLE) or neocortical temporal lobe epilepsy (NTLE) share similar clinical pictures, patterns of electroencephalography (EEG) recordings, and magnetic resonance imaging (MRI)-invisible lesions, the divergent surgical outcomes necessitate accurate differentiation between the two types of temporal lobe epilepsy preoperatively to elaborate on tailored surgical strategies. This study aimed to comprehensively explore the different metabolic connectivity topological changes in MTLE and NTLE, as well as their association with surgical outcomes. ***Materials and Methods:*** This study enrolled a cohort of 91 patients with intractable MTLE, 46 patients with intractable NTLE, and 40 healthy individuals with similar age. Each individual's metabolic connectome, as determined by Kullback-Leibler divergence similarity estimation for the 2-18F-fluorodeoxyglucose positron emission tomography (18F-FDG PET) image, was employed to conduct a comprehensive analysis of the cerebral metabolic network in MTLE and NTLE. In addition, alterations in network connectivity were assessed by extracting and evaluating the strength of edge connectivity and weighted connectivity in comparison to the healthy controls. Furthermore, key disparity between MTLE and NTLE groups was identified. By utilizing

these two connectivity strength metrics with the cerebellum, we explored the network properties of connectivity and its association with prognosis in surgical patients. ***Results:*** Both MTLE and NTLE patients exhibited substantial alterations in the connectivity of the metabolic network at the edge and nodal levels when compared to healthy controls (P<0.01, FDR corrected). The key disparity between MTLE and NTLE was observed in the cerebellar regions. In MTLE, there was a predominance of increased connectivity strength in the cerebellum. Whereas, a decrease cerebellar connectivity was identified in NTLE. It was found that in MTLE, higher edge connectivity and weighted connectivity strength in the contralateral cerebellar hemisphere correlated with improved surgical outcomes. Conversely, in NTLE, a higher edge metabolic connectivity strength in the ipsilateral cerebellar hemisphere suggested worse surgical prognosis. ***Conclusion:*** These results suggest that MTLE and NTLE might possess distinct compensatory mechanisms and propagation networks. The cerebellum exhibits distinct topological characteristics in the metabolic network connections between patients with MTLE and NTLE. The hyper- or hypo-metabolic connectivity in the cerebellum may be a prognostic biomarker of surgical prognosis, which might aid in therapeutic decision-making for intractable temporal lobe epilepsy individuals.

Correlation of epileptic seizure type with ^{18}F-FDG PET metabolic brain networks

H. Zhang, *J. Liu, F. Yang;*
The second hospital&clinical medical school. Lanzhou University, Lanzhou, CHINA.

Aim/Introduction: 18F-fluorodeoxyglucose positron emission tomography (18F-FDG PET) has been widely used for presurgical localization of epileptic foci and prognosis estimation. In recent years, some studies have analyzed the brain metabolic connectivity alterations in epilepsy patients with 18F-FDG PET-based complex network analysis. So far, metabolic connectivity based on 18F-FDG PET using complex network analysis for evaluating different types of epileptic seizures has not yet been studied. The aim of this study was to analyze the pattern of glucose metabolism in the brain of different seizure types of epilepsy using the 18F-FDG PET metabolic brain network, and thus to show the changes in the brain network activity, which would provide a basis for revealing the longitudinal changes in the brain during the progression of epilepsy. ***Materials and Methods:*** 214 epileptic patients with complete clinical data who underwent 18F-FDG PET-CT were were retrospectively included, 214 other patients who excluded neurological diseases and were matched for age and gender were selected as normal control group. The PET images of all patients were spatially normalized into Montreal Neurological Institute space, the brain was segmented into 116 brain regions using 116 anatomical automatic labeling and 18F-FDG uptake values were calculated for each region. Group-level brain metabolic network connectivity was constructed by measuring Pearson's correlation coefficients between each pair of brain regions, and then graph theory-based brain network analysis was used to compare changes in metabolic connectivity between the two groups of epileptic patients. ***Results:*** Comparing patients in the generalized clonic seizure group and the other seizure group separately with the control group, the other seizure group exhibited greater modularity, lower average, overall efficiency, clustering coefficient, and longer path lengths ($P < 0.05$). Patients in the generalized clonic seizure group showed a slight decrease in metabolic network connectivity compared to the HC group, and more brain regions with abnormal metabolic connectivity than the other seizure group. Moreover, Hub nodes of the metabolic network on PET scans were altered in both groups compared with the control group, but the whole-brain connectivity in both groups still had small-world properties. ***Conclusion:*** Cerebral metabolic network connectivity is more severely impaired in patients with generalized clonic seizure epilepsy than in other seizures. The shifting of Hub nodes is expected to be responsive to the process of self-adaptation of brain function during the longitudinal progression of epilepsy, and to be a new marker for assessing the severity of epilepsy.

GLP-1r radioligands, effects of the chelator and synthesis route on receptor binding and competitive displacement in vivo

C. Malbert[1], *R. Allouche[2], S. Migliari[3], M. Horowitz[4], K. Jones[4];*
[1]AniScan, Saint-Gilles, FRANCE, [2]Paltech, Paris, FRANCE, [3]Nuclear Medicine and molecular imaging dept, University Hospital of Parma, Parma, ITALY, [4]Dept of Medicine, University of Adelaide, Adelaide, AUSTRALIA.

Aim/Introduction: The GLP-1 receptor (GLP-1r) is expressed in the duodenum, pancreas, and portal vein, and exhibits a down-regulation in insulin-resistant individuals. Accordingly, its quantification may prove pivotal to the management of type 2 diabetes. Several radioligands for GLP-1r, including DO3A, DOTA and NODAGA derivatives, have been developed for 68Ga labelling, however, their in vivo binding capabilities remain to be evaluated with the exception of DO3A which is no longer commercially available. We have quantified, in vivo, the binding and displacement of DOTA and NODAGA GLP-1r radioligands on the GLP-1r. ***Materials and Methods:*** Twelve female miniature pigs (65 ± 4 kg) received either DOTA or NODAGA exendin-4 radioligands after increasing doses of the GLP-1r agonist (exenatide - 0, 0,5 and 1 µg/kg) during dynamic abdominal PET imaging (GE). [68Ga]DOTA-Exendin-4 (Y25, Pi-chem) and [68Ga]NODAGA-Exendin-4 (Y55, Pi-chem) were synthesized using custom build sequences for an automated platform (Scintomics). Several purification strategies were tested, including hydrophilic-lipophilic balance (HLB) and reversed-phase (light C18 and tC2) routes. The final radioligands were analyzed using a UV-Radio-HPLC method derived from Velikyan et al (1). PET imaging was coupled with high-frequency arterial input function (AIF) measurement achieved within an arterial-venous loop. Radio metabolites and the original fraction were measured 5, 10, and 15 min after injection using radio-HPLC after chaotropic plasma preparation. Target occupancy was calculated as specific volume (Vs) using Pmod compartmental modeling with dynamic images and original fraction corrected AIF as inputs. ***Results:*** The radiochemical purity of the synthesized compound was not different (93, 95, 94, and 98 % for Y25/C18+, Y55/HLB, Y55/C18+, and Y55/tC2, respectively). In contrast, there were significant differences in radiochemical yield (41%, 45%,

19%, and 74% for Y25/C18+, Y55/HLB, Y55/C18+, and Y55/tC2). A significant non-specific uptake in the liver (a GLP-1r free organ) confirmed by the absence of displacement following increasing doses of the agonist was identified for Y25/C18+ and Y55/HLB. Surprisingly, pancreatic Y55/HLB was not displaced by increasing agonist doses with identical Vs before and after Exenatide. In contrast, Y55/tC2 exhibited a classical displacement outcome at both the portal vein and pancreas with increased agonist doses. ***Conclusion:*** The NODAGA-exendin-4 moiety appears superior to DOTA for GLP-1r labeling. In vivo, the calculation of Vs in GLP-1r competitive conditions indicates that the reversed-phase approach is superior to the recently proposed hydrophilic-lipophilic balance. ***References:*** (1) Velikyan et al, Am. J. Nucl. Med. Mol. Imaging 2017.

EPS-065

Development of a radiosynthesis method and a novel quality control system to determine quality of ^{68}Ga-MAA: is a TLC enough to assess radiopharmaceutical quality?

***S. Migliari*[1],** *A. Gagliardi[1], M. Scarlattei[1], G. Baldari[1], A. Bianchera[2], S. Bruno[3], R. Bettini[2], L. Ruffini[1];*
[1]Nuclear Medicine Division, Azienda Ospedaliero-Universitaria of Parma, Parma, ITALY, [2]Food and Drug Department, University of Parma, Parma, ITALY, [3]Food and Drug Department, University of Parma, Parma, ITALY.

Aim/Introduction: 99mTc-labeled macroaggregated human serum albumin (MAA) is commonly used for lung perfusion scintigraphy. European Pharmacopoeia describes only the TLC method to assess quality of 99mTc-MAA that differentiates between 99mTc-MAA and free [99mTc]pertechnetate. 99mGa-MAA particles have been recently introduced for lung perfusion PET/CT imaging and literature reports only TLC method to evaluate radiochemical purity (RCP). Although TLC is a very simple and convenient technique, it has low sensitivity and it's rather than a qualitative method. Therefore we spent many efforts to develop a quality control (QC) system including a new radio-UV-HPLC method to assess the RCP of 68Ga-MAA together with an efficient synthesis method. ***Materials and Methods:*** Gallium-68 was obtained eluting a GMP 68Ge/68Ga generator with HCl, collected and pre-purified on a SCX cartridge, using an automated synthesis module. The elute was added to a reactor containing commercially available MAA suspended in NaCl and HEPES buffer. The suspension was incubated scaling up the labelling temperatures (25°-45°-75°-95°C) for 20 minutes. A QC system was developed: Radio-TLC to detect free Ga-68 and a new Radio-UV-HPLC method to detect both free Ga-68 and 68Ga-HSA, to determine RCP of 68Ga-MAA. Microscope analysis and Sprytec laser diffraction system were used to evaluate morphological structure and size distribution of 68Ga-MAA. To eliminate HEPES buffer 68Ga-MAA was filtered from the bottom using a low protein-binding filter (3µm) and then the transferred into the final vial by passing 10 mL of NaCl from the top to the bottom of the filter. ***Results:*** Radio-TLC method detected only Ga-68, while the developed radio-UV-HPLC discriminated both Ga-68 and 68Ga-HSA. 68Ga-MAA obtained at 25°C/45°C revealed both impurities, while at 75° the only impurity was Ga-68. The setup conditions showed that 95°C temperature provided 68Ga-MAA with a RCP of 100%, high specific activity (425.66 GBq/g) and labeling efficiency (>99%), preserved morphological structure and size distribution compared to the original, with a particle diameter range between 25-50µm assuring the diagnostic efficacy. ***Conclusion:*** Our production process of 68Ga-MAA eliminates the need for organic solvents, prewash or final purification steps and it's carried out in a sterile room preserving the sterility of the radiopharmaceutical. Our QC system based on Radio-TLC and the developed Radio-UV-HPLC proved to be efficient and essential to determine the RCP% of 68Ga-MAA. The entire radipharmaceutical production process provides 68Ga-MAA with high efficiency, specific activity and RCP, making them easily accessible for routine use in perfusion imaging using PET/CT.

EPS-066

Comparison of Approaches for Increasing Affinity of Affibody Molecules for Imaging of B7-H3: Dimerization and Affinity Maturation

***M. Oroujeni*[1,2],** *M. Carlqvist[2], E. Ryer[2], A. Orlova[3], V. Tolmachev[1], F. Frejd[1,2];*
[1]Department of Immunology, Genetics and Pathology, Uppsala University, 751 85 Uppsala University, Uppsala, SWEDEN, [2]Affibody AB, 171 65 Solna, Stockholm, SWEDEN, [3]Department of Medicinal Chemistry, Uppsala University, 751 83 Uppsala, Uppsala, SWEDEN.

Aim/Introduction: B7-H3 is an immune checkpoint protein, which is a promising molecular target for immune therapy of malignant tumours. Sufficient B7-H3 expression level is a precondition for a successful therapy. Radionuclide molecular imaging is a promising technique for visualizing expression levels of molecular targets in vivo. The use of small radiolabelled targeting proteins would enable high-contrast radionuclide imaging of molecular targets if adequate binding affinity and specificity of an imaging probe could be provided. Affibody molecules, small engineered affinity proteins based on a non-immunoglobulin scaffold, have demonstrated an appreciable potential for the use as radionuclide imaging probes. Affinity maturation of anti-B7-H3 Affibody molecules as an approach to improve the binding affinity and targeting properties was recently investigated. In this study, we tested the hypothesis that a dimeric format may be an alternative option to increase the apparent affinity of Affibody molecules to B7-H3 and accordingly improve imaging contrast. ***Materials and Methods:*** Two dimeric variants of anti-B7-H3 Affibody molecules, ZAC12*-ZAC12*-GGGC and ZAC12*-ZTaq_3-GGGC, were produced, characterized and labelled with 99mTc as a commonly used radionuclide for SPECT imaging in clinics. ZTaq is an Affibody originally selected as a binder to Thermus aquaticus (Taq) DNA polymerase, which doesn't interact with any mammalian proteins. Thus, ZAC12*-ZTaq_3-GGGC is a monovalent bi-Affibody. In vitro characterization was performed using B7-H3-expressing cell lines. A head-to-head biodistribution of the dimeric variants of the Affibody molecules and the monomeric SYNT-179 (all labelled with 99mTc) was studied in mice bearing B7-H3-expressing SKOV-3 xenografts. Uptake in B7-H3-negative Ramos xenografts was used as a specificity control. ***Results:*** Both variants were successfully labelled with Tc-99m (99mTc) with high radiochemical yield and purity and demonstrated specific binding to B7-H3-expressing cells in vitro and in vivo. [99mTc]Tc-ZAC12*-ZAC12*-GGGC showed subnanomolar affinity (KD1=0.28±0.10 nM, weight =68%), which was 7.6-fold higher than for [99mTc]Tc-ZAC12*-ZTaq_3-GGGC (KD=2.1±0.9 nM). Head-to-head biodistribution of both dimeric variants of Affibody molecules compared with monomeric affinity matured SYNT-179 in mice bearing B7-H3-expressing SKOV-3 xenografts demonstrates that both dimers have lower tumour uptake and lower tumour-to-organ ratios compared to monomeric SYNT-179 Affibody molecule. ***Conclusion:*** The improved functional affinity by dimerization does not compensate the disadvantage of increased molecular size for imaging purposes.

EPS-067

[18F]F-AIF-NOTA-Octreotide Synthesis Optimization and Patient Response

C. Gomes[1], *A. C. Bispo[1], P. B. Pujatti[2], V. Kramer[3];*
[1]R2IBF, Duque de caxias, BRAZIL, [2]INCA, Rio de Janeiro, BRAZIL, [3]Acrux Radiopharma, Santiago, CHILE.

Aim/Introduction: [18F]F-AIF-NOTA-Octreotide (OCT) is a radiopharmaceutical developed for the diagnosis and monitoring of neuroendocrine tumors. Aiming to allow large-scale production and supply over long distances, optimizations were carried out to the synthesis process already implemented in order to maintain a high quality standard, synthesis yield, radiochemical purity, reproducibility and stability. ***Materials and Methods:*** Different amounts of sodium ascorbate as an antioxidant were tested (1.5 mg/mL and 3.3 mg/mL), in order to prevent radiolysis observed with higher fluorine-18 activities. Single and dual beam tests were also performed, as well as variations of cyclotron current values (75 µA and 130 µA), with the same irradiation time, which directly impact the amount of fluorine-18 generated. All tests were followed by chromatographic analysis to monitor radiochemical purity parameters and radiolysis status.A clinical study with 38 patients was also carried out in order to examine the impact of the new synthesis protocol on the image quality of the studies, where [18F]F-AIF-NOTA-Octreotide (4 MBq/kg) was applied to detect lesions during staging, restaging and follow-up of grade I and II (Ki67 < 15%) neuroendocrine tumors. ***Results:*** The initial synthesis protocol (1.5 mg/mL of sodium ascorbate; single beam; 37 µA) didn't allow an initial activity of fluorine-18 above 37 GBq, presenting increased radiolysis events and low radiochemical purity (60.38%). The increase in antioxidant concentration, to 3.3 mg/mL, allowed commercial initial synthesis conditions to be achieved with 174 GBq of starting fluorine-18 activity, presenting an average uncorrected yield of 30.72%, 60 GBq of OCT and 98.82% radiochemical purity. Next, dual beam tests with the same irradiation time, and a higher total current (130 µA), were performed to obtain a greater amount of fluorine-18. These tests resulted in a average of 109 GBq of OCT, with averages of 300 GBq starting fluorine-18 activity, uncorrected yield of 25.34% and radiochemical purity of 98.43%.Changes in physiological uptake in target organs and kinectics of tumor uptake, measured by tumor to background ratios 60, 90 and 120 minutes post intravenous injection were not observed between the radiopharmaceuticals produced by both protocols, with maximum tumor to background rations achieved 60 minutes p.i.. ***Conclusion:*** The modifications made to the synthesis protocol throughout the optimization of the process proved to be of great importance in obtaining a greater amount of [18F]F-AIF-NOTA-Octreotide, without affecting its quality or its effectiveness and safety, allowing it's availability to a greater number of patients in a large country.

EPS-068

Labelling of a Bruton's Tyrosine Kinase (BTK) Inhibitor [11C]BIO-2008846 in three different positions and evaluated through PET scans in NHP

S. Nag[1], *A. Morén[1], P. Datta[1], Y. Khani Meynaq[1], M. Kaliszczak[2], C. Halldin[1];*
[1]Karolinska Institutet, Stockholm, SWEDEN, [2]Biogen MA Inc, Cambridge, MA, UNITED STATES OF AMERICA.

Aim/Introduction: Bruton's tyrosine kinase (BTK) is a key player in the B-cell receptor signaling pathway. BTK inhibitors have garnered attention as potential anti-cancer drugs for B-cell therapies and for treating immunological disorders like rheumatoid arthritis and multiple sclerosis (MS). The development of new BTK inhibitors with reversible binding and improved selectivity is crucial. Currently, there is a need for tools to directly measure BTK receptor engagement. PET imaging of BTK offers a promising noninvasive method to assess target expression and engagement. This study involved radiolabeling BIO-2008846 in three different positions with carbon-11, and PET measurements were conducted in non-human primates using [11C]BIO-2008846-B to assess brain kinetics. ***Materials and Methods:*** Radiolabeling was achieved at three different position via either by [11C]carbonylation ([11C]BIO-2008846-A) or by [11C]methylation ([11C]BIO-2008846-B/C) reaction. NHP underwent two PET measurements on same day. The first PET measurement was performed with [11C]BIO-008846-B followed by the second PET measurement after pretreatment with BIO-008846 (1 mg/kg bw) 7 min prior to injection. The plasma input function corrected for radio-metabolites was measured for each scan. The total volume of distribution (VT) which is equivalent to the equilibrium partition coefficient for the drug between brain and plasma were calculated for a selection of regions. The occupancy was calculated using revised Lassen plot. Radiometabolite in plasma were analysed using gradient HPLC. ***Results:*** [11C]BIO-008846-A/B/C were synthesized successfully with radiochemical purity (>99%), and molar activity >42 GBq/µmol for [11C]BIO-008846-A and >500 GBq/µmol for [11C]BIO-008846-B/C. All the compounds [11C]BIO-008846-A/B/C were found to be stable in sterile saline for 60 min. The distribution of [11C]BIO-008846-B in the primate brain was homogenous and the whole brain uptake was 1.8% ID at baseline and max 3.2% after pretreatment. The lack of conclusive evidence for a change in regional VT values following a pharmacological dose suggest that any specific binding component of [11C]BIO-008846-B is negligible compared to the free and non-specific components in the living brain. Radiometabolite studies demonstrated only more polar radiometabolites were formed with about 10% unchanged radioligand remaining 30 min post injection for both PET experiments. ***Conclusion:*** This study demonstrated good brain uptake. Although there was a minor variability in [11C]BIO-2008846 distribution across various brain regions, the kinetics were consistent with passive diffusion and the free concentration and non-specific binding being the dominating components.

EPS-069

68Ga-labeled novel ACC-targeted probes for precise monitoring of acquired drug resistance in melanoma

J. Ye, *X. Wang, W. Yang, F. Kang, J. Wang;*
Xijing Hospital, Xi'an, CHINA.

Aim/Introduction: Acquired resistance to BRAF mutation-targeted therapy has become a major clinical problem hindering the treatment of melanoma, and its precise monitoring is the core and key to improve the prognosis, but there is a lack of effective ways of non-invasive monitoring. Our previous study revealed that enhanced fatty acid synthesis is a key mechanism mediating acquired resistance to targeted therapy in BRAF-mutant melanoma. Therefore, this project aims to develop a molecular probe targeting acetyl-coacarboxylase (ACC), a key rate-limiting enzyme in the fatty acid synthesis pathway, to elucidate the quantitative and qualitative relationship between ACC and acquired resistance to targeted therapies and to monitor the evolution of fatty acid synthesis resistance through PET molecular imaging. ***Materials and Methods:*** Probes with different lengths of PEG chains were prepared by using the ACC inhibitor ND630 as the lead compound and modifying the metal chelating groups by

the coupling design method. The 68Ga labeling was performed by conventional metal chelation method. The radiochemical purity and in vitro stability were determined by HPLC. All probes were subjected to in vivo distribution and micro-PET dynamic imaging in tumor bearing mice to determine maximum tumor uptake and optimal imaging time. The probes with the best imaging results were selected for subsequent studies. ***Results:*** Four probes were designed and synthesized, and the chemical purities were than 98% by analytic-HPLC. The 68Ga labeling rate of all four probes was more than 60%. The radiochemical purity was > 98% after solid-phase purification. The in vitro stability in saline and in mouse serum was evaluated at 4 h by radio-HPLC, all probes showed high in vitro stability. The in vivo distribution and micro-PET imaging results in tumor bearing mice showed that all probes could image tumors, with 68Ga-DEACC showing the highest tumor uptake with a SUVmax of 1.1. Modification of the PEG3 chain accelerated the clearance of the probe in vivo, but tumor uptake was also reduced to some extent. In vivo imaging results were similar for different chelating groups NOTA and DOTA. All probes have a high physiological uptake in the heart and liver and are mainly metabolized by the liver and intestines. ***Conclusion:*** A series of 68Ga-labeled ACC-targeting probes were successfully prepared, among which 68Ga-DEACC has the potential to be used to monitor the evolution of fatty acid synthesis resistance, which is worthy of further study, and further probe optimization and evaluation are in progress.

EPS-070

Bn_2DT3A - a novel acyclic chelator for radiolabelling under mild conditions with gallium-68

G. Stasiuk[1], *T. W. Price[1], I. Renard[1], V. Kubíček[2], P. Hermann[2], S. J. Archibald[1];*
[1]King's College London, London, UNITED KINGDOM,
[2]Charles University, Prague, CZECH REPUBLIC.

Aim/Introduction: Gallium-68 with a half-life of 68 minutes requires fast radiolabelling under mild conditions to allow radiolabelling of tracers with sensitive targeting vectors. The most wide-spread chelator for gallium68 is the cyclic DOTA requiring elevated temperatures and acidic conditions excluding the use of targeting vectors unstable under these conditions. In order to overcome this limitation we developed the hexadentate acyclic chelator Bn2DT3A with improved coordination kinetics for radiolabelling under mild conditions.1 ***Materials and Methods:*** Synthesis of Bn2DT3A was undertaken in 6 steps. Radiolabelling with gallium68 of Bn2DT3A was carried out in phosphate buffer under different conditions and purified via semipreparative column chromatography. Serum stability was tested by incubating purified [68Ga][Ga(Bn2DT3A)(OH)]- with serum at 37°C and analysed via radio-HPLC. in vivo study with [68Ga][Ga(Bn2DT3A)(OH)]- was performed in health healthy Sprague-Dawley rats ***Results:*** Bn2DT3A forms with Ga3+ a hexadentate mer-mer complex with a stability constant of 18.25. Depending on the pH, two different complexes are formed, whereas above pH 5 an additional hydroxy group is coordinating which increases the complex' in vitro and in vivo stability. Labelling with gallium68 gives good radiochemical yields, but different products depending on the pH and temperature. At pH 4 [68Ga][Ga(Bn2DT3A)] is formed, which showed to be unstable upon incubation in fetal bovine serum (FBS) at 37 oC after 30 minutes. Radiolabelling at pH 7.4 and 100 µM ligand concentration gives the hydroxy coordinating complex [68Ga][Ga(Bn2DT3A)(OH)]- in > 90% radiochemical yield (RCY) at room temperature within 15 minutes. Performing the reaction at 60 °C gives a similar RCY within 5 minutes. In addition to its stability in FBS (no decomplexation after 2 h) in vivo administration in healthy rats showed rapid renal clearance and negligible unspecific uptake. ***Conclusion:*** We successful synthesised and radiolabelled Bn2DT3A at pH 7.4 with gallium-68 at room temperature with radiochemical yields up to 90%. The formed complex showed excellent stability over 120 min in FBS (fetal bovine serum) at 37 °C. in vivo experiment showed very promising sstability and fast renal clearance. ***References:*** Price, T. W. et al. Bn2DT3A, a Chelator for 68Ga Positron Emission Tomography: Hydroxide Coordination Increases Biological Stability of [68Ga][Ga(Bn2DT3A)(OH)]-. Inorg. Chem. Aim/Introduction: To develop a novel FAP cyclic peptide imaging agent, Al18F-FAP-NOX, evaluate its in vitro and in vivo properties, and explore its feasibility for expressing FAP in PET/CT of tumors. ***Materials and Methods:*** Al18F-FAP-NOX was manually labeled and synthesized. The in vitro stability of Al18F-FAP-NOX was determined using radio high-performance liquid chromatography (Radio-HPLC). The lipid water partition coefficient Log P, in vitro cell uptake experiments, PET/CT imaging and biodistribution in 293T-FAP tumor-bearing mice were conducted to preliminarily evaluate the pharmacokinetics and biological efficacy of Al18F-FAP-NOX in nude. Simultaneously perform the first-in-human clinical PET/CT imaging. ***Results:*** Al18F-FAP-NOX was successfully synthesized with a yield of 26.28% without attenuation correction. In vitro experiments have shown that Al18F-FAP-NOX exhibits good stability and hydrophilicity in PBS (Log P = -3.02 ± 0.08). In cell experiments, the uptake of Al18F-FAP-NOX in HT1080-FAP cells reached the plateau phase at 15 minutes (at 15 minutes: 7.31 ± 0.53 %ID/mio cells), exhibiting high cellular uptake and retention. The uptake of Al18F-FAP-NOX could be significantly inhibited by DOTA-FAP-2286, indicating that Al18F-FAP-NOX has the ability to bind with FAP with high specificity. The PET/CT results of 293T-FAP tumor-bearing mice in vivo showed that Al18F-FAP-NOX was highly uptaken in FAP-positive tumor tissues (at 60 minutes: 12.47 ± 1.66 %ID/g), while uptake was very low in FAP-negative tumors, with only 0.65 ± 0.57%ID/g at 60 minutes after injection. The drug was mainly excreted through the kidneys. The biodistribution results were similar to the PET/CT imaging results of tumor-bearing mice. The first-in-human experimental imaging showed an abnormal increase in uptake of tumor lesions. ***Conclusion:*** Al18F-FAP-NOX has been successfully synthetized in this study, demonstrating good stability and hydrophilicity. It could be quickly distributed to tumor tissue in vivo. The first-in-human clinical PET/CT imaging showed certain diagnostic ability for lung cancer lesions. It is a promising cyclic peptide agent for PET imaging.

EPS-072

New P2Y12 radioligands for PET imaging of neuroinflammation

M. Richard, *E. Pincemail, M. Peyronneau, C. Denis, A. Winkeler, B. Kuhnast;*
Université Paris-Saclay, CEA, CNRS, Inserm, BioMaps, Orsay, FRANCE.

Aim/Introduction: Neuroinflammation (NI) is a common phenomenon to all neurodegenerative diseases. One consequence of NI is the activation of microglia, the primary immune cells of the central nervous system. The expression of P2Y12 receptors at the surface of microglia is modulated during NI and these receptors could thus be used as biomarkers to monitor microglia state in vivo with positron emission tomography (PET) imaging.1,2 To this end, we selected a pyrazolo-pyridazine scaffold presenting a high affinity for P2Y12 receptors3 and prepared precursor derivatives for radiolabeling with carbon-11 or fluorine-18. ***Materials and Methods:*** Eight reference compounds were synthesized and their affinity for P2Y12 receptors was evaluated in vitro by a radioligand binding assay. Their metabolism was examined by in vitro experiments on mice and rat microsomes and mass spectrometry to predict their in vivo biotransformation. These in vitro experiments allowed us to select the best candidates and to implement their radiolabelling. ***Results:*** Radiomethylation was carried out on an iPHASE C-11 Pro2 automate in acetone in basic conditions at 80°C for 3 minutes and the expected radioligand was obtained after 45 min in a 11.8 ± 5.4 % radiochemical yield with a molar activity of 46.7 ± 22.5 GBq/µmol (n = 7, decay-corrected). Radiofluorination was performed on a TRASIS AllInOne automate with dry $K^{[18F]}F$/K222 complex and the radiolabelled ligand was obtained in 50 min in a 25 ± 5 % radiochemical yield with a molar activity of 102 ± 15 GBq/µmol (n = 4, decay-corrected). The purity of the radioligands (over 95 %) and the good radiochemical yields enabled their in vitro study by autoradiography and their in vivo evaluation by PET imaging of a P2Y12 rat model and of non-human primates. ***Conclusion:*** One carbon-11 and one fluorine-18 radiotracer have thus been evaluated in vitro by autoradiography and in vivo by imaging of healthy rat and of a P2Y12 rat model. Although their affinity for P2Y12 was in the nanomolar range, the preliminary in vivo results seem to indicate that the ligands do not cross the blood brain barrier, impeding their further use as radiotracers of neuroinflammation. ***References:*** [1] Villa, A. et al. Preparation, characterization, and preclinical evaluation of mucin-targeted radionuclide labeled probes

J. Ding[1], *D. Wen[2], Z. Wang[1], J. Tao[1], T. Liu[1], D. Zhou[3], Z. Yang[1], H. Zhu[1];*
[1]Peking University Cancer Hospital & Institute, Beijing, CHINA, [2]Affiliated Hospital of North Sichuan Medical College, Nanchong, CHINA, [3]Tongji University, Shanghai, CHINA.

Aim/Introduction: MUC1 in the Mucins family is a highly glycosylated transmembrane protein whose overexpression is commonly associated with gastric, breast, ovarian, lung, and pancreatic cancers. In addition, there are differences in glycosylation of MUC1 between tumor and normal tissues. Based on the above two, a MUC1-targeting antibody 16A, labeled with 89Zr, was developed. ***Materials and Methods:*** The radiochemical purity and in vitro stability of 89Zr-16A was analyzed by radio-TLC. Cellular uptake, cellular internalization(4°C and 37°C) and affinity assays were performed in adherent cultured A549, 293T-MUC1 and 293T-COSMCKO-MUC1, B16-OVA-MUC1 and B16-OVA-COSMCKO-MUC1, and SGC79101 cells. Female KM mice (n=3) were sacrificed 2 h, 24 h, 48 h, 72 h, 96 h and 120 h after radiotracer injection to determine the bio-distribution of 89Zr-16A in normal mice. At the same timepoint, micro-PET scans were performed in SGC7901, MKN45, B16-OVA-MUC1/COSMC-knockout group, A549, SW780 and BxPC3 models, and 89Zr-labeled IgG was set as the control group. ***Results:*** 89Zr-16A was obtained with a radiochemical yield of 73.75% and radiochemical purity higher than 95%. It was stable within 120 h in vitro. The uptake of 89Zr-16A in COSMC-knockout B16-OVA-COSMCKO-MUC1 cells was significantly higher than that in wild type B16-OVA-MUC1 cells (20.78±2.79% vs 2.99±0.09%, 4 h). DFO modification had less effect on 16A affinity (expressed as EC50 value) (13.99 nM vs. 31.22 nM). The internalization rate of 89Zr-16A in COSMC-knockout cells was higher than that in wild type cells (4°C: 82.23-60.64% vs. 46.61-28.65%; 37°C: 75.21-56.27% vs. 44.96-24.82%). Both biodistribution and micro-PET imaging results showed that 89Zr-16A was largely cleared from the blood within 24 h and was mainly metabolized by the liver. micro-PET images showed that the maximum standardized uptake value (SUVmax) of 89Zr-16A in the SGC7901 model with high MUC1 expression (9.95) was significantly higher than that in the MKN45 model with low MUC1 expression (2.35). In addition, 89Zr-16A had higher tumor uptake in B16-OVA-MUC1(4.48)/B16-OVA-COSMCKO-MUC1(5.67), A549(6.47), SW780(3.42) and BxPC3(3.12) models. 89Zr-IgG used as a control, the specificity of 89Zr-16A in tumor uptake in SGC7901 and B16-OVA-COSMCKO-MUC1 models was initially demonstrated. ***Conclusion:*** High tumor uptake of 89Zr-16A was observed in lung, bladder, pancreatic, and gastric cancer models. Among them, the tumor specificity was validated in SGC7901 model. Moreover, COSMC-knockout cells showed higher selectivity to 89Zr-16A than wild-type cells, which might be due to the abnormal expression of MUC1 (as in tumor cells). 89Zr-16A has shown potential for clinical translation as a tumor MUC1-targeting PET probe.

EPS-074

A ^{177}Lu-nucleotide Coordination Polymer-incorporated Thermosensitive Hydrogel with Anti-inflammatory and Chondroprotective Capability for Osteoarthritis Treatment

P. Liu[1,2], *H. Shuo[1];*
[1]Xiangya Hospital, Central South University, Changsha, CHINA, [2]University of Wisconsin-Madison, Madison, WI, UNITED STATES OF AMERICA.

Aim/Introduction: Osteoarthritis (OA) poses a significant health burden with its cartilage destruction and inflammation. Radiosynoviorthesis (RSO) employing intra-articular radiopharmaceutical injection shows promise in attenuating OA, yet faces challenges due to toxicity and rapid dissipation of radioactive isotopes. This study aimed to develop a novel RSO-based therapeutic strategy by utilizing metal-organic coordination polymers (MCPs) as carriers of radioactive 177Lu, with adenosine monophosphate (AMP) as ligands. Then, the resulting 177Lu-AMP was incorporated into a chitosan/β-glycerophosphate thermosensitive hydrogel matrix to construct 177Lu-AMP@CG hydrogel for effective OA treatment. ***Materials and Methods:*** MCPs were explored as carriers for 177Lu3+, utilizing AMP nucleotides due to their optimal affinity. Molecular dynamics simulations elucidated the binding mechanisms, followed by the fabrication of 177Lu/AMP dispersed within a CS/β-glycerophosphate hydrogel (177Lu/AMP@CG). The sol-gel transition behaviour, rheological properties, and in vitro release kinetics were evaluated. The anti-inflammatory and chondroprotective effects of 177Lu/AMP@CG were assessed in vitro. The local retention of 177Lu/AMP@CG in rat knee joint was investigated using SPECT/CT imaging. Finally, the OA rat model

was constructed to evaluate the in vivo synovial inflammation alleviation, cartilage protection and regeneration, and biosafety of 177Lu/AMP@CG, using [18F] FDG PET/CT imaging and histological analysis. ***Results:*** 177Lu/AMP@CG exhibited controlled release kinetics, prolonged retention, anti-inflammatory effects, and chondroprotective properties. In an OA rat model, 177Lu/AMP@CG demonstrated enhanced retention of 177Lu within the joint cavity, enabling a single-dose intra-articular injection to provide long-term OA treatment without adverse effects. Combining 177Lu-based RSO with the pharmacological properties of chitosan-based hydrogel yields exceptional anti-inflammatory, cartilage repair and protective effects. ***Conclusion:*** In this study, the 177Lu-nucleotide coordination polymer-incorporated thermosensitive hydrogel was successfully prepared and proved to be applicable in OA treatment. We underscored the significant local retention capacity of the 177Lu-AMP@CG hydrogel and the potential of anti-inflammatory and chondroprotective strategy toward OA treatment.

EPS-075

Design of innovative FAP-target modules for simultaneous delivery of CAR T-cell and radiotherapy

S. Mattiussi[1], *H. Boutier[2], U. M. Battisti[1], L. R. Loureiro[2], C. Arndt[2], A. Feldmann[2], M. P. Bachmann[2], M. M. Herth[1];*
[1]University of Copenhagen, Copenhagen, DENMARK, [2]Institute of Radiopharmaceutical Cancer Research, Dresden, GERMANY.

Aim/Introduction: Tumor-targeting therapies based on small molecules targeting tumor-microenvironment (TME)-specific proteases such as the fibroblast activation protein (FAP) have emerged as a suitable target for radioligand therapies[1]. Switchable chimeric antigen receptor (CARs) T-cells such as the Universal CAR-T cells, that can be redirected to FAP-expressing cells of the TME with FAP-specific target modules (TMs), offer a promising approach for enhancing safety and effectiveness in cancer immunotherapy[2]. In this work, we design and synthesize novel small-molecule-based FAP-specific TMs that allows for both UniCAR T-cell therapy and the simultaneous delivery of radioligands and chemotherapeutics. We will accomplish this using pretargeted approaches utilizing the tetrazine ligation[3]. ***Materials and Methods:*** We have developed a dimeric structure to target FAP, with the goal of increasing accumulation and prolonging tumor retention by connecting two UAMC1110 moieties. The fast and selective Copper(I)-catalyzed Azide-Alkyne Cycloaddition (CuAAC) was used to attach the E5B9 peptide epitope, required for the redirection of the UniCAR T-cells. Two different TMs were synthesized, one with a DOTA chelator for 68Ga and 177Lu labeling, and a second with TCO moiety for pretargeted approaches, enabling the use of the 18F and 211At. ***Results:*** The dimeric UAMC1110 was synthesized according to published procedures[4] (overall yield: 68%). After purification, a coupling reaction between the azide-PEG-NHS ester and a free amino group of the linker was performed. After careful optimization of the click reaction, we were able to substantially improve the yield of the intermediate (from 13% to 35%). In the last step, the radiolabeling components were introduced, affording the final compounds. Compound's identity was confirmed by HPLC and LC-MS. Future biological studies will assess the potential of our TMs to redirect UniCAR T-cells to FAP-expressing cancer cells. ***Conclusion:*** Two new UniCAR TMs based on homodimeric UAMC1110 were synthesized. The compounds will be evaluated in vitro for their ability to maximize the anti-tumor effect in the near future. ***References:*** 1. Journal of Medicinal Chemistry, (2014), 3053-3074, 57(7). 2. EPS-076

A Covalent FAP-Targeted Radiopharmaceuticals Based on ^{99m}Tc-/^{188}Re-Theranostic Ligand

M. Xu, *Z. Liu;*
Changping Laboratory, Beijing, CHINA.

Aim/Introduction: Fibroblast activation protein (FAP) targeted radiopharmaceuticals have been widely evaluated with 18F, 68Ga, and 177Lu, the currently most commonly used positron and β-nuclide. While 99mTc-based SPECT scans are more widely used and cost-effective in clinical imaging, rare 99mTc labeled FAP-targeted radiopharmaceuticals have been reported and applied clinically. In this study, a covalent group was installed to the 99mTc and 188Re labeled FAP-targeted radiopharmaceuticals to develop a theranostic tandem. ***Materials and Methods:*** A Sulphur (VI)-Fluoride Exchange (SuFEx) chemistry-based linker was employed as the covalent compound. The chelator was fine-tuned for stable labeling with 99mTc and 188Re, both of which were sourced from generators. A series of linkers were screened for the synthesis of hydrophilic tricarbonyl complexes. The obtained complexes were investigated in vitro through binding and competition experiments using HT-1080-FAP and HT-1080 cell lines. The SPECT imaging, biodistribution studies, and therapeutic investigations were conducted in HT-1080-FAP tumor-bearing mice and patient-derived xenografts (PDX) animal models. ***Results:*** The lead candidate, 99mTc-CTR-FAPIs, exhibited specific binding to HT-1080-FAP cells with high affinity. The SPECT imaging of HT-1080-FAP and PDX models demonstrated that 99mTc-CTR-FAPIs had a higher tumor uptake (SUV max = 4.23 ± 0.56 at 3 h post-injection) and clearer background. Additionally, the SPECT imaging revealed prolonged retention of 188Re-CTR-FAPIs in the tumor. The 188Re-CTR-FAPIs was employed for the treatment of HT-1080-FAP tumors, resulting in notable inhibition of tumor growth. ***Conclusion:*** A covalent FAP-targeted radiopharmaceutical, CTR-FAPIs, represents a potent tracer for 99mTc-based diagnostic SPECT scans and 188Re-based radionuclide therapy, both of which are generator-based radionuclides.

EPS-077

Fully Automated Radiosynthesis of [^{124}I]I-AT-01 for Clinical Multi-Centre PET Imaging of Systemic Amyloidosis

C. Wichmann[1], *Z. Cao[1], H. Panopoulos[2], A. Cichocki[2], S. Poniger[3], N. Guo[1], U. Ackermann[2], F. Scott[1], R. Boktor[2], N. Anderson[4], M. Latter[5], N. Angell[6], M. Klein[6], S. Gronwald[6], S. Guthrie[6], P. Mollee[4], A. Scott[1];*
[1]Olivia Newton-John Cancer Research Institute, Heidelberg, AUSTRALIA, [2]Austin Hospital, Heidelberg, AUSTRALIA, [3]iPhase Technologies Pty Ltd, Rowville, AUSTRALIA, [4]Princess Alexandra Hospital, Woolloongabba, AUSTRALIA, [5]Royal Brisbane and Women's Hospital, Brisbane, AUSTRALIA, [6]Attralus Inc, San Francisco, CA, UNITED STATES OF AMERICA.

Aim/Introduction: Systemic amyloidosis is a multisystem protein deposition disease caused by aggregation and deposition of various abnormally folded proteins. Most patients present with either cardiac or renal involvement and prognosis is poor in the absence of intervention. Diagnostic biopsies are challenging due to the heterogeneous nature of amyloid deposits. AT-01 is a novel amyloidophilic peptide which electrostatically binds to diverse

forms of human amyloid independent of fibril precursor proteins. Radioiodinated [124I]I-AT-01 has shown uptake in clinically diagnosed organs, and undiagnosed organs correlating with expected systemic amyloid distribution in a first-in-human study [1]. Here we describe development of automated radiosynthesis of [124I]I-AT-01 to facilitate multi-centre clinical PET imaging of systemic amyloidosis. ***Materials and Methods:*** Based on our prior work on 89Zr-automation, automated radiolabelling of AT-01 with 124I, formulation, and sterile filtration was established using a disposable cassette-based synthesis module. Starting activity, peptide amount, and final product volume were optimized to satisfy patient dose requirements avoiding further manual intervention. Quality control was performed on the formulated product to satisfy clinical release and stability criteria over 24 hours. ***Results:*** Radiolabelling reactions were performed in sodium phosphate (0.5M, pH 5) aided by a small amount of ascorbate and Pierce iodination reagent which gave >97% conversion after 10 minutes at ambient temperature. Overall process yield of formulated sterile [124I]I-AT-01 was 64% ± 1% (n=3) at end-of-synthesis (EOS) with a process time of 40 minutes. Product was formulated in a volume of 9mL with maximum total and apparent specific activities at EOS of 71MBq and 68MBq/mg, respectively. Patient dose activity was fixed to 37MBq and corresponding patient protein dose was 555µg ± 11µg (n=3). Radiochemical purity by RP-HPLC and immunoreactive fraction at EOS were 99.6% ± 0.0% (n=3) and 96.4% ± 0.5% (n=3), respectively, and dropped to 97.9% ± 1.0% (n=3) and 92.0% ± 3.2% (n=3), respectively, after storage at 4-8°C for 24 hours. pH of formulated [124I]I-AT-01 was 6.66 ± 0.09 (n=3) and sterility and endotoxin levels passed clinical release criteria. ***Conclusion:*** Fully automated production of [124I]I-AT-01 for clinical use was achieved with minimal exposure to the operator and excellent product stability over 24 hours. This demonstrates feasibility of automated clinical production of peptidic 124I-radiopharmaceuticals for multi-centre studies. ***References:*** [1] Wall, J.S., Martin, E.B., Endsley, A. et al. First in Human Evaluation and Dosimetry Calculations for Peptide 124I-p5+14—a Novel Radiotracer for the Detection of Systemic Amyloidosis Using PET/CT Imaging. Mol Imaging Biol 2022;24(3):479-488.

EPS-078

[18F]FDS: Implementation of an automated production process and its quality control

M. Liagre[1], *L. Breuil[1,2], C. San[1], S. Specklin[3], B. Hosten[2,1];*
[1]Claude Kellershohn Unit, Saint-Louis research Institute, AP-HP. Nord Paris Cité University, Saint-Louis Hospital, pharmacy, Paris, FRANCE, [2]Paris Cité University, INSERM, UMRS-1144, Therapeutic Optimization in Neuropsychopharmacology, Paris, FRANCE, [3]Paris-Saclay University, CEA, CNRS, Inserm, BioMaps, SHFJ, Orsay 91400, France, Orsay, FRANCE.

Aim/Introduction: [18F]FDS, 2-deoxy-2-[18F]fluorosorbitol, is an experimental radiotracer obtained by reduction [18F]FDG (2-deoxy-2-[18F]fluoroglucose) reduction using sodium borohydride (NaBH4). The pharmacokinetic of [18F]FDS makes it a potentially interesting radiotracer in neurology, infectiology, and nephrology. In this work, we propose a method for automated radiosynthesis of [18F]FDS combined with a quality control (QC) method adapted to clinical research. ***Materials and Methods:*** [18F]FDS radiosynthesis was based on a published process and was adapted on a radiosynthesizer. The modification of the following parameters was studied to optimize the radiosynthesis : [18F]FDG flow rate on the NaBH4 cartridge, addition of an alumina column, kit purge through the cartridges with NaCl and air. QC performed on the preparations included pH measurement, boron determination, radiochemical purity (RCP) by radio high pressure liquid chromatography (rHPLC) and thin layer chromatography (TLC). ***Results:*** Seven automated productions were carried out. The duration of the syntheses was 53±8.5 min and the pH was 6-7. Among the productions, 3 showed [18F]FDG total reduction (TR) associated with a RCP of 100% measured by rHPLC (tR[18F]FDS =3.4 min), 3 showed [18F]FDG partial reduction (PR) (RCP < 70%, tR[18F]FDG =12 min) and 1 reduction was uninterpretable. The 3 PR productions can be attributed to a higher flow rate of [18F]FDG through the NaBH4 cartridge, which does not provide sufficient contact time for effective reduction. The non-decay corrected yields for the TR productions were 55%, 57%, 43%, respectively. In TLC, 14 mobile phases were tested and 2 allowed a better resolution of the [18F]FDS and [18F]FDG peaks: acetone/methanol/water/ammonia (70/20/7.5/2.5), Rf[18F]FDS: 0.7, Rf[18F]FDG: 1.3, and acetonitrile+0.1%TFA/water (80/20), Rf[18F]FDS: 0.8, Rf[18F]FDG: 1.0, associated respectively with an ITLC-SG and silica gel 60 stationary phase. The amounts of boron assayed on 3 samples were 1800 mg/L, 2023 mg/L and 1787 mg/L. To reduce these concentrations, an alumina column has been added and the kit purge avoids the NaBH4 cartridge. ***Conclusion:*** In this work, we have developed an automated production process for [18F]FDS using a simple method of total reduction of [18F]FDG that can be easily implemented. This process was validated using a robust QC method by rHPLC but is still restrictive in routine. The development of the simplified QC method by TLC would favor the use of [18F]FDS in routine. However, the writing of an investigational medicinal product dossier can already be considered. ***References:*** Kit-based synthesis of 2-deoxy-2-[18F]-fluoro-d-sorbitol for bacterial imaging, Mota et al. Nature Protocols, 2021.

EPS-079

Optimization and Quality Control of Automated [68Ga]Ga-Citrate Radiosynthesis with a GAIA® synthesis module

O. Perrin[1], *Y. Soualy[1], C. Fersing[2], L. Barthelemi[1], D. Alize[1];*
[1]Department of Nuclear Medicine, Nîmes University Hospital, Nîmes, FRANCE, [2]Department of Nuclear Medicine, Montpellier Cancer Institute, Montpellier, FRANCE.

Aim/Introduction: Positron emission tomography-computed tomography (PET-CT) has emerged as an essential tool in medical imaging, allowing both functional and morphologic imaging with excellent resolution. This method utilizes radiolabeled molecules, with a preference for short-lived positron-emitting isotopes like fluorine-18 and gallium-68. Among these, gallium-68 stands out due to its short half-life, making it an ideal candidate for PET imaging studies. The present study seeks to refine and optimize the automated radiosynthesis process of [68Ga]Ga-Citrate with a GAIA® module (Elysia-Raytest), a radiotracer with applications in inflammation and infection imaging. ***Materials and Methods:*** The research methodology was based on literature-derived methods, which were adapted to accommodate the available equipment. Automated syntheses were carried out on a GAIA® V2 module. Two distinct radiosynthesis strategies were evaluated, each employing different cation exchange cartridges (Accell Plus or PS-H+ cartridge) : 4mL of citrate solution at a concentration of 136mM is passed over each cartridge. To ensure the robustness and reliability of the optimized process, a comprehensive suite of quality control tests was deployed : organoleptic characteristics, pH, radiochemical purity (by TLC and HPLC, measured immediately post-synthesis and subsequently every hour for 4 hours), as well as biological evaluations, aiming to guarantee the safety, purity, and efficacy of the synthesized [68Ga]Ga-Citrate. ***Results:*** Systematic

optimization of the radiosynthesis process focused on adjustment of citrate concentration and volume, and selection of the cation exchange column. These modifications significantly improved synthesis efficiency. Notably, the PS-H+ cartridge demonstrated a remarkable synthesis yield of 72%, in contrast with the suboptimal 16% yield obtained with the Accell Plus cartridge. Quality control results confirmed the success of the optimization process, validating the purity and safety of the synthesized [68Ga]Ga-citrate. Radiochemical purity was found to exceed 99% in both TLC and HPLC, and all other quality controls achieved the required standards. In continuation of these promising results, further syntheses are required to validate the method, ensuring the robustness and reproducibility of the optimized radiosynthesis process. ***Conclusion:*** In this study, the automated radiosynthesis of [68Ga]Ga-citrate was successfully optimized on a GAIA® V2 module. This advancement holds promising prospects for PET imaging in inflammation and infection. Our methodology, grounded in established literature and customized to suit the available equipment, lays foundations for further clinical investigations. Therefore, future efforts could be directed towards the elaboration of an investigational medicinal product dossier (IMPD) follow by exploring its potential applications in clinical PET.

EPS-080

Breakthrough in ^{11}C methylation of biologically interesting molecules: the case of [^{11}C]PiB

P. Novelli, *S. Cerfontaine, R. Gerardy, F. Morelle, L. Trump, C. Warnier;*
Trasis, Ans, BELGIUM.

Aim/Introduction: Alzheimer's disease (AD) is a progressive neurodegenerative disorder, the foremost factor in dementia worldwide, resulting in brain atrophy, memory impairment, cognitive decline, and ultimately neuronal death. AD is often associated with amyloidal plaques consisting of β-amyloid (Aβ) peptides that aggregate in different shapes and patterns in specific brain areas. It has been demonstrated through research that these Aβ aggregates can be identified several years prior to the onset of symptoms, enabling the possibility of early diagnosis and risk prediction [1].Concerning the Carbon-11 area, surely the [^{11}C]PiB is the gold standard radiotracer for targeting and detection of Aβ plaques and other Aβ-containing lesions in humans, already successfully used to diagnose AD at early stage. ***Materials and Methods:*** The scientific literature outlines three main radiolabeling methods for [^{11}C]PiB: the use of [^{11}C]CH3I, the use of [^{11}C]CH3OTf and the [^{11}C]CO2 fixation-reduction. Initially, the strategy was to use the [^{11}C]CH3I followed by removal of a protected group. The implementation of [^{11}C]CH3OTf has eliminate the need for deprotection and reduced the synthesis time. Currently the [^{11}C]CH3OTf strategy leads to the best yield and the best Specific Activity of the final product [2].The proposed study aims to present how the full synthetic automatic process of the [^{11}C]PiB using a Trasis AIO 24 synthesizer was developed. Thanks to its unique components the process move from the molecular sieve adapted to trap [^{11}C]CO2, to the methylating agent produced through a silver triflate reactor, to the labeling and the purification of the final product using the incorporated HPLC system. ***Results:*** The tests carried out at high activity (final product activity ≥ 7 GBq) showed that the process is reliable, reproducible (yield 18±4% (n=5)) and the resulting product is stable up to even 2 hours. All the production satisfied the QC criteria and specifications (USP chapter 823) necessary for its utilization in human studies [3]. ***Conclusion:*** The presented [^{11}C]PiB example shows that the optimization of the platform has therefore the potential to create a methylation agent able to be used in a wide range of ^{11}C-labeling tracers in a efficiently, reproducibly, and most importantly quickly way. ***References:*** 1] Heeman, F. et al. EPS-081

A fully automated synthesis of [^{18F}]Fluro-L-meta-tyrosine (FMT) on AllInOne synthesizer

P. Novelli[1], *M. Otabashi[1], C. Lemaire[2], L. Trump[1], J. Morelle[1], C. Warnier[1];*
[1]Trasis, Ans, BELGIUM, [2]University of Liege, Llege, BELGIUM.

Aim/Introduction: The [^{18F}]FDOPA is the most used tracer in the imagining of the dopaminergic pathway of the brain. However, is mainly metabolized in peripheral tissues by aromatic amino acid decarboxylase (DDC) to [^{18F}]fluorodopamine and by catechol-O-methyl transferase (COMT) to [^{18F}]3-O-methyl-6-fluoro-DOPA (OMFD1). OMFD is able to crosses the blood-brain barrier bidirectionally, and distributes widely throughout the brain, compromising image contrast and making its quantitative analysis very complicated. On the contrary, [^{18F}]FMT is not a substrate for COMT and ca be a better PET tracer for the in vivo clinical research imaging of cerebral dopamine system (2). Different methods are proposed to synthesize [^{18F}]FMT however, to this day, is possible to obtain only a feeble yields (8-26% d.c.) and there is no offer for ready to use kits for cassette-based routine production(3,4,5). ***Materials and Methods:*** In this work we have improved the [^{18F}]FDOPA synthesis method to produce [^{18F}]FMT under cGMP conditions using the Trasis AllinOne synthesizer. We report a new synthesis of [^{18F}]FMT via a multi-step synthesis that include, labelling, solid phase reduction and halogenation, chiral phase transfer alkylation, strong acid deprotection, HPLC purifications and final formulation (6, 7). ***Results:*** This synthetic method provided a radiochemical yields over 20% n.d.c. (>30% corrected; n=15) using a starting activities from 100 to 200 GBq after 80 min production. ***Conclusion:*** The formulated product was demonstrated stable over 8 hours with a radiochemical purity higher than 99% (enantiomeric purity always above 97%) and a total impurities amount lower than 0.5 µg/ml. ***References:*** 1 Pauwels et al. / European Journal of Pharmacology 257 (1994) 53-582 VanBrocklin et al. / Applied Radiation and Isotopes 61 (2004) 1289-12943 DeJesus et al /Journal Of Nuclear Medcine 38 (1997) 6304 Craig et al Chem. EPS-082

A cassette-based process for the multidose production of [^{11}C]Acetate on the AllinOne

L. Trump, *S. Cerfontaine, R. Gerardy, C. Warnier;*
Trasis, Ans, BELGIUM.

Aim/Introduction: [^{11}C]Acetate is a versatile PET tracer used in cardiology for studying myocardial perfusion and oxygen metabolism, and in oncology for studying liver cancer and brain tumors.[1] Existing processes for the synthesis of [^{11}C]Acetate are well described in the literature and are based on home-made [2-4] or commercial full or partially fixed-tubing systems [5-7]. The challenge with existing processes in a routine production environment is to develop, validate and implement a cleaning procedure of the production equipment after each run. This work

aims at developing a fully automated and cassette based process that offers high production yields while minimizing the workload of production personnel. ***Results:*** Cyclotron-produced [^{11}C]CO2 is first concentrated and purified on the AllinOne's molecular sieve, which also makes [^{11}C]CO2 transfer and the subsequent radiolabelling robust to all site and cyclotron configurations. [^{11}C] CO2 is then thermally desorbed and transferred to the Grignard reagent (CH3MgCl) where its carboxylation reaction yields acetate. After quenching and dilution with aqueous acetic acid, the reaction mixture is purified on solid phase extraction (SPE) cartridges. Finally, [^{11}C]Acetate is dispensed through a sterile filter in an isotonic citrate buffer. Careful process development and optimization resulted in an all-time-high [^{11}C]Acetate yield of 53±3% n.d.c. in 10 minutes (RCY = 74% d.c., RCP ≥ 99 %). Up to 16 GBq per batch of [^{11}C]Acetate have been produced using this process: the delivered product complies with monograph 04/2023:1920 of the Eur.Ph., with a confirmed final product stability of more than 2 hours. ***Conclusion:*** We herein report the development of a single-use cassette, reagent kit and process for the synthesis of [^{11}C]Acetate on the AllinOne. With its cassette-based and GMP-compatible approach delivering multi-patient doses of [^{11}C]Acetate, this new manufacturing process is specifically designed for use in routine PET diagnosis in hospitals that need to produce [^{11}C]Acetate on a regular basis. ***References:*** [1] Am J Nucl Med Mol Imaging 2012; 2(1):33-47 [2] J Label Compd Radiopharm 2006; 49: 263-267 [3] Applied Radiation and Isotopes 67 (2009) 581-589 [4] Nuclear Medicine and Biology 38 (2011) 1135-1142 [5] Applied Radiation and Isotopes 65 (2007) 691-695 [6] Applied Radiation and Isotopes 69 (2011) 691-698 [7] Applied Radiation and Isotopes 82 (2013) 7-11.

EPS-083

Optimized cassette-based process for [^{18F}]FMZ production: an outlook to generic ArylBpin radiolabellings in GMP environment

L. Trump[1], *T. Gendron[2], R. Gerardy[1], V. Quesneau[1], Y. Haumont[1], V. Kassin[1], V. Gouverneur[3], M. Trewell[4], C. Warnier[1];*
[1]Trasis, Ans, BELGIUM, [2]University of Liège, Liège, BELGIUM, [3]University of Oxford, Oxford, UNITED KINGDOM, [4]University of Cardiff, Cardiff, UNITED KINGDOM.

Aim/Introduction: [^{18F}]Flumazenil (FMZ) is an imidazobenzodiazepine tracer used in PET imaging to identify alterations in neuronal density and study neuronal disorders such as Huntington's disease or epilepsy. While this PET tracer has historically been difficult to bring to the clinic due to technical limitations of historical labelling methods, the emergence of ArylBPin radiofluorination technology[1,2] offered a promising approach to [^{18F}]FMZ manufacturing [3]. ArylBPin chemistry can however be challenging in some aspects and its industrialization to full-blown, readily available GMP processes has to the best of our knowledge remained unheard of. ***Results:*** In this work, we report the successful industrialization of the automated [^{18F}]FMZ production process on the AllinOne synthesis module, which was also translated into readily available consumables. The project comprised 3 main axes of development; (1) a process for the synthesis of GMP-grade FMZ-BPin precursor and the corresponding purification and analytical methods for release and stability studies. (2) a process to manufacture the CuPy4OTf2 catalyst with the objective to overcome existing procurement issues of this compound with existing vendors and make it available for nuclear medicine applications. (3) a cassette, kit and automated process for the routine production of [^{18F}]FMZ for human use. The resulting process delivers [^{18F}]FMZ with excellent yields (30% n.d.c., <1hour) at multi-patient dose levels. Both the FMZ-BPin precursor and radiolabelled [^{18F}]FMZ pass the quality requirements for human use as per the relevant general monographs of the Ph.Eur. ***Conclusion:*** This process and the release of ready-to-use kits for the ArylBPin-mediated manufacturing of [^{18F}]FMZ are the first step towards the clinical deployment of this radiolabelling technology that has the potential to bring to the clinic many otherwise inaccessible F18-labelled PET tracers. Further work will be dedicated to demonstrating the compatibility of these precursor manufacturing advances as well as of the automated radiosynthesis process with other ArylBPin precursors of clinical interest. ***References:*** - [1] Mossine A.W, Org. EPS-084

Development of adsorption/desorption material for novel ^{68}Ge/^{68}Ga generator

J. Lee, *J. Park;*
Korea Atomic Energy Research Institute, Jeollabuk-do Jeongeup-si, KOREA, REPUBLIC OF.

Aim/Introduction: With the increasing global use of 68Ge/68Ga generators in medical applications, there is an urgent need for research into the column materials of these generators and their adsorption and desorption capabilities for the radionuclides 68Ge and 68Ga. In this study, we developed microsized beads for a 68Ge/68Ga generator system, utilizing chitosan and titanium dioxide to ensure high adsorption/desorption capacity for 68Ge (parent nuclide) and 68Ga (daughter nuclide), respectively, while maintaining stability in hydrochloric acid. ***Materials and Methods:*** The 68Ge/68Ga generator column material was synthesized using a low molecular weight chitosan-based TiO2 adsorbent via physical trapping, resulting in a durable 68Ge/68Ga generator column material. Long-term adsorption/desorption studies demonstrated a higher separation factor of 68Ge/68Ga across the examined concentration range of HCl (0.01 M to 1.0 M). ***Results:*** The prepared chitosan-TiO2 adsorbent (CLA) exhibited acid resistance capabilities, with >70% 68Ga elution yield and 10-3 to 10-4% 68Ge breakthrough. Notably, the labeling efficiency of DOTA and NOTA using the generator-eluted 68Ga was highly encouraging, confirming efficiencies of 99.65% and 99.69%, respectively. Thus, the behavior of CLA towards 68Ge/68Ga adsorption/desorption and stability with aqueous HCl suggests a high potential for ionexchange solid-phase extraction in the 68Ge/68Ga generator column material. ***Conclusion:*** We have demonstrated that the synthesized CLA can serve as a novel column material for a 68Ge/68Ga generator. Given the imperative for medical radioisotope generators to provide elution with high purity and specific activity, our developed column material addresses these requirements, offering promising elution efficiency and stability while maintaining a high purity (>99.9%) of 68Ga elution with 10-3 to 10-4% 68Ge breakthrough. Moreover, it can effectively filter impure metals, ensuring optimal labeling yields for 68Ga-radiopharmaceuticals. ***References:*** [1] Rösch, F. Past, present and future of 68Ge/68Ga generators. Therapy with the somatostatin receptor antagonist DOTA-LM3 labeled with terbium-161: Interim results of the Phase 0 Study in patients with gastroenteropancreatic neuroendocrine tumors
J. Fricke[1], *F. Westerbergh[2], L. McDougall[1], C. Favaretto[1,3], E. Christ[4,5], G. Nicolas[1], S. Geistlich[3], F. Borgna[3], M. Fani[1], P. Bernhardt[2,6], N. van der Meulen[3], C. Müller[3,7], R. Schibli[3,7], D. Wild[1,5];*
[1]Division of Nuclear Medicine, University Hospital Basel, Basel, SWITZERLAND, [2]Department of Medical Radiation Sciences, Institute of Clinical Sciences, Sahlgrenska Academy at University of Gothenburg, Gothenburg, SWEDEN, [3]Center for Radiopharmaceutical Sciences, Paul Scherrer Institute (PSI), Villigen-PSI, SWITZERLAND, [4]Division of Endocrinology, University Hospital Basel, Basel, SWITZERLAND, [5]ENETS Center of Excellence for Neuroendocrine and Endocrine Tumors, University Hospital Basel, Basel, SWITZERLAND, [6]Department of Medical Physics and Biomedical Engineering, Sahlgrenska University Hospital, Gothenburg, SWITZERLAND, [7]Department of Chemistry and Applied Biosciences, ETH Zurich, Zurich, SWITZERLAND.

Aim/Introduction: The goal of this Phase 0 study (NCT05359146) was to determine the absorbed doses in tumors and relevant organs after a test injection of [161Tb]Tb-DOTA-LM3 and [177Lu]Lu-DOTATOC in a cohort of grade 1 and 2 gastroenteropancreatic neuroendocrine tumor patients. ***Materials and Methods:*** In this randomized, cross-over, prospective, single-center, open-label Phase 0 study, six of eight patients were evaluated to date. Patients received 1 GBq [161Tb]Tb-DOTA-LM3 and 1 GBq [177Lu]Lu-DOTATOC over a 4-week interval. Quantitative SPECT/CT imaging was performed ~3, ~24, ~72, and ~168 h after infusion of both radiopharmaceuticals to calculate tumor and organ absorbed doses (3D dosimetry using a Monte-Carlo-based OSEM algorithm). ***Results:*** After injection of only 1 GBq [161Tb]Tb-DOTA-LM3, SPECT/CT revealed excellent image quality with intense tumor uptake in all patients and a median of the mean (range) effective tumor half-life of 100 hours (49-130 hours) for [161Tb]Tb-DOTA-LM3 compared to [177Lu]Lu-DOTATOC (75 (41-108) hours). The median (range) of the mean tumor absorbed doses of [161Tb]Tb-DOTA-LM3 and [177Lu]Lu-DOTATOC were 46 (25-98) and 8 (3-14) Gy/GBq, respectively. The median (range) kidney, spleen and bone marrow absorbed doses were 3.2 (2.4-3.8), 4.4 (4.4-6.9), 0.3 (0.2-0.5) Gy/GBq for [161Tb]Tb-DOTA-LM3 and 0.7 (0.5-0.8), 1.2 (1.2-4.7), 0.04 (0.02-0.05) Gy/GBq for [177Lu]Lu-DOTATOC, respectively. According to CTCAE v5.0, there were grade 1 adverse events (anemia, leukopenia, thrombopenia) in four of the six patients after the infusion of 1 GBq [161Tb]Tb-DOTA-LM3. ***Conclusion:*** [161Tb]Tb-DOTA-LM3 shows a 7-fold higher tumor absorbed dose compared to [177Lu]Lu-DOTATOC. The tumor-to-bone marrow absorbed dose ratio for [161Tb]Tb-DOTA-LM3 was 1.4-fold lower compared to [177Lu]Lu-DOTATOC. The administration of 1 GBq [161Tb]Tb-DOTA-LM3 was safe in all patients without relevant adverse events. Note: It is planned to present the final results of all eight patients.

OP-253
A multicenter phase 2 randomised controlled trial comparing ^{177}Lu-Dotatate and capecitabine combination treatment with ^{177}Lu-Dotatate in neuroendocrine tumor patients.
M. Becx[1], *J. Hofland[1], J. Nonnekens[1], E. Krenning[1], D. Wyld[2], F. Verburg[1], T. Brabander[1], W. de Herder[1];*
[1]Erasmus MC, rotterdam, NETHERLANDS, [2]Royal Brisbane and Women's Hospital, Brisbane, AUSTRALIA.

Aim/Introduction: Peptide receptor radionuclide therapy (PRRT) with [177Lu]Lu-[DOTA0,Tyr3]octreotate (177Lu-DOTATATE) is an effective and safe treatment option for patients with metastatic neuroendocrine tumors (NET). In advanced NET patients, 177Lu-DOTATATE has been proven to prolong progression-free survival (PFS) and preserve quality of life. However, objective response rates (ORR) are limited. The use of radiosensitizers could increase efficacy without the need for higher PRRT dose. Capecitabine is a pro-drug of 5-fluorouracil which inhibits deoxythymidine monophosphate via thymidylate synthase, leading to a decrease in DNA synthesis and repair. The combination of 177Lu-DOTATATE with capecitabine has only been studied in heterogeneous, single arm studies. In this phase II study, we investigated whether capecitabine has an additional cytotoxic or radiosensitizing effect on top of 177Lu-DOTATATE. ***Materials and Methods:*** This is a phase II randomized controlled trial in patients with advanced somatostatin receptor-positive gastroenteropancreatic or bronchopulmonary NET. Patients were treated with either 177Lu-DOTATATE and capecitabine combination therapy or 177Lu-DOTATATE only. Every patient received four cycles of 7.4 MBq 177Lu-DOTATATE. Patients treated with capecitabine received 1650 mg/m2/day for two weeks starting at the time of 177Lu-DOTATATE administration. Primary endpoints were ORR, PFS and median overall survival (OS). Toxicity was evaluated as a secondary endpoint. ***Results:*** 111 patients were enrolled and randomized for treatment with 177Lu-DOTATATE/capecitabine (n=50) or 177Lu-

DOTATATE (n=61). The ORR was 32% in the 177Lu-DOTATATE/capecitabine group and 44% in the 177Lu-DOTATATE group (p = 0.222). There was no significant change in PFS with 45.7 months (95% CI 34.2-57.2) in the 177Lu-DOTATATE/capecitabine group versus 31.7 months (95% CI 24.8-38.7) in the 177Lu-DOTATATE group (p = 0.629), with a hazard ratio of 0.761 (95% CI 0.501-1.157). Also, OS was not significantly different with 75.8 months (95% CI 58.9-92.6) and 61.4 months (95% CI 45.2-77.6) months, respectively (p = 0.530), and a hazard ratio of 0.842 (95% CI 0.539-1.315). There were no significant differences in the occurrence of short-term haematological or renal toxicities between the 177Lu-DOTATATE/capecitabine group and the 177Lu-DOTATATE group. Long-term haematological toxicity as myelodysplastic syndrome or acute myeloid leukaemia was 6% in the 177Lu-DOTATATE/capecitabine group and 3.3% in the 177Lu-DOTATATE group (p=0.656). ***Conclusion:*** In this randomized phase II trial, capecitabine combination therapy with 177Lu-DOTATATE did not improve response rates or survival compared to 177Lu-DOTATATE alone.

OP-254

Early Outcomes of ^{225}Ac-DOTA-LM3 Radiopeptide Therapy for Resistant Neuroendocrine Tumors: An Assessment Using Theranostic Response Criteria In Solid Tumors (THERCIST)

A. Eismant[1], *L. Greifenstein[1], E. Perrone[2], R. P. Baum[1];*
[1]CURANOSTICUM Wiesbaden-Frankfurt, Center for Advanced Radiomolecular Precision Oncology, Wiesbaden, GERMANY, [2]Institute of Nuclear Medicine, Università Cattolica del Sacro Cuore, Rome, ITALY.

Aim/Introduction: The benefits of somatostatin receptor antagonists, including enhanced uptake and prolonged tumor retention [1], present promising avenues for receptor radionuclide therapy. Combining somatostatin receptor antagonists with alpha emitters like 225Ac represents an innovative approach, potentially serving as salvage therapy for patients refractory to 177Lu- and 90Y-labelled somatostatin receptor agonists or 177Lu-labelled antagonists alone. ***Materials and Methods:*** We assessed treatment outcomes in 12 patients (8 males, 4 females; mean age 41.5 years) with G3 neuroendocrine tumors (7 pancreatic, 2 duodenal, 2 rectal, 1 gastrinoma; Ki67 (%) 27.5±22.5, mean 26.5%), resistant to all conventional regimens including peptide receptor therapy (PRRT) with SSTR agonists. Therapy involved 225Ac-DOTA-LM3 (6 treatments, 16.5±8.5 MBq; mean 13.4 MBq), with 10 sessions combining 225Ac-DOTA-LM3 (12.5±7.5 MBq; mean 9.5 MBq) with 177Lu-DOTA-LM3 (5.1±3.3 GBq, mean 4.9 GBq) as TANDEM. Treatment response was evaluated post-therapy using 68Ga-DOTA-LM3 PET/CT (223±172 days after therapy; mean 129 days) with THERCIST. ***Results:*** As per THERCIST criteria, we observed partial molecular responses after 9 treatments (56%) in 8 patients (67%), minor molecular responses after 4 treatments (25%) in 1 patient (8%), stable molecular disease after 2 treatments (13%) in 2 patients (17%), and progressive disease after one treatment (6%) in one patient (8%). Post-therapeutic tumor volume reduction averaged 48% (41% with 225Ac-DOTA-LM3; 52% with TANDEM DOTA-LM3), with a similar decrease of 49% noted for hepatic metastases (50% with 225Ac-DOTA-LM3; 48% with TANDEM DOTA-LM3). ***Conclusion:*** Our preliminary findings suggest higher therapeutic efficacy of 225Ac-DOTA-LM3 compared to existing data on outcomes with 177Lu-PRRT [2], underscoring the potential of 225Ac-DOTA-LM3 as a new therapeutic agent for refractory metastatic neuroendocrine tumors. ***References:*** [1] Baum RP, Zhang J, Schuchardt C, Müller D, Mäcke H. Preliminary Safety Results of Phase 1 Trial of Lu-177-DOTATATE in Combination with Olaparib in Metastatic SSTR+ Gastroenteropancreatico Neuroendocrine Tumor

F. Lin, *I. Shamis, J. Zou, J. Carrasquillo, B. Turkbey, E. Mena, L. Lindenberg, C. Chen, C. Millo, P. Herscovitch, R. Maass-Moreno, K. Pacak, J. del Rivero;*
National Institutes of Health, UNITED STATES OF AMERICA, Bethesda, MD, UNITED STATES OF AMERICA.

Aim/Introduction: Gastroenteropancreatic neuroendocrine tumors (GEP-NETs) are somatostatin receptor (SSTR) expressing tumors that can be treated with Lu-177-DOTATATE. As ionizing radiation kills tumors via DNA damage, combination therapy with olaparib, a poly-ADP-ribose polymerase inhibitor that blocks single-stranded DNA repair, is theorized to synergistically enhance Lu-177-DOTATATE's efficacy but may also exacerbate radiation-induced toxicity. We present the in-progress safety results of a phase 1/2 trial testing this combination in metastatic GEP-NETs. ***Materials and Methods:*** In this standard 3+3 dose escalation, single-center phase 1/2 study (NCT04086485), Lu-177-DOTATATE is given at fixed dose of 200 mCi x 4 cycles with olaparib being escalated from dose level (DL) 1 at 50mg to 100mg (DL2), 200mg (DL3), and 300mg (DL4) bid. Olaparib dosing starts 2 days prior to Lu-177-DOTATATE until 28 days post, for a total of 30 days with each Lu-177-DOTATATE administration. Eligibility includes SSTR+ tumors and progressive disease by RECIST within 36 months of enrollment. Specific DNA-repair mutations such as BRCA are not required for eligibilitiy. Dose limiting toxicities (DLTs) are defined as any grade 4+ hematological (except lymphocyte count) or any grade 3+ non-hematologic adverse event (AE) related to treatment that occurred within 5 weeks of the first cycle. The study opened for enrollment in September 2022 and will require up to 33 patients for full accrual. ***Results:*** As of April 2024, 11 patients have been treated on study with 3 patients each on DLs 1-3, and 2 patients on DL4. Six patients have completed therapy with all 4 cycles of Lu-177-DOTATATE, 3 have completed 3 cycles, and 2 have had 1 cycle of treatment. For safety, no DLTs have been reported in any patients. One patient needed to have a dose reduction for one of the Lu-177-DOTATATE cycles due to a grade 3 non-hematological AE that occurred outside of the DLT window (hyperglycemia). For AEs, 9 patients have data that have been analyzed. Of these 9, all (100%) had at least 1 reported treatment-related AE with 2/9 (22%) reporting at least 1 SAE (excluding grade 3+ lymphocyte count decreased). Most common AEs include leukopenia (78%), abnormal serum prolactin levels (55%), hyponatremia/hyperkalemia (44%), thrombocytopenia (33%), and anemia (33%). Grade 1 creatinine elevation in 3/9 (33%) and liver enzyme elevation in 1/9 (11%) of patients were observed. ***Conclusion:*** Preliminary data suggests that Lu-177-DOTATATE at 200 mCi is well tolerated in combination with olaparib up to 300 mg bid, the FDA-approved single agent dose.

OP-256

Interim results of ^{212}Pb-VMT-α-NET Targeted Alpha Therapy in Metastatic Gastro-entero-pancreatic Neuroendocrine Tumors: First In-human Clinical Results on Safety and Efficacy

***D. Malik*[1],** *I. Sen[1], P. Thakral[1], S. S. Das[1], S. Kapoor[2], J. Kumari[1], N. Singh[1], N. Rana[1], M. Koley[1], J. Gupta[1], D. Thakrani[1], M. Schultz[2]; [1]Fortis Memorial Research Institute (FMRI), Gurugram, INDIA, [2]Perspective Therapeutics, Iowa, IA, UNITED STATES OF AMERICA.*

Aim/Introduction: Targeted alpha therapy using 212Pb has garnered growing interest. The proprietary molecule 212Pb-VMT-α-NET has demonstrated remarkable performance in preclinical studies. The objective of this study was to investigate the interim results on safety and efficacy of 212Pb-VMT-alpha-NET therapy (TAT) in patients with advanced, progressive, 177Lu-DOTATATE refractory, somatostatin receptor (SSTR) positive, metastatic gastro-entero-pancreatic neuroendocrine tumors (GEP-NETs). ***Materials and Methods:*** The Institute Ethics Committee (IEC No: 2023-002-EMP-40) approved this exploratory first-in-human study. In our ongoing study (November 2022 to April 2024), we enrolled ten patients with well-differentiated NETs. These patients underwent a screening 68Ga-DOTANOC PET/CT scan to confirm high SSTR expression and progressive disease following prior therapies. 212Pb-VMT-α-NET was administered at a dosage of 50 µCi/kg body weight, with an interval of 08-weeks for up to 4 cycles. Hematologic, kidney, and liver function tests were repeated after each cycle at 2, 4, and 8-week intervals. Treatment-related side-effects were assessed every 2 weeks through physical examinations, laboratory results and evaluation of adverse events using the CTCAE v5.0 grading system. Efficacy assessment included evaluating clinical response and radiological changes. Objective radiological response was measured using contrast-enhanced CT scans (RECIST 1.1 criteria) and receptor expression was observed on 68Ga-DOTANOC PET/CT scans. Alterations in 68Ga-DOTANOC uptake only, were also considered as indicators of treatment response. ***Results:*** Out of ten heavily pre-treated patients included in this study, seven patients completed all four cycles of therapy, however, three patients progressed and succumbed to disease in due course of study. Treatment was well tolerated in all patients, with most common treatment-related adverse events were nausea, fatigue, and alopecia. None of the patients experienced grade 3 or 4 hemato-toxicity, renal insufficiencies or hepatotoxicity, At the time of assessment, the morphological response assessment indicated a partial response in 4 out of 7 patients, while 3 out of 7 patients showed stable disease. All patients demonstrated an improvement in their quality of life and clinical symptoms. ***Conclusion:*** The interim results of the 212Pb-VMT-α-NET therapy seems to be encouraging following favourable clinical as well as radiological response in seventy percent of patients. Also, the treatment appears to be safe, with minimal and transient side effects. However, the long-term survival data will emerge with extended follow-up.

OP-257

Prediction of patient progression-free survival with 177Lu-DOTATATE in clinical practice: NEPTUNE-SEPTRALU model for patient selection

Aim/Introduction: Peptide receptor radionuclide therapy (PRRT) is increasingly recognized for its efficacy in treating neuroendocrine neoplasms (NENs). As clinical trials evaluate the optimal sequencing and integration of PRRT, accurately predicting individual patient outcomes has become essential. Our study aims to develop and validate a model to predict progression-free survival (PFS) in patients undergoing PRRT ***Materials and Methods:*** The data for this study were collected from the SEPTRALU study (NCT04949282), a comprehensive national registry supported by the Spanish Society of Nuclear Medicine and Molecular Imaging (SEMNIM). This registry records outcomes for patients with advanced NENs treated with 177Lu-DOTATATE under various clinical conditions. We used an accelerated failure time model to estimate PFS, which was internally validated using bootstrap methods. The resulting NEPTUNE model was transformed into a nomogram and is accessible through an online calculator (https://www.prognostictools.es/Neptune/calculator/calculator.aspx). ***Results:*** As of October 2023, the registry included 713 patients, with 624 meeting the inclusion criteria and having available follow-up data. The cohort primarily consisted of males (59%, n=368), with a median age of 61.2 years (range 18 to 88). Most participants (90.3%, n= 563) had a good performance status (ECOG-PS 0-1). The primary tumor locations were pancreatic (36%, n=225), midgut (28%, n=175), bronchopulmonary (10%, n=62), paragangliomas/pheochromocytomas (6%, n=37), other gastroenteropancreatic (11%, n=69), and other non-gastroenteropancreatic (9%, n=56). A significant portion (35.4%, n=221) received PRRT as a second-line treatment. The median duration from oncological diagnosis to PRRT initiation was 40 months (range 0.5-288 months). Common previous treatments included somatostatin analogs (90.4%, n=564), everolimus (42.5%, n=265), chemotherapy (26.4%, n=165), and sunitinib (18.6%, n=116). The median PFS was 27.2 months (95% CI, 23.5-31.8), and overall survival was 48.5 months (95% CI, 41.2-61.7). The model's prognostic factors included ECOG performance status, Ki67 index, tumor origin, site of metastasis, Krenning score from scintigraphy or Gallium PET, time from diagnosis to PRRT initiation, and the number of prior systemic antineoplastic treatments. The model demonstrated strong calibration and discrimination, supported by a bootstrap-adjusted Harrell's C-index of 0.693 (95% CI, 0.666-0.726). ***Conclusion:*** The NEPTUNE-SEPTRALU nomogram confirms the feasibility of predicting individual outcomes for patients with advanced NENs treated with 177Lu-DOTATATE, offering a sound basis for patient selection.

Peptide receptor radiopeptide therapy (PRRT) using the 225Actinium- and 225Actinium/177Lutetium-labelled (TANDEM) somatostatin-receptor (SSTR) antagonist DOTA-LM3 in patients with neuroendocrine neoplasms (NEN): A retrospective study concerning safety and survival

[2]CURANOSTICUM Wiesbaden-Frankfurt, Center for Advanced Radiomolecular Precision Oncology, Wiesbaden, GERMANY.

Aim/Introduction: PRRT with 225Actinium-labelled somatostatin-receptor antagonists such as DOTA-LM3 is a promising therapy option for progressive NEN due to high tumour uptake, and prolonged tumour retention. This retrospective study in advanced NEN-patients analyses the safety and overall survival (OS) after 225Ac-DOTA-LM3 PRRT, both as monotherapy and in combination with 177Lutetium (TANDEM). ***Materials and Methods:*** Between March 2022 and February 2024, 28 patients (19 men, 9 women; age 36-85 years) received 225Ac-DOTA-LM3 PRRT based on 68Ga-DOTA-LM3 PET/CT findings. Primary NEN: pancreas (n=16), small intestine (n=7), rectum (n=2), pheochromocytoma (n=1), aesthesioneuroblastoma (n=1), CUP-NEN (n=1). Premedication (antiemetics/dexamethasone) and para-aminohippuric acid (PAH) for renal protection were administered. CTCAE v.5.0 was used to grade haematological, renal, and hepatic adverse events, considering patients with ≥1 follow-up visit (n=25). ***Results:*** In total, 44 225Ac-DOTA-LM3 cycles were administered over 23 months (17 monotherapies, 27 TANDEM). At the time of analysis, 15 patients had received one cycle, monotherapy or TANDEM (2-20 MBq 225Ac); 11 patients had received two cycles (8.9-29.9 MBq 225Ac) and 2 patients three cycles (26.4 and 31.9 MBq 225Ac). Mostly mild and transient acute reactions were reported after PRRT: emesis (n=7); nausea (n=6); flare pain (n=6); flushing (n=5); diarrhoea (n=2); fatigue (n=1); hypertension (n=1). During follow-up, three patients died (OS 12-20 months) due to post-surgical complications (one) and disease progression after initial response (two). 25 patients are still alive (follow-up 1-18 months). After PRRT (vs. baseline): 26 patients showed anaemia G1/G2 (vs.19), 4 anaemia G3 (vs.2); 7 patients showed leukocytopenia G1/G2 (vs.3), 2 leukocytopenia G3 (vs.1). Absolute neutrophil count G3 occurred in one patient three weeks after TANDEM-PRRT. Ten patients developed thrombocytopenia G1/G2 (vs.5), and 5 patients thrombocytopenia G3. One acute myeloid leukaemia was diagnosed 12 years after the first 90Y-DOTATOC PRRT. After therapy, renal impairment G1/G2 occurred in 6 patients (vs.4), and renal insufficiency G3 in 2 patients. Hepatic function worsened in one patient with heavy liver involvement (from G2 to G3). ***Conclusion:*** This retrospective analysis demonstrates the safety of 225Ac-DOTA-LM3 PRRT in terms of acute and long-term adverse events: few patients (with extensive bone metastases) developed new G3 haematological toxicity; one leukaemia (3 months after TANDEM, 12 years after initial PRRT); two renal insufficiency G3 (one known neurogenic bladder with recurrent urinary infections; in the other patient, PRRT-related toxicity was excluded by biopsy). No significant PRRT-related hepatotoxicity was observed. 225Ac-DOTA-LM3 PRRT showed encouraging survival outcomes in patients unresponsive to 177Lu-DOTATATE or 177Lu-DOTATOC.

Aim/Introduction: Radiolabeled somatostatin analog (SSA) therapy is established for unresectable or metastatic neuroendocrine tumors (NETs). However, A potential disadvantage of 177Lu-DOTATATE is its rapid blood clearance, resulting in relatively short tumor retention. So, through combining Evans blue (EB, albumin binder) and altering the linker we developed an optimized EB-modified radiolabeled SSA, 177Lu-LNC1010. Following preclinical in vitro and in vivo biological evaluation, advanced/metastatic SSTR2-positive NETs. ***Materials and Methods:*** SPECT imaging and biodistribution studies of 177Lu-LNC1010 was performed to visualize the radioligand distribution in vivo and absolute tumor uptake. This was an open-label, non-randomized, first-in-human, dose-escalation, and investigator-initiated trial (IIT) involving patients with advanced/metastatic SSTR2-positive NETs. A '3+3' design was adopted, starting the treatment with 2.22 GBq of 177Lu-LNC1010, with treatment cycles spaced 8 weeks apart. The primary objectives were to determine the safety, tolerability, and maximum tolerated dose of 177Lu-LNC1010. ***Results:*** High binding affinity of LNC1010 (IC50 = 20.39 nM) for SSTR2 was confirmed in vitro. SPECT imaging and biodistribution studies of 177Lu-LNC1010 demonstrated significantly improved tumor uptake and retention than those of 177Lu-DOTATATE. Administration of 177Lu-LNC1010 was well tolerated, with no adverse or life-threatening events in any patients. None of the 3 patients experienced dose-limiting toxicity (DLT) in Group A (2.22 GBq/cycle). Grade(G)4 thrombocytopenia was recorded in one patient in Group B (3.33 GBq/cycle); hence, another three patients were enrolled in Group B, and none experienced DLT. G4 hematologic toxicities were recorded in two patients in Group C (4.99 GBq/cycle). G3 thrombocytopenia was recorded in one patient in Group D (EB-TATE, 3.33 GBq/cycle). G3 hepatotoxicity was observed in two patients from Groups C and D. No nephrotoxicity was observed. No significant difference in whole-body mean effective dose was observed between 177Lu-LNC1010 and 177Lu-EB-TATE (0.23±0.06 vs. 0.23±0.08 mSv/MBq, P=1.00), however ,177Lu-LNC1010 exhibited 2.7-, 4.0-, and 3.0-fold higher radiation doses in the metastatic lymph nodes, liver, and other metastases than those of 177Lu-EB-TATE, respectively. In patients treated with 177Lu-LNC1010, 5 (42%) had a partial response, 5 (42%) had stable disease, and 2 (17%) had progressive disease. The objective response rate and disease control rate were 25% and 83%, respectively. ***Conclusion:*** The first-in-human trial with 177Lu-LNC1010 is well tolerated in patients with advanced NETs, with high radiation doses delivered to the tumor lesions. In addition, the dose-escalation study identified 3.3 GBq/cycle as the

optimal therapeutic dose for future trials. Further investigations through multicenter, prospective, and randomized controlled trials are needed.

Aim/Introduction: 177Lu-DOTATATE is an effective and safe therapy for well-differentiated neuroendocrine neoplasm (NEN) patients, evidenced by the NETTER-1 phase 3 trial. For patients experiencing disease progression after initial response, additional 177Lu-DOTATATE cycles as salvage therapy can be considered. However, literature on salvage PRRT is limited, covering diverse patient profiles, cycle numbers, follow-up durations, and varied responses and toxicities. The purpose of this study is to evaluate the clinical practice experiences with PRRT retreatment (rPRRT) from the SEPTRALU registry. ***Materials and Methods:*** SEPTRALU (NCT04949282) is a multicenter national registry of NENs treated with PRRT. A case eligible for registration is defined as any adult with a metastatic, unresectable, somatostatin receptor (SSTR) overexpressing, histologically confirmed neoplasm, who receives at least one cycle of 177Lu-DOTATATE, following the clinical practices of each center. rPRRT was defined as the administration of several additional doses of PRRT some time after the completion of the initial four cycles, possibly having received some other oncological treatment in between, and in the context of radiological progression. ***Results:*** Seventy-one rPRRT patients (41% female, average age 55) were included. The primary tumor locations were mainly ileal (35%) and pancreatic (34%), with 35% being functional tumors. The majority had hepatic (85%), bone (25%), and peritoneal (14%) metastases. Histologically, the mean Ki67 index was 10%, with 32% of patients having a Ki67 index ≥10%; WHO grade 1: 37%, grade 2: 49%, and grade 3: 14%. The first PRRT (PRRT1) was administered as second (35.5%) and third-line (27%) treatment. All patients received four doses, achieving an overall response rate (ORR) of 61.7% and a progression-free survival (PFS) of 35 months. The average interval between the end of PRRT1 and rPRRT was 29.3 months. For rPRRT , patients received between 1 to 4 doses at rates of 100%, 66%, 24%, and 17%, respectively. Treatment discontinuation was mainly due to progression (18%). The ORR for rePRRT was 17.6% with a clinical benefit rate of 58.8% and PFS was not reached after 10 months of follow-up, with a 10-month PFS rate of 78%. No new toxicity alerts were reported. Univariate analysis identified a previous response to PRRT1 as a predictor of radiological response to rPRRT (p=0.004). ***Conclusion:*** PRRT retreatment presents a viable therapeutic strategy for advanced NENs, with favorable efficacy and identifiable response predictors, notably previous response to PRRT. Future trials are expected to provide further insights into the optimal duration and sequencing of rPRRT.

DARP in-mediated PNA-based pretargeting: in vitro proof-of-principle.
E. Papalanis[1], *M. Oroujeni[1], K. Westerlund[2], J. Clinton[2], A. Van Deventer[3], A. Eriksson Karlström[2], V. Tolmachev[1];*
[1]Uppsala University, Uppsala, SWEDEN, [2]KTH, Stockholm, SWEDEN, [3]KI, Stockholm, SWEDEN.

Aim/Introduction: The human epidermal growth factor receptor 2 (HER2) is overexpressed in 20% of breast cancers. Designed ankyrin repeat protein (DARPin) G3 is an engineered scaffold protein (ESP) that binds to HER2 with a high affinity (KD= 90 pM) [1] and has been successfully used in clinics. A limiting factor for targeted radionuclide therapy using ESPs is the high renal accumulation. A pretargeting methodology based on Peptic Nucleic Acid (PNA) using another type of ESP, affibodies, has previously shown a reduction in renal uptake. This methodology is based on hybridization between a primary agent containing a recognition tag HP1 and a secondary agent HP2 complementary to HP1 [2]. HP2 contains a DOTA chelator enabling the labeling with 177Lu. Our aim was to test whether the PNA-pretargeting could be applied for DARPin-G3. ***Materials and Methods:*** HP1 was fused with DARPin-G3 using sortase A-mediated ligation. Authenticity of DARPin-G3-HP1 and HP2 was evaluated using mass spectroscopy. The affinity of DARPin-G3-HP1 to HER2 was measured using surface plasmon resonance (SPR). DARPin-G3-HP1 and HP2 were radiolabeled with 125I and 177Lu respectively. In vitro specificity and internalization assays were conducted using the HER2-expressing cell lines, SKOV3 and BT474. LigandTracer was used to measure the affinity of [125I]I-G3-HP1 to HER2-expressing living cells and binding of [177Lu]Lu-HP2 to G3-HP1-pretreated cells. ***Results:*** Mass-spectroscopy confirmed that the coupling of HP1 with DARPin-G3 was successful. SPR demonstrated a high affinity (0.64 nM) of the G3-HP1 to HER2 at 25 o C. Radiolabeling of DARPin-G3 -HP1 with 125I and HP2 with 177Lu resulted in high radiochemical purities, >97%. The in vitro experiments showed that DARPin-G3 -HP1 binding to HER2 expressing cells is saturable i.e. is specific. [177Lu] Lu-HP2's binding to G3-HP1-pretreated cells can be blocked by pre-saturation of HER2 with cold G3 and by saturation of HP1 with cold HP2. The binding of [177Lu]Lu-HP2 was negligible without pre-treatment of cells with G3-HP1. The binding affinities of [125I]I-G3-HP1 to HER2-expressing cells and of [177Lu]Lu-HP2 to G3-HP1-pretreated cells were 318 pM and 160 pM respectively. ***Conclusion:*** The data show that in vitro pretargeting using G3-HP1/[177Lu]Lu-HP2 system is HER2-mediated and PNA-dependent A high targeted specificity and affinity were demonstrated in vitro. ***References:*** [1] Zahnd C et al. Therapeutic efficacy and safety of intraperitoneally administered ^{211}At labeled gold nanoparticles for cancer peritoneal dissemination

H. Kato[1], *Y. Kadonaga[1], K. Kaneda-Nakashima[2], K. Ooe[1], X. Huang[3], E. Hilmayanti[3], A. Shimoyama[3], K. Kabayama[1], Y. Xiaojie[4], H. Haba[4], Y. Kon[1], A. Toyoshima[1], K. Fukase[3];*
[1]Institute for Radiation Sciences, The University of Osaka, Suita, Osaka, JAPAN, [2]Osaka University Graduate School of Science, Suita, Osaka, JAPAN, [3]Osaka University Graduate School of Science, Toyonaka, Osaka, JAPAN, [4]Nishina Center for Accelerator-Based Science, RIKEN, Tokyo, JAPAN.

Aim/Introduction: Peritoneal dissemination is a very poor prognosis condition for which no effective treatment has been established. Integrins are considered to be the key molecules of cell adhesion involved in cancer cell invasion and metastasis. The aim of this study was to evaluate the intraperitoneally administered astatinated nanoparticle with PEG and cyclic RGD peptide modifications mPEG-S-AuNP[211At]-c[RGDfK(C)] with respect to its kinetics, safety, and therapeutic efficacy. ***Materials and Methods:*** Fluorescent protein-expressing C6 rat glioma cells and human pancreatic cancer cells BxPC3 were seeded intraperitoneally in nude mice and intraperitoneally injected with mPEG-S-AuNP[211At]-c[RGDfK(C)] (0.98 ± 0.19 MBq for C6 models, 1.1 ± 0.035 MBq for BxPC3 models) or saline 7 days and 5 days later, respectively. The distribution of radio isotope was evaluated by scintigraphy up to 42 hours after administration. Intraperitoneal tumor growth was observed by fluorescence imaging. ***Results:*** In vitro studies have confirmed the cellular internalization of the nanodrug and the inhibitory effect of the nanodrug on tumor cell viability when it was administered to cultured tumor cells. In the peritoneal seeding model, the establishment of peritoneal dissemination was confirmed by fluorescence imaging. In nude mice intraperitoneally seeded with C6 rat glioma cells, 23 days after administration, the animals were dissected and intraperitoneal tumors were harvested. Tumor mass was significantly lower in the drug-treated group compared with controls. For the BxPC3 peritoneal dissemination model, a survival analysis revealed that the drug significantly prolonged overall survival. It was found that the administered radioisotope showed little transfer to the blood and remained in the abdominal cavity for a long time. Although transient weight loss, leukopenia, and thrombocytopenia were observed by one week post-administration, then a recovery trend was evident thereafter. One month after administration, no abnormalities in blood counts, blood biochemistry, or histology of intra-abdominal organs were found. ***Conclusion:*** The kinetics, safety, and therapeutic efficacy of intraperitoneally administered astatinated nanoparticle mPEG-S-AuNP[211At]-c[RGDfK(C)] on the intraperitoneal dissemination of malignant tumors expressing integrins that recognize RGD peptides.

^{161}Terbium-labeled Gold Nanoparticles for Nanoscale Brachytherapy

E. Salvanou[1], *A. Apostolopoulou[1], S. Xanthopoulos[1], S. Koelewijn[2], P. van Overeem[2], G. Laurent[3], R. Bazzi[3], F. Denat[4], S. Roux[3], P. Bouziotis[1];*
[1]INRASTES, NCSR "Demokritos", Athens, GREECE, [2]Terthera b.v., Breda, NETHERLANDS, [3]Université de Franche-Comté, CNRS, Chrono-environnement, Besançon, FRANCE, [4]Université de Bourgogne, CNRS, ICMUB, Dijon, FRANCE.

Aim/Introduction: Gold nanoparticles (AuNPs) are useful multifunctional carriers able to deliver radioisotopes and provide imaging and therapy capabilities. Terbium-161 (161Tb) is an attractive radioisotope for theranostic applications, due to its beta-particle and Auger emissions for therapy, in combination with its low energy γ-ray emission, allowing imaging with Single Photon Emission Computed Tomography (SPECT). Injectable radiopharmaceuticals exhibit outstanding therapeutic effects along with minimizing the discomfort associated with brachytherapy procedures1,2. In this perspective, radioactive nanoparticles could represent a promising alternative to conventional brachytherapy with superior results3,4. Our aim was the development and evaluation of AuNPs and gold nanoflowers (AuNFs) radiolabeled with 161Tb via a DOTA-derivative chelator as a nanobrachytherapy agent for the treatment of breast cancer. The obtained radio-nanomedicines were evaluated for their radiolabeling stability, in vitro cytotoxicity, ex vivo biodistribution and therapeutic efficacy in tumor animal models. ***Materials and Methods:*** Au@TADOTAGA nanoparticles (AuNPs) and Au@TADOTAGA nanoflowers (AuNFs) were radiolabeled with 5-30 MBq [161Tb]TbCl3 and the percentage of incorporated 161Tb was determined by instant thin-layer chromatography (ITLC). In vitro stability of the 161Tb-labeled nanoconjugates was evaluated at room temperature (RT) and in the presence of serum up to 21d. In vitro cytotoxicity of AuNPs, AuNFs, [161Tb]Tb-AuNPs, [161Tb]Tb-AuNFs and [161Tb]TbCl3 against 4T1 cells was determined by the MTT assay. Ex vivo biodistribution and therapeutic efficacy were assessed on SCID mice bearing 4T1 breast cancer tumors. ***Results:*** Radiochemical yield of both [161Tb]Tb-AuNPs and [161Tb]Tb-AuNFs was >98% after 1h incubation at 75°C and 850rpm. The radionanoconjugates were stable at RT and serum up to 21d post-radiolabeling. Cytotoxicity studies in 4T1 cells showed a concentration and time-dependent toxicity especially for the AuNFs. Ex vivo biodistribution showed enhanced retention at the injection site. Tumor regression was observed after intratumoral injection of both radionanoconjugates. ***Conclusion:*** Radiolabeling of both AuNPs and AuNFs with 161Tb was fast and robust. In vitro cytotoxicity on 4T1 cells of the radiolabeled and non-radiolabeled AuNFs was higher, when compared to AuNPs. Therapeutic efficacy studies showed that both 161Tb-labeled nanomedicines led to tumor regression. Based on these preliminary results, we conclude that [161Tb]Tb-AuNFs and [161Tb]Tb-AuNPs should be further investigated in other cancer models, to assess their therapeutic potential as nanobrachytherapy agents. ***References:*** 1. Protein Embedded and Intrinsically Radiolabeled [^{188}Re]ReO$_x$ Nanoparticles for Concurrent Radio-photothermal Therapy

S. Ghosh[1,2], *S. Patra[1,2], A. Chakraborty[1,3], K. C. Barick[1,4], A. Guleria[1,5], C. Kumar[1,2], R. Chakravarty[1,2];*
[1]Homi Bhabha National Institute, Mumbai, INDIA, [2]Radiopharmaceuticals Division, Bhabha Atomic Research Centre, Mumbai, INDIA, [3]Radiation Medicine Centre, Bhabha Atomic Research Centre, Mumvai, INDIA, [4]Chemistry Division, Bhabha Atomic Research Centre, Mumbai, INDIA, [5]Radion and Photochemistry Division, Bhabha Atomic Research Centre, Mumbai, INDIA.

Aim/Introduction: Boosting therapeutic efficiency is the essential key for translating any anticancer nanomedicine from preclinical investigations to clinical practice. Herein, we have synthesised

human serum albumin (HSA) encapsulated radioactive rhenium oxide nanoparticles ([188Re]ReOx-HSA NPs) for combined radiotherapy and photothermal therapy. ***Materials and Methods:*** 188Re was obtained from an in-house developed 188W/188Re-generator. [188Re]ReOx-HSA NPs were synthesised by a controlled reduction of 188ReO4- in HSA medium. Photothermal efficiency of the nanoformulation was investigated by illuminating it with a 808 nm laser (0.8 W cm-2) at different concentrations of the NPs for different time periods. Cell cytotoxicity of the NPs was checked in B16F10 cell lines. The anticancer effect of the NPs was evaluated by incubating ReOx-HSA NPs and [188Re]ReOx-HSA NPs in B16F10 cell lines followed by irradiation with an NIR laser after 12 h of incubation. In-vivo SPECT/CT imaging, autoradiography and biodistribution studies were performed after intratumoral injection of radiolabelled NP in B16F10 tumour-bearing C57BL/6 mice. Systematic tumour regression studies and histopathological analyses were performed to demonstrate therapeutic efficacy in the aforesaid mice model after intratumoral injection of [188Re] ReOx-HSA NPs followed by irradiation of the tumour by NIR laser for 5 minutes. ***Results:*** [188Re]ReOx NPs (size 6 - 8 nm) possessed high colloidal and radiochemical stability. The temperature of the aqueous ReOx NPs dispersion with a concentration of 500 ppm was raised from 25 to 45 oC under laser irradiation for 5 minutes. The photothermal conversion efficacy of the NPs was ~28%. The MTT assay confirmed that even at 500 ppm concertation of the non-radioactive NPs, > 90% of cells survived. Whereas, upon laser exposure on cells incubated with radioactive NPs, only 20% of cells were alive demonstrating the therapeutic efficacy. Uniform dose distribution and retention of the radiolabelled NPs in the tumour volume were observed via SPECT/CT imaging and autoradiography studies. In a tumour regression study, tumour growth was significantly arrested with ~ 18.5 MBq dose and simultaneous laser irradiation. In histopathological analysis, loss of mitotic cells was apparent in the tumour tissue of treated groups whereas no significant damage in lungs, kidney, and liver tissue morphology was observed. Serum biochemistry and blood parameters of the treated mice were also comparable with healthy mice. ***Conclusion:*** This work demonstrates the potential of [188Re]ReOx-HSA NPs towards concurrent radiation and photothermal therapy for personalized cancer care management. ***References:*** 1. Radiobiological comparison of yttrium-90 and holmium-166 in liver cancer cells

J. Perrin[1], *C. Ntihabose[1], J. Zink[1], E. de Blois[1], M. Konijnenberg[1], A. Denkova[1], J. Nonnekens[1];*
[1]Erasmus MC, Rotterdam, NETHERLANDS.

Aim/Introduction: Hepatocellular carcinoma (HCC) is the 4th cancer-related cause of death worldwide in 2020. Liver cancer is often diagnosed late, with a 70% of recurrence 5 years after treatment. A promising therapy is radioembolization, which deliver radioactive microspheres to the tumor site by intra-arterial injection. The currently available microspheres in the clinic are radiolabeled with either yttrium-90 or holmium-166. Although several studies showed the benefits of radioembolization in unresectable liver cancer compared to standard care, there is currently no study comparing these two radionuclides and thus the selection is currently not based on radiobiological knowledge. Both radionuclides are β- emitters, however yttrium-90 shows a higher β- energy (2.28MeV) and longer half-life (64.1h) compared to holmium-166 (1.81MeV and 26.8h). Whether this difference in physical characteristics will result in a difference in therapeutic efficacy and under which conditions has yet to be determined. ***Materials and Methods:*** In this project, we are studying the radiobiological impact of yttrium-90 and holmium-166 on 3 HCC human cell lines in vitro with different proliferation rates (Hep3b 30 hours, PLC 17 hours and Huh7 27 hours), to analyze whether proliferation speed influences sensitivity to each radionuclide. In vitro dosimetry was realized with the MCNP software to calculate the activity concentration needed for both radionuclides to reach a total absorbed dose of 1.5Gy or 2.5Gy over a cell culture period of 24h. Subsequently, survival and DNA damage were measured by clonogenic survival assay and staining of 53BP1 and γH2AX protein foci, respectively. ***Results:*** Holmium-166 and yttrium-90 showed a similar, dose-dependent reduction of survival in all three cell lines. While both radionuclides have a similar impact on cell survival at identical doses, the DNA damage induction is different. After 24h of irradiation, yttrium-90 irradiated cells show a dose-dependent increase of DNA damage as expected, but holmium-166 irradiated cells do not. This discrepancy in DNA damage induction can be explained by the difference in dose rate, which is higher for holmium-166 than for yttrium-90. Further studies on real-time DNA damage induction kinetics will allow us to better understand the impact of both radionuclide at the DNA level. ***Conclusion:*** Both radionuclides seem to have a similar toxicity on the HCC cell line in vitro. However, if the discrepancy in DNA damage induction is confirmed, further experiments combining them with DNA repair targeting drugs could lead to improved therapy efficiency.

OP-277

^{90}Y-labeled montmorillonite microspheres for intra-arterial brachytherapy of hepatocellular carcinoma

N. Liu, *X. Su;*
Department of Nuclear Medicine, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, CHINA.

Aim/Introduction: The intra-arterial administration of radioactive microspheres is an alternative therapy option for treating primary hepatocellular carcinoma (HCC). Currently, the clinically used radioembolization microspheres, 90Y-labeled glass microspheres and resin microspheres, are complicated to prepare and expensive, thus there is an urgent need to develop a new type of radioactive microspheres with simple preparation, low-cost, and stable radiolabeling. Montmorillonite (MMT), as a naturally occurring layered silicate clay mineral, have micro ~ nano-scale size distribution upon different process technology, and the hard Lewis bases (Si-O, Al-O) on its surface are able to stabilize metal ions, so we envisioned the possibility of yttrium 90-labeling on MMT microspheres and its application for embolization radiotherapy of HCC. ***Materials and Methods:*** 90Y-labeled MMT microspheres were prepared by simple temperature-controlled mixing MMT solution and 90YCl3. Size distribution and zeta potentials of montmorillonite were analyzed on a Malvern Zetasizer. The phase purities of MMT were characterized by X-ray diffractometer. The radiolabeling yield and serum stability study were tested by Mini-Scan radio-TLC Strip Scanner (BioScan, USA). For the in vivo studies, 90Y-labeled MMT microspheres was administrated on mouse HepG2 tumor model and rabbit VX2 liver tumor model to verify the in vivo radiostability and therapeutic effect. ***Results:*** The size of the used MMT was 20-70 μm, which was suitable for embolizing the microvessels of HCC. Meanwhile, the negative potential of its surface and the strong Lewis base

have very high adsorption efficiency for 90Y3+. Importantly, it can keep the radiolabeling stability in serum and animals during 14 days' observation. Next, intratumoral administration of 90Y-MMT was performed in HepG2 tumor-bearing mice, we found that 90Y-MMT could be stably retained in the tumor region and could completely eliminate the tumor growth during 14-days' monitoring. In the rabbit VX2 liver tumor, DSA-guided intravascular brachytherapy can accurately deliver 90Y-MMT to the tumor site, which can be monitored by PET scanning, and also the tumor inhibition can be seen based on 18F-FDG uptake. Immunostaining and immunoblotting results also confirmed the powerful tumor suppression. ***Conclusion:*** In summary, we successfully developed 90Y-labeled MMT microspheres for efficient locoregional intravascular brachytherapy of HCC. The merit of 90Y-MMT with controlled size, good radiostability and good radioembolization effect do good for effectively inhibit tumor growth, indicating the powerful interventional radioembolization candidate for HCC therapy. ***References:*** (1) Theranostics 2023, 13(7), 2114-2139. OP-278

Delivery of the Auger Therapeutic [^{125}I]IUdR via Nanocarriers for Treatment of Glioblastoma

N. Straathof[1], *Q. Tang[1], A. Y. Nielsen[2], K. Ravn[1], V. S. Gammelsrød[2], B. Halle[3], H. Thisgaard[2], A. I. Jensen[1];*
[1]DTU Health Tech, Copenhagen, DENMARK, [2]Odense University Hospital, Odense, DENMARK, [3]Odense University Hospital, Dept. of Neurosurgery, Odense, DENMARK.

Aim/Introduction: Glioblastoma (GBM) is the most common primary cancer in the brain. Life expectancy is extremely low with a median survival of 16 months. Even after the current treatment, a combination of surgery, external irradiation and temozolomide chemotherapy, the recurrence rate is 100%. While the bulk tumor can be removed, the key challenge is the infiltration of GBM cells into the surrounding healthy brain. These infiltrating cells are mostly unaffected by current treatments being main cause of recurrence. We present a novel approach to eradicate infiltrating GBM cells, harnessing the potent Auger radiotherapeutic [125I] iododeoxyuridine ([125I]IUdR). Stealth liposomes capable of sustained release of [125I]IUdR were developed. These liposomes can be infused into the healthy brain after surgical removal of bulk tumor with a wide distribution enabled by convection enhanced delivery (CED). As a target-agnostic therapy, released [125I]IUdR is taken up by all proliferating infiltrating GBM cells and incorporated into their DNA, killing them via Auger electron emission. ***Materials and Methods:*** We synthesized a library of [125I]IUdR-Cn prodrugs with Cn being different lipid-anchors conjugated via an ester-linker. All prodrugs were radiolabeled with iodine-125, purified and loaded into preformed liposomes (LIPs) in a cold-kit like manner in high yield. Loaded LIPs were then assessed for their esterase-triggered release rate of [125I]IUdR in relevant biological media, including rat brain homogenate. In vitro, we assessed CellTiterBlue and clonogenic growth in GBM cells. DNA incorporation of released [125I]IUdR was assessed both in vitro and in vivo. Imaging and ex vivo biodistribution after intracranial administration was performed in glioblastoma-bearing rodents. ***Results:*** LIPs loaded with lead prodrug; [125I]IUdR-C18, were prepared in good RCY (62%) and an optimal in vitro release of [125I]IUdR over 2 to 7 days was observed, corresponding with GBM cell division timelines and duration of CED. Cell viability studies demonstrated comparable cytotoxicity in LN229 GBM cells as free [125I]IUdR. In vivo data showed significant retention in the brain up to several days, low uptake in off-target organs, and, crucially, in vivo DNA uptake of [125I]IUdR. ***Conclusion:*** We report a novel radioligand therapy concept; [125I]IUdR releasing liposomes for eradicating infiltrating GBM cells. Our results demonstrate high in vitro cytoxicity and promising in vivo properties. This novel Auger radiotherapy holds promise as adjuvant to current GBM treatments with the key feature of potential efficacy against highly heterogeneous GBM cell populations. Efficacy studies and adaptation to iodine-123 are on-going. ***References:*** [1] Thisgaard et al. Theranostics 2016.

OP-279

Therapeutic Effects of [^{64}Cu]Cu-Labeled Nanoparticle Albumin-bounded Paclitaxel in a SPARC-Expressing Xenograft Mouse Model

J. Kim[1,2,3], *J. Park[1,2,3], S. Lee[1,3,4], Y. Lee[1,4,5], G. Cheon[1,3], K. Kang[1,2,3], H. Youn[1,3,4];*
[1]Department of Nuclear Medicine, Cancer Imaging Center, Seoul National University Hospital, Seoul, KOREA, REPUBLIC OF, [2]Department of Biomedical Sciences, Seoul National University Graduate School, Seoul, KOREA, REPUBLIC OF, [3]Cancer Research Institute, Seoul National University College of Medicine, Seoul, KOREA, REPUBLIC OF, [4]Cancer Imaging Center, Seoul National University Hospital, Seoul, KOREA, REPUBLIC OF, [5]Radiation Medicine Research Institute, Medical Research Center, Seoul National University College of Medicine, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: Secreted Protein Acidic and Rich in Cysteine (SPARC) is highly expressed in various tumor cells, facilitating the tumor-specific uptake of albumin. This study employs nanoparticle albumin-bound paclitaxel (nab-paclitaxel), a conjugate of paclitaxel and human serum albumin, to explore the SPARC-mediated tumor uptake and specific anticancer effects. ***Materials and Methods:*** We selected the glioblastoma cell line U87MG for its high SPARC expression and generated SPARC-negative variants through retroviral transduction using SPARC-specific shRNA. SPARC expression levels were confirmed by Western blotting. The nab-paclitaxel was radiolabeled with [64Cu]Cu using Click chemistry. Seven male balb/c-nu mice were xenografted with U87MG cell line on the left upper limb and U87MG-shSPARC on the right. Each mouse received an intravenous injection of 12 MBq of [64Cu]Cu-nab-paclitaxel, and PET images were acquired at 0, 4, 8, and 24 hours post-injection to assess in vivo distribution. ***Results:*** In vivo PET imaging revealed a 1.8-fold higher signal in SPARC-positive tumors compared to SPARC-negative tumors (16.5 %ID/g in U87MG vs. 9.16 %ID/g in U87MG-shSPARC), confirming SPARC-mediated uptake of nab-paclitaxel. Post-treatment, SPARC-positive tumors showed more than one-third reduction in volume within five days. ***Conclusion:*** Our findings demonstrate that nab-paclitaxel undergoes SPARC-mediated cellular uptake, leading to significant therapeutic effects on SPARC-expressing tumors. These results underscore the potential of nab-paclitaxel as a theranostic probe in SPARC-positive tumors. ***References:*** Park et al. Secreted protein acidic and rich in cysteine mediates active targeting of human serum albumin in U87MG xenograft mouse models. Theranostics. 2019 Oct 11;9(24):7447-7457.

Production, Radiochemical Separation and Radiolabeling of Gold Nanoparticle Bioconjugates with ^{211}At for Targeted Alpha Therapy

S. Ghosh[1,2], *D. Banerjee[1,3], R. Chakravarty[1,2];*

[1]Homi Bhabha National Institute, Mumbai, INDIA, [2]Radiopharmaceuticals Division, Bhabha Atomic Research Centre, Mumbai, INDIA, [3]Radiochemistry Division (BARC), Variable Energy Cyclotron Centre, Kolkata, INDIA.

Aim/Introduction: Targeted alpha therapy (TAT) is now emerging in advanced cancer management due to the short range and high linear energy transfer (LET) of α-particles. Astatine-211 has attained significant interest for TAT over other α-emitters as it emits only one α-particle per decay which alleviates certain concerns related to in vivo administration and also simplifies dosimetry calculations. In this study, we have produced 211At via 209Bi (α, 2n) 211At reaction in a cyclotron and radiochemically separated it for formulation of nanoradiopharmaceuticals. ***Materials and Methods:*** Natural bismuth oxide target in pelletized form wrapped in Al foil (foil thickness ~25.4 μm) was irradiated with 30 MeV α-beam in an AVF cyclotron. The irradiated target was first cooled down and dissolved in 2 M HNO3 at room temperature. Subsequently, Bi was precipitated as Bi(OH)3 using 2 M NaOH followed by the separation of ionic sodium astatide solution by centrifugation and membrane filtration. The radiochemically separated 211At was used for labelling cyclic RGD peptide conjugated gold nanoparticles (Au-RGD NPs) by surface adsorption. The radiochemical stability of 211At-Au-RGD NPs was evaluated under physiological conditions. ***Results:*** The batch yield of 211At at the end of irradiation was 6.0 ± 0.3 MBq.μA-1.h-1. The overall separation yield of 211At was ~ 80% with >99.9 % radionuclidic purity. The γ-spectra of the decayed samples did not show the presence of extraneous radioisotopes. Graphite furnace atomic absorption spectrometry (GFAAS) analysis of the decayed samples confirmed that the bismuth level was < 1 ppm in the radiochemically separated samples. In the synthesis procedure of the Au NPs, the RGD peptide acted as both reducing and stabilizing agent and thus precluded the need for using toxic surfactants. Such NPs (particle size 8.4±0.8 nm) are not only biocompatible but also target the integrin αvβ3 receptors which are overexpressed on tumour endothelial cells of varying cancer types. Au-RGD NPs could be labelled with 211At adopting a non-covalent approach. The radiolabelling yield was found to be > 99 % and the radiolabelled nanoparticles retained their integrity under physiological conditions over a period of 21 h. ***Conclusion:*** The present strategy simplifies 211At production in terms of purification and would increase affordable access to this radioisotope for TAT of cancer. ***References:*** 1. Parker C, Lewington V, Shore N, Kratochwil C, Levy M, Lindén O, et al.,JAMA Oncol (2018);4:1765-72.

OP-281

A robust two-step deep learning method for pseudo-CT generation for PET-MR attenuation correction in brain

G. Krokos, *J. Mackewn, S. Yakub, R. Srinivasan, S. Jeljeli, S. Kinsella, P. K. Marsden, A. Hammers;*

King's College London, London, UNITED KINGDOM.

Aim/Introduction: One of the main obstacles for absolute quantification of brain PET-MR images is the accuracy of the attenuation correction map (μ-map). Several studies have attempted to improve the μ-map accuracy by employing deep-learning techniques. However, rigorous evaluation on PET images is limited. This study introduces and evaluates a deep-learning approach which combines MR with pseudo-MR images for performing attenuation correction on brain PET-MRI. ***Materials and Methods:*** Paired CT, T1- and T2-weighted images of 106 adult patients who underwent brain $^{[18F]}$FDG PET-CT and PET-MR scanning on the Siemens mMR were used to generate a pseudo-CT using a residual 3D-UNET by training: 1) The T1-weighted images (DL-T1), 2) the T1- and T2-weighted images (DL-T1+T2) and 3) the T1-weighted images to generate a pseudo-T2 before using both T1-weighted and pseudo-T2 as input to method 2 (DL-T1+pT2). All methods were tested on six different patients who underwent $^{[18F]}$FDG PET-CT scanning followed by a simultaneous PET-MR scan on a Siemens mMR. An accelerated T1-weighted (T1acc) image on which the network was not trained on, was also acquired on those patients and used as input to methods 1 and 3. Whole brain, grey matter (GM), white matter (WM) and cerebrospinal fluid (CSF) masks were applied to the reconstructed PET images to estimate the relative mean absolute error (rMAE), using CT-based attenuation correction as reference. The results were also compared to the manufacturer's Dixon with bone atlas (Dixon-BA) and UTE methods. ***Results:*** rMAE for DIXON-BA and UTE was 5.0±6.3% and 9.0±11.1%, respectively, (weighted mean ± standard deviation) in the whole brain which was decreased to 2.8±3.6% for DL-T1+T2. Bias and standard deviation were more than halved in GM and CSF for DL-T1+T2 compared to the manufacturer-provided sequences. All deep learning-based methods had similar performance (rMAE range in whole brain: 2.8-3.6%). However, a few voxels in the ventricles and blood vessels were misclassified to bone or air in three patients when using DL-T1 with the effect being further exacerbated for T1acc leading to a ~60% bias in those voxels. No misclassifications were noted when the T2-weighted or pseudo-T2 image were also used for the prediction of the pseudo-CT. ***Conclusion:*** Deep learning-based attenuation correction using anatomical images can substantially decrease bias in the reconstructed PET images compared to the manufacturer-provided sequences. Inclusion of both T1- and T2-weighted images can increase robustness and generalisability. Scanning time could also be reduced by using a predicted T2-weighted image.

OP-282

External validation of deep learning-based attenuation correction for chest FDG PET/MRI using Zero-TE MRI and unpaired PET/CT data

M. Nogami[1,2], *H. Matsuo[1], M. Tachibana[1,3], J. I. Inukai[1], F. Zeng[1], T. Kurimoto[4], K. Kubo[1], H. Okazawa[2], T. Murakami[1];*
[1]Kobe University Hospital, Kobe, JAPAN, [2]University of Fukui, Fukui, JAPAN, [3]Kakogawa City Hospital, Kakogawa, JAPAN, [4]GE HealthCare, Hino, JAPAN.

Aim/Introduction: Attenuation correction (AC) of bone components in the chest on positron emission tomography-magnetic resonance images (PET/MRI) is challenging due to the complicated anatomical structures and limited delineation of the bone on MRI. A deep learning approach using unsupervised generative adversarial networks (GANs) with adaptive layer-instance normalization for image-to-image translation (U-GAT-

IT) in combination with a modality-independent neighborhood descriptor (MIND) performed in our previous study yielded a pseudo-CT (pCT) generation with bone components from Zero echo-time (ZTE) MRI for AC in the chest. The purpose of this study was the external validation of the deep learning approach. ***Materials and Methods:*** 360 studies with chest FDG PET/MRI, including central-frequency-adjusted and bias-corrected ZTE and CT components of PET/CT, were utilized for training unsupervised GANs with a U-GAT-IT/MIND model. Data from thirty patients who underwent chest FDG PET/MRI in two institutions (fifteen patients for each) were assessed for external validation. PET was reconstructed by conventional pCT (conv-pCT) and deep-learning-based pCT with bone components (DL-pCT) and evaluated by placing fixed regions of interest in the spine and the liver. The similarity of the CT Hounsfield Unit (HU) histogram of the bone was measured by the correlation coefficients between CT and pCT in the same patient. The coefficients of conv-pCT and DL-pCT were statistically compared in the two institutions. Bone and liver mean SUV by conv-pCT and DL-pCT were also statistically compared in the two institutions. ***Results:*** The mean coefficients of conv-pCT and DL-pCT in Institution 1 were 0.150±0.157 and 0.703±0.194, and those in Institution 2 were 0.162±0.119 and 0.729±0.196, respectively. The coefficients of DL-pCT were significantly higher than those of conv-pCT in both institutions ($p<0.0001$). The mean SUV of the bone by conv-pCT and DL-pCT in Institution 1 were 1.34±0.37 and 1.44±0.37, and those in Institution 2 were 1.36±0.29 and 1.45±0.38, respectively. The mean SUV of the bone by DL-pCT was significantly higher than that by conv-pCT ($p<0.0001$). The mean SUV of the liver by conv-pCT and DL-pCT in Institution 1 were 2.42±0.44 and 2.38±0.52, and those in Institution 2 were 2.45±0.44 and 2.42±0.43, respectively. The mean SUV of the liver by DL-pCT was significantly higher than that by conv-pCT ($p<0.0001$). ***Conclusion:*** The similarity of the CT HU histogram of the bone and SUV difference of normal bone and liver showed a similar trend between the two institutions, suggesting the deep-learning approach is valid in quantitative value for the external patient data.

OP-283

A comparative study on deep-learning-based approaches for denoising ultra-fast whole-body [18F] FDG PET/CT

L. C. Silva, *C. S. Constantino, F. P. M. Oliveira, D. C. Costa; Champalimaud Foundation, Lisboa, PORTUGAL.*

Aim/Introduction: This study aims to compare different deep-learning-based approaches to improve image quality of ultra-fast whole-body [18F]FDG PET acquisitions. ***Materials and Methods:*** 772 whole-body [18F]FDG PET scans were included in the training (625+50 for validation) and testing (97) of three versions of the U-Net: 3D, 2.5D (coronal, sagittal and axial planes) and 2.5D_3CAx (3 axial channels). Mean squared error (MSE) was employed as the loss function. Included studies belong to a public dataset [1] and were acquired either on a United Imaging uExplorer or a Siemens Vision Quadra PET/CT scanner, from two different centres. Acquisition duration reduction factor was either 1/2, 1/4, 1/10, 1/20, 1/50 or 1/100, from the reference (5-10min/AFOV). MSE, intraclass correlation coefficient (ICC) and peak signal-to-noise ratio (PSNR) were used for a voxel-wise comparison between deep-learning-denoised (DL) and reference images. Further quantitative analysis was performed in terms of the mean concentration (Cmean) and signal-to-noise ratio (SNR=Cmean/standard deviation) in the liver and lungs (regions with expected uptake uniformity). A custom weighted rank score, ranging from 1 (lowest) to 4 (highest), was used to compare methods: 25% MSE, 10% ICC, 20% PSNR, 12.5% |ΔCmean|liver, 12.5% |ΔCmean|lungs, 10% SNRliver and 10% SNRlungs. ***Results:*** Voxel-wise MSE, ICC and PSNR between reference and DL-denoised images showed a statistically significant improvement relative to the original (not denoised) ($p<0.001$, Wilcoxon signed-rank). Statistically significant differences in these metrics were also observed between the different models ($p<0.001$, Wilcoxon signed-rank). The obtained custom scores were of 1.00 for the original (not denoised) test set, and 3.75, 3.25 and 2.00 for the test set denoised with the 3D, 2.5D and 2.5D_3CAx U-Nets, respectively. SNR in the liver was 17±4 for the reference, 5±4 for the original (not denoised) images and 21±9, 19±9, 15±7 for the 3D, 2.5D and 2.5D_3CAx U-Nets, respectively. Focusing on the 68 ultra-fast acquisitions (reduction factors of either 1/10, 1/20, 1/50 or 1/100), liver SNR was 17±4 [reference], 4±2 [not denoised], 22±11 [3D], 18±9 [2.5D] and 13±6 [2.5D_3CAx]. The custom rank-based scores are maintained for this subset. ***Conclusion:*** All three implemented DL-based strategies proved to be viable for denoising ultra-fast whole-body [18F]FDG PET scans, having achieved comparable quantitative image quality compared to the reference. However, the 3D U-Net was the best-performing network overall and when considering solely the ultra-fast acquisitions. ***References:*** [1] Xue et al. "A cross-scanner and cross-tracer deep learning method for the recovery of standard-dose imaging quality from low-dose PET". EJNMMI, 49(6):1843-1856, 2022.

OP-284

Deep Learning Time-of-Flight (ToF) Enhancement of Theranostic and FDG non-ToF PET Scans

A. Mehranian[1], *S. D. Wollenweber[2], K. M. Bradley[3], P. A. Fielding[4], M. Huellner[5], A. Iagaru[6], M. Dedja[7], T. Colwell[2], F. Kotasidis[8], R. Johnsen[2], F. P. Jansen[2], D. R. McGowan[7,9];*
[1]GE Healthcare, Oxford, UNITED KINGDOM, [2]Ge Healthcare, Waukesha, WI, UNITED STATES OF AMERICA, [3]Cardiff University, Cardiff, UNITED KINGDOM, [4]University Hospital of Wales, Cardiff, UNITED KINGDOM, [5]Zurich University Hospital, Zurich, SWITZERLAND, [6]Stanford University, Stanford, CA, UNITED STATES OF AMERICA, [7]Oxford University Hospitals NHS FT, Oxford, UNITED KINGDOM, [8]GE Healthcare, Zurich, SWITZERLAND, [9]University of Oxford, Oxford, UNITED KINGDOM.

Aim/Introduction: To evaluate a deep learning-based time-of-flight (DLToF) model trained to enhance the image quality of FDG and a range of theranostic non-ToF PET images, reconstructed using BSREM algorithm, towards ToF images. ***Materials and Methods:*** A 3D residual U-NET model was trained using 8 different tracers (FDG:74% and non-FDG:26%) from 11 sites from 3 continents. A total of 309 training and 33 validation datasets scanned on GE Discovery MI (DMI) ToF scanners were used for development of DLToF models of three strengths: low (L), medium (M) and high (H). The training and validation pairs consisted of target ToF and input non-ToF BSREM reconstructions using site-preferred regularisation parameters (beta values). The contrast and noise properties of each model were defined by adjusting the beta value of target ToF images. A total of 60 DMI datasets, consisting of a set of 4 tracers (18F-FDG, 18F-PSMA, 68Ga-PSMA, 68Ga-Dotatate) and 15 exams each, were collected for testing and quantitative analysis of the models based on standardised uptake value (SUV) in regions of interest (ROI) placed in lesions, lungs and liver. Each dataset includes 5 image series: ToF and non-ToF BSREM with the same regularization (beta value), as well as one series for each of the three DLToF strengths. A subset of 32 datasets (4

tracers, 8 exams) were then selected for blinded clinical scoring by 4 readers based on diagnostic confidence, lesion detectability and image noise/quality on a 5-point Likert score. ***Results:*** Lesion SUVmax difference (%) in non-ToF BSREM, and DLToF-L, -M and -H images with respect to reference ToF BSREM images showed the following results: for ^{18}F-FDG (38 lesions) -39±16, -38±16, -25±17, -7±24; for ^{18}F-PSMA (35 lesions) -42±10, -39±13, -23±20, -7±28; for 68Ga-PSMA (23 lesions) -33±10, -26±12, -18±11, -4±15; for 68Ga-Dotatate (32 lesions) -34±13, -38±13, -25±17, -12±22, respectively. Quantification results in liver and lung also showed ToF-like performance of DLToF models. Clinical readings for lesion detectability in ToF BSREM, non-ToF BSREM, and DLToF-L, -M and -H images were as following: for ^{18}F-FDG 4.00±0.48, 3.81±0.43, 3.66±0.6, 4.12±0.37, 4.28±0.27; for ^{18}F-PSMA 4.69±0.13, 3.31±0.45, 3.59±0.43, 4.31±0.26, 4.75±0.14; for 68Ga-PSMA 4.34±0.30, 3.41±0.59, 3.91±0.52, 4.28±0.29, 4.44±0.19; for 68Ga-Dotatate 4.09±0.34, 4.12±0.41, 4.09±0.55, 4.28±0.33, 4.25±0.27, respectively. For other metrics, DLToF models presented ToF comparable scores. ***Conclusion:*** This study demonstrated that the DLToF models are suitable for both FDG and non-FDG theranostic tracers and could be utilised for digital BGO PET-CT scanners to provide ToF comparable image quality.

OP-285

Lesion-Dependent Recovery Coefficient Predictions Using Machine Learning Protocols

A. Ocampo[1,2], *C. Miller[3], L. Polson[3], S. Kurkowska[4], P. Esquinas[5], N. Nuñez[1], C. Uribe[3];*
[1]Fundación Valle del Lili, Cali, COLOMBIA, [2]Universidad del Valle, Cali, COLOMBIA, [3]BC Cancer, Vancouver, BC, CANADA, [4]Pomeranian Medical University, Szczecin, POLAND, [5]Molecular Imaging and Therapy, BC Cancer, Vancouver, BC, CANADA.

Aim/Introduction: SPECT segmentation for lesion activity quantification is challenging due to the limited spatial resolution of SPECT images. CT-based segmentation often underestimates the total activity within lesions, with errors mostly influenced by the lesion size and the signal-to-background (SBR) activity concentration ratio. Recovery coefficients (RCs) can be used to correct for inaccuracies in lesion activity quantification, but they require modelling the dependence of RCs with the characteristics of the lesions and image quality. The aim of this work was to develop a machine learning model that predicts accurate lesion-specific recovery coefficients based on lesion size, activity and background concentrations. ***Materials and Methods:*** We performed Monte-Carlo simulations using SIMIND of multiple Jaszczak phantoms with twelve total spheres of 9.5, 12.7, 14.24, 15.9, 19.1, 19.04, 23.84, 25.4, 28.64, 31.8, 38.1 and 47.7 mm diameter. The phantom and the spheres were filled with a solution of Lu-177. SBR between spheres and background were varied from 1:2 to 300:1. The simulated acquisition involved 96 projections, with a duration of 15 seconds per projection. Images were reconstructed with the OSEM algorithm using our PyTomography software, which included CT-based attenuation correction and triple energy window scatter correction. Segmentation was performed by placing voxelized-spherical ROIs created in Python considering spheres-position and radius, which were used to determine each sphere's volume and mean activity concentration. The background concentration was measured using a 3 cm diameter sphere placed in the centre of the phantom. These values were used as inputs to train 6 machine-learning regression models to predict RCs. Decision Tree (DT), Support Vector Machine (SVM), and K-Nearest Neighbor with ten neighbors (KNN) were used as nonparametric regression models. Linear Regression, Random Sample Consensus (RANSAC) and Kernel Ridge (KR) using a polynomial kernel were parametric models used. The mean absolute percentage error (MAPE) was used to evaluate the models. ***Results:*** Nonparametric models yielded MAPE of 0.04, 0.16, and 0.1 for DT, SVM, and KNN, respectively. MAPE over the parametric models were 0.24, 0.31, and 0.35 to KR, LR, and RANSAC, respectively. Intra and extrapolation behavior of nonparametric models were tested and their MAPEs were 0.14, 0.15 and 0.29 for KNN, DT and SVM, respectively. ***Conclusion:*** Our results show that nonparametric models accurately predict lesion-dependent recovery coefficients that can be used for lesion quantification and dosimetry. We are now focusing on developing models using simulated anthropomorphic phantoms and different segmentation methods.

OP-286

Towards Uncertainty Estimation in PET Partial Volume Correction with a Diffusion Probabilistic Model

Y. Sun[1], *O. Mawlawi[2];*
[1]Rice University, Houston, TX, UNITED STATES OF AMERICA, [2]MD Anderson Cancer Center, Houston, TX, UNITED STATES OF AMERICA.

Aim/Introduction: Most image reconstruction research focus on methods that produce pixel-wise estimates without quantification of the reconstruction uncertainty/accuracy of which regions in the resultant images are most susceptible to error. In this work, we estimate the statistical and systematic uncertainty of resultant images from a diffusion probabilistic model when applied to partial volume correction (PVC) of brain PET images (DiffPVC). ***Materials and Methods:*** Our DiffPVC model [1] uses a modified image-conditioned denoising diffusion probabilistic pipeline which employs an attention U-Net to correct for partial volume effect (PVE). To estimate statistical uncertainty, we sample DiffPVC 100 times using different random noise ensembles. To estimate systematic uncertainty, we train an ensemble of 10 conditional diffusion models [2], where each model is initialized with random weights, and then for each learned model, we sample the DiffPVC 100 times. To train the model, we selected ten F^{18} FDG brain PET scans acquired for 6min on a Siemens Quadra and reconstructed using OSEM (0mm as reference, 5mm gaussian filter as PVE) were selected. For each patient, we selected 56 continuous axial images. We then tested the model using one additional patient dataset from the Quadra (in-distribution, ID) and one dataset from a Discovery-690 scanner (out-of-distribution, OOD). All models were fine-tuned using the ADAM optimizer on the PyTorch platform and executed on NVIDIA A100 GPUs. Image quality was evaluated using PSNR/SSIM, while uncertainty was determined using variance, squared bias, and squared error maps of resultant images. ***Results:*** Resultant mean predictions of PVC images show PSNR/SSIM values of 35.13dB/0.982 and 37.58dB/0.962 for statistical and systematic uncertainty respectively when compared to the ground truth (GT) images (0mm) for ID datasets. Similar results were observed for the OOD dataset. However, uncertainty maps showed regions of varying statistical and systematical variance, bias, and error distributions in the predicted images, with OOD results showing higher bias and error than ID results. ***Conclusion:*** Diffusion models allow the spatial representation of uncertainty metrics beyond the routine use of PSNR/SSIM. These metrics further enrich the assessment of the resultant images with respect to the ground truth. ***References:*** [1] "DiffPVC: A Conditional Diffusion Model for Partial Volume Correction in Brain PET Imaging". OP-287

Impact of Tissue-Dependent Spatially-Variant Positron Range Correction for Gallium-68 on Patient PET Reconstructions

P. Gavriilidis[1,2,3], *M. Koole[3], F. P. Jansen[4], F. M. Mottaghy[5,1], R. Wierts[1];*
[1]Maastricht University Medical Center, Maastricht, NETHERLANDS, [2]Maastricht University, Maastricht, NETHERLANDS, [3]KU Leuven, Leuven, BELGIUM, [4]Ge Healthcare, Waukesha, WI, UNITED STATES OF AMERICA, [5]RWTH University Hospital, Aachen, GERMANY.

Aim/Introduction: The 68Ga PET image quality is negatively affected by the distance travelled by the positrons before annihilation, the so-called positron range (PR). In particular, the PR of 68Ga depends on the underlying tissue (electron) density, an effect which is not considered in tissue-independent positron range correction (PRC) techniques. In this study we investigate the impact of a tissue-dependent spatially-variant PRC (Heterogeneous PRC) on image quality. ***Materials and Methods:*** The PR distribution profiles of 68Ga in water, bone, and lung tissue were obtained via Monte Carlo simulations. Heterogenous PRC was performed by incorporating those uniform profiles for the underlying tissue in the PET reconstruction algorithm [1]. A total of 15 patients (68Ga-PSMA: 4, 68Ga-DOTATOC: 11) containing 78 lesions were imaged in PET/CT. Cubic sections containing tissue interfaces of different tissue types were segmented from the patient CT images. In each section, a 68Ga point source was placed in the center. PR distribution profiles were obtained using Monte Carlo simulations and were compared to the corresponding heterogeneous PRC profiles. Moreover, Q.Clear reconstructions (PSF + ToF) of the PET data were performed. Three reconstruction settings were compared, non-PRC (β=700), water-based tissue-independent PRC (β=600), and heterogeneous PRC (β=600). The contrast-to-noise ratio (CNR) of each lesion was calculated as the difference between the mean lesion activity concentration and mean background activity concentration scaled by the background noise. The Wilcoxon signed rank test (α=0.05) was performed and the p-value was adjusted for multiple comparisons using Bonferroni correction. ***Results:*** The heterogeneous PRC profiles showed good agreement to those obtained via Monte Carlo simulations. However, discrepancies, typically about 11%, were observed when the point source was located close to the tissue boundaries. In soft-tissue lesions (32) the tissue-independent and heterogeneous PRC showed similar increase in CNR of 8.0% ($p<0.001$) and 7.9% ($p<0.001$), respectively, compared to the non-PRC. For bone lesions (35), the tissue-independent PRC showed higher increase in CNR (13,1%, $p<0.001$) compared to heterogeneous PRC (11.4%, $p=0.004$) with no statistical significant difference between the two PRCs. In lung lesions (11), the heterogeneous PRC resulted in greater increment than the tissue-independent PRC (21.9%, $p=0.003$, vs 6.6%, $p=0.003$), which was statistically significant ($p=0.006$). ***Conclusion:*** 68Ga-PRC using PR distribution profiles resulted in CNR improvements in PET patient images. For soft-tissue and bone lesions, tissue-independent PRC showed similar improvement compared to heterogeneous PRC. However, for lung lesions, heterogeneous PRC outperformed tissue-independent PRC. ***References:*** [1] Kertész H, et al., Front Physiol. 2022.

OP-288

Impact of time-of-flight and point-spread-function correction on commonly utilized PET image quality parameters in a wide variety of PET-CT scanners

O. Sipilä[1], *A. Mustonen[2];*
[1]HUS Diagnostic Center, Helsinki University Hospital and University of Helsinki, Helsinki, FINLAND, [2]Department of Physics, University of Helsinki, Helsinki, FINLAND.

Aim/Introduction: The influence of time-of-flight (TOF) and point-spread-function (PSF) correction on recovery coefficients (RCs), percent background variability (PBV), accuracy of corrections (AOC) and background coefficient of variation (COV) was studied using 12 PET-CT scanners and a NEMA image quality (IQ) phantom filled permanently with 68Ge. ***Materials and Methods:*** The 68Ge-filled NEMA IQ phantom included six hot spheres with diameters of 10, 13, 17, 22, 28 and 37 mm with a concentration ratio of 4:1 to background, and a cold lung insert. During a five months period, the phantom was imaged using 12 PET-CT scanners, including analog and digital systems from two major vendors. With every scanner, the phantom was imaged 20 times with five minutes bed position centered in the middle plane of the hot spheres without moving the phantom in-between. The imaging protocol was standardized as closely as possible between the scanners, including 256x256 matrix, voxel size of 3x3x3 mm3, OSEM reconstruction with iterations times subsets between 40-50, no post-reconstruction filtering, and CT based attenuation and scatter correction. In addition, in datasets 1 TOF and PSF correction were used, in datasets 2 only TOF but not PSF correction, and in datasets 3 neither TOF nor PSF correction. For the RCs, the max, mean and peak activity concentrations for all spheres were measured from the datasets and divided by the known activity concentration. The results from the corresponding 20 repetitions were averaged. Also, PBV, AOC and COV were computed and averaged. Results from datasets 1, 2 and 3, including all scanners, were pairwise compared using Wilcoxon signed rank test with $p = 0.05$. ***Results:*** For the max, mean and peak RCs of different sphere sizes, significant differences were found in 91 % of pairwise comparisons between datasets 1, 2 and 3. For PBV, datasets 1 produced significantly smaller values than datasets 2 and 3 for all sphere sizes, and datasets 2 smaller values than datasets 3 except for the two smallest spheres. For AOC, datasets 1 and 2 produced significantly smaller values than datasets 3, and datasets 1 clearly but not significantly smaller values than datasets 2. For COV, results for datasets 1 were significantly smaller than for datasets 2 and 3. ***Conclusion:*** Without uncertainties related to phantom filling, the significant impact of TOF and PSF correction on commonly utilized QA parameters of PET was confirmed, even outstanding the impact of different scanner models.

OP-289

Tumour Margin Thickness Inference for ^{99m}Tc Radio-guided Surgery Using Internal Conversion Electrons

J. Moo[1], *P. Marsden[2], A. Reader[2], K. Vyas[1];*
[1]Telix Pharmaceuticals (United Kingdom), London, UNITED KINGDOM, [2]King's College London, London, UNITED KINGDOM.

Aim/Introduction: In 99mTc radio-guided surgery (RGS) using intraoperative probes, it is not possible to delineate the boundary between cancerous and healthy tissue. In this study, the feasibility of inferring tumour thickness and depth using signal measured from an intraoperative probe was explored with convolutional neural networks (CNNs). Given the difference in the emission energies and tissue interaction properties between the gammas,

internal conversion (IC) electrons and X-rays from 99mTc, the ratio of emissions will vary for a given source distribution [1]. Hence, a CNN can learn these features alongside any other pertinent information present in the training dataset to perform source thickness and depth inference. ***Materials and Methods:*** Training data were experimentally collected with 99mTc sources of different thicknesses and depths, and used to train a CNN to infer source thickness and infer whether the emission depth is above or below a certain value. Data was collected using an intraoperative probe with a complementary metal-oxide semiconductor (CMOS) sensor, optimised towards the detection of IC electrons from 99mTc [2]. The network input is a collection of 500 emission events measured from a given thickness or depth. where each emission event is a 25 × 25 image. The test performances of the thickness and depth inference networks were evaluated through computing the root mean squared error (RMSE) and the area under the receiver operating characteristic curve (AUC) respectively. ***Results:*** For thicknesses between 500 µm and 1250 µm, the network trained for thickness inference was able to achieve a RMSE of approximately 90 µm. For depth inference, the performance with the classifier trained at a threshold of 23 µm is promising regarding the ability to differentiate between superficial and non-superficial sources. While the classifier demonstrates AUC scores above 0.7 for micron depth ranges, the performance worsens at millimetre depth ranges. However, for prostatectomies, cancerous tissue that is within 100 µm of the surgical margin is associated with an increased risk of recurrence [3], which is within the feasible range. ***Conclusion:*** Overall, the proposed methods were able to infer source characteristics that may be valuable for intraoperative tumour margin evaluation using 99mTc RGS. Future work may focus on evaluating the proposed methods with data that reflects clinical conditions by using more realistic radiotracer distributions. ***References:*** [1] J. Moo et al., IEEE NSS/MIC, 2022 [2] J. Moo et al., IEEE TRPMS, 2022 [3] J.P. Izard et al., Am. J. Surg. Pathol, 2014.

The prognostic role of ^{18}F-FDG PET/CT in patients with locally advanced resectable esophageal squamous cell carcinoma(ESCC) submitted to neoadjuvant PD-L1 blockade therapy: A single-center prospective study

R. Yang, *Y. He, Z. Zheng, Y. Lin, H. Gao, H. Shi;*
Department of Nuclear Medicine, Zhongshan Hospital, Fudan University, Shanghai, CHINA.

Aim/Introduction: Neoadjuvant immunotherapy combined with chemotherapy or chemoradiotherapy has been explored in several clinical trials for locally advanced resectable ESCC, and the potential role of 18F-FDG PET/CT-derived parameters as biomarkers has been investigated. However, due to the potentially distinct tumor response patterns of immunotherapy compared to traditional therapies, the therapeutic effects of immunotherapy on tumors were unable to be predicted separately. This prospective study aimed to evaluate whether 18F-FDG PET/CT-derived parameters could prognosticate the precise impact of immunotherapy alone on tumor regression, and aid in targeting the population suitable for mono-immunotherapy. ***Materials and Methods:*** Patients with ESCC who underwent two cycles of neoadjuvant PD-L1 blockade adebrelimab followed by surgery were enrolled in NATION-1907 trial (NCT04215471). 18FDG PET/CT scans were performed before immunotherapy (scan-1) and a median of 3 days before surgery (scan-2). SULmax, SULpeak and TLR (SULmax of lesion/SULmean of liver) were documented for primary tumors and lymph nodes, among which lesions>1cm3 were segmented with a threshold of 50% of SULmax, and then SULmean, TLG, MTV were calculated. The percentage change of all the metabolic parameters(Δ%change) was also recorded. Responders were identified as patients with residual viable tumor of ≤33% according to histological evaluation. Kaplan-Meier curves were used to compare OS and PFS between PET/CT parameters on cut-off values. ***Results:*** A total of 18 patients were included for this analysis, with 10 classified as responders and 8 as non-responders. The degree of pathological regression exhibited a negative correlation with all metabolic parameters of scan-2 and the Δ%change between two scans. Moreover, all metabolic parameters of scan-2, except MTV, were significantly lower in responders compared to non-responders. Additionally, %ΔMTV, %ΔTLG and %ΔTLR were significantly higher in the non-responder group(all $p<0.05$). ROC curves indicated that SULpeak of scan-2 demonstrated the highest diagnostic power (sensitivity: 80%, specificity: 100%; cut-off: 5.05).%ΔMTV also exhibits excellent performance in predicting responders, with an AUC of 0.883(cut-off: -37.7%). Furthermore, none of the patients with a Δ%MTV of -37.7% or more at the primary tumor site experienced a relapse (median 46 months since surgery), and patients' PFS could be significantly predicted by Δ%MTV ($p<0.05$). In lymph nodes analysis, the percentage reduction of the metabolic parameters and the residual viable tumor of LNs also showed statistically significant differences. ***Conclusion:*** The metabolic parameters of 18F-FDG PET/CT could predict responders to neoadjuvant mono-immunotherapy in resectable ESCC, which may facilitate personalized immunotherapy and serve as a stratification tool in larger-scale studies.

OP-291

The value of a multiparameter diagnostic model based on 2-$^{[18F]}$FDG PET/CT metabolic parameters and clinical variables in the differential diagnosis of non-metastatic extrahepatic cholangiocarcinoma and cholangitis

C. Jianbo[1,2], *G. Wang[1,3], J. Zhang[1,2], Y. Han[1,2], Y. Pan[1,2], C. Li[1], J. Liu[1], X. Xu[1], B. Xu[1];*
[1]Department of Nuclear Medicine, The First Medical Center, Chinese PLA General Hospital, Beijing, CHINA, [2]Graduate School, Chinese PLA General Hospital, Beijing, CHINA, [3]Nuclear Medicine Department, Beijing Friendship Hospital, Capital Medical University, Beijing, CHINA.

Aim/Introduction: The cholangiocarcinoma (CCA) is a malignant tumor originating from the epithelium of the bile duct and peribiliary glands, the classification of CCA divides tumors into intrahepatic (iCCA) and extrahepatic (eCCA), with eCCA further categorized as perihilar (pCCA) and distal (dCCA) lesions. The only treatment modality with the potential for curative intent in CCA is surgical resection. The accurate diagnosis of early CCA is crucial as it offers a chance for cure through surgery in patients at an early-stage. The 2-$^{[18F]}$FDG PET/CT has clinical value in the diagnosis, staging, evaluation of treatment response, and prediction of prognosis in different anatomical subtypes of CCA.

Therefore, the aim of our study is to evaluate the diagnostic value of a multiparameter model based on 2-[18F]FDG PET/CT metabolic parameters and clinical variables in differentiating non-metastatic eCCA from cholangitis. ***Materials and Methods:*** In total, 122 patients (86 non-metastatic eCCA patients and 29 cholangitis patients) with bile duct space-occupying lesions who underwent 18F-FDG PET/CT were included. The patients underwent surgical procedures and pathological examinations, during which baseline characteristics and clinical variables were systematically documented. The metabolic parameters of 2-[18F] FDG PET/CT, including SUVmax (maximum standard uptake value), SUVmean (mean standard uptake value), SUVpeak (peak standard uptake value), MTV (metabolic tumour volume), TLG (total lesion glycolysis) and SUVR (tumour-to-normal liver standard uptake value ratio), were evaluated. The differential diagnostic efficacy of each independent parameter and multiparameter combination model was evaluated using the receiver operating characteristic (ROC) curve. The improvement in diagnostic efficacy using a combination of the above multiple parameters was evaluated by integrated discriminatory improvement (IDI), net reclassification improvement (NRI) and bootstrap test. ***Results:*** The ROC curve showed that MTV had the highest diagnostic ability among the 18F-FDG PET/CT metabolic parameters (area under the curve [AUC]=0.669; sensitivity=0.655; specificity=0.663; positive predictive value [PPV]=0.396; negative predictive value [NPV]=0.851). The combined diagnostic model of cholangiolithiasis, fever, carbohydrate antigen 19-9 (CA19-9) >37 ng/ml and MTV showed an AUC of 0.863 (sensitivity=0.884, specificity=0.724, PPV=0.905, NPV=0.677). The diagnostic efficiency of the model was improved significantly compared with MTV (IDI=0.302, P<0.001; categorical NRI=0.344, P<0.001; D=3.022; boot: n=2000; boot: stratified=1; P=0.003). ***Conclusion:*** The multiparameter diagnostic model composed of 18F-FDG PET/CT metabolic parameters (MTV) and clinical variables, including cholangiolithiasis, fever, and CA19-9>37 ng/ml, has good diagnostic efficacy in the differential diagnosis of non-metastatic eCCA and cholangitis.

OP-292

^{68}Ga-labelled Prostate-Specific Membrane Antigen PET/MR for imaging patients suspected of hepatocellular carcinoma

X. Song[1], *C. Qin[1], Y. Song[1], S. Sun[2], W. Ruan[1], Y. Gai[1], C. Wan[2], X. Lan[1];*
[1]Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA, [2]Department of Hepatobiliary Surgery, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA.

Aim/Introduction: Prostate-specific membrane antigen (PSMA) is an ideal target for prostate cancer diagnosis and therapy. Many radiolabeled drugs targeting PSMA have been developed and shown great potential for current clinical application. PSMA expresses on neovessels in some tumors, including hepatocellular carcinoma (HCC). This study aims to evaluate the diagnostic value of [68Ga]Ga-PSMA-11 PET/MR for HCC. ***Materials and Methods:*** Twelve patients highly suspected of HCC were prospectively enrolled in this single-center study. All patients underwent [68Ga]Ga-PSMA-11 PET/MR with resection of main suspicious liver lesions and histopathologic verification. Contrast-enhanced CT/MR (ceCT/MR) was performed simultaneously in 7 patients. All lesions were visually evaluated and semi-quantitatively analyzed. Uptake greater than surrounding normal tissue was considered positive and equal to or less than surrounding normal tissue was considered negative. Volumes of interest were drawn around the lesions, and maximal standard uptake value (SUVmax), tumor-to-liver ratios (TLR) and tumor-to-blood ratios (TBR) were calculated. All metastatic lesions were determined by intraoperative detection or comprehensive imaging evaluation. The diagnostic efficiency of [68Ga]Ga-PSMA-11 PET, ceCT/MR and [68Ga]Ga-PSMA-11 PET/MR were calculated. Quantitative analysis of PSMA expression on immunohistochemistry was performed by Image J, and its correlation with SUVmax was analyzed. ***Results:*** Twelve patients (10 men, 58.75±12.08 years old) were enrolled in this study, including 10 HCC, 2 intrahepatic cholangiocarcinomas (ICC) and 4 hemangiomas patients. SUVmax, TLR and TBR of all HCC primary tumors were 11.30±6.54, 3.41±1.84, 2.50±1.96, respectively. SUVmax, TLR and TBR were 4.40±1.84, 1.34±0.64, and 1.53±0.75, respectively in 2 ICC lesions. All 6 hemangiomas lesions exhibited negative uptake with SUVmax, TLR and TBR 2.88±1.07, 0.91±0.39 and 1.12±0.44, respectively. There were significant differences in the SUVmax, TLR or TBR between HCC primary tumors and hemangiomas. When using positive as the diagnostic criterion for HCC and negative as non-HCC with only intrahepatic lesions counted, the accuracy, sensitivity, specificity, positive predictive value, and negative predictive value of [68Ga]Ga-PSMA-11 PET were 83.3% (15/18), 80% (8/10), 87.5% (7/8), 88.9% (8/9), and 77.8% (7/9), respectively. The diagnostic accuracy of ceCT/MR was 77.8% (8/10, 1/2, and 5/6 for HCC, ICC and hemangiomas, respectively). The combination diagnostic accuracy of [68Ga]Ga-PSMA-11 PET/MR and ceCT/MR increased to 88.9%. Moreover, there were correlations between PSMA staining score and SUVmax (R2=0.6209) in HCC primary tumors. ***Conclusion:*** Contrast-enhanced [68Ga]Ga-PSMA-11 PET/MR may be more beneficial for accurate diagnosis and staging in patients with HCC than [68Ga]Ga-PSMA-11 PET and ceCT/MR alone.

Evaluating the potential of PSMA theranostics for upper digestive tract cancers, a prospective study

E. Croteau[1,2,3], *F. Lemay[1,3,4], Y. Collin[1,3,5], S. Breton[1,2], C. Wilhelmy[1], B. Guérin[1,2], E. Turcotte[1,2], G. Turgeon[1,3,6], E. Espinosa[2], E. Lavallée[2], A. Tétu[1,3], M. Pavic[1,3,7], K. Tremblay[1,3], E. Rousseau[1,2,3];*
[1]Sherbrooke University, Sherbrooke, QC, CANADA, [2]Centre de Recherche du Centre Hospitalier Universitaire de Sherbrooke, Sherbrooke, QC, CANADA, [3]Institut de recherche sur le cancer de l'Université de Sherbrooke (IRCUS), Sherbrooke, QC, CANADA, [4]Gastroenterology department, CIUSSS de l'Estrie-CHUS, Sherbrooke, QC, CANADA, [5]Surgery department, CIUSSS de l'Estrie-CHUS, Sherbrooke, QC, CANADA, [6]Nuclear Medicine department, CIUSSS de l'Estrie-CHUS, Sherbrooke, QC, CANADA, [7]Hematology-oncology department, CIUSSS de l'Estrie-CHUS, Sherbrooke, QC, CANADA.

Aim/Introduction: Upper digestive tract cancers are an important health issue with limited survival (less than 30% with 5-year survival for esophageal, gastric, biliary, and pancreatic adenocarcinoma). When metastatic/unresectable, therapeutic options are limited. Endoradiotherapy, could be an elegant solution for systemic therapy and is usually well-tolerated. Case reports and small prospective studies have documented that upper-digestive tract cancers can show Prostate Specific Membrane Antigen (PSMA)-targeting radiotracer uptake on positron emission tomography (PET). However, frequency of PSMA uptake and eligibility for PSMA-targeted therapy remains uninvestigated. We aimed to prospectively determine, with 68Ga-PSMA PET, the proportion of upper digestive tract cancers that

meet criteria for 177Lu-PSMA treatment, which is the first step in bringing this new line of therapy to cancer patients(1-8). ***Materials and Methods:*** This prospective clinical trial (NCT05214820) was approved by the local ethics committee. Patients with upper digestive tract adenocarcinoma, confirmed by pathology, with active or progressive disease on computed tomography (CT) were included. We excluded patients with more than one active cancer and with ECOG score > 3. Participants underwent PET with 68GaPSMA-617 labeled with cyclotron-produced gallium-68, on a Siemens Biograph Vision PET/CT. We evaluated eligibility based on the VISION trial criteria for prostate cancer endoradiotherapy and reported the level of uptake of the most intense lesion as SUVmaxbw as well as its scoring on the PROMISEv2 scale(9-10). ***Results:*** We recruited 17 adults (12 men, 5 women; 66.7±8.7 years of age) with gastric (2), esophageal (6), biliary (3), and pancreatic (6) adenocarcinoma. The mean of the SUVmaxbw of the hottest lesion per patient was 6.50±3.52. For PROMISEv2 PSMA expression score, 5 cases (29%) had no-uptake (score-0), 5 (29%) had low-uptake (score-1), 7 (41%) had intermediate-uptake (score-2), and 0 (0%) had high-uptake (score-3). According to the VISION study criteria, 12% (2/17) of patients were considered treatable with 177Lu-PSMA. With PROMISEv2 scores, 41% (7/17) had uptake considered positive for PSMA radioligand therapy. ***Conclusion:*** We demonstrated that sufficient PSMA radiopharmaceutical accumulation for therapy occurred in at least 12% of patients with upper digestive tract cancers according to VISION criteria used for prostate cancer therapy. This suggests eligibility for a new line of therapy for these patients. However, a prospective therapeutic clinical trial will be needed to ascertain endoradiotherapy efficacy, since response to this treatment might be different in upper digestive tract cancers than in prostate cancer. ***References:*** Brenner.cmaj, 2020.192(9): p.E199-205; Canadian Cancer Society, Cancer-specific stats 2020; Malik.ClinNuclMed, 2018.43(7): p.529-532; Marafi.ClinNuclMed, 2019.44(7): p.e439-e441; Chahinian AsiOceanJNuclMedBiol, 2020.8(2): p.136-140; Shetty.Tomography, 2018.4(4): p.182-193; Backhaus EurJNuclMedMolImaging, 2018.45(5):p.860-877; Vujik.Cancers(Basel), 2022.14(24): p.6209; Sartor NEnglJMed.2021.385(12): p.1091-1103; Seifert.Eur Urol.2023.83(5): p.405-412.

Assessment of postsurgical liver remnant by [99mTc]Tc-Mebrophenin hepatobiliary SPECT/CT (HBS-SPECT/CT) scintigraphy in primary and secondary liver neoplasms

M. Astudillo Sarmiento, *A. Peña Fuentes, I. Vinagre Perez, J. Lavilla, G. Portilla, M. Prieto Calvo, N. Santos Etxaburu, P. Minguez Gabiña, R. Nuñez Muñoz, Y. Carreres Ortega, R. Valverde Jorge, A. Esteban Figueruelo, D. Tovar Echeverri, J. Genollá Subirats, I. Fernandez Tercero, M. Jimenez Alonso, C. Moreno Capdevilla;*
Hospital Universitario De Cruces, Barakaldo, SPAIN.

Aim/Introduction: The main aim is to correlate the data obtained through computed tomography volumetry and hepatobiliary scintigraphy (Graaf and HIBA index) with the risk of developing postoperative liver dysfunction. ***Materials and Methods:*** A cohort study was performed using univariate analysis in patients who underwent major hepatic resection from August 2017 to July 2022 at the Cruces University Hospital. ***Results:*** A total of 49 patients were included, 12 of them (24.5%) developed liver dysfunction after major hepatic resection. The median value for the percentage of volume increase in future liver remnant was 2% (0-5%) in patients with dysfunction compared to 31% (2-45%) in patients without dysfunction (p=0,04). The mean Graaf's index was 2.05±0.21%/min/m2 in patients with dysfunction compared to 2.77±0.84%/min/m2 in patients without dysfunction (p=0,04). The area under the curve obtained as a cut-off value of 2.8%/min/m2 for de Graaf`s index (AUC=0,54) and 25% for the HIBA´s index (AUC=0,59). ***Conclusion:*** Patients who developed liver dysfunction had lower scores for the percentage of volume increase of the future liver remnant and Graaf`s index compared to those without dysfunction with statistical significance. However, more research is needed in order to establish a cut-off value for de Graaf index and HIBA index which may predict liver dysfunction.

OP-295

Radiomics and Machine Learning in Gall Bladder cancer vs cholecystitis: simplifying the diagnostic dilemma

P. Singh, *T. Singhal, G. K. Parida, S. Mandal, P. S. Patro, B. Pattnaik, K. Agrawal;*
Aiims Bhubaneswar, Bhubaneshwar, INDIA.

Aim/Introduction: Gall bladder cancer(GBCa) is an aggressive malignancy with poor prognosis. However, its diagnosis can be challenging and is often confused with cholecystitis, particularly xanthogranulomatous cholecystitis. Neither clinical symptoms, laboratory tests, nor conventional radiological techniques offer a reliable method for differential diagnosis. Thus, we investigated utility of 18F-FDG PET-CT derived radiomic features(RF) and a machine learning model(MLM) to accurately distinguish GBCa from cholecystitis. ***Materials and Methods:*** Patients with suspected GBCa who underwent ^{18}F-FDG PET-CECT were included in the study. Experienced Nuclear Medicine physicians manually delineated regions of interest(ROIs), and intensity-threshold restrictions of 25% and 35% were applied to create three distinct sets of ROIs and high-dimensional RF were extracted using LIFEx(v7.6). Univariate analysis was applied to each RF as well as metabolic parameters(SUVmax, MTV and TLG), using area-under-curve(AUC) of receiver-operator-curve(ROC) and p-value computed by Mann-Whitney-U test. p-value<0.05 was considered significant. Histopathological examination(HPE) was taken as the gold standard. RF with an AUC>0.7 were further refined with least absolute shrinkage and operator(LASSO) algorithm. A support vector machine(SVM)-based MLM was developed using Rv.4.1.3, with 75% of data for training and 25% for validation. Model's performance was assessed using ROC curves and compared with metabolic parameters. Similarly, another SVM-based MLM was developed to predict the probability of metastatic disease. ***Results:*** The study included 41 GBCa patients (14 males, median age-57, range: 35-76 years). Among these, 35 had GBCa while and 6 had cholecystitis on final HPE. A total of 161-RF were extracted from each ^{18}F FDG PET-CT image at three intensity thresholds, with the most significant results observed at 35% threshold. Univariate analysis revealed that 20 RF were statistically significant predictors of outcome. In multivariate analysis the best SVM-LASSO model consisted of 3 RF at 35% threshold(Table-1).The SVM-MLM achieved a sensitivity and specificity of 88.89% & 50% with AUC 0.944 compared to 77.1% & 33.4% for SUVmax at a cut-off of 5.23 and 80% & 50% for TLG at a cut-off of 46.6 with an AUC of 0.757 and 0.767 respectively. Thus, SVM-MLM demonstrated superior performance compared to metabolic parameters with an overall accuracy of 81.8%. Similarly, SVM-LASSO model for metastatic disease prediction included 4 RF at 25% threshold and achieved a sensitivity, specificity, and accuracy of 83.3%, 66.67%, and 66.67% respectively with AUC of 0.778. ***Conclusion:*** SVM-MLM can be instrumental in effectively predicting the histology (GBCa vs cholecystitis) as well as distant metastasis in cases with Suspected GBCa.

OP-296

[^{68}Ga]Ga-RYZ-GPC3; a glypican-3 targeted diagnostic radiopharmaceutical for hepatocellular carcinoma molecular imaging. A future game-changer in HCC?

***A. Braat*[1],** *C. Lapa*[2], *W. A. Weber*[3], *M. G. E. H. Lam*[1], *M. Eiber*[3], *A. Dierks*[2], *R. A. Bundschuh*[2], *A. J. Poot*[1];
[1]*University Medical Center Utrecht, Utrecht, NETHERLANDS,* [2]*University of Augsburg, Augsburg, GERMANY,* [3]*Technische Universität München, München, GERMANY.*

Aim/Introduction: Hepatocellular carcinoma (HCC) is the most common primary liver cancer. To date, imaging of HCC is difficult, challenging for disease staging (especially for extrahepatic disease) and has barely improved over the past decades. Glypican-3 (GPC3) is a cell-surface receptor highly expressed by HCC but not by normal or cirrhotic liver tissue. Here we report initial clinical results of GPC3 targeted PET-imaging with [68Ga]Ga-RYZ-GPC3 , a peptide based GPC3 ligand in patients with known or suspected HCC. ***Materials and Methods:*** [68Ga]Ga-RYZ-GPC3 was obtained upon labeling the peptide precursor with 68Ga from a 68Ge/68Ga-generator and heating at 90^{0}C for 10 min followed by sterile filtration. After administration of [68Ga]Ga-RYZ-GPC3, a dynamic or static PET/CT scan was acquired between 45 minutes and 4 hours post-administration. Radiotracer uptake was measured by standardized uptake values (SUVs) for the following tissues: (suspected) HCC lesions, non-tumor bearing healthy liver (HL), renal cortex, blood pool activity in the left ventricle (BP) and gastric fundus. Additionally, tumor-to-healthy liver ratios (TLR) were calculated. ***Results:*** Twenty-four patients (five patients dynamic; 19 patients static protocol) were scanned. Two patients had no lesion detected and did not have an HCC during follow-up. In total, 50 lesions were detected and analyzed. Mean SUVmax of these lesions was 19.6 (range 2.7 - 95.3) and mean SUVmean was 10.1 (range 1.0 - 49.2) at approximately 60 minutes p.i.. Uptake in HL and BP rapidly decreases over time and becomes negligible 45 minutes after administration (SUVmean<1.6), with a continuous declining trend to 4 hours after administration (Mean SUVmean = 1.0). The opposite was observed for HCC lesions, for which SUVs and TLRs continuously increased for up to 4 hours after administration. In individual lesion analysis, TLR was the highest between 60 - 120 minutes post-injection. Uptake in the gastric fundus gradually increased for up to 45 minutes (to SUVmax 31.3) and decreased gradually afterwards. ***Conclusion:*** [68Ga]Ga-RYZ-GPC3 allows for high contrast imaging of GPC3-positive liver tumors, with a rapid clearance from normal organs and overall favorable biodistribution. Thereby, [68Ga]Ga-RYZ-GPC3 is promising for HCC diagnosis and staging.

Evaluation of the Neovasculature of Hepatocellular Carcinoma with Multiparametric [68Ga]-PSMA-11-PET/MRI: A Proof-of-Concept Study

***W. Roll*[1],** *B. Noto*[2], *T. Krähling*[2], *D. Ventura*[1], *K. Rahbar*[1], *F. Rennebaum*[3], *F. Büther*[1], *P. Schindler*[2];
[1]*Department of Nuclear Medicine, University Hospital Münster, Münster, GERMANY,* [2]*Department of Radiology, University Hospital Münster, Münster, GERMANY,* [3]*Medical Clinic B, Department of Gastroenterology, Hepatology, Endocrinology, Infectiology, University Hospital Münster, Münster, GERMANY.*

Aim/Introduction: Prostate-specific membrane antigen (PSMA) is expressed not only in prostate cancer but also in tumor-associated neovasculature and may be a potential theranostic in many solid cancers. This study aims to explore the feasibility of multiparametric (mp) [68Ga]-PSMA-11-PET/MRI in providing detailed imaging of the tumor neovasculature in patients with hepatocellular carcinoma (HCC), thereby potentially predicting treatment response and improving patient management. ***Materials and Methods:*** Six treatment-naïve patients with intermediate- and advanced-stage HCC underwent mpPSMA-PET/MRI on a 3T PET/MRI hybrid system prior to stage- and guideline-appropriate anti-neoangiogenesis treatment (transarterial chemoembolization or radioembolization, immunotherapy). The mpMRI protocol included intravoxel incoherent motion diffusion-weighted imaging (IVIM-DWI), T1- and T2*-weighted mapping, and dynamic contrast-enhanced (DCE) imaging. Dynamic PET was acquired simultaneously over 40 minutes. We analyzed tracer and contrast agent kinetics for both [68Ga]-PSMA ligands and gadolinium (GD), comparing tumor tissue with adjacent non-tumor liver tissue. ***Results:*** Preliminary results indicate enhanced GD and PSMA uptake in tumor neovasculature compared to normal liver tissue, suggesting different kinetic profiles. Quantitative analysis of imaging data revealed significant differences in perfusion characteristics and vascular permeability between HCC lesions and non-tumor liver tissue [mean Ktrans (10-3/min): HCC, 796±330 vs. non-tumor, 227±165, p=0.0036; mean ADC (10-3 mm^2/s): HCC, 1.30±0.29 vs. non-tumor, 2.23±0.20, p<0.0001; mean T2* (ms): HCC, 39±4 vs. non-tumor, 18±5, p=0.004] highlighting the potential of mpPSMA-PET/MRI to delineate tumor physiology at the molecular level ***Conclusion:*** mpPSMA-PET/MRI appears to be a promising tool for advanced characterization of HCC, providing superior insights into the tumor microenvironment and vascular properties. These findings may facilitate more tailored therapeutic strategies, particularly in intermediate and advanced HCC, where anti-neoangiogenesis therapies play a critical role.

[1]*Nuclear Medicine, IRCCS Azienda Ospedaliero-Universitaria di Bologna, BOLOGNA, ITALY,* [2]*Department of Hepatobiliary Surgery and Liver Transplant, IRCCS Azienda Ospedaliero-Universitaria di Bologna, BOLOGNA, ITALY,* [3]*Pathology Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, BOLOGNA, ITALY,* [4]*Department of Radiology, IRCSS Azienda Ospedaliero-Universitaria di Bologna, BOLOGNA, ITALY,* [5]*Nuclear medicine, Alma Mater Studiorum University of Bologna, BOLOGNA, ITALY,* [6]*Nuclear medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY.*

Aim/Introduction: While contrast-enhanced CT(ceCT) and ceMRI are the standard imaging modalities for Hepatocellular Carcinoma(HCC), they offer limited insight into the biological aspects. Hence the need of other techniques capable of providing additional information. Preliminary investigations revealed PSMA overexpression in HCC vessels. This study aimed to assess whether 68Ga-PSMA-11 PET biodistribution reflects PSMA-expression in vitro from resected liver. ***Materials and Methods:*** The MORE-PSMA study is a pilot prospective single-center investigation. From September 2021 to March 2024 all patients with suspicion of HCC eligible for Liver Transplantation(LT) or Hepatic Resection(LR), naive for systemic therapy were screened. Following ultrasound, ceCT, or biopsy, eligible patients underwent both ceMRI with hepatospecific-contrast and PSMA-PET within a 3-month timeframe. No treatments were allowed between PSMA-PET and

MRI. PSMA-PET and ceMRI images were read by 3 independent blinded nuclear medicine physicians and by 2 radiologists, respectively. PSMA-PET and ceMRI results were compared with post-operative histological examination. Anatomopathological analyses included histological diagnosis of HCC and Edmondson-grading. Immunohistochemical evaluation of PSMA-expression involved assessing both percentage of PSMA-expressing vessel cells and intensity, with intensity visually graded on a four-point scale (negative, mild, moderate, strong), and a composite score generated from intensity multiplied by percentage (immunoreactive score,IRS). ***Results:*** 33patients underwent ceMRI and PSMA-PET, of whom 25/33(76%) underwent surgery [22/25 (88%) male; mean age 65yo(range 26-81 yo)]. 7/25(28%) received LT; 18/25(72%) LR. Histology confirmed HCC in 21/25(84%), 2/25(8%) showed high-grade-dysplasia-nodules(HGDN), 1/25(4%) was pseudotumor, 1/25 was negative for HCC. Median size of HCC nodules on ceMRI was 28(range 15-49mm). PSMA-PET was positive in 23/25(92%)patients, achieving a detection rate of 100% for HCC (median lesion'sSUVmax=12; median liver background SUVmax=6). PSMA-IHC-expression was observed in endothelial cells across all lesions, while no expression was detected in cancer cells. IRS was strong in 10/21(48%)cases, moderate in 4/21(19%), mild in 1/21(5%), negative in 6/21(28%) cases. A moderate Spearman correlation was observed between IRS and SUVmax (p=0.02) and between percentage and SUVmax (p=0.017). There was a trend between Edmondson and SUVmax. Sensitivity for PSMA-PET and ceMRI was 100%vs95%, specificity 50% vs 25%; PPV 91% vs 87%; NPV 100% vs 50%; and accuracy 92% vs 86%, respectively. ***Conclusion:*** Our preliminary findings showed elevated PSMA-ligand-uptake on PET imaging and a correlation between 68Ga-PSMA-11 PET and PSMA tissue expression in HCC. Also, PSMA-PET exhibited a superior detection rate for HCC, showing heightened sensitivity, NPV and accuracy when compared with ceMRI. These findings support further exploration of PSMA-PET as an imaging biomarker for HCC.

OP-299

Metabolic Tumor Volume at baseline [18F]FDG-PET/CT independently predicts the time to treatment failure and the relapse-free survival in antibiotic-naïve patients with pyogenic spondylodiscitis

F. Lanfranchi[1], *C. Delucchi[2], S. Maggio[2], V. Iannaccone[2], F. D'Amico[1], T. Di Raimondo[1], D. Dubois[1], L. A. Peñuela[1], B. Sambucco[1], L. Sofia[1], M. Riondato[2], G. Sambuceti[1,2], M. Bauckneht[1,2];*
[1]Nuclear Medicine, Department of Health Sciences (DISSAL), University of Genoa, Genoa, ITALY, [2]IRCCS Ospedale Policlinico San Martino, Genoa, ITALY.

Aim/Introduction: Pyogenic spondylodiscitis presents a clinical challenge that can lead to long-term complications. Reliable early predictors of clinical outcomes in these patients are currently lacking. Despite its growing importance in diagnosing and managing spondylodiscitis, the prognostic value of [18F]FDG-PET/CT has been insufficiently explored. ***Materials and Methods:*** Patients clinically diagnosed with pyogenic spondylodiscitis who underwent [18F]FDG-PET/CT at IRCCS Policlinico San Martino between 2020 and 2023, were retrospectively enrolled. Inclusion criteria included: 1) absence of previous spine surgery; 2) absence of onco-hematological diseases; 3) absence of corticosteroid treatment. Although antibiotic therapy at the time of imaging was documented, it did not serve as an exclusion criterion. Key laboratory markers such as C-reactive protein, procalcitonin, white blood cell differential counts, lactate dehydrogenase (LDH), and creatinine levels were collected. For each lesion, the standardised uptake value maximum (SUVmax), metabolic tumor volume (MTV), and total lesion glycolysis (TLG) were quantified from [18F]FDG-PET/CT images. Baseline [18F]FDG-PET/CT scans were evaluated as predictors of time to treatment failure (TTF) and relapse-free survival (RFS). ***Results:*** A total of eighty patients (119 lesions) were retrospectively enrolled. Of these, 65% (78 lesions) were antibiotic-naïve, while 35% (41 lesions) had received antimicrobial treatments for 1-14 days. Baseline demographics, clinical, and laboratory characteristics were balanced between the two groups. All patients adhered to the prescribed treatment until full recovery. The median clinical follow-up period was 15 months (range: 3-59 months). In the antibiotic-naïve group, the univariate analysis identified procalcitonin (p=0.001), neutrophils (p=0.009), lymphocytes (p=0.039), monocytes (p=0.027), SUVmax (p=0.025), MTV (p<0.001), and TLG (p<0.001) as predictors of TTF. LDH (p=0.076), MTV (p<0.001), and TLG (p=0.017) were predictors of RFS. The multivariate model confirmed MTV as the sole independent predictor of TTF (p=0.033) and RFS (p=0.009). When categorised according to the Youden's index, patients with lesions exhibiting an MTV ≥ 30 mL (23.1%) had a median TTF of 8.7 weeks (95%CI 8.0-9.5) and an RFS of 11.0 months (95%CI 11.0-11.0), whereas the remaining subgroup did not reach the median for either endpoint (p<0.001 for both). No baseline lab marker or metabolic measure from [18F]FDG-PET/CT significantly predicted TTF and RFS in patients receiving antibiotic therapy. ***Conclusion:*** Before initiating antimicrobial treatment, [18F]FDG-PET/CT-derived MTV independently predicts TTF and RFS in patients with pyogenic spondylodiscitis, facilitating early risk stratification that could potentially enhance subsequent clinical management. This prognostic capability diminishes in patients already under antibiotic therapy.

OP-300

Usefulness of ^{18}F-FDG PET/CT in the detection of prosthetic infection after reconstruction of the aortic arch and thoracic aorta using the Thoraflex device

B. Hervás-Sanz[1], *J. L. Díaz-Moreno[1], L. M. Gràcia-Sánchez[1], I. E. Sánchez-Rodríguez[1], P. C. Notta[1], M. Pudis[1], P. Perlaza-Jiménez[1], A. I. Fritsch-Medina[1], J. J. Robles-Barba[1], J. J. Martín-Marcuartu[1], C. Díez-López[2], J. González-Costello[2], L. Herrador-Galindo[2], F. Escrihuela-Vidal[3], N. Sabé-Fernández[3], I. C. Grau-Garriga[3], M. Potocnik[4], D. Toral-Sepúlveda[4], A. Blasco-Lucas[4], F. Sbraga[4], J. E. Toscano-Fernández[4], J. Sánchez-Vega[2], M. Cortés-Romera[1];*
[1]Nuclear Medicine-PET (IDI) Department, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, SPAIN, [2]Cardiology Department, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, SPAIN, [3]Infectious Disease Department, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, SPAIN, [4]Cardiovascular Surgery Department, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, SPAIN.

Aim/Introduction: The Elephant Trunk prosthesis (Thoraflex) is a novel vascular device that, unlike traditional devices, simulates vascular anatomy. It is used for the replacement of the aortic arch and thoracic aorta in patients with aneurysms of different etiologies. Its use is increasing and it is necessary to know the management of the infectious complication and the clinical impact of [18F]FDG-PET/CT in Thoraflex. The objectives of this study are: to assess the usefulness of [18F]FDG-PET/CT in the detection of infection; to identify the morphometabolic characteristics that allow differentiation between post-surgical inflammatory changes and infection; to correlate PET/CT findings with clinical data. ***Materials and Methods:*** Retrospective descriptive study in Thoraflex-bearing patients who presented clinical suspicion of infection and underwent [18F]FDG-PET/CT study for diagnostic purposes between March 2016 and February 2024. The median time between surgery and acquisition of [18F]FDG-PET/CT was 29.1 months. Demographic data, vascular device, symptomatology and PET/CT study characteristics were analyzed, contrasting with the final diagnosis decided in a multidisciplinary committee. ***Results:*** 6 patients with a total of 10 studies were analyzed (2 women and 4 men), with a mean age of 56.8 years (30-73). Among 8 studies that PET/CT classified as positive, 7 were true positive, 1 false positive. Between the 2 negative PET/CT studies, all were true negative. False-positive PET was not considered as such clinically and prolonged antibiotic treatment was discouraged. In 5 of the 7 true positive studies, the highest metabolic activity was observed in the body of the prosthesis with a mean SUVmax of 5 mg/dl and in 2 studies in the sutures, with a higher mean SUVmax value (11 mg/dl).In the 2 negative studies a SUVmax of 4 mg/dl was observed and the metabolic activity visualized was attributed to post-surgical inflammatory activity. Likewise, these two studies presented findings compatible with respiratory infection.The false-positive study showed a focal uptake of high metabolic rate on PET/CT images that ultimately corresponded with inflammatory activity.CT imaging identified suspicious signs of infection (thickening, enlargement and fat trabeculation) in 6 of the 8 studies considered as positive. Positive patients presented higher SUVmax semiquantitative index and higher elevation of leukocytes than negative patients. ***Conclusion:*** [18F]FDG PET/CT is a useful noninvasive method to detect infection related to Thoraflex devices.The [18F]FDG-PET/CT allowed the rejection of all negative patients avoiding unnecessary surgeries and prolonged cycles of antibiotherapy. PET-CT has an important role in clinical and therapeutic decision making in complex patients.

OP-301

The Relationship Between PET/CT Metabolic Parameters and Inflammation Parameters and Final Clinical Diagnosis in Patients Who Have F^{18} FDG PET/CT Examination with Suspicion of Large Vessel Vasculitis

O. Bayrakci, *B. Cagdas, H. San;*
Bilkent City Hospital, Departmant of Nuclear Medicine, Ankara, TÜRKIYE.

Aim/Introduction: Diseases characterized by damage to vascular structures as a result of inflammation in the aorta and its main vascular branches are called Large Vessel Vasculitis (LVV). Inflammation parameters obtained from routine blood biochemistry are the first-line tests in diagnosing LVV . In suspected cases F18 FDG PET/CT is a nuclear medicine examination frequently used to make and assist in diagnosis. In our study, it was aimed to show the relationship between F18 FDG PET/CT findings and blood biochemical inflammation parameters. ***Materials and Methods:*** 80 patients who were referred to F18 FDG PET/CT examination with a preliminary diagnosis of LVV in our clinic, who did not have any other diseases that could cause inflammation were included. Final clinical diagnoses were scanned from clinician notes and recorded as LVV negative, suspicious and positive. In the F_{18} FDG PET/CT examination, the involvement of the aorta and its branches was visually evaluated according to the liver parenchyma and divided into three groups. Target/Liver ratio (T/ Lmax), Metabolic Volume (MV) and Total Glycolysis (TG) values. In addition, inflammation parameters were noted from blood tests that were less than 15 days apart from the PET/CT test. Chi-Square, Mann Whitney, Spearman tests and ROC analyzes were performed on the obtained parameters using the IBM SPSS 22 program . ***Results:*** In the F^{18} FDG PET/CT examination , a significant difference was detected in SUVmax , CRP, CRP/Albumin and Ferritin parameters between the negative group and the cases that were considered positive in visual scoring ($p<0.01$). In the ROC analysis performed to measure the diagnostic performance in LLV in the SUVmax parameter, sensitivity and specificity were found to be 100% and 93%, respectively, for the cut-off value of 3.18 g/ml. In the BDV positive group, a significant difference was detected in CRP and CRP/Albumin parameters between the groups with two positive and three positive visual scores on F^{18} FDG PET/CT ($p<0.05$). Additionally , a significant positive correlation was detected between MV and CRP (Rho =0.40) and TG and CRP (Rho =0.46) in clinically BDV positive cases ($p<0.05$). ***Conclusion:*** Concordance was found between inflammatory parameters and visual scoring evaluated on F^{18} FDG PET/CT. In addition to visual evaluation, it was evaluated that metabolic parameters obtained from F^{18} FDG PET/CT examination could be useful in cases where the final clinical diagnosis is incomplete.

OP-302

Liver based-standardization approach for improved consensus reading of [18F]FDG PET scans in patients with Takayasu arteritis

C. Bezzi[1,2], *A. Tomelleri[3], C. Campochiaro[3], F. Fallanca[2], E. Baldissera[3], S. Ghezzo[2], S. Resta[1], P. Mapelli[1,2], L. Dagna[3,1], A. Chiti[1,2], M. Picchio[1,2];*
[1]Vita-Salute San Raffaele University, Milan, ITALY, [2]Nuclear Medicine Department, IRCCS San Raffaele Scientific Institute, Milan, ITALY, [3]Unit of Immunology, Rheumatology, Allergy and Rare Diseases, IRCCS San Raffaele Scientific Institute, Milan, ITALY.

Aim/Introduction: The role of [18F]FDG PET in the diagnosis and monitoring of patients with Takayasu arteritis (TAK) is constantly increasing; yet, challenges persist due to the lack of image standardization and consensus reading, which are essential for enhancing reading reliability. We propose a novel approach for standardizing PET scans acquired from different tomographs in a cohort of TAK patients. ***Materials and Methods:*** A pool of 60 [18F]FDG PET scans performed between 2013-2023 corresponding to 35 TAK patients and characterized by no vascular tracer uptake was selected. Image acquisition was performed using different scanners: PET/CT Discovery-690 (n=15), Discovery-STE (n=15), Discovery ST (n=15) and Signa PET/MRI 3 Tesla (n=15) (GE Healthcare). An OSEM 3D algorithm was used for PET image reconstruction, both for PET/CT and PET/MRI. Images were converted to standardized uptake value (SUV) units and resampled to 3x3x3mm. A 10-voxel (3cm) diameter sphere was applied on the liver image of each scan, and SUV statistics of the defined region, including mean and standard deviation (SD), were derived. PET scans were cropped around the thorax to remove the background (80x60x75 voxels), and SUV statistics of the cropped image were measured. The cropped scans were

then standardized using the mean and SD of the sphere on the liver, and SUV statistics were measured again on both the liver sphere and the cropped image. Mann-Whitney U test was used to assess SUV differences among all pairs of tomographs, both before and after standardizaton. ***Results:*** Before standardization, at the liver sphere-level, a statistically significant difference in SUV mean values was observed for 690 vs.ST (p=0.016), 690 vs.STE (p=0.002), and Signa vs.ST (p=0.023), but not for Signa vs.690 (p=0.590), Signa vs.ST (p=0.772), and ST vs.STE (p=0.455). After standardization, no significant difference was observed between any of the combinations (p>0.05). In addition, at the PET image-level, before standardization a statistically significant difference in SUVmean values was observed for Signa vs.690 (p=0.003), 690 vs.STE (p=0.008), Signa vs.ST (p=0.016), and ST vs.STE (p=0.040), but not for 690 vs.ST (p=0.934) and Signa vs.STE (p=0.507). After standardization, all observed differences disappeared (p>0.05), except for 690 vs.ST (p=0.020). ***Conclusion:*** The applied methodology can facilitate the comparison of images acquired with different scanners, improving [18F]FDG PET scans consensus reading, comparability of SUV statistics, and thus TAK patients' diagnosis and monitoring. Future studies will aim to validate the technique on a larger series of patients, and to automate the procedure.

OP-303

Quantitative PET/CT Parameters as Prognostic Biomarkers in Giant Cell Arteritis

R. Durmo, *C. Marvisi, C. Ricordi, G. Besutti, L. Spaggiari, F. Leoni, F. Muratore, P. Giorgi Rossi, C. Salvarani, A. Versari;*
AUSL-IRCCS of Reggio Emilia, Reggio Emilia, ITALY.

Aim/Introduction: This study aimed to asses the diagnostic and prognostic value of a novel quantitative parameter obtained from FDG PET/CT imaging, total inflammation vascular volume (TIVV), in patients with Giant Cell Arteritis (GCA). ***Materials and Methods:*** GCA patients enrolled in a prospective trial and treated with three boluses of intravenous methylprednisone and weekly subcutaneous tocilizumab (TCZ) monotherapy for 52 weeks were included. PET/CT scans were performed at diagnosis and repeated at weeks 24, 52, and 74. TIVV was calculated using a semiautomatic approach with FIJI software for each PET scan. Total inflammation glycolytic volume (TIGV) was also obtained by multiplying TIVV by SUVmean. Visual analysis using PET vascular activity score (PETVAS) was also conducted. The EULAR criteria were utilized to define clinically active disease. ***Results:*** 18 patients (72% female, mean age 68.5 years) for a total of 61 PET scans were included, of which 29 in active disease. The TIVV mean values were 82 (SD 67) and 262 (SD 181); for TIGV were 187 (SD 153) and 608 (SD 414), and for PETVAS were 9.0 (SD 4.5) and 15.2 (SD 5.6), in relapse and active disease, respectively. In a cross-sectional regression analysis TIVV, TIGV and PETVAS were strongly associated with clinically active disease, with OR of 5.55 (95% CI 2.36-13.07), 6.31 (95% CI 2.53-15.78) and 4.65 (95% CI 1.98-10.91). Over a follow-up time of 24 months, 10 patients experienced disease relapse. Cox hazard model showed a strong association of TIVV and TIGV with time to relapse, with HR of 2.67 (95% CI 1.03-6.92) and 2.41 (95% CI 1.01-5.76), respectively. Conversely, PETVAS exhibited a weaker prognostic role (HR 2.03; 95% CI 0.84-4.92). ***Conclusion:*** Our findings suggest that, in patients with GCA, semiautomatic quantitative PET parameters, such as TIVV and TIGV, which quantify the inflammatory active volume of vessels, represent promising biomarkers and may overcome visual analysis.

OP-304

Utility of ^{18}F-FDG PET/CT Semiquantitative and Qualitative Assessment Methods in the Baseline and Follow-up of Patients with Giant Cell Arteritis

D. Patrut, *I. Navales Mateu, J. Mestre Torres, M. Simo Perdigó, A. Palomar Muñoz, R. Bellviure-Meiro, S. Asadurova, F. Velazquez, M. Solans Laque, F. Martinez Valle, C. Gamez Cenzano;*
University Hospital Vall d´Hebron, Barcelona, SPAIN.

Aim/Introduction: To assess the utility of the PET vascular activity score (PETVAS) in the basal PET/CT and during the follow-up in patients with giant cell arteritis (GCA). To evaluate the impact of including the vertebral arteries (PETvVAS). ***Materials and Methods:*** We conducted a retrospective study of patients diagnosed with GCA between 2012 and 2023, who had a basal PET/CT within 15 days after the start of steroids and a follow-up PET/CT between 6-15 months thereafter. We evaluated the scans according to the EANM recommended visual PET/CT grading scale (VS): grade 3 positive and grade 2 possibly positive. We calculated PETVAS and PETvVAS. ***Results:*** We included 24 patients with a median age of 76.6 years (72.2-79.4), 54.2% women. All patients were classified according to 2022 GCA classification criteria. Temporal artery biopsy was done in 16 patients, being positive in 10 (62.5%). Ischemic symptoms were present in 7 (29.2%) and systemic symptoms in 14 (58.3%). All patients received steroids (8 (33.3%) including methylprednisolone bolus) as part of the treatment. Methotrexate was initiated in 3 patients (12.5%) at diagnosis and in 11 (45.8%) between the two PET/CTs. Basal PET/CT showed VS≥2 in 100% of the scans. 20 (83.3%) displayed grade 3 uptake. Vertebral arteries were the most frequently positive vascular territories (12/24) and were the sole arteries exhibiting a VS3 in one-third of the patients (8/24). The follow-up PET/CT was acquired after 281 (249-340.5) days. Twenty-three (95%) patients were in clinical remission, but PET/CT was still showing persistent uptake of at least grade VS2 in 19 (79.2%) patients (63.1% of them with grade 3). We evaluated PETVAS and PETvVAS in both scans and analyzed them based on the presence or absence of clinical relapse (Table 1). ***Conclusion:*** Considering VS≥2, rather than VS=3, as a threshold for positivity increased diagnostic sensitivity from 83% to 100%. The reduction in PETVAS and PETvVAS values remains low even after steroid and methotrexate treatment, correlating poorly with clinical responses, and does not seem to predict disease relapses. Due to frequent and intense vertebral vascular involvement, its incorporation into PETVAS analysis might improve disease activity evaluation and warrants assessment in a larger patient cohort.

OP-305

Extracardiac Findings in Suspected Infective Endocarditis, Added Value of ^{18}F-FDG PET/CT

A. Padilla Bermejo[1], *F. Pena Pardo[1], M. Amo Salas[2], M. Sicilia Pozo[1], R. Angulo Amorese[1], J. Gatón Ramírez[1], N. Disotuar Ruiz[1], B. González García[1], D. Martínez Osorio[1], J. Rodríguez Gómez[1], M. Talavera Rubio[1], V. Poblete García[1];*
[1]Nuclear Medicine Department, University General Hospital of Ciudad Real, Ciudad Real, SPAIN, [2]Mathematics Department, Castilla La Mancha University, Ciudad Real, SPAIN.

Aim/Introduction: To evaluate the usefulness of 18F-FDG PET/CT in the assessment of extracardiac findings and to determine the association of indirect signs of infection/inflammation on ^{18}F-FDG PET/CT, in patients with suspected native valve endocarditis (NVE), prosthetic valve endocarditis (PVE) or cardiac implantable electronic devices (CIED) infection. ***Materials and Methods:*** A retrospective study including patients with suspected NVE or

PVE or CIED infection from April 2019 to January 2022. 18F-FDG PET/CT from head to upper thighs acquisition at 60 min and thoracic delayed acquisition at 120-180 min was performed (10 min/bed), all patients under myocardial suppression. The diagnosis of endocarditis was established by a multidisciplinary team. The presence of extracardiac findings was determined and followed up to establish their significance, classifying them as increased focal or diffuse uptake. Focal findings might be of infectious or tumoral origin among others, whereas bone marrow (BM) and/or spleen diffuse uptake could represent indirect signs of infection/inflammation in this setting. SUVmax was determined in spleen and vertebral body of L2 for BM assessment, classifying as positive those values higher than hepatic SUVmax. ***Results:*** Eighty-five patients were assessed: 34 with NVE, 33 with PVE and 18 with CIED. Infective endocarditis was finally considered definite in 27 patients and 9 patients were diagnosed with CIED infection. Among all patients included, 84% were on antibiotic treatment, initiated an average of 11 days before the 18F-FDG PET/CT scan. Of the 85 subjects included, 21 (24.7%) had inadequate myocardial suppression defined as persistent myocardial uptake greater than blood pool activity, but only 8 (9.4%) of them were not finally assessable. ^{18}F-FDG PET/CT identified 39.4%, 38.2% and 38.9% extracardiac manifestations in NVE, PVE and CIED infection, respectively. The prevalence of bone marrow hypermetabolism was 25.5% (30/85), 22.1% (26/85) in case of splenic hypermetabolism, 12.5% (15/85) of both simultaneously and 48.2% (41/85) in case of splenic and/or BM hypermetabolism. ***Conclusion:*** The use of PET/CT in suspected cases of endocarditis or device infection could help to detect indirect signs of infection to support the diagnosis. It is also useful to identify possible infective foci of unknown or alternative origin.

OP-306

Association between cardiovascular inflammation and alterations in immune system induced by HIV infection detected on ^{18}F-FDG PET/MRI

J. Garcia[1], *R. Olivero[1], J. Romero[1], E. Riera[1], I. Arrieta-Aldea[2], E. Cañas-Ruano[3], J. Du[3], P. Bassa[1], R. Guerri[3];*
[1]CETIR ASCIRES, Barcelona, SPAIN, [2]Infectious service. Hospital del Mar, Barcelona, SPAIN, [3]Hospital del Mar, Barcelona, SPAIN.

Aim/Introduction: Activation of the immune system and inflammation in HIV infection promote the development of comorbidities such as cardiovascular disease. New antiretroviral treatments (ART) aim to control virus replication, but fail to suppress inflammation completely. We aimed to assess biomarkers of HIV-induced inflammation at baseline and 1-year post-ART by means of whole-body ^{18}F-FDG PET/MRI. ***Materials and Methods:*** Prospective study including 14 newly diagnosed asymptomatic HIV patients (90% stage A1-3; 10% stage B). A ^{18}F--FDG PET/MRI (PET/MR 3.0T Signa.GE) was performed at baseline and 1-year post-ART, with patient implementation of a fat-rich diet/carbohydrate restriction for 7 days before procedure. Whole-body PET/MRI: PET emission (3 min./bed), MRI (T1/T2/diffusion sequences). Cardiac MRI (CMR): anatomical and functional sequences: dynamic/native T1 pre-contrast/T2 3Dpost-contrast/4Dflow. Analysis by MN and CMR specialists at baseline and 1-year post-ART: Qualitative vascular assessment in 4 grades as compared to liver reference uptake (Meller et al.). Quantitative assessment (SUVmax) and ratio (liver-reference) of ^{18}F--FDG uptake. Estimation of native T1 and T2 values in 16 myocardial segments. ***Results:*** In three patients (21.4%) baseline CMR showed a decreased left ventricular ejection fraction (LVEF), with normalization post-ART. Native T1 (pre-contrast) values ruled out diffuse fibrosis, and T2 values showed no signs of myocardial edema at baseline or post-ART. All patients (100%) showed adequate myocardial suppression at baseline and post-ART. Four patients (28.6%) showed baseline ^{18}F-FDG vascular uptake (score>3), two in ascending thoracic aorta and two in both ascending and descending thoracic aorta, all disappearing post-ART. All patients (100%) showed baseline lymphadenopathy uptake (ratio>4); supra (n:14) and infradiaphragmatic (n:13), the most frequent location being laterocervical (n:14) and inguinal (n:13), highly variable on number of territories affected (nine patients >6). Seven patients (50%) showed resolution, and the remaining seven a decrease extension (0 patients >5): 7 supra and 2 infradiaphragmatic (5 axillar, 2 inguinal). All 14 patients (100%), with a ratio >4, showed baseline and post-ART persistent adenoid uptake, 9 (64.3%) splenic, all of them resolved post-ART, and 7 (50.5%) gastric, 3 persistent post-ART. ***Conclusion:*** Cardiovascular biomarkers assessed on ^{18}F-FDG PET/MRI showed baseline activity in 28.6% of patients with large vessel uptake and low LVEF in 21.4%, with post-ART normalization. All patients presented with significant lymph node 18F-FDG uptake, with either post-ART normalisation or decreasing extension. All patients showed persistent adenoid uptake post-ART, 64.3% showed splenic uptake with post-ART resolution in all cases, and 21.4% showed gastric uptake with post-ART resolution in 57.1%. ***References:*** JAMA.2012:25; 308(4):379-386.doi:10.1001/jama.2012.6698.

OP-307

Brain metabolic connectivity and neurological symptoms persistence in Long-COVID

A. Martini[1], *G. Carli[2], S. Camminiti[3], L. Kieferle[4], D. Perani[5], S. Sestini[1];*
[1]Nuclear Medicine Unit, S. Stefano Hospital, Prato, ITALY, [2]Department Neurology, University Michigan, Ann Arbor, MI, UNITED STATES OF AMERICA, [3]Department Brain Behavioral Science, Pavia, ITALY, [4]Neurology Unit, S. Stefano Hospital, Prato, ITALY, [5]Nuclear Medicine Unit, San Raffaele Hospital, Milano, ITALY.

Aim/Introduction: Univariate PET imaging findings reveal acute-phase brain hypometabolism in SARS-CoV-2 patients, particularly in frontal-insular cortex, which improves with recovery. Despite this, prolonged neurological symptoms persist in long-COVID patients. Using multivariate approach, our study delves into comprehensive brain metabolic connectivity in SARS-CoV-2 survivors from acute to chronic phases, aiming to understand the persistence of neurological symptoms in long-COVID patients. ***Materials and Methods:*** Study included 43 pts with neurological symptoms and FDG-PET, divided in two sub-groups for comparative purposes, e.g. the first group of 24 acute-sub-acute patients (7 pts at ≤ 1 m after onset; 4 pts ≥ 1-m, 7 pts ≥ 2-m and 6 pts ≥ 3-m) and second of 19 pts with long-COVID (4 pts ≥ 4-m, 5 pts ≥ 5 m, 3 pts ≥ 6-m, 4 pts ≥ 7-8-m, and 3 pts ≥ 12-m).Brain metabolic connectivity analysis was performed to investigate changes in large scale brain networks (anterior and posterior default mode ADMN, PDMN; executive, ECN; attentive, ATTN; limbic, LIN; anterior salience, SAN) of acute-subacute and long-COVID patients compared with 30 age-matched HCs. Voxel-wise IRCA was applied to derive networks connectivity. Mean ^{18}F-FDG seed uptake for each clinical group was set as variable of interest in multiple regression models, testing for voxel-level correlations with whole brain metabolic activity in different groups (p-uncorrected <0.005, K≥100 voxels FEW corrected at cluster level). Differences in network topography and spatial extension were measured according to Dice similarity coefficient and number of correlated voxels. SPM12 was used to investigate metabolic alterations at group level using statistical comparison between each group and HC. ***Results:*** Acute and

sub-acute showed severe hypometabolism in several cortical regions mainly in fronto-insular cortex that showed progressive reduction during time. At 6-12-m, no brain hypometabolism was detected. In contrast, connectivity analyses revealed significant reduction in resting state networks extension from acute-subacute to long-COVID patients (+ 39% to - 77%). Acute-subacute patients presented with hyperconnectivity in several networks mainly in SAL and ATTN (Dice 0.43), while long-COVID patients presented with hypoconnectivity in ATTN (Dice 0.23) and EXC (Dice 0.29), SAN (Dice 0.32), LIN (Dice 0.35). ***Conclusion:*** Although dysfunction of fronto-insular cortex is confirmed to be transient and reversible, neuro-COVID patients presented with compensatory or pathological phenomena of hyperconnectivity during acute-subacute phase (mainly SAL, ATTN) followed by resting state networks impairment (ATTN, ECN, SAN, LIN) during chronic phase, which likely explains persistence of memory and executive impairment in long-COVID patients.

e-Poster Presentations Session 5: Oncology & Theranostics Committee: Novel Tracer and Oncology Imaging

EPS-085
Preclinical and clinical evaluation of a radiolabeled LNC1010 as a theranostic agent for molecular imaging and therapy in nasopharyngeal carcinomas
Y. Pang, *L. Zhao, J. Chen, H. Chen;*
The First Affiliated Hospital of Xiamen University, Xiamen, CHINA.

Aim/Introduction: Somatostatin Receptor 2 (SSTR2) targeted radiopharmaceutical 68Ga-DOTATATE has demonstrated potential advantages in preclinical and clinical applications for nasopharyngeal carcinomas (NPC). In this study, we designed a novel SSTR2-targeting vector, denoted as LNC1010, based on DOTATATE with a truncated Evans blue (EB) binding moiety. We optimized the pharmacokinetics of LNC1010 and evaluated its performance in small-animal Positron Emission Tomography (PET) and Single Photon Emission Computed Tomography (SPECT) imaging and PRRT compared to DOTATATE using a SSTR2-positive C666-1 NPC xenograft mice model. Additionally, we also attempted PRRT in an advanced NPC patient with lung metastasis and achieved satisfactory results. ***Materials and Methods:*** The binding characteristic of LNC1010 was assessed in vitro using C666-1 NPC cells. As a targeting vector with potential therapeutic application, we comprehensively evaluated the preclinical pharmacokinetics of 68Ga/177Lu-LNC1010 and 68Ga/177Lu-DOTATATE in C666-1 NPC tumor xenografts using PET and SPECT, as well as biodistribution and PRRT experiments. Furthermore, we conducted 68Ga-DOTATATE PET/CT imaging before and after 177Lu-LNC1010 PRRT and multiple time-point 177Lu-LNC1010 SPECT imaging during treatment in an advanced NPC patient with lung metastasis. These investigations aimed to provide valuable information for the development of more effective SSTR2-targeted radiotracers and their application in PRRT for future advanced NPC treatment. ***Results:*** LNC1010 exhibited higher uptake and specific targeting to C666-1 NPC cells in vitro. In C666-1 NPC tumor xenografts, 68Ga/177Lu-LNC1010 demonstrated higher uptake and longer retention time in PET and SPECT imaging compared to 68Ga/177Lu-DOTATATE, making it a more suitable therapeutic radiopharmaceutical for PRRT application in NPC. Biodistribution studies further confirmed significantly higher tumor uptake of 177Lu-LNC1010 compared to 177Lu-DOTATATE at 4 h post-injection. Compared to 177Lu-DOTATATE, 177Lu-LNC1010 showed greater tumor growth inhibition in C666-1 NPC xenograft mice. In the subsequent translational study, 177Lu-LNC1010 PRRT revealed a great remission of lymph node and lung metastases in advanced NPC, with decreased tumor size and radiotracer uptake in most lesions. ***Conclusion:*** Compared to 177Lu-DOTATATE, 177Lu-LNC1010 demonstrated significantly increased tumor uptake and retention in NPCs, thereby improving the therapeutic efficacy and extending the clinical indication of PRRT, providing a promising treatment option in patients with advanced NPC.

EPS-086
Head-to-head comparison of [68Ga]Ga-DOTA-FAPI-04 and $^{[18F]}$FDG PET/CT for the evaluation of tonsil cancer and lymph node metastases: a single-centre retrospective study
M. Ji, *G. Ma, Z. Yang, B. Gu, C. Liu, X. Du;*
Fudan University Shanghai Cancer Center, Shanghai, CHINA.

Aim/Introduction: The aim of this study was to compare the diagnostic value of [68Ga]Ga-DOTA-FAPI-04 and $^{[18F]}$FDG PET/CT imaging for primary lesions and metastatic lymph nodes in patients with tonsil cancer. ***Materials and Methods:*** We retrospectively studied 21 patients with tonsil cancer who underwent [68Ga]Ga-DOTA-FAPI-04 and $^{[18F]}$FDG PET/CT scans within two weeks. The maximum standardised uptake value (SUVmax) and tumour-to-background ratio (TBR) of the two tracers were compared using the Mann-Whitney U test. In addition, we analysed the change in TNM stage of patients and the sensitivity, specificity and accuracy

of metastatic lymph nodes under the two methods of diagnosis. We then further analysed the impact of HPV factors on tracer selection. ***Results:*** A total of 22 primary lesions in 21 patients were examined.68Ga-FAPI detected 20 primary lesions and 18F-FDG detected 9 lesions. [18F]FDG PET/CT showed higher uptake at primary foci than [68Ga]Ga-DOTA-FAPI-04 (P = 0.006). 68Ga-FAPI PET/CT showed higher TBR compared to 18F-FDG[18F]FDG PET/CT (P < 0.001). There was no significant difference in SUVmax and TBR between [68Ga]Ga-DOTA-FAPI-04 and [18F]FDG PET/CT in lymph node analysis (p > 0.05). The specificity and accuracy of [68Ga]Ga-DOTA-FAPI-04 PET/CT were higher than those of [18F]FDG PET/CT in diagnosing metastatic cervical lymph nodes (all P < 0.05). In the T stage assessment, [18F]FDG accurately diagnosed the T stage in 6 patients, while [68Ga]Ga-DOTA-FAPI-04 diagnosed in 15 patients. As for the N stage, the results were similar for [68Ga]Ga-DOTA-FAPI-04 and [18F]FDG (15 versus 14). ***Conclusion:*** This study showed that [68Ga]Ga-DOTA-FAPI-04 can accurately detect primary tumours in patients with tonsil cancer. [68Ga]Ga-DOTA-FAPI-04 may complement [18F]FDG in preoperative cervical lymph node staging.

EPS-087

Applicability of NI-RADS and Hopkins Criteria for Newly Diagnosed Head and Neck Cancers

G. Kaya[1], *M. Tuncel[1], N. Süslü[2], G. Güler[3], M. Çağlar Tuncalı[1];*
[1]Hacettepe University Medical School Department of Nuclear Medicine, Ankara, TÜRKIYE, [2]Hacettepe University Medical School Department of ENT and Head-Neck Surgery, Ankara, TÜRKIYE, [3]Hacettepe University Medical School Department of Pathology, Ankara, TÜRKIYE.

Aim/Introduction: NI-RADS and Hopkins-Criteria proposed to be used evaluating head-neck cancer PET-CT imaging to assess recurrence. To guide the surgeon, it is essential to point out metastatic lesions at the neck while staging newly diagnosed patients. The study's objective is to investigate the applicability of NI-RADS and Hopkins criteria on the staging PET-CT images of newly-diagnosed patients. ***Materials and Methods:*** Patients with newly diagnosed head-neck cancer who underwent F^{18}-FDG PET-CT were included. In this retrospective single-center study, the performance of lesion detection of NI-RADS, Hopkins-Criteria, and Expert-Nuclear-Medicine-Physician opinion were confirmed with pathology results of extensive neck dissection. Patient-based and lesion-based analysis were done. NI-RADS >2, Hopkins >3 lesions accepted as metastatic. ***Results:*** Thirty-two patients (F/M: 11/21) were included in the study. The mean age was 59.5(±2.7) years. The primary site was at the oral-cavity in eleven, lips in nine, other types of origin in twelve patients. Most of the lesions were SCC(29, 91%). Eleven(34%) were well-differentiated, fourteen(43%) were moderately-differentiated, and four were poorly-differentiated cancer(n:29). Local invasive disease was seen in 27/32. Mean primary-lesion-short-axis was 27.5(±3.5) cm, and mean SUVmax was 11.3(±1). A total of 1260 lymph nodes(LN) were dissected, and per-patient mean dissected-LN was 39(±4). Fourteen patients(44%) had biopsy-proven metastatic cervical-LN(s). Total 89 LN (30 level-I, 34 Level-II, 20 Level-III, 5-others) were addressed at PET-CT and 73(82% of the addressed and 6% of the total) LN diagnosed as metastatic (median size and SUVmax were 11(4-31) mm and 7.3(1-14) respectively). For addressed LN 56(63%), 60(67%), 66(74%) of them evaluated as metastatic according to NI-RADS, Hopkins and expert-opinion respectively. Sensitivity, specificity, negative-predictive-value, positive-predictive-value, kappa-correlations and AUC-values of ROC-analysis were; 71.2%, 75%, 0.327 (p<0.01), 36.3%, 92.9% and 0.731 for NI-RADS; were 75.3%, 68.7%, 37.9%, 91.7%, 0.335 (p<0.01) and 0.720 for Hopkins; 83.6%, 68.8%, 47.8, 92.4%, 0.447 (p<0.01) and 0.762 for expert-opinion, for the PET-CT-addressed LN respectively. NI-RADS and Hopkins methods were strongly correlated with expert opinion (Pearson-correlations: 0.853 and 0.798, p<0.01 respectively). Best pathology-"evaluation-method" correlation found with expert opinion (0.458, p<0.05). Expert opinion strong-moderately correlated with size (0.680, p<00.1), SUVmax(0.763, p<0.01), absence-of-hilus (0.544, p<0.01), irregular margins, necrosis. Metastasis-status moderately-correlated with LN's size, SUVmax, absence-of-hilus (0.420, p<0.01). No-correlation observed between primary-tumor-features mentioned above. ***Conclusion:*** Performance of NI-RADS and Hopkins-Criteria for LN-evaluation are comparable with expert-opinion and can be used for staging head-neck cancer patients for standardization of reporting. LN size, SUVmax and also absence-of-hilus may be incorporated in the referred methods.

EPS-088

Head-to-Head Comparison of ^{68}Ga-DOTATATE and ^{18}F-FDG PET in EBV-positive nonkeratinizing Nasopharyngeal Carcinoma

M. Qi, *R. Huang;*
Department of Nuclear Medicine, West China Hospital of Sichuan University, Chengdu, CHINA.

Aim/Introduction: Head-to-Head comparison of the diagnostic efficacy and prognosis predictive value of 68Ga-DOTATATE and 18F-FDG PET in patients with EBV-positive nonkeratinized NPC. ***Materials and Methods:*** Patients meeting the inclusion criteria underwent 18F-FDG and 68Ga-DOTATATE whole-body PET within one week prior to any treatment. ***Results:*** (1)68Ga-DOTATATE PET demonstrated a comparable detection rate to 18F-FDG PET in visualising primary tumors, and both are 100% (26/26). The 18F-FDG uptake was significantly higher than the 68Ga-DOTATATE uptake in primary NPC tumors (median SUVmax:15.00 vs.9.73, P =0.001). The skull base extension from NPC could be clearly visualised on 68Ga-DOTATATE PET at a detection rate of 100% (12/12) and which was higher than 91.7% (11/12) of 18F-FDG PET. Among the primary tumor volumes delineated with different thresholds of 68Ga-DOTATATE PET and 18F-FDG PET, the delineation volume of 68Ga-DOTATATE 35% SUVmax as threshold had the highest credibility and consistency level with the volume measured by enhanced MRI (6.62cm3 vs. 5.80cm3, ICC:0.96, P<0.001).68Ga-DOTATATE PET and 18FDG PET showed 101/108(93.5%) and 103/108(95.4%) regional lymph nodes metastases, respectively(P=0.552), and 18F-FDG demonstrated significantly higher uptake than 68Ga-DOTATATE (median SUVmax:10.81 vs 6.05, P<0.001). Furthermore,54/92(58.7%) and 89/92(96.7%) distant metastases were detected by 18F-FDG and 68Ga-DOTATATE PET, separately(P<0.001), and 68Ga-DOTATATE can detect more tiny bone metastases. There was no difference in 68Ga-DOTATATE and 18F-FDG uptake in overall distant metastases, with a median SUVmax of 5.41 vs. 5.24 (P=0.324). There were 4 (15.4%), 8 (9.0%) and 11 (10.7%) lesions TLR of 68Ga-DOTATATE uptake in in primary tumors, regional lymph nodes metastases and distant metastases higher than 2, respectively. (2) Plasma EBV DNA was positively correlated with total MTV, total TLG, total SRETV and total TLSRE.(3) Patients with TLG > 192.0g , maximum DOTATATE SUVmax>14.5,total SRETV>33.8 cm3,and total TLSRE>191.2 g had significantly shorter PFS. ***Conclusion:*** (1)68Ga-DOTATATE PET/CT is a promising imaging modality for detecting primary and metastatic NPC, with favourable image contrast and diagnostic efficacy comparable to that of 18F-FDG

PET. (2) The delineation volume of 68Ga-DOTATATE 35%SUVmax as thresholds had the highest credibility and consistency level with the volume measured by enhanced MRI. (3) Plasma EBV DNA was positively correlated with total MTV, total TLG, total SRETV and total TLSRE. (4) Both 18F-FDG and 68Ga-DOTATATE PET parameters had predictive value for response evaluation and PFS in NPC patients.

EPS-089

Predictive value of neck imaging reporting and data system (NI-RADS) in surveillance of head and neck Squamous Cell Carcinoma (SCC) using FDG PET/CTPredictive value of neck imaging reporting and data system (NI-RADS) in surveillance of head and neck Squamous Cell Carcinoma (SCC) using FDG PET/CT

***S. Singh*[1],** *P. Wadhwa*[2], *K. Verma*[1], *M. Suhaib*[1], *A. Singh*[1], *A. Chaudhary*[1], *S. Nigam*[1];
[1]*Globe Healthcare, Lucknow, INDIA,* [2]*United Imaging, New Delhi, INDIA.*

Aim/Introduction: Neck Imaging Reporting and Data System (NI-RADS) offers a standardised approach for patient management. FDG PET/CT is a valuable tool in the surveillance of SCC due to its ability to detect metabolic activity indicative of disease. The aim of this study is to investigate the predictive value of NIRADS for the surveillance of patients with head and neck SCC using FDG PET/CT. ***Materials and Methods:*** This retrospective study included 120 patients with head and neck squamous cell carcinoma who were treated with curative intent with surgery, chemotherapy, radiation therapy, or their combination. Patients underwent PET/CT scanning 3 months after the curative treatment. NI-RADS scoring was performed for the primary site as well as regional lymph nodal sites. Distant metastases evaluation was also done on the whole-body PET/CT images. Patients were segregated into different NI-RADS categories on first surveillance FDG PET/CT and were subsequently followed up clinically, with subsequent imaging (PET/CT or MRI), USG neck (for nodal recurrence) or biopsy as indicated. Changes in the NIRAD scoring on subsequent follow-up scans was documented. Recurrence free survival was estimated for this cohort. ***Results:*** We observed a positive correlation between the depth of invasion (DOI), size and disease recurrence with the Pearson correlation coefficient (r) of 0.3 (P-value=0.1). There was a positive correlation between lymph nodes with NIRADS score in regional neck nodes. Univariate association analysis demonstrated a strong association between the NI-RADS score and ultimate disease recurrence, with P < .001 for primary and regional sites. The rate of tumour recurrence was significantly different among the NIRADS 1-2a, 2b-3 and 4 categories and the recurrence rate was higher for higher NIRADS scores at first imaging. The overall negative predictive value (NPV) of the NI-RADS 1-2 was 90%. 90% patients with NIRADS score of 1-2a on first surveillance PET scans showed no recurrence at 2 years whereas 65% of patients with NIRADS score of 2b-3 had no recurrence during 2 year follow-up. Patients with NIRADS score of 4 in the first surveillance PET scan demonstrated a 2 year recurrence free survival in only 35% of patients. ***Conclusion:*** NI-RADS scoring system using FDG PET/CT can be reliably used to predict disease recurrence in patients with head and neck squamous cell carcinoma treated with curative intent. ***References:*** Wangaryattawanich et al. AJNR, 2018. Abdelrahman et al. Egyptian Journal of Radiology and Nuclear Medicine, 2020.

Can pretherapeutic 2-[18F]FDG-PET/CT texture analysis predict prognosis of head and neck tumor patients?

***F. Bschorer*[1],** *J. Kurth*[2], *M. Heuschkel*[2], *S. Schwarzenböck*[2], *V. Barsegian*[3], *B. Krause*[2];
[1]*University Medical Centre Rostock, Department of Oral and Maxillofacial Surgery, Rostock, GERMANY,* [2]*University Medical Centre Rostock, Department of Nuclear Medicine, Rostock, GERMANY,* [3]*Helios Kliniken Schwerin, Department of Nuclear Medicine, Schwerin, GERMANY.*

Aim/Introduction: There is evidence that results of a texture analysis of 2-[18F]FDG-PET/CT (FDG-PET/CT) is associated with patient outcome in several cancers [1]. The aim of this study was to investigate if textural parameters extracted from a pretherapeutic FDG-PET/CT might be predictive for the prognosis of head and neck tumor patients. ***Materials and Methods:*** Thirty-two patients (mean age: 66.1 ± 10,6 y; 27 male, 5 female) with head and neck tumors underwent FDG PET/CT before cancer treatment. Known prognostic factors for head and neck cancer (age, gender, smoking, alcohol, primary tumor location and size, pretherapeutic staging parameters) were recorded. Quantitative PET-parameter like metabolic tumoral volume (MTV), SUVmax SUVmean, total lesion glycolysis (TLG), and also textural features (e g. asphericity, sphericity, entropy levels) were extracted for each lesion using the software LifeX [2]. We performed univariate and multivariate analysis for overall survival (OS) and progression free survival (PFS) using Kaplan-Meier analysis and Cox-proportional hazards model. ***Results:*** Mean follow-up duration was 22.3 months for the entire cohort and 26.2 months for the surviving patients. In the univariate analysis tumor size, MTV, asphericity, TLG, sum entropy were significantly associated with OS. In the multivariate analysis, asphericity was an independent prognostic factor for OS (p = 0.006, HR = 14.22) ***Conclusion:*** In our study, asphericity was independently associated with poor overall survival. Thus, textural analysis of pretherapeutic FDG PET/CT in head and neck cancer patients could be helpful for patient-specific risk stratification for tumor treatment and post-therapeutic follow-up. For instance, a more individualized follow-up might be determined based on individual risk. ***References:*** 1. Gillies R et al (2016). Radiology, 278(2), 563-577.2. Nioche C,et al. (2018). EPS-091

The Selection of Reference Region for PET-CT with ^{18}F-FET Evaluation of the Pons in Children

D. Susin, *E. Gromova;*
MIBS, Saint-Petersburg, RUSSIAN FEDERATION.

Aim/Introduction: The aim of the study was to assess the relative distribution of uptake radiolabelled amino acids in the posterior cranial fossa structures in children with a normal brain to select optimal reference region to brainstem lesion analysis. ***Materials and Methods:*** For retrospective analysis 30 children (aged 3-16 years) examined by PET-FET were selected. Entry criteria included untreated children with normal brainstem and cerebellum. Pons-to-cerebellum ratio (PCR) and pons-to-frontal cortex ratio (PFR) were analysed. For each ratio, six calculation methods were used, depending on the size of the region of interest (ROI) and the SUV statistics (maximum, mean, peak SUV in the 10 mm ROI or mean SUV in the banana-shaped ROI). ***Results:*** The FET uptake in the pons and cerebellum was significantly higher than in the frontal cortex in both groups, regardless of the measurement method used (p<0.05). The PCR showed no significant differences PET-FET scans (p>0,05).

Conclusion: The results allow us to recommend the cerebellum as a reference structure in the analysis of PET-FET in children with brainstem lesions.

EPS-092

^{18}F-FDG PET-CT features of cervical carcinoma of unknown primary in 192 patients

L. Chen, *Y. Xiao, R. Xie;*
Yunnan Cancer Hospital, the Third Affiliated Hospital of Kunming Medical University, Kunming, CHINA.

Aim/Introduction: To investigate the value of 18F-FDG PET-CT in CCUP patients with cervical lymphadenopathy as the primary sign. ***Materials and Methods:*** A total of 192 consecutive patients who underwent 18F-FDG PET-CT scan with swollen lymph nodes in the neck as the first sign from January 2019 to October 2022 were retrospectively analyzed (141 males, 49 females, age range 15-79 (53.96±13.05) years). The pathological diagnosis or long-term clinical follow-up(≥6 months) were the golden diagnosis. The diagnostic sensitivity, specificity, accuracy, positive predictive value and negative predictive value of PET-CT were calculated. Pearson correlation coefficient was employed to analyze the relationship between the SUVmax of the primary tumor and cervical lymph node metastasis, and independent sample t test was used to analyze the relationship between the SUVmax of different pathological types of cervical metastasis. ***Results:*** Primary tumors were confirmed in 147 patients, among which head and neck tumors were the most common etiology in this study, accounting for 76.2% (112/147). The diagnostic sensitivity, specificity, accuracy, positive predictive value and negative predictive value were 97.3%(147/151),68.2%(28/41),91.1%(175/192),91.8%(147/160)and 87.5%(28/32), respectively. There was no significant correlation between the SUVmax of primary lesions and cervical metastases(P>0.05) . There was no significant difference in SUVmax between adenocarcinoma and squamous cell carcinoma(P>0.05). The detection rate of primary lesions in patients with squamous cell carcinoma of metastatic cervical lymph node is higher than that in patients with adenocarcinoma(x2=4.712, P<0.05). Patients with the primary tumor on the right side often have right cervical lymph node metastasis, and vice versa. When the primary tumor involves both sides, bilateral cervical lymph node would be involved. In cases where the primary tumor was located in high-level neck, cervical metastases were often located in the upper and middle cervical, and vice versa. ***Conclusion:*** 18F-FDG PET-CT plays a crucial role in detecting the primary tumor of CCUP. The specific distribution and SUVmax of cervical metastases can shed a light on finding the primary tumor especially when it is unclear.

EPS-093

Detection of malignancy in paraneoplastic neurological syndromes - do we need ^{18F}PET/CT or is conventional CT sufficient?

C. Hünnekens[1], *R. Ebner[2], F. Kuhnle[2], F. Schöberl[3], M. Brendel[1], G. Sheikh[1];*
[1]Department of Nuclear Medicine, University Hospital, LMU Munich, Munich, GERMANY, [2]Department of Radiology, University Hospital, LMU Munich, Munich, GERMANY, [3]Department of Neurology, University Hospital, LMU Munich, Munich, GERMANY.

Aim/Introduction: ^{18F}Fluorodeoxyglucose (FDG) - positron emission tomography (PET)/computed tomography (CT) has proven to be an exceptional diagnostic tool in oncology, providing functional as well as morphological information. Conventional CT, on the other hand, is limited to morphological imaging, but is less expensive, less time consuming and has better availability. Our goal was therefore to evaluate the suitability of ^{18F}FDG-PET/CT compared to conventional CT for the detection or exclusion of malignancy in paraneoplastic neurological syndromes (PNS). ***Materials and Methods:*** In our ongoing retrospective analysis we so far evaluated a total of 447 patients with PNS who underwent ^{18F}FDG-PET with diagnostic contrast enhanced CT in our department between March 2013 and March 2024. PET/CT scans were classified as positive or negative for malignancy based on PET/CT reports and the results were validated by either imaging or long-term clinical follow-up. In a second step, only the CT component of a subcohort was independently read by two radiologists with 3 years of experience, blinded to the PET/CT results and also classified as positive or negative for malignancy. Sensitivity, specificity, positive and negative predictive values (PPV and NPV) as well as accuracy were calculated for PET/CT and conventional CT, respectively. ***Results:*** The prevalence of malignancy in our cohort of PNS patients was 7.61%. 69 PET/CTs (28 with and 41 without malignancy) were selected for the separate reading of their CT component. Of the ^{18F}FDG-PET/CTs, 32 were true positive, 12 false positive, 401 true negative, and two false negative, while conventional CT yielded 36 true positives, six false positives, 76 true negatives and 20 false negatives. Sensitivity, specificity, PPV, NPV and accuracy for ^{18F}FDG-PET/CT/conventional CT were 0.94/0.64, 0.97/0.93, 0.73/0.86, 0.99/0.79 and 0.97/0.81, respectively. ***Conclusion:*** The preliminary results from our retrospective analysis suggest the superiority of ^{18F}FDG-PET/CT for malignancy screening in paraneoplastic neurological syndromes, but conventional CT may be an alternative in cases where the former is not available. Further evaluation with a larger CT cohort to validate these observations and a cost-effectiveness analysis will follow.

EPS-094

Relationship Of Pet/Ct Data And Histopathologic Findings In Patients With Unknown Primary Cancer With Isolated Brain Mass

A. Aslan, *Ü. Korkmaz Kara, F. Üstün;*
Trakya University, Merkez, TÜRKIYE.

Aim/Introduction: Cancer of unknown origin (CUP) is a condition where the primary site of cancer cannot be determined despite thorough investigation. Brain masses are one of the common presentations of CUP. Identifying the primary lesion and other metastases is crucial in determining the appropriate treatment. We studied the relationship between PET/CT data and pathology results in CUP patients with brain masses. ***Materials and Methods:*** Images of 55 patients who underwent FDG imaging with this indication were evaluated. FDG avid lesions, metabolic PET parameters and histopathological diagnoses were recorded. In those with more than one suspicious focus on FDG-PET/CT, the lesions with the highest SUVmax were considered the dominant focus. ***Results:*** After correlating with histopathology, it was discovered that the primary focus was on the lung in 35 patients, the brain in 15 patients, and other regions in 5 patients (Table1). PET/CT scan showed the same focus as the histopathological diagnosis in 48 patients (87.2%). The most common site for lymph node metastasis was the paratracheal station. The most common histopathological subtype in the primary lung group was adenocarcinoma. The mean SUVmax value of primary and brain lesions was higher in women compared to men. When the groups were changed to lung, brain and others, higher age values were

found in the lung category(63) than in the brain category(55). The mean SUVmax values of dominant metastases were significantly lower in the lung group than in the others group. No metastasis was detected in the group with a primary brain tumor. The mean values of brain lesion/normal cortex were lower in the lung and brain groups than in the others group. ***Conclusion:*** Among occult cancers for which PET/CT is performed with an isolated brain mass, the most common clinical diagnosis is lung cancer, especially adenocarcinoma. FDG-PET/CT scans are very accurate and sensitive in detecting lung cancer and its metastases. Additionally, FDG-PET/CT can help determine whether an isolated brain mass is a primary brain tumor with 98% sensitivity and 67% specificity despite strong FDG uptake in the cerebral cortex. Therefore, in cases where an FDG PET/CT study is performed due to an isolated brain mass, if an FDG avid primary focus cannot be detected throughout the body, it should be kept in mind that this may be due to the low FDG uptake of the primary focus, or it may be because the brain lesion is the actual primary focus.

EPS-095

Predicting pathological complete response after neoadjuvant immunochemotherapy and radiation therapy in locally advanced rectal cancer with ^{68}Ga-FAPI PET, ^{18}F-FDG PET and contrast-enhanced MRI: A lesion to lesion comparison with histopathology

X. Zhang, *Y. Feng, B. Yang, X. Lan;*
Huazhong University of Science and Technology, Wuhan, CHINA.

Aim/Introduction: Neoadjuvant therapy in patients with locally advanced rectal cancer (LARC) has achieved good pathologic complete response (pCR) rates, potentially eliminating the need for surgical intervention. This study investigated preoperative methods for predicting pCR following neoadjuvant short-course radiotherapy (SCRT) combined with immunochemotherapy. ***Materials and Methods:*** Treatment-naïve participants with histologically confirmed LARC were enrolled from February, 2023 to July, 2023. Before surgery, the participants received neoadjuvant SCRT followed by two cycles of capecitabine and oxaliplatin plus camrelizumab. 68Ga-labeled fibroblast activation protein inhibitor (68Ga-FAPI) PET/MR, 18F-FDG PET/CT and contrast-enhanced MRI were performed before treatment initiation and before surgery in each participant. PET parameters, morphological and MR imaging features, the size and number of lesions were also collected from each scan. Each parameter's sensitivity, specificity, and diagnostic cutoff were derived via ROC curve analysis. ***Results:*** A total of 25 eligible participants were enrolled (18 men, 7 women; mean age, 58.8 years), and all participants had microsatellite instability-high/deficient mismatch repair LARC. The postoperative pathology illustrated pCR was achieved in 9 of 20 participants (45.0%). In the visual evaluation, both 18F-FDG and 68Ga-FAPI PET were limited to forecasting pCR. Contrast-enhanced MRI had a high rate of missed diagnosis with a sensitivity of 55.56%. In the quantitative evaluation, ΔFAPI-SULpeak% had the largest area under the curve (0.93) with high specificity (sensitivity=77.78%, specificity=100.0%, cutoff=63.92%). A combination named ΔFAPI-SULpeak% or contrast-enhanced MRI improved the sensitivity to 88.89% while retaining a high specificity of 100.0% in this set of participants. ***Conclusion:*** 68Ga-FAPI PET is a promising imaging modality for predicting pCR following SCRT combined with immunochemotherapy. The combination named ΔFAPI-SULpeak% or contrast-enhanced MRI may provide the guidance in selecting patients who can forgo surgery after neoadjuvant therapy.

EPS-096

OneStop ^{68}GaFAPI04/^{18}F-FDG Dual-Low Activity TotalBody PET/CT Scan: More Theranostics Information Available

H. Gao, *Z. Zheng, H. Yu, W. Mao, Y. Lin, Y. He, R. Yang, Y. Xie, H. Shi;*
Department of Nuclear Medicine, Zhongshan Hospital, Fudan University, Shanghai, CHINA.

Aim/Introduction: 68Ga-fibroblast activation protein inhibitor (FAPI) probes have demonstrated promising complementary values to 2-18F-fluoro-2-deoxy-D-glucose (18F-FDG) in positron emission tomography/computed tomography (PET/CT) for tumor imaging, and hold significant value in theranostics. This study aims to explore the feasibility of a new one-stop 68Ga-FAPI-04/18F-FDG dual-low activity imaging protocol, providing more diagnostic and therapeutic information for oncological applications. ***Materials and Methods:*** We prospectively enrolled 40 patients with eight types of tumors confirmed by pathology. All patients underwent a one-stop 68Ga-FAPI-04 (0.925 MBq/kg) PET (PETFAPI) followed by an additional 18F-FDG (1.85 MBq/kg) injection for a 60 min dynamic acquisition (PETDUAL), with a single diagnostic CT to generate the PET/CT. PETDUAL was reconstructed at 10 min intervals (PETD0-10, PETD10-20, PETD20-30, PETD30-40, PETD40-50, PETD50-60). Lesion detectability and target-to-background ratios (TBRs) for tumors and metastatic lesions were analyzed using both single and dual-tracer PET/CT. The period from 30 to 60 min was then segmented into 5 min intervals for further evaluation (PETD30-35, PETD35-40, PETD40-45, PETD45-50, PETD50-55, PETD55-60). PETD50-60 and PETD55-60 were considered the references in each group. ***Results:*** Compared to the single 68Ga-FAPI-04 PET/CT, the dual-tracer PET/CT showed similar performance in detecting primary tumors (41 vs. 42, $P > 0.999$), whereas TBRs were significantly higher in PETFAPI ($P > 0.05$). Notably, more metastases were identified in PETD50-60 than in PETFAPI (95 vs. 50, $P < 0.001$). One poorly-differentiated gastric tumor (15% signet ring cell) , 42 suspected lymph nodes, two peritoneal metastases, and one liver metastasis were detected on PETDUAL but not identified on PETFAPI. In images reconstructed over 10 min intervals, the lesion detection rate showed no significant differences among PETD10-20, PETD20-30, PETD30-40, PETD40-50, and PETD50-60 (all $P>0.05$). Both PETD30-40 and PETD40-50 detected all lesions identified in PETD50-60, and there were no significant differences in the TBRs between PETD40-50 and PETD50-60 ($P > 0.05$). In images reconstructed over 5 min intervals from 30 to 60 min, the lesion detection rate did not differ significantly among these images ($P > 0.05$). The TBRs for primary lesions in PETD40-45, PETD45-50, and PETD50-55, as well as for metastatic lesions in PETD50-55 showed no significant differences compared to PETD55-60 ($P > 0.05$). ***Conclusion:*** The one-stop dual-tracer dual-low activity PET imaging protocol demonstrated greater lesion detectability and provided additional theranostics information, while reducing radiation exposure and shortening duration.

EPS-097

Whole body bone scan or multifield-bone SPECT/CT in the assessment of metastases in oncological patients

J. Gatón Ramírez[1], *E. Noriega Álvarez[2], F. López-Bermejo García[1], M. Contreras Ameduri[1], M. Sicilia Pozo[1], C. Lucas Lucas[1], G. Molina Mendoza[1], A. Padilla Bermejo[1], J. Rodríguez Gómez[1], F. Pena Pardo[1], M. Talavera Rubio[1], V. Poblete García[1];*
[1]Nuclear Medicine Department, University General Hospital of Ciudad Real, Ciudad Real, SPAIN, [2]Nuclear Medicine Department, University Hospital of Guadalajara, Guadalajara, SPAIN.

Aim/Introduction: To analyse the agreement between whole body scan (WBS) and multifield SPECT/CT for the detection of blastic bone metastases in oncological patients. ***Materials and Methods:*** A retrospective study including consecutive oncology patients (p) referred for screening of metastatic bone involvement (October/2023-April/2024).Planar images of WBS (anterior and posterior views) and SPECT/CT images (from vertex to the upper third of the lower limbs) were acquired.Two Nuclear medicine physicians assessed the images randomly and blindly without access to clinical information or results of any other techniques reports. Location, skeletal involvement (oligometastatic [≤ 5 lesions] or polymetastatic [>5]), and the presence of a "superscan" pattern were assessed, analysing if new lesions were found in SPECT/CT vs. WBS. Additionally, the agreement between both techniques was evaluated using Cohen's Kappa coefficient (k). ***Results:*** Seventy-six patients (17 women) were evaluated, median age 70 years (42-90); 58/76p (76.3%) with prostate cancer, 15/76p (19.7%) with breast cancer, and 3/76p (3.91%) with other tumours (digestive or lymphomas). WBS showed suspicious lesions in 17/76p (22.4%), while SPECT/CT did it in 16/76p (21.1%). The agreement between both techniques was almost perfect (k=0.883; p<0.001). Furthermore, WBS showed polymetastatic involvement in 47.1% of patients (8/17p), while SPECT/CT did so in 58.8% (10/17p). The agreement between both techniques in distinguishing between oligometastatic and polymetastatic bone disease was substantial (k=0.750, p=0.02).SPECT/CT changed the therapeutic management in 5 patients (29.4%): 3/5p shifted from oligo to polymetastatic involvement, and 2 false positive of WBS (with 2 suspicious foci on WBS corresponding to benign findings in SPECT/CT). ***Conclusion:*** Despite the small size of the sample, the results suggest that the systematic incorporation of multifield bone SPECT/CT instead of WBS for osteoblastic metastases screening could lead to a change in the management in a significant percentage of oncological patients.

EPS-098

First-in-human study of a novel bifunctional PET tracer ^{68}Ga-DOTA-NI-FAPI-04 with FAPI and hypoxia-sensitive moieties

J. Zang[1], *Y. Luo[2], G. Wang[1], W. Jin[2], L. Zhu[2], H. Kung[3], W. Miao[1];*
[1]The First Affiliated Hospital, Fujian Medical University, Fuzhou, Fujian, CHINA, [2]Beijing Normal University, Beijing, CHINA, [3]University of Pennsylvania, Pennsylvania, PA, UNITED STATES OF AMERICA.

Aim/Introduction: Fibroblast activation protein (FAP) is highly expressed in cancer-associated fibroblasts (CAFs). However, the objective response rate of targeted FAP radionuclide therapy was relatively low, suggesting that insufficient uptake of FAP inhibitor agents in tumor tissues and radio-resistance caused by tumor hypoxia. To improve this situation a novel bifunctional radiotracer, 68Ga-DOTA-NI-FAPI-04, containing FAP targeting moiety together with a hypoxia-sensitive 2-nitroimidazole (NI) group was developed. Preclinical studies have demonstrated that 68Ga-DOTA-NI-FAPI-04 exhibited favorable tumor binding affinity and improved tumor uptake and retention compared with 68Ga-DOTA-FAPI-04 without the NI group. This study explores the clinical application of 68Ga-DOTA-NI-FAPI-04 as well as comparison with 68Ga-DOTA-FAPI-04 and 68Ga-FAP-2286. ***Materials and Methods:*** Twelve patients with 5 different types of cancer underwent 68Ga-DOTA-NI-FAPI-04 PET/CT for initial study. For comparison, 9 patients underwent paired 68Ga-DOTA-NI-FAPI-04 and 68Ga-DOTA-FAPI-04 PET/CT and 3 patients underwent paired 68Ga-DOTA-NI-FAPI-04 and 68Ga-FAP-2286 PET/CT, respectively. Among of them, six patients underwent serial dynamic PET scans for 68Ga-DOTA-NI-FAPI-04 for dosimetry evaluation, and the others underwent scans at 60 and 120 min. Standardized uptake values (SUV) were measured for semi-quantitative comparison. ***Results:*** Biodistribution of 68Ga-DOTA-NI-FAPI-04 in humans showed uptakes in thyroid glands, pancreas, salivary glands, kidneys, heart content, spleen, liver, muscle, and urinary bladder. SUVmean values of normal organs decreased in all patients over time, except for the bladder. The highest average SUVmean was observed in the thyroid glands, decreasing from 12.3 at 3 min to 3.7 by 120 min (a decline of 69.9%). Tracer uptake in the tumor showed rapid and steady vales (Avg. SUVmax of 11.5, 12.7, 12.9, 13.0 and 12.8 at 3, 15, 30, 60 and 120 min, respectively). The lesions were clearly visualized by 15-min, and the detection of tumor improved at the 60 and 120 min. The uptake of 68Ga-DOTA-NI-FAPI-04 was significantly higher than that of 68Ga-DOTA-FAPI-04 and 68Ga-FAP-2286 (68Ga-DOTA-NI-FAPI-04 vs. 68Ga-DOTA-FAPI-04: 15.30±8.71 vs. 10.20±5.29 at 60 min, 14.07±7.58 vs. 10.20±3.79 at 120 min; 68Ga-DOTA-NI-FAPI-04 vs. 68Ga-FAP-2286: 14.51±4.88 vs. 10.83±4.54 at 60 min, 15.04±4.68 vs. 11.88±4.14 at 120 min, respectively, P value < 0.05). 68Ga-DOTA-NI-FAPI-04 provided a superior lesion detection in cancer patients. ***Conclusion:*** A bifunctional PET tracer, 68Ga-DOTA-NI-FAPI-04, showed significantly improved tumor uptake and retention than 68Ga-DOTA-FAPI-04 and 68Ga-FAP-2286, suggesting that hypoxia-sensitive moiety (nitroimidazole, NI) may play an important role. Further study of 68Ga-DOTA-NI-FAPI-04 in humans is warranted to explore the physiological mechanisms and clinical applications.

EPS-099

Value of ^{18}F-FAZA dynamic PET compared to intravoxel incoherent motion magnetic resonance imaging in sarcoma patients

S. Mirshahvalad[1], *A. Farag[1], E. Ragaini[1], E. Taylor[2,3], D. Shultz[2], P. Veit-Haibach[1];*
[1]University Medical Imaging Toronto, Toronto Joint Department Medical Imaging, University Health Network, Sinai Health System, Women's College Hospital, University of Toronto, Toronto, ON, Canada, Toronto, ON, CANADA, [2]Princess Margaret Cancer Centre, University Health Network, Toronto, Canada, Toronto, ON, CANADA, [3]Department of Radiation Oncology, University of Toronto, Toronto, Canada, Toronto, ON, CANADA.

Aim/Introduction: To correlate dynamic parameters derived from 18F-FAZA PET with MRI-assessed intravoxel incoherent motion (IVIM) in soft-tissue sarcoma. ***Materials and Methods:*** In this REB-approved retrospective study, we included 20 patients with non-metastatic high-risk (grade 2+) soft-tissue sarcoma patients who underwent simultaneous 18F-FAZA PET and MRI. 18F-FAZA PET/MRI was performed with 5 MBq/kg of 18F-FAZA. Dynamic PET imaging was initiated simultaneously with injection and was acquired for 20 minutes. 2D echo-planner IVIM sequence was also acquired with multiple b-values. The tumour was contoured on the MRI component. IVIM maps were calculated, including true diffusion coefficient (D), pseudo-diffusion coefficient (D*), and perfusion fraction (f). On the dynamic PET images, 18F-FAZA kinetic parameters, including k1, k2, k3, k4, and vt, were extracted from the same segmentations. K1 (ml/cm3/min) was defined as the rate constant of perfusion from blood to tissue, k2 (min-1) the rate constant representing transport from interstitium to blood, k3 (min-1) the tracer accumulation rate constant in the tissue, k4 (min-1) the dissociation rate constant (de-phosphatization) of accumulated 18F-FAZA, and vt (mL·cm−3) 18F-FAZA total volume distribution. Additionally, k1/k2 was calculated, representing

perfusion-to-transport ratio. Spearman's rank correlation was performed to assess the relationship between the studied parameters. P-values <0.05 were considered statistically significant. ***Results:*** In this population (mean age= 58; male%= 90%), all tumor were located in the limbs or thorax. Average values for k1, k2, k3, k4, vt, D, D*, and f were 0.34 ±0.31, 0.64 ±0.60, 0.46 ±0.41, 0.0.79 ±0.64, 1.72 ±0.71, 123.123.41 ±33.38, 1488.65 ±415.81, and 158.32 ±32.93. k1/k2 and vt were correlated with f (rs= -0.588 and rs= -0.624; p=0.017 and p=0.010, respectively) and vt correlated with D* (rs= -0.49; p=0.05). Other dynamic parameters showed no correlations with IVIM values, though some trended in the plotted figures. ***Conclusion:*** Dynamic PET-based kinetic parameters correlated with perfusion parameters derived from IVIM MRI. Thus, adding early dynamic PET to the 18F-FAZA PET protocol may provide information regarding tissue perfusion.

EPS-100

Radiomics based on 2-[18F]FDG PET/CT can differentiate non-metastatic gallbladder cancer and cholecystitis

Y. Han[1], *Y. Pan[1], J. Zhang[1], C. Li[1], J. Liu[1], Y. Wang[2], X. Xu[1], Y. Sun[1], G. Wang[3], B. Xu[1];*
[1]The First Medical Center, Chinese PLA General Hospital, Bei Jing, CHINA, [2]GE Healthcare China, Pudong New Town, Shanghai, China, Shang Hai, CHINA, [3]Nuclear Medicine Department, Beijing Friendship Hospital, Affiliated to Capital Medical University, Bei Jing, CHINA.

Aim/Introduction: Gallbladder cancer (GBC) is the most common malignant tumor of the biliary tract worldwide and most patients are diagnosed in the late stage of gallbladder cancer. However, clinical symptoms of GBC and cholecystitis may present similarities, and there are no specific laboratory tests available to distinguish between GBC and cholecystitis. In addition, some imaging examination appearances exhibited by GBC may also be similar to cholecystitis. The accurate differential diagnosis between GBC and cholecystitis poses a significant clinical challenge, as it directly impacts the treatment and prognosis of patients. The aim of this study is to develop and validate radiomics based on 2-[18F]fluoro-D-glucose positron emission tomography (2-[18F]FDG PET/CT) parameters for differentiating between non-metastatic gallbladder cancer (GBC) and cholecystitis. ***Materials and Methods:*** A total of 108 patients with non-metastatic GBC and 33 patients with cholecystitis confirmed by pathological examination were included in our study. The patients were allocated into a training group and a testing group in a ratio of 7:3. The radiomics features extracted from 2-[18F]FDG PET/CT were subjected to analysis, with the utilization of the mRMR and LASSO regression algorithm for data dimension reduction. The clinical, radiomics and combined models were constructed. The receiver operating characteristic (ROC) curve and decision curve were plotted to assess the differentiating performance and the diagnostic performance measures were assessed by sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV). The DeLong test was used to compare the ROC curves of the combined model, radiomic model and clinical model in both groups. ***Results:*** The area under curve (AUC) of the clinical model and radiomics model was 0.754 (sensitivity=0.513, specificity=0.917) and 0.940 (sensitivity=0.882, specificity=0.875) in the training group, respectively; 0.691 (sensitivity=0.938, specificity=0.333) and 0.906 (sensitivity=0.781, specificity=1.000) in the testing group, respectively. In combined models, the AUC was 0.964, the sensitivity was 0.781 and the specificity was 1.000 in the training group; the AUC was 0.938, the sensitivity was 0.908 and the specificity was 0.958 in the texting group. ***Conclusion:*** The radiomics based on 2-[18F]FDG PET/CT could effectively distinguish non-metastatic GBC from cholecystitis; combining radiomics and clinical variables could more effectively differentiate non-metastatic GBC from cholecystitis. The combined prediction model can serve as potential decision support tools and avoid more patients receiving unnecessary treatment.

EPS-101

Can tumor-to-liver (T/L) ratio predict progression free survival in patients with post-chemotherapy seminoma residual

S. Ghosh[1], *A. Agrawal[2], V. Rangarajan[2], S. Choudhury[1];*
[1]ACTREC, Tata Memorial Centre, Navi Mumbai, INDIA, [2]TMH, Tata Memorial Centre, Parel, Mumbai, INDIA.

Aim/Introduction: To predict progression free survival using tumor-to-liver ratio in patients with residual seminomatous disease post-chemotherapy. ***Materials and Methods:*** Patients with a residual mass of ≥3cm on post chemotherapy FDG PET/CT scan were included in the study. The ratio of SUVmax for the lesion to that of the normal liver which is the tumor-to-liver ratio was calculated for each patient. An ROC plot of the T/L ratio was made to get an optimum cut-off value. For determining the progression free survival (PFS), the duration from date of FDG PET/CT scan to the date of last follow-up/progression was calculated. The T/L ratio cut-off value was then used to study the difference in PFS between the 2 groups using the Kaplan-Meier analysis and the p-value obtained from log-rank test. ***Results:*** 49 male patients with were included in the study. All patients had their FDG PET/CT scan done between 8-12 weeks of chemotherapy. Lesions were ≥3cm. SUVmax for the residual lesion and the normal liver was determined which was used for calculation of T/L ratio. The ROC plot of T/L ratio had an AUC of 87.9%. The maximum Youden's index was 0.795, at which the T/L ratio cut-off was 1.21. 23 patients had T/L ratio ≤1.21 and this group had only 1 event. Whereas, 26 patients had T/L ratio >1.21 with 7 events. The p value is 0.037. Since the total no-of events was less than 50%, median PFS was not reached. ***Conclusion:*** The residual masses in seminoma post chemotherapy might just harbor non-viable fibrotic tissue and thus T/L ratio is a very robust method to determine viable disease in such masses. Majority of the events occurred when the T/L ratio was >1.21. Thus, this cut-off value can be utilized to determine the viability in residual seminomatous diseases and also be an added prognostic factor. ***References:*** 1. Ghosh, Suchismita; et al. Evaluation of post-chemotherapy residual seminomatous masses by [18]F-fluorodeoxyglucose PET/CT using tumor-to-liver ratio - conundrum or solution? EPS-102

[68Ga]Ga-FAPI-04 PET/MR imaging strategy for Krukenberg tumours from gastric signet-ring-cell carcinoma

T. Wang, *G. Huang, J. Liu;*
Department of Nuclear Medicine, Ren Ji Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA.

Aim/Introduction: To compare performance of whole-body [68Ga]Ga-FAPI-04 and [18F]FDG PET imaging in the detection of Krukenberg tumors (KTs), primary site and extra-ovarian metastases of gastric signet-ring-cell carcinoma (GSRCC), and evaluate the value of [68Ga]Ga-FAPI-04 PET/MR imaging strategy in the assessment of KTs from GSRCC. ***Materials and Methods:*** Twelve patients with twenty-three KTs from GSRCC, who underwent both [68Ga]Ga-FAPI-04 pelvic PET/MR and whole-body [68Ga]Ga-FAPI-04 and [18F]FDG PET imaging were retrospectively analyzed. [68Ga]Ga-FAPI-04 and [18F]FDG uptakes were compared by using Wilcoxon signed-rank test or paired t tests. McNemar's test was used to compare diagnostic accuracy and lesion detectability between two modalities. Two-tailed P<0.05 was considered statistically significant. Immunohistochemistry staining was utilized to analyze the fibroblast activation protein (FAP) expression in KTs. ***Results:*** A total of 12 patients with 23 KTs from GSRCC (8 synchronous and 4 metachronous) were evaluated. [68Ga]Ga-FAPI-04 was superior to [18F]FDG PET in detecting primary sites of GSRCC (100% [11/11] vs. 18.2% [2/11], p = 0.002), involved lymph nodes (90.9% [10/11] vs. 54.5% [6/11], p=0.046) and peritoneal metastases (100% [12/12] vs. 41.7% [5/12], p=0.008), with higher SUVmax and TBR (all p < 0.005). Both tracers had limited value in identifying KTs, with 100% false negative rate on [68Ga]Ga-FAPI-04 PET and a low detection rate of 8.7% on [18F]FDG PET. Fap immunohistochemistry showed negative or slight FAP expression in neoplastic signet ring cells and ovarian stroma. [68Ga]Ga-FAPI-04 PET/MR imaging strategy greatly improved the detection rate of Krukenberg tumors (87%, 20/23). After adding diffusion-weighted imaging (DWI), the detection rate was further improved (87.5% vs. 100%, p=0.083). [68Ga]Ga-FAPI-04 PET/MR imaging strategy either upgraded TNM staging or changed treatment management in twelve patients. ***Conclusion:*** [68Ga]Ga-FAPI-04 PET outperformed [18F]FDG PET in detecting primary site (primary tumor and local recurrence) and most extra-ovarian metastases of GSRCC, but both tracers had limited value in identifying Krukenberg tumors. Pelvis MRI potentially compensates for the limitation of [68Ga]Ga-FAPI-04 PET imaging in identifying Krukenberg tumors. [68Ga]Ga-FAPI-04 PET/MR imaging strategy significantly improved the detection rate of Krukenberg tumors from GSRCC.

EPS-103

Cross-Sectional Analysis of Metabolic Tumor Burden Detected by F18 FDG PET/CT and Circulating Tumor DNA in Advanced Breast Cancer

R. Tokac, *E. Bayram Tokac, A. Aykut, A. Durmaz, H. Akin, U. Yararbas, A. Argon;*
Ege University, Izmir, TÜRKIYE.

Aim/Introduction: Liquid biopsy is favoured for its non-invasive nature and its significant role in the prognosis of advanced breast cancer. The variant allele frequency (VAF) reflects the mutation rate in circulating tumour DNA (ctDNA), with the maximum VAF (VAFmax) expected to increase with increasing tumour burden. The correlation between metabolically active tumour burden as assessed by FDG PET/CT and prognostic factors in breast cancer has been established. This study retrospectively examines the correlation between VAFmax, mutation status and metabolic tumour burden. ***Materials and Methods:*** Of 83 patients with stage 4 breast cancer who underwent liquid biopsy, 40 also received FDG-PET/CT imaging without concurrent treatment. The mean age of the patients was 44.05 ± 10.72 years, and the mean interval between FDG PET/CT and liquid biopsy was 14.7 ± 12.99 days. Whole-body FDG-PET/CT imaging was performed after FDG administration according to guidelines, together with low-dose CT imaging. Images were analysed and MTV, TLG, SUVmax and SUVmean were calculated. Peripheral blood samples underwent NGS analysis using the AVENIO cfDNA Isolation Kit for ctDNA analysis, mutations and VAFmax determination. Statistical analysis was performed using SPSS 29 software. ***Results:*** The mean SUVmax, SUVmean, MTV and TLG were 13.58 ± 5.96, 5.29 ± 2.08, 161.71 ± 269.55, 759.42 ± 1281.99, respectively. ctDNA was detected in 23 patients (57.5%) by liquid biopsy, with a mean VAFmax of 10.56 ± 0.2%. Of these, 5 (12.5%) had 1 mutation, 10 (25%) had 2 mutations, 6 (15%) had 3 mutations and 1 patient (2.5%) had 4 and 5 mutations respectively. The median number of mutations was 1.36. Statistical analysis revealed higher MTV (p: 0.026) and TLG (p: 0.039) in patients with detected ctDNA. Weak but positive correlations were found between VAFmax and MTV (r: 0.375, p: 0.017), TLG (r: 0.356, p: 0.024), SUVmax (r: 0.381, p: 0.015). Positive correlations were observed between the number of mutations and MTV (r: 0.457, p: 0.003) and TLG (r: 0.373, p: 0.018). The association between number of mutations and MTV (p: 0.001) and TLG (p: 0.006) became stronger with 2 or more mutations. The association between SUVmean and VAFmax and between SUVmax and SUVmean with mutation status was statistically insignificant. ***Conclusion:*** This study highlights the relationship between VAFmax, mutation status and metabolic tumour burden. The combination of FDG-PET/CT with liquid biopsy may help to develop prognostic algorithms for advanced breast cancer and guide future testing to benefit specific groups.

EPS-104

Role of PET/MRI n diagnosis and prognosis of hepatocellular carcinoma using two metabolic tracers: F18-FDG and F18 FEC

M. Nejabat, *T. Servus, A. Ba Ssalamah, L. Beer, G. Karanikas, M. Hacker, S. Rasul;*
Radiology & Nuklearmedizin, Wien, AUSTRIA.

Aim/Introduction: To evaluate the diagnostic and prognostic benefit of PET/MRI examination using two metabolic tracers, [18F]-fluorodeoxyglucose (FDG) and [18F]-fluoroethylcholine (FEC) in HCC patients and to clarify whether there is a correlation between the tumour marker alpha-fetoprotein (AFP) and the uptake of both tracers in the tumour ***Materials and Methods:*** In this retrospective study, we included 30 patients who were referred to the Department of Radiology and Nuclear Medicine, Division of Nuclear Medicine, Medical University of Vienna (MUW) between December 2014 and September 2017 with a suspected diagnosis of HCC for further diagnostics. Each patient received a diagnostic PET/MRI scan with both tracers. Clinical and para-clinical data such as various PET parameters in term of standardized uptake values of the tumour as well as radiological parameters in terms of contrast media enhancement and the diffusion restriction of the liver lesions were collected. ***Results:*** The suspicion of malignancy was confirmed in 25 of 30 patients. FDG-PET/MRI showed diagnostic accuracy of 83.3% (sensitivity 92.0%, specificity 40.0%), and the FEC alone showed a diagnostic accuracy of 75.9% (sensitivity 87.5%, specificity 20.0%). The combination of both tracers showed diagnostic accuracy of 93.1% with a sensitivity of 95.8% and a specificity of 80.0%. In terms of survival, disease progression occurred in a total of 14 patients (46.7%) with a median follow-up of 52.4 ± 29.4 weeks, of whom 11 (64.7%) were graded G2 and 3 were diagnosed with HCC based on imaging features. Progression could not be assessed in the two G4 patients.There was a correlation between AFP and SUVmax for FEC in tumour tissue (p=0.050), SUVmax for FDG in tumour tissue (p=0.009), SUVmean for FDG in tumour tissue (p=0.004) and TLR for FDG (p=0.019).

Conclusion: According to our results, combined PET/MRI with FDG and/or FEC seems to have good potential for improving the diagnosis of HCC. Taking histology results into account, FDG was shown to be slightly better than FEC at detecting HCC.

EPS-105

Potentials of [18F]FDG PET/CT for the Assessment of Pathological Response to Neoadjuvant Therapy in Breast Cancer: A Prospective Study

F. Gelardi[1,2], *R. De Sanctis[3,4], P. Tiberio[4], R. Zanca[3,4], B. Fernandes[4], M. Rodari[4], A. Chiti[1,2], M. Sollini[1,2], L. Antunovic[2];*
[1]Università Vita-Salute San Raffaele, Milano, ITALY, [2]IRCCS Ospedale San Raffaele, Milano, ITALY, [3]Humanitas University, Pieve Emanuele (MI), ITALY, [4]IRCCS Humanitas Research Hospital, Rozzano (MI), ITALY.

Aim/Introduction: Pathological complete response (pCR) to neoadjuvant chemotherapy (NAC) is a milestone in breast cancer (BC) management to identify patients with better prognosis. The revolutionary new frontier is to omit surgery in selected cases with an excellent response to NAC, improving patient outcomes and cost-effectiveness. Residual Cancer Burden (RCB) is a new approach to standardising the response to NAC. In addition, RCB accurately predicts recurrence and survival across BC subtypes. We investigated the potential utility of [18F]FDG PET/CT as a non-invasive predictive tool to assess response to NAC in BC patients prior to surgery. ***Materials and Methods:*** We prospectively enrolled patients with newly diagnosed BC who were candidates for preoperative NAC. All patients underwent baseline and preoperative [18F]FDG PET/CT. Clinicopathological data were collected. Response to NAC was defined as pCR or non-pCR on final histopathology, supplemented by RCB index assessment. Semiquantitative PET parameters (baseline, preoperative and delta absolute and tumour/background SUVs) were extracted from the primary tumour on baseline and preoperative PET/CT scans. The Kruskal-Wallis test was used to assess differences between groups. The Bonferroni test was used to correct for multiple comparisons. Multivariate logistic regression analysis was performed to identify potential predictors of response to NAC. Statistical significance was set at $p<0.05$. ***Results:*** We included 134 BC patients, predominantly with HER2-positive disease (n=74) and stage II disease (n=104). Sixty-nine patients achieved pCR after NAC and the RCB index was assessed in 130/134 patients. Baseline SUVmax correlated with tumour aggressiveness according to BC subtype, HER2 expression, ki-67, and tumour grading ($p<0.001$). Among all parameters, preoperative SUVmax was superior in identifying responders to NAC (pCR 1.2 vs non-pCR 1.8; $p<0.001$) and discriminating between different RCB classes (1.2 vs 1.5 vs 1.7 vs 3.9 for RCB-0, I, II, III, respectively; $p<0.001$); similar results were obtained according to BC subtype and HER2 expression. The best performance was seen in TNBC and HER2-negative BC ($p<0.001$ for both). Multivariate logistic analysis identified preoperative SUVmax as a significant predictor of pCR (OR 0.26; $p<0.001$) and RCB class (OR 4.2; $p<0.001$). ***Conclusion:*** Semi-quantitative parameters derived from preoperative [18F]FDG PET/CT are promising predictors of response to NAC in BC patients who are candidates for surgery across different BC subtypes. Our results push the boundaries of BC management and promote the integration of [18F]FDG PET/CT into the decision-making process for preoperative non-invasive assessment of response to NAC.

Technologists' Track Oral Presentations 2: Technologists Committee: Diagnosis and Therapy

OP-311

Confirming patient cohort dose rate demographics to allow personalised restrictions following 177Lu Oxodotreotide therapy

F. Hogg;
Gartnavel General Hospital, Glasgow, UNITED KINGDOM.

Aim/Introduction: The Beatson West of Scotland Cancer Centre (BWoSCC) provides a National service for the treatment of NETs using 177Lu oxodotreotide. Therapy patients are treated as inpatients with an overnight stay and receive standardised restrictions on discharge to reduce exposure to members of the public. These restrictions are based on the 95th percentile retention rate determined by Levart1. The aim of this work is to use dose rate measurements of therapy patients at the time of administration and discharge for comparison with published results and to allow a personalised approach to restrictions based on their estimated retention at discharge. ***Materials and Methods:*** Data from 289 patients (143 male & 146 female) were reviewed including dose rates taken at 1m and 2m, both immediately post administration and 24hours post administration, and patient BMI. Patients are typically prescribed 7400MBq per administration. Dose rates were normalised for activity and for BMI. Patients BMI range from 13.5kg/m2 to 42kg/m2 (average from males = 27.2 kg/m2; females = 27.1 kg/m2). ***Results:*** The patients had a mean administered dose of 7435MBq (range 3700MBq-8067MBq). The ratio of dose rates from 2m to 1m was found to be 3.4±0.1 The average retention at discharge was found to be 25%. This compares with an average retention of 24% reported by Levart. Patient dose rates normalised for activity were plotted against BMI with trendlines suggesting a similar relationship between both sexes. Unlike previous work by Bellamy2, there was no statistically significant difference between the dose rates of females and males either with (p-value=0.133) or without (p-value=0.565) normalisation for BMI. ***Conclusion:*** By establishing similar retention levels at discharge, we can use the range of retention rates described by Levart to allow more personalised patient restrictions. ***References:*** 1 Radiation precautions for inpatient and outpatient 177 Lu-Dotatate peptide receptor radionuclide therapy of neuroendocrine tumours D.Levart, E.Kalogianni, B Corcoran, N Mullholland and G.Vivian. Radiomic analysis on 177Lu-DOTATATE post-treatment scans: imaging optimization and whole body-SPET radiomics comparison

F. Montanini[1], *A. Monaci[1], S. Valente[1], V. Briganti[1], E. M. Abenavoli[1], D. Lavacchi[1], L. Antonuzzo[1], D. Volterrani[2], G. Boni[2], V. Berti[1];*
[1]Azienda Ospedaliero-Universitaria Careggi, Florence, ITALY, [2]Azienda Ospedaliero-Universitaria Pisana, Pisa, ITALY.

Aim/Introduction: While the majority of radiomics research on neuroendocrine tumors (NETs) has concentrated on 68Ga-DOTATOC PET images, there is a rising interest in extending radiomics to conventional nuclear medicine imaging. Tipically, 177Lu-DOTATATE RadioLigand therapy (RLT) includes a whole-body planar and an abdominal SPET acquisition. The goal of this study is to optimize the standard procedure for extracting radiomic profiles from planar imaging and to compare planar and SPET radiomics. ***Materials and Methods:*** We conducted a retrospective analysis on 49 patients, from two different centers, affected by well-differentiated progressive, metastatic gastroenteropancreatic NET. All patients received RLT and underwent whole body scans (WBS) 0-2 days after each treatment cycle. We examined a total of 183 WBS and 108 SPETs, all acquired on three dual-headed gamma camera (Siemens E.Cam, GE Discovery NM 630, GE Discovery NM/CT 670). Preprocessing operations included image intensity normalization to ensure all scans were comparable. This was done, using ImageJ software, by dividing each image by the mean counts value of a ROI positioned on the same anatomical region for each patient: the two selected regions were the spleen (S-norm) and the 3rd lumbar vertebra (V-norm). Patients' livers were then manually segmented in LIFEx 7.6.0. Default settings were chosen for texture features extraction. ***Results:*** Texture extraction was performed on all planar and SPET images from one center, given the ongoing nature of the study. Correlations between intensity-based features measured on S-norm and V-norm images showed weak, yet statistically significant r values. Conversely, the correlation between histogram-based and 2nd order features measured on S-norm and V-norm images demonstrated a robust association, reflected in high r values. V-norm intensity-based features exhibited significantly higher values and lower standard deviations when compared to S-norm intensity-based variables. When comparing features measured on planar and SPET scans, a strong correlation was observed between intensity-based variables, whereas the correlation between histogram-based and 2nd order features was not significant. ***Conclusion:*** Initial findings indicated that the most effective intensity normalization approach for 177Lu-DOTATATE images involved proportional scaling to lumbar vertebra activity, resulting in decreased variability compared to scaling to spleen activity. Correlations between features assessed using the two different scaling methods were weak for intensity-based features and strong for histogram and 2nd order features. Except for intensity-based features, radiomic features derived from planar images were found to be incomparable to those obtained from SPET scans.

OP-313

Isolated Limb Perfusion and Nuclear Medicine: How I do it

C. Noé, *P. Ferreira, M. Matter, J. O. Prior;*
CHUV, Lausanne, SWITZERLAND.

Aim/Introduction: Isolated limb perfusion (ILP) is an option for the treatment for with limb soft tissue sarcoma patients, whose removal is risky (neoadjuvant ILP) or impossible (exclusive ILP). Surgical resection of a sarcoma is often difficult and must be done with a safety margin of healthy tissue to avoid the risk of recurrence and later formation of metastasis. In the event the sarcoma has not been removed with enough margins, or with tumoral tissue left in place, a new conventional surgery may not be the best treatment, as it may lead to sacrifice important anatomical structures or even to amputation. ILP combines the administration of TNF (Tumor Necrosis Factor), Melphalan (chemotherapy) and hyperthermy (30°C) using nuclear medicine counting to ensure patient safety. We report on our 25-year experience with ILP and present this methodology in detail. ***Materials and Methods:*** ILP treats the whole affected limb and is performed by isolating the blood circulation with a tourniquet and the use of a heart-lung machine for extracorporeal circulation (ECC). This interrupts all exchanges between the blood circulation of the limb and the rest of the body. Very high doses of TNF and Melphalan can then be administered into the isolated circulation to treat the tumor. With the nuclear medicine, the injection of a Tc-99m Vasculocis (human albumin) in the ECC will monitor the possible threatening leakage of the TNF and Melphalan into the systemic circulation to avoid vital risk for the patient during the procedure. A calculation of the leakage rate can be made in real-time to keep a safe limit of 5%, otherwise the ECC must be immediately interrupted and the limb flushed with physiological solutions. ***Results:*** Between 2000-2023, 128 patients underwent ILPs, with 78 (61%) having a positive leakage from the limb to systemic circulation (mean 1.6%±1.48%, range: 0% to 5%) and 50 (39%) patients had no or negative leakage from the systemic circulation to the limb (mean -0.66%±0.95%, range: -4% to -0.1%). The ECC had to be interrupted in only in 3 cases (2.3%) because of leaks reaching 5% or more. ***Conclusion:*** ILP treatment to patients with sarcoma aims at obtaining a clinically relevant response while keeping their limb without detriment to overall survival. Controlling leaks using nuclear medicine helps avoid a vital risk for the patient and increase procedure safety during the administration of TNF and chemotherapy.

OP-314

The relevance of bone SPECT scintigraphy in the diagnosis and treatment of Unilateral Condylar Hyperplasia (UCH) in St. Antonius Hospital, the Netherlands

M. Schwillens-Dirkx, *P. Okletey, J. Lavalaye;*
St. Antonius Hospital, Nieuwegein, NETHERLANDS.

Aim/Introduction: Unilateral condylar hyperplasia is a growth disorder of the condylar mandibles and in some cases of the maxilla. This can result in facial asymmetry due to the disproportional growth of the condyles on one side of the face. There are no known causes of UCH and the growth rate of the affected side of the face is indeterminable. Bone SPECT scintigraphy is regarded as a useful tool in the diagnosis and treatment of UCH by the dental surgeons. With hyperactivity of the affected condyle, a condylectomy is performed to stop the growth disorder. This retrospective analysis was performed to assess outcome of SPECT imaging and clinical decision making. ***Materials and Methods:*** Patients with suspected UCH were intravenously injected with Tc-99m DPD. After an incubation period of 3-4 hours a SPECT scan of the head was acquired using a Siemens dual head gamma camera in a 128 x 128 matrix, a 180 degrees rotation and 45 seconds per view. Because of ALARA in a young patient group, no SPECT/CT was performed. In the quantitative analysis of the 3D reconstruction, a VOI of fixed volume (1.76) was drawn in the right and left condyle. A 10% difference in mean counts was diagnosed as positive UCH. ***Results:*** Between 2019 and 2023 bone SPECT was performed on 103 patients with suspected UCH, 55 females and 48 males. The age ranged from 9 to 52 years, the mean±SD was 19.3±7.4 years. Bone SPECT was positive in 49 patients, negative in 35 patients and discongruent in 19 patients. SPECT was classified discongruent when the results were inconsistent with the clinical findings and the mean activity

at the contralateral condyle exceeded 10%. Repeated bone SPECT in two patients with discongruent results, showed a negative result. Condylectomy was performed in all patients with a positive SPECTscan. Histopathological specimens of the resected condyles showed no abnormalities, no reoperations were performed during follow-up and no significant differences related to sex and age were found. ***Conclusion:*** In our hospital a positive bone SPECT is the main criterion for performing a condylectomy in suspected UCH. If the SPECT result is negative or discongruent, a condylectomy is not performed. Discongruence can be explained by extinguished UCH with compensatory growth or catch-up growth. Compared to literature our rate of discongruence is quite high so repeating the bone SPECT in case of discongruence after at least six months is to be considered.

OP-315

Evaluation of Treatment Efficacy of Radioactive Iodine-131 Treatment for Feline Hyperthyroidism: Western Australian experience.

S. Tagore[1], *P. Tually[1], G. Currie[2], N. Reid[3];*
[1]TeleMedVET, Perth, AUSTRALIA, [2]Charles Sturt University, Wagga Wagga, AUSTRALIA, [3]Epsom Ave Small Animal Clinic, Perth, AUSTRALIA.

Aim/Introduction: This study aimed to evaluate how 99mTc-Pertechnetate scintigraphy informed 131I therapy (RAI) dose determination in treating feline hyperthyroidism. 131I dose determination was calculated based on the percentage uptake and adjusted using a morphology based weighting factor. ***Materials and Methods:*** This was a retrospective internal quality audit following standard of care. A total of 65 cats were treated during the evaluation period. Pre-treatment clinical examination including baseline haematology, serum biochemistry, urinalysis, and resting thyroxine (T4) was performed by a dedicated Veterinarian to assess suitability for scintigraphy and potentially 131I therapy. Where appropriate, thyroid medication was withdrawn 2 weeks prior to appointment. Planar and SPECT imaging was performed to calculate uptake values and assess thyroid morphology. 131I was administered subcutaneously and titrated against an established dose algorithm. The cats remained in a feline purpose-built facility post-treatment until dose reading (at 1m) fell below 1µSv/hour. ***Results:*** Forty-one of sixty-five cats had post-therapy follow-up and represent the following analysis. Study demonstrated a success rate of 90.2% with euthyroid achieved by 6 months post RAI. Post therapy T4 level had a mean of 34.3 nmol/L and the mean change in T4 was 66.2%. Prior to therapy, the mean T4 levels were 102 nmol/L with a range of 9-257 nmol/L with 87.8% of cats above the normal range (13-48 nmol/L). 131I dose ranged between 94MBq-219MBq. There was no statistically significant difference in morphology based on age, gender and 131I dose. While there was no statistically significant variations in baseline T4 or percentage uptake among bilateral symmetrical, bilateral asymmetrical and unilateral disease, ectopic disease had statistically higher T4 (P=0.0176) and uptake (P=0.0002), and all values in or below the T4 normal range were unilateral. ***Conclusion:*** Our West Australian experience demonstrates the feasibility and effectiveness of using 99mTc-Pertechnetate scintigraphy to guide 131I dose determination in the treatment of feline hyperthyroidism. While optimising dose for individual cats provides improved outcomes over standard dosing approaches, there remains room to refine the algorithm used to determine individual 131I doses. ***References:*** Alonzi, C. et al. Scan speed reduction in post-therapy [177Lu]Lu-PSMA SPECT/CT: How fast can we go without affecting accuracy of dosimetry calculations?

G. Post, *J. F. Homan, W. Noordzij, O. V. Ivashchenko;*
UMCG, Groningen, NETHERLANDS.

Aim/Introduction: Accurate dose estimation in [177Lu]Lu-PSMA therapy is crucial for organs at risk such as the kidneys. However, the current method involves lengthy scans, causing discomfort for patients with bone metastases common in prostate cancer, financial pressure and image quality problems due to the motion. Our research aims to optimise this process by investigating acceptable scan reduction while maintaining the accuracy of the calculate dose to organs at risk. ***Materials and Methods:*** A total of 11 post-therapy imaging sequences from patients undergoing [177Lu]Lu-PSMA therapy were selected. For each, two post-therapy SPECT/CT scans, performed at 1- and 7-days post-administration of 7.4 GBq of [177Lu]Lu-PSMA were used. The SPECT projection data was acquired using a dual-head camera with a 3/8" NaI detector, medium-energy collimator, an energy window centred at 208 keV, and a lower scatter window, 64 projections per detector, 14 seconds per projection, covering two field of views (FOVs). To simulate shorter scan durations, the original projections were downgraded to 75%, 50%, and 25% of the counts using Hermes Hybrid reconstruction software. Subsequently, each set of projections was reconstructed using Monte Carlo-based OSEM algorithms, incorporating calibration factors for 177Lu quantification. Kidney dosimetry was performed using a mono-exponential model using the ICRP-103 phantom with the Olinda 2.0. The resulting absorbed kidney doses, mean activity and noise level in the kidneys was calculated for all cases. ***Results:*** The relative difference in the calculated absorbed dose for kidneys, when compared to the initial acquisition, was -1.2±3.6, 0.5±3.0, and 0.6±3.7%, for 75%, 50%, and 25% scans, respectively. Activity concentration values in the kidney have changed by an average of 2.0±2.5, 2.4±3.1 and 3.5±4.4%, for 75%, 50% and 25% scans on day 1, and 3.3±6.7, 6.8±11.2, 7.4±12.0%, for day 7 scans. At the same time, the noise propagation of reduced scans on day 7 (9.1, 25.7 and 63.85% increase for scans with 75%, 50% and 25% of counts) was significantly higher than that of day 1 (2.1, 6.4 and 8.9%).*with respect of the original scan with 64 projections/detector, 14s/projection scan ** average ± standard deviation for 11 post-therapy imaging sequences ***Conclusion:*** Our findings demonstrate the feasibility of reducing the scan duration of post-therapy [177Lu]Lu-PSMA scans to 3.7 (25%) and 11.2 (75%) minutes per bed position for day 1 and day 7, respectively, without significantly compromising the accuracy and uncertainty of the post-therapy dose calculation for kidneys.

OP-317

One-Stop-Shop SynNeurGe assessment - Feasibility of a single-day protocol using [^{123}I]-Ioflupane single-photon-emission-computed tomography and cardiac [^{123}I]-Meta-Iodobenzylguanidine scintigraphy in patients with suspected Parkinson's disease

E. Schröder[1], *R. Wagner[1], J. Gnörich[1], S. Kunte[1], S. Katzdobler[2,3,4],*

C. Palleis[2,3,4], A. Bernhardt[2], A. Jäck[2], J. Levin[2,3,4], G. Höglinger[2,3,4], M. Brendel[1,3,4], M. Scheifele[1];
[1]Department of Nuclear Medicine, LMU Hospital, Ludwig-Maximilians-University of Munich, Munich, GERMANY, [2]Department of Neurology, LMU Hospital, Ludwig-Maximilians-University of Munich, Munich, GERMANY, [3]German Center for Neurodegenerative Diseases (DZNE) Munich, Munich, GERMANY, [4]Munich Cluster for Systems Neurology (SyNergy), Munich, GERMANY.

Aim/Introduction: Due to new advances in molecular and imaging biomarkers, a biological classification of Parkinson's disease (PD) called SyNeurGe [1] has been proposed for research use recently. [123I]-Ioflupane dopamine transporter single-photon-emission-computed tomography (DaT-SPECT) and cardiac [123I]-Meta-Iodobenzylguanidine (MIBG) scintigraphy are included in this biological classification scheme as central imaging biomarkers for the assessment of dopaminergic function and cardiac sympathetic denervation. In order to fulfill this prospectively high imaging demand and optimize diagnostic workup we propose a single-day protocol including DaT and MIBG imaging. ***Materials and Methods:*** We performed a single-day protocol including DaT-SPECT and cardiac MIBG scintigraphy in five patients with clinically diagnosed α-synucleinopathies (4 male; 69.0±8.8 years). The radiotracers were injected simultaneously and cardiac imaging was performed at 3.5 hours after injection followed by brain imaging at 4 hours after injection using standard protocols for MIBG-scintigraphy and DaT-SPECT. In order to exclude relevant binding of MIBG in the brain as well as DaT in the heart we also performed brain scans in MIBG patients as well as chest scans in DaT patients. ***Results:*** Four out of the five patients which were suspected of PD or multiple systems atrophy with Parkinsonian phenotype (MSA-P) showed a significantly reduced DaT-SPECT binding (z-score < -2) in at least one hemisphere (mean z-score: -4.1±1.25) as well as a pathological heart to mediastinum ratio in the MIBG scan (mean H/M ratio: 1.3±0.26). Interestingly the patient with a normal DaT and MIBG scan (mean z-score: -1.58; H/M ratio: 2.29) was clinically suspected of MSA with cerebellar phenotype (MSA-C). Both DaT and MIBG scans could visually be interpreted without any signs of imaging artifacts or decrease in imaging quality. Single tracer imaging confirmed no relevant uptake of [123I]-Ioflupane in the heart or [123I]-MIBG in the brain. ***Conclusion:*** A single day protocol for DaT and MIBG imaging facilities efficient biological characterization of Parkinsonian syndromes. An additional brain FDG-PET scan may be added after dual SPECT imaging to obtain all SyNeurGe neurodegeneration criteria at one day. ***References:*** 1. OP-318

[18F]Fluorocholine PET/CT significantly reduces the amount of negative scan results compared to [99mTc]-sestamibi and [99mTc]-pertechnetate scintigraphy SPECT/CT

M. Rode, *H. Reilev Moeller, L. Lange Oestergaard, P. Holdgaard; Lillebaelt Hospital, University Hospital of Southern Denmark, Vejle, DENMARK.*

Aim/Introduction: [99mTc]-sestamibi and [99mTc]-pertechnetate scintigraphy SPECT/CT (Tc-99m) has previously been the preferred method for locating potential parathyroid adenomas in patients with hyperparathyroidism. This procedure however is time-consuming, contributes to a high radiation dose and has a reported moderate detection rate in the literature: 61-88% and many negative exams. [18F]fluorocholine PET/CT (FCH) is a newer procedure with a reported detection rate: 73-97%. High detection rates are important as it enables precise surgical interventions, thus reducing the number of bilateral neck explorations (BNE). The aim of this study was to compare the number of negative scan results between FCH as a replacement of Tc-99m in patients with hyperparathyroidism. ***Materials and Methods:*** Two groups, each consisting of 82 consecutive patients, had scan results compared. The first group were FCH patients; the second group were the last 82 Tc-99m patients prior to the implementation of FCH. Image acquisitions were on a conventional dual-headed gamma camera for planar subtraction, wash-out, SPECT/CT for Tc-99m. FCH was with a LSO/SiPM-based (249 ps. timing resolution) PET/CT system. The scan results had three categories: Negative with no adenomas reported, clearly positive or equivocal with a possible adenoma reported. The difference in reported detection rates between scan-types were analysed using a Chi2 test. FCH findings were compared with histopathology. ***Results:*** The number of patients where the image acquisition failed to detect a potential parathyroid adenoma (negative) was 5 (6%) for FCH compared to 34 (42%) for Tc-99m. Patient scans reported as positive were 59 (72%) for FCH and 22 (27%) for Tc-99m, and equivocal findings were reported in 18 patients (22%) for FCH compared to 26 patients (32%) for Tc-99m. In addition, four patients had a negative Tc-99m SPECT/CT initially and were re-referred for FCH, were three scans now showed a possible adenoma. FCH significantly reduced the number of negative scans and increased the number of positive scans (p<0.00001). Fifty FCH patients had 51 adenomas removed were FCH correctly identified 50 (98%). ***Conclusion:*** In patients with hyperparathyroidism, using FCH leads to a significantly better performance than Tc-99m. In addition, FCH is able to locate parathyroid adenomas in patients with a previous negative SPECT/CT. The very low number of patients with a negative FCH compared with Tc-99m is clinically very important when considering implementing FCH, as it signifies numerous patients avoid BNE and only have to undergo minimal invasive surgery.

Evaluation of a reduced dose 123I-Ioflupane in patients examined with SPECT for clinically uncertain parkinsonism

G. Abell[1], *S. Skauge[1], T. Keil[1], S. Øen[1], A. Karlberg[1,2];*
[1]Department of Radiology and Nuclear Medicine, St. Olavs hospital, Trondheim University Hospital, Trondheim, NORWAY, [2]Department of Circulation and Medical Imaging, Norwegian University of Science and Technology, Trondheim, NORWAY.

Aim/Introduction: Dopamine transporter imaging with 123I-Ioflupane is regularly used in patients with clinically uncertain Parkinsonian Syndromes. EANM/SNMMI guideline recommends administering 110-250 MBq and acquiring > 1.5 Mcts in the SPECT images for this examination. The aim of this retrospective study was to evaluate if halving the dose of 123I-Ioflupane (from 185 MBq to 92.5 MBq) affects the reported diagnoses in these patients. ***Materials and Methods:*** 485 patients were included in this study. SPECT-acquisitions (180 min post injection) were performed on a dual head digital SPECT/CT-system with wide energy high resolution parallel-hole collimators, 159 keV±10% energy window, 30 sec/frame, 11-15 cm rotational radius, 360° rotation and 3° angular step. The «standard-dose group» (n=277) and the «half-dose group» (n=208) were compared for discrepancies. The nuclear medicine physicians' reported diagnoses were categorized into «normal», «pathological» or «uncertain». Striatal binding ratios (SBR) for striatum (L/R), putamen (L/R) and caudatus

(L/R) were assessed for quantitative analysis. A Z-test was used to compare differences in proportions between reported diagnoses in the standard-dose group and half-dose group, and the Mann-Whitney U test were applied to compare differences in SBR between patients reported as normal and pathological. An alpha level of 0.05 were used for all statistical tests. ***Results:*** The mean total detected events were 4.6±0.7 Mcts and 2.4±0.4 Mcts in the standard-dose group and the half-dose group respectively. The proportion of patients reported as normal increased significantly with half-dose compared to standard-dose (+0.10, 95%CI [0.01, 0.19], p=0.03), while the proportion of patients reported as pathological and uncertain decreased (-0.08, 95%CI [-0.17, 0.01], p=0.09 and -0.02, 95%CI [-0.07, 0.03], p=0.433, respectively). There were significant differences in median SBR between patients reported as normal and pathological for all regions in the standard-dose group (ΔSBR: 0.96-1.17, p<0.001). For the half-dose group, the differences in median SBR between patients reported as normal and pathological were smaller for all regions (ΔSBR: 0.17-0.48), causing significant differences only for striatum (L), putamen (L) and caudatus (L) (p<0.02). ***Conclusion:*** Half-dose of 123I-Ioflupane fulfills the guidelines' criteria of > 1.5 Mcts in the SPECT-images. However, a significant larger proportion of patients was reported as normal in the half-dose group compared to the standard-dose group. This was probably caused by a smaller difference in SBR values between patients reported as normal and pathological in the two groups, implying that half the dose caused a more difficult diagnostic situation for the physicians.

FAPi PET/CT in the assessment of myositis-related myocardial involvement
O. Kulterer[1], *K. Kastrati[2], T. S. Nakuz[1], H. Kiener[2], A. Göllner[1], H. Lechner-Radner[2], D. Aletaha[2], P. Mandl[2], M. Hacker[1];*
[1]Division of Nuclear Medicine, Department of Biomedical Imaging and Image-guided Therapy, Medical Uni, Vienna, AUSTRIA, [2]Division of Rheumatology, Department of Internal Medicine III, Medical University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: Idiopathic inflammatory myopathies (IIM) are rare autoimmune disorders marked by skeletal muscle weakness, atrophy, and consequent physical disability. These disorders often feature extramuscular involvement, manifesting in various complications such as arthritis, cardiac-, skin- or pulmonary involvement, underscoring the systemic impact of IIM (1). Previous research has indicated that patients with IIM-associated interstitial lung disease (ILD) have higher fibroblast activation as compared to non-ILD patients. The aim of our study was to investigate fibroblast activation in the myocardium of IIM-ILD patients with proven cardiac involvement, compared to patients with no previous cardiac history. ***Materials and Methods:*** We enrolled IIM patients with verified cardial involvement as demonstrated via cardiac magnetic resonance imaging (MRI). Additionally, we included patients with inflammatory bowel disease and thyroid carcinoma without known cardiac conditions. All patients underwent FAPi PET/CT imaging. We assessed cardiac FAPi uptake by calculating the target to background ratio (TBR), which involved measuring the maximum standardized uptake volume (SUVmax) of the heart and correcting it for the blood pool. ***Results:*** Among patients with IIM-ILD and confirmed cardiac involvement (n=5), there was a marked increase in TBRmax values as compared to patients undergoing [68Ga]68Ga-DATA5m.SA.FAPi PET/CT imaging for different medical conditions (n=10), p=0,02. This suggests a potential relationship between IIM-related cardiac involvement and increased fibroblast activation within the myocardium. ***Conclusion:*** Our data unveil a notable elevation in fibroblast activation among IIM patients with myocardial involvement as compared to control patients, indicating the potential of FAPi PET/CT as a valuable diagnostic tool for the detection of myocardial involvement in IIM cases. These findings suggest that FAPi PET/C imaging may serve as a tool to identify and assess cardiac complications in IIM patients, facilitating earlier diagnosis and more targeted management strategies. ***References:*** Kastrati K, Nakuz TS, Kulterer OC, Geßl I, Simader E, Mrak D, Bonelli M, Kiener HP, Prayer F, Prosch H, Aletaha D, Langsteger W, Traub-Weidinger T, Blüml S, Lechner-Radner H, Hacker M, Mandl P. OP-322
Patterns of myocardial fibroblast activation in patients with terminal heart failure scheduled for left ventricular assist device implantation
J. Diekmann[1], *A. Schöde[2], C. P. Czerner[1], D. Berliner[3], J. Hanke[2], J. T. Thackeray[1], J. D. Schmitto[2], A. Ruhparwar[2], J. Bauersachs[3], F. M. Bengel[1];*
[1]Hannover Medical School (MHH), Department of Nuclear Medicine, Hannover, GERMANY, [2]Hannover Medical School (MHH), Department of Cardiothoracic Surgery, Hannover, GERMANY, [3]Hannover Medical School (MHH), Department of Cardiology and Angiology, Hannover, GERMANY.

Aim/Introduction: Prior work described cardiac fibroblast activation protein (FAP) overexpression early after acute myocardial infarction and in response to pressure overload. Little is known about FAP patterns in end stage heart failure, which may have implications for outcome and response to left ventricular assist device (LVAD). ***Materials and Methods:*** 9 patients with end stage heart failure underwent PET/CT with 18F-Flurpiridaz and 68Ga-FAPI-46 directly prior to LVAD implantation (7 with ischemic cardiomyopathy, ICM, 2 with dilated cardiomyopathy, DCM). 18F-Flurpiridaz yielded regional perfusion defects, absolute flow (MBF) at rest and functional parameters. FAPI images were analyzed using volume-of-interest technique to determine SUV and extent of cardiac FAP-overexpression (FAP-volume). ***Results:*** Patients presented with high NT-proBNP (14430±15169ng/l) and low LVEF (19±5%). Mean global resting MBF was low (0.61±0.12ml/min/g). Variable FAPI uptake intensity was detected in the left ventricular myocardium (mean SUVpeak 3.1±0.9, range 1.8-4.6). Uptake in other organs (liver, spleen, bone marrow, lungs) was low. Myocardial FAP-volume correlated with creatine kinase (r=0.697, p=0.041) but not with NT-proBNP. Also, FAP-volume did not correlate with parameters of LV function including LVEF, volumes and mass, but showed a significant inverse correlation with

absolute resting myocardial blood flow (r=-0.704 , p=0.040). All 7 patients with ICM had resting perfusion defects. Despite long-term history of myocardial infarction (MI; 6/7 patients, time range 2mo-27yrs prior to PET), elevated FAP-uptake was present in the infarct area, matching the perfusion defect. One patient with history of MI (14 years ago) did not show FAP uptake in the perfusion defect area. In DCM, only one of two patients showed relevant yet diffuse myocardial FAP-expression in the absence of regional perfusion defects. ***Conclusion:*** Extent and severity of myocardial fibroblast activation is highly variable in patients with end stage heart failure scheduled for LVAD. Ongoing active replacement fibrosis in chronic infarct regions needs to be distinguished from interstitial fibrotic activity in viable myocardium. The impact of fibroblast activation patterns on the response to LVAD remains to be determined. Additionally, LVAD implantation provides access to tissue for future ex vivo validation.

Visualization and quantification of somatostatin receptor 2 ($SSTR_2$) and $\alpha_v\beta_3$ expression in cardiovascular disease (CVD): Analysis of [^{64}Cu]Cu-DOTATATE and [^{68}Ga]Ga-NODAGA-E[c(RGDyK)]2 (RGD) PET/CT scans from a Phase II trial cohort

H. A. Khare[1], *E. A. Carlsen[1], M. E. K. Jensen[1], M. Græbe[2], T. Binderup[1], R. S. Ripa[1], A. Kjær[1];*
[1]Cluster for Molecular Imaging, Copenhagen University Hospital – Rigshospitalet & Department of Biomedical Sciences, University of Copenhagen, Denmark, Copenhagen, DENMARK, [2]Vascular Research Unit, Department of Vascular Surgery, Rigshospitalet, Copenhagen, DENMARK.

Aim/Introduction: Inflammation and angiogenesis play pivotal roles in the development of atherosclerosis. PET tracers, such as [64Cu]Cu-DOTATATE (64Cu-DOTATATE) and [68Ga]Ga-NODAGA-E[c(RGDyK)]2 (68Ga-RGD), allow non-invasive visualization of somatostatin receptor subtype 2 (SSTR2) and αvβ3 integrin expression, which respectively represent inflammation and angiogenesis(1,2,3). The objective of this study was to explore the suitability of two PET-tracers, 64Cu-DOTATATE and 68Ga-RGD, for detection and quantification of cardiovascular disease (CVD). ***Materials and Methods:*** A total of 52 patients were PET/CT scanned with 64Cu-DOTATATE & 68Ga-RGD. The patients were divided in two groups as 'Control' and 'CVD'. Patients in the control group (N=27) did not have any known CVD or risk factors, e.g. diabetes or hypercholesterolemia. In the other group (N=25), patients either had known CVD or risk factors. Retrospective analysis of the scans involved calculating the mean maximum target-to-background ratios (mTBRmax) in six arterial segments. ***Results:*** 64Cu-DOTATATE and 68Ga-RGD uptake in the CVD group was consistently higher compared to the control group in all aortic segments. Specifically, 64Cu-DOTATATE uptake in the thoracic (3.6±0.4 vs 2.8±0.2, P=0.06), ascending aorta (3.5±0.4 vs 2.7±0.2, P=0.06) for CVD vs. controls. Likewise, uptake of 68Ga-RGD were in the thoracic (2.2±0.1 vs 2.0±0.1, P=0.03) and ascending aorta (2.2±0.1 vs 2.0±0.1, P=0.07). ***Conclusion:*** Based on this retrospective analysis, 64Cu-DOTATATE and 68Ga-RGD both showed higher uptake in the CVD group compared to control group demonstrating that both tracers seem to be able to distinguish between the CVD and controls. ***References:*** 1. OP-324

Factors Associated with a Myocardial Uptake on Oncologic Somatostatin-Positron Emission Tomography Investigations and Differentiation from the Myocardial Uptake of Acute Myocarditis

T. Larive, *C. Boursier, M. Claudin, J. Varlot, L. Filipetti, O. Huttin, V. Roch, L. Imbert, M. Doyen, A. Lambert, D. Mandry, Z. Lamiral, E. Chevalier, P. Marie;*
CHRU Brabois, rue du Morvan, Vandœuvre-lès-Nancy, FRANCE.

Aim/Introduction: Myocardial somatostatin-PET uptake is observed in most patients with acute myocarditis (AM) but also in some oncology patients referred for routine somatostatin-PET. This raises concerns about the specificity of somatostatin-PET for detecting myocarditis. The current study aims to identify (i) factors associated with the detection of myocardial uptake on somatostatin-PET recorded for oncology indications and (ii) differential PET criteria that characterize myocardial uptake in AM patients. ***Materials and Methods:*** We analyzed i) factors associated with the detection of myocardial [68Ga]Ga-DOTA-TOC uptake in 508 [68Ga]Ga-DOTA-TOC PETs from 178 patients, performed for a confirmed or suspected oncologic disease (Onc-PET group) and ii) PET criteria that could differentiate myocardial [68Ga]Ga-DOTA-TOC uptake in 31 patients with an MRI-ascertained AM (AM-PET group) from the Onc-PET group. ***Results:*** Significant myocardial uptake was detected in 137 (26.9%) Onc-PETs and was independently associated with somatostatin analog treatment (Exp(Beta) (95 %CI): 0.805 (0.728-0.890), p<0.001) and age (1.005 (1.001-1.009), p=0.012). A comparable model was selected for predicting the myocardial/blood SUVmax ratio (i.e. somatostatin analog treatment (p<0.001) and history of coronary artery disease (CAD) p=0.022)). Myocardial uptake was detected in 12.9% (25/193) of Onc-PETs from patients treated with somatostatin analogs but in 43.4% (59/136) of untreated patients over the median of 64 years of age. Myocardial uptake was apparent in all 31 AM-PETs, with volume and intensity of uptake dramatically higher than in the 137 Onc-PETs showing myocardial uptake. A myocardial/blood SUVmax ratio threshold of 2.20 provided a sensitivity of 87% (27/31) and a specificity of 88% (44/50) for differentiating myocardial uptake between AM-PETs and an Onc-PET group restricted to patients with comparable clinical characteristics to the AM group (≤ 64 years of age, no CAD history, no somatostatin agonists). A myocardial uptake volume threshold of 18 cm3 provided a comparable diagnostic accuracy (sensitivity: 84% (26/31), specificity: 94% (47/50). ***Conclusion:*** Myocardial uptake is detected in 26.9% of somatostatin-PETs recorded for oncology indications. This rate is decreased by somatostatin analog treatments and increased in older individuals. However, somatostatin-PET, analyzed with the quantitative criterion of uptake intensity or volume, is able to identify acute myocarditis and to differentiate it from myocardial uptake of other origins.

OP-325

Utility of 68-Ga-DOTANOC PET/CT in Evaluation of Treatment Response in Patients with Cardiac Sarcoidosis

C. Patel, *S. Sagar, D. Khan, M. Y S, B. Nayak, S. K V, B. Chandra, P. Gupta, N. Parekh, S. Seth;*
AIIMS Delhi, New Delhi, INDIA.

Aim/Introduction: We aimed to assess the utility of 68-Ga-DOTANOC PET/CT (PositronEmission Tomography/Computed Tomography) in evaluation of treatment response in patients with cardiac sarcoidosis (CS), which is characterized by diverse clinical presentations and variable responses to therapy. ***Materials and Methods:*** We conducted a retrospective analysis involving 68-Ga-DOTANOC PET/CT scans from 30 patients diagnosed with CS. 68-Ga-DOTANOC PET/CT imaging was carried out using dedicated PET/CT scanners (Biograph mCT, Siemens Inc. and Discovery PET/CT, GE) approximately 45-60 minutes after intravenous administration of 2-3 mCi of radiotracer. Interpretation of all scans was performed by two experienced nuclear medicine physicians. Quantitative analysis included calculation of SUVmax (maximum standardized uptake value) and the ratio of SUVmax to the mean SUV of the background for the lesion exhibiting the highest uptake. ***Results:*** The study included a total of 30 patients diagnosed with CS. All patients underwent 68-Ga-DOTANOC PET/CT imaging both at baseline and at follow- up after receiving standard treatment regimens. The mean age was 39.5 ± 10.3 years (range 17-61 years), with a male-to-female ratio of 4:3. The median duration between the baseline and follow-up DOTANOC scans was 8.9 ± 2.1 months. In 22/30 patients with CS, DOTANOC scans revealed a reduction in SUVmax values post-treatment compared to baseline scan (mean SUVmax 1.363 ± 0.60 vs. 0.915 ± 0.34). Additionally, there was adecrease in the ratio of SUVmax to the mean SUV of the background post-treatment compared to baseline scan (mean ratio of SUVmax to the mean SUV of the background 2.370± 0.61 vs. 1.286 ± 0.27). This reduction in SUVmax and the ratio correlated with clinical improvement and resolution of inflammatory lesions on follow-up imaging. Among the remaining 8 patients, 7 showed an increase in SUVmax (mean SUVmax 0.865 ± 0.21 vs. 1.174 ± 0.28), while one patient exhibited stable disease on follow-up scan. ***Conclusion:*** 68-Ga DOTANOC PET/CT can be a valuable additional tool for evaluatingtreatment response in patients with cardiac sarcoidosis.

OP-326

ECG-gated $^{[18F]}$-FDG-PET/CT is useful in imaging patients with symptomatic cardiac sarcoidosis

S. Notohamiprodjo, *J. Kraus-Deuringer, A. Villagran Asiares, W. A. Weber, S. G. Nekolla;*
TUM School of Medicine and Health, Munich, GERMANY.

Aim/Introduction: The diagnosis of cardiac sarcoidosis (CS) with 18F-FDG PET/CT demands proper patient preparation with 12h low carbohydrate, high fat and protein diet. However, patient compliance is not always given, leading to the challenging situation to differentiate between CS granulomas and incomplete suppression of physiological FDG-uptake. We hypothesize that by using ECG-gated FDG-PET/CT the regional myocardial contractile function in CS is substantially decreased compared to normal functioning myocardium. ***Materials and Methods:*** In this pilot study, we investigated 10 patients with confirmed cardiac sarcoidosis and 6 oncological patients without heart disease who underwent FDG-PET/CT as control population. ECG-gated digital FDG-PET/CT was performed after overnight fasting protocol to suppress physiological myocardial FDG-uptake. To assess the contractile function, count-based method for measuring myocardial wall thickening from gated FDG-PET images was used. The diastolic-to-systolic wall-thickening was calculated as percent increase from diastolic thickness. Lower limit of normal wall-thickening was defined as mean wall thickening - 2 standard deviations. The extension/number of segments of FDG-uptake was determined. Polar maps of motion and thickening parameter, histograms and cine-images of wall thickening were generated. ***Results:*** Myocardial FDG-uptake of control population showed diffuse but almost heterogeneous uptake pattern without focal spots. The regional variation of FDG-uptake was 14%. The myocardial wall-thickening was highly dependent from LVEF and the average wall-thickening was found as 53.7%. In CS patients average myocardial wall-thickening in areas of enhanced FDG-uptake was 15.3%, significantly lower than in control population ($p < 0.05$). ***Conclusion:*** In a hypothetic case where differentiation between CS granuloma and incomplete suppression of physiological myocardial FDG-uptake is challenging, analysis of myocardial wall-thickening with gated PET/CT may be helpful.

OP-327

In cardiac sarcoid, comparison of cardiac MRI late gadolinium enhancement distribution and F^{18} FDG-PET-CT metabolic activity related to ventricular tachycardia

K. Tweed[1], *H. Cheow[2], S. Agrawal[1], M. Thillai[1], J. Quijano-Campos[1], L. K. Williams[1];*
[1]Royal Papworth Hospital, Cambridge, UNITED KINGDOM,
[2]Cambridge University Hospitals, Cambridge, UNITED KINGDOM.

Aim/Introduction: To compare cardiac MRI and FDG PET-CT characteristics in cardiac sarcoid with reference to incidence of ventricular tachycardia ***Materials and Methods:*** Single centre retrospective series of 38 patients with histologically confirmed extra-cardiac sarcoid and consecutive paired cardiac MRIs and fluorodeoxyglucose (FDG) PET-CT, compared to electrophysiology outcomes within 3 months of either examination. The distribution of late gadolinium enhancement (LGE) and FDG accumulation were compared on a segmental level using the 17-segment model denotation of left ventricular anatomy with extension to include the right ventricle. Patients with known ischaemic heart disease were excluded. Wilcoxon signed rank test was conducted to examine the differences between the distributions of total segments displaying LGE and those indicating FDG uptake. ***Results:*** There was a statistically significant difference ($z = -3.78$, $p < 0.001$) between the distributions of LGE and FDG uptake. Among the study participants, the median number of segments exhibiting LGE was 4 (mean = 4.92, SD = 2.93, range = 2 to 13), whereas for segments demonstrating FDG uptake, the median was 0 (mean = 2.08, SD = 3.83, range = 0 to 15). The location of matched late gadolinium enhancement and FDG accumulation were basal, mid and apical septum as well as basal to mid anterior wall. Patients without VT had a median maximum standardised uptake value (SUVmax) value of 0.1, in contrast to a median SUVmax of 3.8 in those with VT. Patients without VT had a median of 0.2 FDG uptake segments (total segments displaying FDG uptake) compared to a median of 3.0 segments in those with VT. This difference was statistically significant ($U = 95.5$, $z = -2.19$, $p = 0.028$), suggesting that the presence of VT was associated with higher median FDG uptake segment values. There was no significant difference in number of LGE segments (or myocardial fibrosis burden) in the patients with or without VT. Left ventricular ejection fraction (LVEF) % displayed a significant negative correlation with SUVmax,

r = -0.33, p = 0.046, suggesting that reduced LVEF % values may coincide with elevated metabolic activity. ***Conclusion:*** In the presence of cardiac MRI confirmed cardiac sarcoid, PET-CT is useful for assessment of metabolic activity in patients with histologically confirmed extra-cardiac sarcoid. Patients with VT had a higher number of segments displaying FDG uptake and a higher SUVmax compared to those without VT.

Synthesis and Evaluation of CYP11B2 selective PAY derivatives for Primary Aldosteronism Imaging
Y. Yagi[1,2], *H. Kimura[2,3], R. Fuseda[3], T. Murakami[4], M. Omokawa[5], S. Kise[2], M. Sone[6], H. Saji[7];*
[1]Kyoto college of Medical Science, Nantan, JAPAN, [2]Kanazawa University, Kanazawa, JAPAN, [3]Kyoto Pharmaceutical University, Kyoto, JAPAN, [4]Kyoto University Hospital, Kyoto, JAPAN, [5]Okayama University, Okayama, JAPAN, [6]St. Marianna University School of Medicine, Kawasaki, JAPAN, [7]Kyoto University, Kyoto, JAPAN.

Aim/Introduction: Primary aldosteronism (PA) is a form of secondary hypertension resulting from the overproduction of aldosterone in the adrenal gland, accounting for 5-10% of hypertension cases. It is a heterogeneous disorder with treatments varying based on unilateral or bilateral nature. Unilateral PA can be cured by surgery, making an accurate diagnosis crucial. However, invasive adrenal vein sampling is often required

because non-invasive methods such as CT and MRI are not enough for diagnosis. We think a non-invasive nuclear medicine diagnostic method can improve PA diagnosis. The development of a nuclear medicine molecular probe specific for CYP11B2, overexpressed in PA patients, was proceeded. We selected the tetrahydropyridoquinolinone structure, which has been reported to have selective CYP11B2 inhibitory activity, and synthesized and evaluated its derivatives. ***Materials and Methods:*** We designed and synthesized five tetrahydropyridoquinolinone derivatives (PAY-1~5). Evaluation of their inhibitory activity for CYP11B2 and selectivity over CYP11B1 has proceeded with V79 cells transfected with these enzymes. The derivatives were then radiolabeled with I-125, followed by a radiotracer biodistribution experiment in healthy mice. Finally, we performed in vitro autoradiography (ARG) using adrenal slices from PA patients to evaluate the selectivity for CYP11B2 and CYP11B1. ***Results:*** We obtained iodine-contained PAY-1,2 for SPECT and fluorine-contained PAY-3,4,5 for PET with relatively good yields. Inhibition assay revealed that PAY-1, an iodine-containing six-membered ring compound, had the highest selectivity (Ratio: 223.95). We obtained [125I] PAY-1 with an RCY of 50%. [125I]PAY-1 biodistribution experiment showed accumulation in the adrenal glands (8.67±1.74 %ID/g at 5 min). In vitro ARG analysis using human adrenal slices showed higher accumulation of radioactivity in the CYP11B2 region than in the CYP11B1 region. This result is consistent with cell experiment results. Therefore, these results suggest [125I] PAY-1 has high selectivity for CYP11B2. ***Conclusion:*** The newly designed radioiodeinated PAY-1 may be promising SPECT probes for primary aldosteronism imaging. ***References:*** [1] |J. Med. Chem. 54, 2307-2319. (2011).

OP-340

Development of iodine-123-based PSMA radiohybrid conjugates as a diagnostic counterpart for targeted alpha therapy with actinium-225

T. Krönke, *M. Ullrich, K. Zarschler, F. Reissig, J. Pietzsch, K. Kopka, S. Stadlbauer, C. Mamat;*
Helmholtz-Zentrum Dresden-Rossendorf, Dresden, GERMANY.

Aim/Introduction: Macropa-PSMA conjugates used for targeted alpha therapy with actinium-225 are extended with an albumin binder.[1,2] Further to improving the pharmacological behaviour in vivo, the introduction of an iodine-containing albumin binder provides the basis for the development of a radiohybrid approach. In addition to the complexation of the alpha emitter 225Ac (t1/2=9.9 d), the introduction of the easily accessible SPECT-compatible radiohalogen 123I (t1/2=13.2 h) into the same molecule is possible. Advantageously, the ideal physical half-life and mild radioiodination conditions allows the imaging of longer circulating radionuclide conjugates. ***Materials and Methods:*** The PSMA-binding motif based on the PSMA-617 structure was synthesised by multi-step peptide coupling and conjugation of the macropa-type complexing agent by Cu-catalysed click chemistry. The labeling precursor was synthesized by replacing the 4-(p-iodophenyl)butyrate with a trimethyltin group to enable labelling with iodine-123 by electrophilic aromatic substitution. To determine the binding affinity, LNCaP cells were incubated with nonradioactive conjugates (with and without lanthanum-139) in a competition assay and spiked with [133La]La-PSMA-617 as a competitive radionuclide conjugate. The influence of the complexing agent and the metal ion loading on the binding affinity was evaluated. ***Results:*** The monomer [123I]I-mcp-M-alb-PSMA was prepared from the tin precursor (DMSO, Iodogen, 20 min, rt, RCY: 49%). The dimer [123I]I-mcp-D-alb-PSMA was labelled under the same conditions. Iodine-127 was added after completion of radiolabelling to iodinate the second stannyl group (RCY: 20%). Both radionuclide conjugates were purified by HPLC. No influence of chelator loading on cell binding was observed. The IC50 and Ki values were comparable across the analogues (mcp-M-alb-PSMA: Ki = 8.46 nM (7.05 - 10.14), La-mcp-M-alb-PSMA: Ki = 8.46 nM (6.72 - 10.66) / mcp-D-alb-PSMA: Ki = 2.35 nM (2.03 - 2.71), La-mcp-D-alb-PSMA: Ki = 2.21 nM (1.64 - 2.96)). Preliminary SPECT images show a biodistribution of [123I]I-mcp-M-alb-PSMA which is comparable with that of [225Ac]Ac-mcp-M-alb-PSMA.[1] ***Conclusion:*** The synthesis of the tin precursors and subsequent radiolabelling with iodine-123 provided two new radionuclide conjugates which act as diagnostic counterparts to the corresponding 225Ac radionuclide conjugates. The introduction of iodine-123, with or without metal ion loading of the macropa chelator, did not alter the PSMA binding affinity. The addition of the albumin binding domain opens up a new aspect for theranostic use as a hybrid radiopharmaceutical and has created the new radiohybrid pair 123I/225Ac. ***References:*** [1] F. Reissig, et al., Theranostics 2022, 12, 7203. [2] F. Reissig, et al., Cancers 2021, 13.

Development, synthesis and evaluations of a PET tracer towards 5T4 oncofetal antigen

Y. He[1], *R. Tian[2], Y. Wu[3], D. Xu[4], T. Chen[2], Y. Guan[3], F. Xie[3], J. Han[1];*
[1]Institute of Radiation Medicine, Fudan University, Shanghai, CHINA, [2]Department of Physiology, School of Basic Medicine, Guizhou Medical University, Guiyang, CHINA, [3]Department of Nuclear Medicine & PET center, Huashan Hospital, Fudan University, Shanghai, CHINA, [4]Department of Thoracic Surgery, Huashan Hospital, Fudan University, Shanghai, CHINA.

Aim/Introduction: Trophoblast glycoprotein, the so-called 5T4, is an oncofetal antigen selectively identified in numerous human cancers [1]. Its expression is mechanically associated with the spread of the cancer cells [2]. This stimulates the development of 5T4-targeting drug therapeutics in preclinical and clinical stages. The aim of current study was to develop a 5T4-specific PET tracer based on a camelid-derived single chain antibody (VHH). ***Materials and Methods:*** A VHH library was constructed by camel immunization. Phage display biopanning and periplasmic extract enzyme-linked immunosorbent assay (ELISA) were carried out to evaluate the specificity of the VHHs toward 5T4. [68Ga]Ga-NOTA-H006 was labeled via the conjugation of 1,4,7-triazacyclononane-1,4,7-triacetate (NOTA) to the selected VHH. The radiotracer was investigated on 5T4 antigen to determine the binding affinity. Biodistribution and MicroPET/CT imaging studies were performed at 30, 60 and 90 min post-injection using nude mice bearing BxPC-3 or MDA-MB-468 xenograft. ***Results:*** A library with a capacity of 1.2 x 1012 colony-forming units was built following successful camel immunization. VHH encoded H006 with a median effect concentration (EC50) of 0.16 nM was selected. After conjugation, [68Ga]Ga-NOTA-H006 with the molar activities of 6.48-54.2 GBq/μmol was prepared with high radiochemical purity (>98%). The radiotracer was stable (RCY>95%) in the final formulation up to 2h storage at room temperature, and it displayed low nanomolar affinity towards 5T4 antigen in vitro. MicroPET/CT revealed a clear visualization of BxPC-3 and MDA-MB-468 xenografts in nude mice. The tissue distribution of [68Ga]Ga-NOTA-H006 showed specific accumulation in BxPC-3 xenografts (3.78 ± 1.37% ID/g at 30 min post-injection) which declined over time (1.86 ± 0.39% ID/g at 90 min post-injection). The slice cut from BxPC-3 xenograft was then confirmed to be 5T4 antigen positive using immunohistochemical

staining. ***Conclusion:*** [68Ga]Ga-NOTA-H006 was successfully developed and its 5T4-specificity was confirmed in vitro and in vivo. This offers opportunities for future studies to image the pathological expression of 5T4 oncofetal antigen in cancer patients. An investigator initiated trial is ongoing to explore the utility of [68Ga]Ga-NOTA-H006 in clinic, together with its kinetics in terms of tumor imaging quality and dosimetry in cancer patients (NCT06162988). ***References:*** [1] Hole et al. OP-342

Development of an Estrogen-related Receptor Gamma (ERRγ) Targeting PET Tracer for Inflammation Imaging

B. Lee[1], *J. Kim[2], J. Ahn[1], K. Lee[1], Y. Lee[1], S. Cho[2], Y. Jeon[2], K. Kim[1];*
[1]Korea Institute of Radiological & Medical Science, Seoul, KOREA, REPUBLIC OF, [2]Daegu Gyeongbuk Medical Innovation Foundation, Daegu, KOREA, REPUBLIC OF.

Aim/Introduction: Estrogen-Related Receptor gamma (ERRγ) has been focused as a novel target for treating inflammation because it plays an important role in various metabolic disorders such as hepatic gluconeogenesis, microbial infection, and type 2 diabetes. A derivative of 4-hydroxytamoxifen, DN200434, is a highly potent and selective inverse agonist to ERRγ (1, 2). Positron emission tomography (PET) imaging technique is a promising tool for diagnosis of diseases noninvasively. In this study, we aimed to develop a DN200434 derivative PET tracer [18F] DN202716 for inflammation imaging. ***Materials and Methods:*** The precursor which had a tosyl living group was reacted with 18F in presence of K222 and K2CO3 in DMSO at 120℃ for 20 min, and then TFA was added to deprotect MOM. The reaction mixture was purified using semipreparative HPLC, and the purity and molar activity of the product was measured by analytical HPLC. The final product was formulated to 5% ethanol in saline solution. In Vitro cell binding assay was conducted in LPS-treated Raw 264.7 cells. Biodistribution study was performed in CPA1 mutated mice (5-weeks-old male mice for acute inflammation model, and 10-weeks-old male and female mice for chronic inflammation models), a PET image was acquired in thigh inflammation-induced C57BR/6 model mouse using turpentine oil. ***Results:*** [18F] DN202716 showed 11.0% of radiochemical yield and over 95% of radiochemical purity. Thee molar activity was 54.1 GBq/μmol. [18F]DN202716 had high stability (over 96%) in both mice and human serum for 3 hours. [18F]DN202716 binding in LPS-treated cells was 2.2-fold higher than in normal cells. In PET images, we found the uptake of [18F]DN202716 in inflammatory right thigh. The mean ROI value of the right thigh was 1.72-fold higher than the ROI of normal left thigh. The biodistribution results showed the increased uptake of [18F]DN202716 in liver, intestine, pancreas, and kidney which are known as ERRγ-expressed organs (3) in all inflammation-model groups than in normal group. ***Conclusion:*** We successfully synthesized an ERRγ targeting PET tracer [18F] DN202716 and analyzed it in vitro and in vivo. This tracer showed increased uptake to ERRγ induced cells and inflammatory regions in animal study. From these results, we expected that the [18F] DN202716 would be a novel PET imaging tracer for inflammation diagnosis. ***References:*** (1) Kim J, Woo SY, Im CY, et al. OP-343

One for all: core-radiolabeled nanomaterial as platform for multimodal imaging and therapy

F. Herranz[1], *A. Herraiz[1], J. Pellico[2], U. Cossio[3], E. Romero-Sanz[4], R. T. de Rosales[2], J. Ruiz-Cabello[3,5,6], M. Morcillo-Alonso[4];*
[1]Medicinal Chemistry Institute, Madrid, SPAIN, [2]King's College London, London, UNITED KINGDOM, [3]CIC biomaGUNE, San Sebastián, SPAIN, [4]CIEMAT, Madrid, SPAIN, [5]Universidad Complutense de Madrid, Madrid, SPAIN, [6]CIBER Enfermedades Respiratorias, (CIBERES), Madrid, SPAIN.

Aim/Introduction: An important part of making new radiometal tracers is creating an effective chelate. A good chelate should have excellent in vivo stability, the ability to easily conjugate with biomolecules, and a wide range of radiometals that can be used. In this study, we focus on the potential of extremely small iron oxide nanomaterials (IONP) as universal "chelators" for both diagnostic and therapeutic radiometals.[1] ***Materials and Methods:*** For the synthesis of single- and double-doped xxM-IONPs, a fast microwave-driven methodology was used. The synthesis was carried out at 100 °C within 10 min and nanoradiotracers were subsequently purified using size-exclusion chromatography. [2] The radiolabeling yield, radiochemical purity, and stability in human serum were evaluated for all synthesised nanotracers. In vivo multimodal imaging was conducted with double doped 68Ga177Lu-IONP, these nanoparticles were injected into healthy mice, and PET/SPECT/CT images were acquired 1 h post-injection. MRI phantoms of 68Ga177Lu-IONP were created to demonstrate the possibility of performing non-nuclear imaging simultaneously with these nanosystems. 177Lu-IONP were used for intratumoral treatment of glioblastoma in a mouse model. ***Results:*** Nine different radiometals were integrated into the core of the nanoparticles. These incorporated isotopes cover the full spectrum of possible uses in nuclear medicine, including 68Ga, 67Ga, 111In, 201Tl, 99mTc, 64Cu, 89Zr, and therapy with 223Ra and 177Lu. The capability of IONP to incorporate several radiometals simultaneously allows for the use of these nanoparticles not only as imaging probes in nuclear medicine, but also as theranostic agents and hybrid probes. The PET/SPECT images obtained using the selected 68Ga177Lu-IONP NPs showed that the signal efficiency was not diminished by the presence of another emitter in the core of the nanoparticle. Finally, we ran a pilot study on the ability of the 177Lu-IONP as therapy against glioblastoma after intratumoral injection, results show how tumour growth is stopped after nanotracer injection. ***Conclusion:*** We carried out a systematic study on the radiometal core doping of iron oxide nanoparticles. Nine different radioisotopes were successfully incorporated, and double doping was demonstrated to be feasible, including isotopes such as 177Lu and 223Ra.The in vivo dual imaging behaviour and efficiency were assessed with 68Ga177Lu-IONP, which is suitable for being used for theranostic purposes. Finally, we demonstrated the therapeutic potential of this approach using a glioblastoma model. ***References:*** [1] Sneddon, Deborah, Current Opinion in Chemical Biology, 2021/ Vol 63, 152-162.[2] Pellico, Juan, et al. OP-344

Development of a Novel Small-Molecule Radiopharmaceutical Pair for Theranostics Targeting Metabotropic Glutamate Receptor 1 in Melanoma

L. Xie, *M. Hanyu, M. Fujinaga, Y. Zhang, K. Minegishi, K. Nagatsu, K. Kawamura, M. R. Zhang;*
Department of Advanced Nuclear Medicine Sciences,

National Institute of Radiological Sciences, National Institutes for Quantum Science and Technology, Chiba, JAPAN.

Aim/Introduction: Metabotropic glutamate receptor 1 (mGluR1), a key player in glutamatergic signaling, is frequently overexpressed in human tumors,including melanoma, while being absent in normal peripheral organs.1 This makes mGluR1 a promising target for cancer theranostics.2 Here, we designed and developed a novel small-molecule radiopharmaceutical pair, 3-iodo-N-[4-[6-(methylamino)pyrimidin-4-yl]-1,3-thiazol-2-yl]-N-[^{11}C]methylbenzamide ([^{11}C]1) and 3-211At-astato-N-[4-[6-(methylamino)pyrimidin-4-yl]-1,3-thiazol-2-yl]-N-methylbenzamide ([211At]1), for theranostic applications in melanoma. ***Materials and Methods:*** [^{11}C]1 was synthesized by reacting a N-desmethyl precursor with [^{11}C]CH3OTf in the presence of NaOH at room temperature for 5 min. Radiolabeling of [211At]1 was achieved by reaction of aryl tin precursor with NCS-containing 211At/MeOH solution. The theranostic potential of the radiopharmaceutical pair was explored for PET imaging and radiotherapy in mGluR1-expressing B16F10 melanoma-bearing mice. ***Results:*** [^{11}C]1 and [211At]1 were obtained with a radiochemical purity of greater than 99% and radiochemical yields of 18.9 ± 5.0 % and 41.2 ± 2.2 %, respectively, based on the total radioactivity of used radionuclides. In vivo PET imaging of [^{11}C]1 clearly visualized the targeted melanomas with good tumor-to-background contrast. Ex vivo biodistribution study confirmed the sustained accumulation of [^{11}C]1, reaching 12.29 ± 2.44 %ID/g tissue at 90 min in the melanomas, with rapid clearance from nontarget organs post injection. In the therapeutic studies, [211At]1 exhibited significant and durable antitumor efficacy with a single treatment (2.96 MBq) in the melanoma model, compared to the controls (0.38 ± 0.02 cm3 vs. 7.88 ± 1.28 cm3 at 13 days post-therapy). No significant changes in body weight, liver function, or kidney function were observed throughout the examination period in melanoma mice injected with 2.96 MBq of [211At]1. ***Conclusion:*** The novel small-molecule radiopharmaceutical pair successfully visualized mGluR1-expressing melanomas using [^{11}C]1 with high contrast PET images, and further treated by [211At]1 without significant toxicity. These results highlight the potential of [^{11}C]1 and [211At]1 as theranostic agents for managing mGluR1-expressing tumors, warranting further investigation in clinical oncology theranostics. ***References:*** 1. Pollock PM, et al. Nat Genet. 2003; 34:108-112. 2.Xie L, et al. Cell Rep Med. 2023;4:100960.

OP-345

An [^{18F}]trifluoroborate-derived BPA ([^{18F}]BBPA) for preclinical boron neutron capture therapy

J. Chen, *Z. Liu;*
Peking University, Beijing, CHINA.

Aim/Introduction: Boron amino acids (BAAs), which uniquely replace the traditional carboxyl group (-COOH) with a trifluoroborate group (-BF3), facilitate the dual use of ^{18}F-labeled positron emission tomography (PET) and boron neutron capture therapy (BNCT) while maintaining an identical chemical structure, differing only in the isotopic form of fluorine used. Trifluoroborate-derived boronophenylalanine (BBPA), a derivative of boronophenylalanine (BPA), has shown potential for replicating the biodistribution characteristics of BPA due to its transportation via the large neutral amino acid transporter type-1 (LAT-1). This study aims to expand on previous research by comprehensively synthesizing and developing BBPA for application in PET-guided BNCT and standalone BNCT, testing its efficacy and boron delivery efficiency in preclinical settings. ***Materials and Methods:*** BBPA was synthesized as a derivative of BPA, incorporating two boron atoms to enhance boron delivery efficiency. Preclinical imaging studies were conducted to assess tumor uptake and boron concentration in tumor tissues using B16-F10 tumor-bearing mice. Different doses of BBPA and BPA were intravenously injected into these mice. The concentration of boron in tumor tissues was quantitatively measured, and the tumor response to BNCT treatment was compared between BBPA and BPA. ***Results:*** Clinical studies highlighted the superior tumor uptake of [^{18F}]BBPA-PET, showing a remarkable tumor-to-normal brain ratio (T/N ratio, 18.7 ± 5.5, n = 11), which exceeds that of common amino acid PET tracers. This has led to [^{18F}]BBPA receiving FDA and CFDA approval for clinical trials. In preclinical studies, BBPA exhibited higher tumor boron concentrations compared to BPA, with 17.4 ± 3.4 ppm achieved at a dose of 250 mg/kg of BBPA versus only 7.6 ± 1.2 ppm with the same dose of BPA. BBPA-based BNCT demonstrated excellent therapeutic effects, significantly inhibiting tumor growth with lower doses compared to BPA, indicating that BBPA could potentially require reduced dosages in clinical settings, enhancing treatment efficacy and patient safety. ***Conclusion:*** In conclusion, this study not only marks a significant stride in the synthesis and development of a novel BAA but also underlines its potential as a dual-function theranostic agent for both PET imaging and BNCT. The dual functionality of BBPA, combined with its effective targeting and retention in tumor tissues, firmly establishes it as a promising candidate in the realm of oncological theranostics. The outcomes of this research are poised to make a substantial impact on precision medicine in cancer therapy, offering new avenues for enhanced patient care and outcomes.

OP-346

[^{177}Lu]Lu-labelled DOTA-MGS5: radiopharmaceutical formulation and dosimetry evaluation for clinical application

T. Zavvar[1], *A. A. Hoermann[1], C. Mair[1], A. Kronthaler[1], L. Joosten[2], G. Franssen[2], P. Laverman[2], M. W. Konijnenberg[3], G. di Santo[1], I. J. Virgolini[1], E. von Guggenberg[1];*
[1]Department of Nuclear Medicine, Medical University of Innsbruck, Innsbruck, AUSTRIA, [2]Department of Medical Imaging, Radboud University Medical Center, 6525 Nijmegen, The Netherlands, Nijmegen, NETHERLANDS, [3]Department of Radiology and Nuclear Medicine, Erasmus Medical Center, Rotterdam, The Netherlands, Rotterdam, NETHERLANDS.

Aim/Introduction: DOTA-MGS5 is a new minigastrin analogue that exhibits improved tumour-to-kidney ratio and in vivo stability, making it a promising candidate for targeting cholecystokinin-2 receptor (CCK2R) expressing neoplasms such as medullary thyroid carcinoma (MTC) and small cell lung cancer (SCLC). For clinical translation of peptide receptor radionuclide therapy with [177Lu]Lu-DOTA-MGS5, an automated synthesis procedure was established and preclinical tests were performed for the radiopharmaceutical formulation. Based on these studies a first in-human dosimetry study could be performed allowing a preliminary dosimetric evaluation. ***Materials and Methods:*** The radiolabelling process was validated using a cassette-based synthesis module, DOTA-MGS5 in GMP quality and a no-carrier added [177Lu]LuCl3 produced from highly enriched ytterbium-176. Product specifications and analytical procedures were defined according to the European Pharmacopoeia monographs available for other radiopharmaceuticals. Biodistribution studies with the radiopharmaceutical formulation were carried out in female BALB/c nude mice xenografted with A431-CCK2R cells. Preclinical dosimetry studies were conducted

to extrapolate dosimetry estimates for dose-limiting organs in humans. A first dosimetry study using [177Lu]Lu-DOTA-MGS5 (1500 MBq, <100 µg) was carried out in a patient with advanced SCLC to evaluate the feasibility of peptide receptor radionuclide therapy (PRRT). ***Results:*** The cassette-based production of [177Lu]Lu-DOTA-MGS5 with a molar activity of >30 MBq/µg resulted in a high radiochemical purity (RCP) of >98%. The final product showed high stability over time, with RCP >96% up to 24 hours after synthesis. The new radiopharmaceutical demonstrated a favourable biodistribution profile in A431-CCK2R xenografted BALB/c nude mice. A high uptake of 31.9±12.8% was confirmed in A431-CCK2R xenografts at 4h p.i. combined with low accumulation of radioactivity in non-target tissues resulting in a tumour-to-kidney ratio >10 and a tumour-to-stomach ratio >6. Pharmacokinetic data obtained in mice and dosimetry extrapolation from mice to humans supported the feasibility of PRRT. In the preliminary patient-specific dosimetry study calculated from the 3D SPECT/CT data up to 4 d p.i. and serial blood sampling up to 2 d p.i., a low risk of kidney and bone marrow toxicity (absorbed doses of <1 Gy/GBq and <0.03 Gy/GBq, respectively) was shown and an absorbed dose >10 Gy/GBq was calculated for tumour lesions. ***Conclusion:*** Various results from preclinical testing support the clinical translation of [177Lu]Lu-DOTA-MGS5 in patients with CCK2R-expressing neoplasms. In the preliminary patient dosimetry performed in a patient with SCLC, a high tumour dose and low radiation burden to non-target tissue were demonstrated, allowing the start of fractionated therapy with [177Lu]Lu-DOTA-MGS5.

Harvesting [^{68}Ga]GaCl$_3$ from solid and liquid targets: a versatile and high-yielding cassette-based process

R. Veronesi[1], *S. Degueldre[1], J. Masset[1], C. Vanasschen[1], D. Szikra[2], J. Morelle[1], C. Warnier[1];*
[1]Trasis, Ans, BELGIUM, [2]University of Debrecen, Debrecen, HUNGARY.

Aim/Introduction: In response to a growing demand for Gallium-68, its cyclotron-mediated production from solid and liquid Zinc-68 targets is gathering increased interest. This methodology allows generating the nuclide in greater quantities than those afforded by Germanium-68 generators (< 2.0 GBq), reducing the cost per dose and resulting in more patients diagnosed. Cyclotron-produced Gallium-68 is usually extracted from the target in a matrix of nitric acid and [68Zn]Zn(NO3)2. Post-irradiation, Gallium-68 must therefore be separated from unwanted impurities (mainly Zinc-68) and formulated in a solution suitable for radiolabelling purposes. We herein report a fully industrialized, high-yielding method for the purification process of [68Ga]GaCl3 from liquid and solid target crudes on a miniAllinOne synthesis module.1 ***Results:*** The process occurs as follows. The dissolved target crude is buffered and passed through two different strong-cation-exchange cartridges in a trapping-elution sequence, ensuring the separation of the nuclide of interest from the parent Zinc-68 and other metallic impurities. The obtained solution complies with monograph 3109 of the Eur. Ph., and its formulation in 5.0 mL 0.1N HCl makes it compatible with existing labeling methodologies. The dissolution of the solid target is an automated feature whenever applicable, for extra 15 minutes of processing. The decay losses of this increased timing are largely compensated by the greater activities of Gallium-68 that solid target irradiation can afford. The resulting plug-and-play process allows the isolation of pure [68Ga]GaCl3 in 18 minutes with uncorrected yields up to 75% (tested up to an output of 10 GBq). After completion of the purification process, recycling of the parent nuclide Zinc-68 is also made possible through its collection in a vial separate from main wastes. ***Conclusion:*** A fully automated process and a set of consumables have been developed for the purification of cyclotron-produced Gallium-68 on the miniAllinOne. This readily available kit is compatible with solid and liquid targets from any supplier, and allows Zinc-68 recovery while delivering state-of-the-art yields of [68Ga]GaCl3 in full compliance with applicable regulations. By setting a new standard in terms of versatility, ease of use and production yields, this process paves the way for a convenient use of cyclotron-produced Gallium-68 in routine clinical practice. Validation of this process at greater activities (> 10 GBq) is ongoing. ***References:***

Bone Metastases Model for Red Marrow Dosimetry during ^{177}Lu-DOTATATE Treatment

L. Hagmarker[1], *J. Hemmingsson[1], J. Svensson[2], T. Ryden[1], M. van Essen[3], A. Sundlöv[4], K. Sjögreen Gleisner[5], P. Gjertsson[3], P. Bernhardt[1];*

[3]Department of Clinical Physiology, Gothenburg, SWEDEN,
[4]Department of Oncology and Pathology, Lund, SWEDEN,
[5]Department of Radiation Physics, Lund, SWEDEN.

Aim/Introduction: Treatment with 177Lu-DOTATATE is generally well tolerated, though bone marrow toxicity can become dose-limiting and persisting. A difficulty in measuring the activity concentration in the bone marrow arises from the existence of infiltrating bone metastases. This study introduces a method for estimating the dose contribution from infiltrating bone metastases to the absorbed dose to the red marrow. ***Materials and Methods:*** 48 patients treated with 177Lu-DOTATATE at Sahlgrenska University Hospital were included in this study. The absorbed doses to the red marrow were calculated using a hybrid planar and SPECT-image methodology and an incorporated compartment model to estimate the specific and nonspecific activity concentration in the red marrow and in infiltrating bone metastases. To identify patients exhibiting notably high uptake from bone metastases, a ratio was calculated between the SPECT uptake in the lumbar vertebrae and the nonspecific activity concentration at 24-hour image. For these patients, a bone metastases model was used to assess the dose contribution from infiltrating metastases. ***Results:*** The median absorbed dose to the red marrow after the first treatment cycle in patients with bone metastases was 0.37 Gy/7.4 GBq (range, 0.29-0.68) using the bone metastases model, and 0.46 Gy/7.4 GBq (range, 0.15-1.55) without the bone metastases model. The median absorbed dose for all patients was 0.35 (0.15-0.74) Gy/7.4 GBq after treatment cycle one, utilizing the bone metastases model. The absorbed dose was significantly correlated to the response of platelets and became stronger when incorporating the bone metastases

model. ***Conclusion:*** A compartment model assessed specific and nonspecific uptake activity concentrations to estimate the absorbed dose to the red marrow. Using the bone metastases model to evaluate the dose contribution from bone metastases in patients with high uptake resulted in stronger correlations between absorbed dose to the red marrow and platelet response. This highlights the need and possibility of bone metastases modelling.

Optimizing ^{225}Ac SPECT acquisition times by using a sparse view imaging protocol: a feasibility study

G. Liubchenko[1], *G. Boening[1], M. Zacherl[1], M. Rumiantcev[1], G. T. Sheikh[1], L. Unterrainer[1,2], F. Gildehaus[1], M. Brendel[1,3,4], S. Resch[1], S. Ziegler[1], A. Delker[1];*
[1]Department of Nuclear Medicine, LMU Hospital, Ludwig-Maximilians-University of Munich, Munich, GERMANY, [2]University of California Los Angeles, Los Angeles, CA, UNITED STATES OF AMERICA, [3]Munich Cluster for Systems Neurology (SyNergy), Munich, GERMANY, [4]German Center for Neurodegenerative Diseases (DZNE) Munich, Munich, GERMANY.

Aim/Introduction: Post-therapeutic SPECT can provide valuable information for dosimetry and response assessment following [225Ac]Ac-PSMA therapy. However, our current 1 hour imaging protocol is challenging for some patients due to severe skeletal pain. As sufficient acquisition time per projection is essential to get a measurable signal above the background level, an alternative option to reduce the overall SPECT acquisition time could be to reduce the number of projections to a necessary minimum, optimized with regard to the desired quantitative accuracy and resolution. ***Materials and Methods:*** A total of five patients injected with 7.7±0.2 MBq of [225Ac]Ac -PSMA-I&T were analyzed. All patients underwent two post-therapeutic SPECT/CT acquisitions at 24 and 48 h post-injection on a Siemens Symbia Intevo T16 system equipped with a HEGP collimator (32 projections per head, 128x128 pixel, 210 s per projection). The acquired SPECT scans were used to create two datasets. One dataset included all 32 projections (1 h acquisition time), while the other dataset included only half of the projections (16 projections and 30 min total acquisition time). Quantitative SPECT reconstructions for both, the 440 keV and 218 keV photopeaks, were carried out via an in-house MAP-EM, including CT-based attenuation correction, resolution modelling and transmission-dependent scatter correction. The RBE-weighted (RBE=5) absorbed doses for kidneys (n=9, segmented using CT) and lesions (n=9, isocontour of 80% of a peak VOI at 24 h post-injection) were calculated using a mono-exponential fit and local dose deposition for both 213Bi (440 keV) and 221Fr (218 keV). ***Results:*** The RBE-weighted absorbed doses for the 1 h SPECT were higher for both photopeaks and regions compared to an acquisition time of 30 min (440 keV: kidneys: +2.6±7%, lesions: +11.7±13%; 218 keV: kidneys: +1.1±7%, lesions: +3.7±16%). For 8 out of 9 kidneys, the differences in the absorbed doses were less than 8% between 1 h and 30 min acquisition time for both photopeaks. For only 2 (440 keV) and 4 (218 keV) out of 9 lesions, the difference in the absorbed doses were less than 10% between 1 h and 30 mins. ***Conclusion:*** Halving of the acquisition time for 225Ac SPECT by using a minimum number of projections may be suitable for the kidneys (differences mostly within 10%), which represent an important risk organ. However, results from this analysis indicate 32 projections being superior over 16 projections for smaller target volumes like lesions.

OP-350

The Impact of Assumptions on Kidney Absorbed Doses When Modelling Redistribution of Daughters for Alpha-Emitter Based Somatostatin Receptor Therapies

M. Kvassheim[1,2], *C. Stokke[1,3];*
[1]Department of Physics and Computational Radiology, Division of Radiology and Nuclear Medicine, Oslo University Hospital, Oslo, NORWAY, [2]Faculty of Medicine, University of Oslo, Oslo, NORWAY, [3]Department of Physics, University of Oslo, Oslo, NORWAY.

Aim/Introduction: Kidney absorbed doses can be simulated for potential alpha-emitter based somatostatin receptor therapies by using data from patients undergoing [177Lu]Lu-DOTATATE therapy and modelling daughter redistribution. Here, we investigate the impact of various assumptions for initial conditions of the biokinetic models for 225Ac, 227Th, 212Pb, 212Bi, and 213Bi by change in kidney absorbed doses. ***Materials and Methods:*** Probe measurements at five time-points post-injection of nine patients undergoing [177Lu]Lu-DOTATATE therapy were used to estimate whole body (WB) time-integrated activity coefficients (TIACs). TIACs for kidneys, tumours, livers, and spleens were estimated from four post-therapy SPECT/CT images per patient. All TIACs were adjusted for the physical half-lives of 225Ac, 227Th, 212Pb, 212Bi, and 213Bi. All alpha decays and 36% of 212Pb decays were assumed to release daughters from the chelator, and ICRP biokinetic models for simulating all daughters' redistributions were run in Simbiology (MATLAB v2023b, MathWorks). For the base model, kidney TIACs were put in the 'Other kidney tissue' compartment, tumours TIACs were put in a compartment exchanging daughters with plasma at the rate of 'soft tissues with slow turnover', spleen TIACs were put in the spleen compartment, and liver TIACs were put in the 'Liver 1' compartment. The remaining WB TIACs were split between the soft tissue compartments exchanging daughters with plasma with fast and intermediate turnover according to the fast and slow exponentials in the fitted time-activity curve. Free daughters released before injection were put in the 'Plasma' compartment and the amount was based on a parent half-life passing between production and injection. The models were rerun when altering these initial conditions and the resulting kidney absorbed doses were compared. ***Results:*** Removing free daughters from the injection on average decreased kidney absorbed doses by 3%, 53%, 20%, 0.2%, and 7% for 225Ac, 227Th, 212Pb, 212Bi, and 213Bi, respectively. For 227Th, moving kidney TIACs from 'Other kidney tissue' to 'Urinary path' on average increased the absorbed kidney doses by 164%. Otherwise, only relocating the remaining WB TIACs changed the average kidney absorbed doses by more than 3%. Relocating remaining WB TIACs minorly affected the result for 227Th, 212Bi, and 213Bi (<4%), but it changed the average kidney absorbed doses from the base model by -6% to 37% for 225Ac and by -24% to 36% for 212Pb. ***Conclusion:*** Assumptions made when modelling daughter redistribution can majorly impact absorbed dose estimates and should be considered carefully.

OP-351

Comparing the Impact of Dosimetry at Different Scales for Alpha and Beta Emitters in Molecular Radiotherapy Using Monte Carlo Simulations

M. Frivik[1,2], *A. Tulipan[3,4], C. Stokke[1,2], M. Kvassheim[2,5];*
[1]Department of Physics, University of Oslo, Oslo, NORWAY, [2]Department of Physics and Computational Radiology, Division of Radiology and Nuclear Medicine, Oslo University Hospital, Oslo, NORWAY, [3]Department of Nuclear Medicine, Division of Radiology and Nuclear Medicine, Oslo University Hospital,

Oslo, NORWAY, [4]Nuclear Medicine/PET center, Department of Radiology, Haukeland University Hospital, Bergen, NORWAY, [5]Faculty of Medicine, University of Oslo, Oslo, NORWAY.

Aim/Introduction: Heterogeneous uptake of radiopharmaceuticals in the kidneys can result in heterogeneous irradiation of kidney structures with varying radiation sensitivities. We investigated the alpha and beta kidney absorbed dose distributions at different scales for therapies with 90Y, 177Lu, 212Pb, and 225Ac, calculated S-factors, and applied them based on data from patients receiving 177Lu-DOTATATE therapy. ***Materials and Methods:*** Three kidney models were created, at the whole kidney, cortex-medulla, and nephron scale. 68Ga-DOTATOC PET/CT images from 5 patients undergoing 177Lu-DOTATATE therapy were used to create the whole kidney and cortex-medulla models. Contrast-enhanced CT images and the PET images were used for modelling renal cortex and medulla. The nephron model consisting of 18 nephrons divided into glomeruli and tubules was created based on information from literature using Blender. Dose deposition for the alpha and beta emissions 177Lu, 90Y, 225Ac, and 212Pb were simulated with GATE. Simulations used all kidney activity in the whole kidney, in only medulla, in only cortex, in only glomeruli, and in only tubules, and S-factors were calculated. Furthermore, the biological uptake and clearance of kidney activity were estimated from four post-therapy SPECT images of the modelled patients. Based on a 68Ga-DOTATOC PET/CT, 80% of the kidney time-integrated activity was put in the cortex for the cortex-medulla model. The simulated kidney activity was adjusted for 90Y, 225Ac, and 212Pb according to their physical half-lives. ***Results:*** General S-factors calculated for the cortex-medulla model are given in Table 1. When applied to DOTATATE therapy, absorbed doses to the whole kidney were (1.7±0.4)×10-3, (4.11.0)×10-4, (4.7±1.4)×10-3, and (8.1±2.3)×10-2 Gy per injected MBq for 90Y, 177Lu, 212Pb, and 225Ac, respectively. Absorbed doses to medulla were (1.72.0)×10-3, (5.06.0)×10-4, (2.61.1)×10-3, and (5.81.8)×10-2 Gy per injected MBq for 90Y, 177Lu, 212Pb, and 225Ac, respectively, and absorbed doses to cortex were (1.30.3)×10-3, (3.11.0)×10-4, (4.53.1)×10-3, and (9.24.8)×10-2 Gy per injected MBq for 90Y, 177Lu, 212Pb, and 225Ac, respectively. ***Conclusion:*** Regions with high activity concentrations receive a higher fraction of the delivered dose for alpha emitters than with beta emitters, as expected. Applied for DOTATATE therapy, if the activity concentration is higher in the medulla as derived from the 68Ga-DOTATOC PET, shorter range alpha radiation will irradiate less of the radiosensitive glomeruli than beta radiation.

OP-352

Image-Based Bone Marrow Dosimetry in Patients Undergoing [^{177}Lu]Lu-PSMA Radioligand Therapy

M. Rumiantcev[1], *S. Resch[1], X. Shen[1], G. Liubchenko[1], M. Brendel[1,2,3], S. Ziegler[1], G. Böning[1], G. Sheikh[1], A. Delker[1]; [1]Department of Nuclear Medicine, LMU Hospital, Ludwig-Maximilians-University of Munich, Munich, GERMANY, [2]German Center for Neurodegenerative Diseases (DZNE) Munich, Munich, GERMANY, [3]Munich Cluster for Systems Neurology (SyNergy), Munich, GERMANY.*

Aim/Introduction: For patients with metastasized castration-resistant prostate cancer (mCRPC) undergoing [177Lu]Lu-PSMA radionuclide therapy, bone marrow irradiation is a dose-limiting factor [1, 2]. Monitoring of the absorbed dose to the bone marrow is advisable to minimize side effects. However, quantification of the activity concentration in the bone marrow is especially challenging for patients suffering from mCRPC due to the presence of bone lesions and the limited resolution of SPECT imaging. The aim of this study is to investigate the uncertainty of image-based bone marrow activity estimation for [177Lu] Lu-PSMA treatment of mCRPC. ***Materials and Methods:*** Pre-therapeutic [18F]F-PSMA-1007 PET images of 175 patients prior to the first cycle of [177Lu]Lu-PSMA treatment were used to generate virtual patient phantoms with realistic bone lesions. To define the bone lesions, segmented (using TotalSegmentator [3]) CT images were registered to the PET images, an SUV threshold of 2 was applied to bones to remove non-specific uptake, followed by Otsu thresholding within the bone compartment. Two criteria were used for patient and lesion selection: the minimum volume per lesion was set to 1 ml and the minimum total lesion volume was set to 10 ml. These virtual phantoms were filled with the expected activity concentrations at 24 h p.i. in bone lesions, kidneys, and background compartment, as extracted from SPECT images of five patients after the first treatment with 7.4 GBq [177Lu]Lu-PSMA-I&T. These activity maps and density maps derived from the patient CT were used to simulate SPECT projection data with SIMIND [4]. An in-house MAP-OSEM algorithm with attenuation correction, scatter correction and Gaussian resolution modelling enabled was used to reconstruct the SPECT images. ***Results:*** As expected, the recovery coefficient (RC) in the bone lesions strongly depends on the lesion volume and shape. For an exemplary virtual patient, the RC varied between 11% and 66% for lesions with a volume between 1 ml and 15 ml. In contrast, the RC for the bone marrow compartment in the vertebrae S1, L5-L1, T12-T1, and C7-C1 was found to be 182%. ***Conclusion:*** The preliminary results indicate a significant overestimation of the bone marrow activity in the presence of bone metastases. Ongoing work is currently being done to find and compare methods for a more accurate estimation of bone marrow activity. ***References:*** [1] DOI: https://doi.org/10.1186/s13550-019-0548-z[2] DOI: https://doi.org/10.2967/jnumed.118.225235[3] DOI: https://doi.org/10.5281/zenodo.6802613[4] DOI: https://doi.org/10.1016/0169-2607(89)90111-9.

OP-353

Predicting cycle 1 salivary gland absorbed dose before ^{177}Lu-PSMA-617 radioligand therapy using pre-therapy ^{68}Ga-PSMA-11 PET uptake metrics

K. Fitzpatrick, *R. Arunachalam, C. Wang, M. Roseland, K. Wong, Y. Dewaraja; University of Michigan, Ann Arbor, MI, UNITED STATES OF AMERICA.*

Aim/Introduction: Xerostomia associated with absorbed dose (AD) to salivary glands is a concern during PSMA radioligand therapy (RLT). We aimed to predict cycle 1 AD to salivary glands from 68Ga-PSMA-11 PET uptake metrics. ***Materials and Methods:*** Sixteen patients undergoing standard 7.4 GBq 177Lu-PSMA-617 RLT received SPECT/CT imaging at 3-4 timepoints post- cycle 1. Baseline 68Ga-PSMA-11 PET/CT scans were available per standard clinical protocol. Two methodologies were used for salivary gland segmentation and 177Lu dosimetry. 1) Deep-learning (DL) / Monte Carlo (MC): DL tools were used to separately segment parotid and submandibular glands on CT of PET/CT and SPECT/CT. Voxel-level dosimetry included MC-based dose-rate estimation and dose-rate fitting/integration. 2) Thresholding/S-value: semi-automated PET (SPECT) thresholding was used to segment parotid and submandibular glands. PET (SPECT) threshold values of 50% (37%) and 48% (51%) of maximum for parotid and submandibular glands were determined from 68Ga and 177Lu phantom experiments. Organ-level dosimetry included time-activity fitting and S-value from ICRP 89, which

PET activity concentration (Bq/mL) exceeding the mean served as a predictor for a binary outcome classifier (defined as AD exceeding the mean) and was tested using leave-one-out cross-validation (LOOCV). ***Results:*** Cycle 1 mean ADs to parotid, submandibular, and combined salivary glands were 3.0±1.6 Gy, 3.9±2.3 Gy and 3.2±1.6 Gy, respectively from the DL/MC method, while mean AD to salivary glands from the thresholding/S-value method was 2.7±1.7 Gy. The correlation with mean AD was stronger when using PET activity concentration compared with using SUV metrics (mean/peak/max). With the DL/MC method, the mean cycle AD to parotid ($r=0.86$; $p<0.001$), submandibular ($r=0.61$; $p<0.001$) and salivary glands ($r=0.81$; $p<0.001$) showed a significant correlation with PET activity concentration. Mean AD to salivary glands was also significantly correlated with the PET activity concentration ($r=0.75$; $p<0.001$) using the thresholding/S-value method. The LOOCV results for prediction of AD gave an area-under-the-curve of 0.88 (sensitivity=0.79; specificity=0.64) for DL/MC and 0.93 (sensitivity=0.98; specificity=0.75) for thresholding/S-value. ***Conclusion:*** A moderately-strong correlation was obtained between AD to salivary glands and activity concentration on pre-therapy 68Ga-PSMA-11 PET, which was robust across different segmentation approaches and AD calculation methods. Following independent validation, such models for predicting ADs pre-therapy may enable patient-specific planning of RLT, which is especially important when considering dose escalation.

OP-354

Lu177 Radioligand therapy: Potential for Modifying Administered Activity to Maximize the Probability of Complication Free Tumor Control

J. Mikell*[1]*, *K. Fitzpatrick[2], M. B. Altman[1], Y. K. Dewaraja[2];*
[1]Washington University in St. Louis School of Medicine, Department of Radiation Oncology, St. Louis, MO, UNITED STATES OF AMERICA, [2]University of Michigan, Ann Arbor, MI, UNITED STATES OF AMERICA.

Aim/Introduction: Therapeutic Index (TI=tumor-to-kidney absorbed dose (AD) ratio) has been reported to decrease with subsequent cycles for PSMA-617 radioligand therapy (RLT), which suggests administering more activity initially for improved outcomes. However, the utility of such TI is unclear in terms of response or toxicity. Tumor control probability (TCP) and normal tissue complication probability (NTCP) models are sigmoidal curves ranging from 0-1 in a dose domain generated from clinical data. Complication-free TCP can be estimated as P+=TCP(1-NTCP) as proposed for external-radiotherapy. For example, a TI of 10 may represent tumor/kidney AD ratios of 0.1Gy/0.01Gy, 40Gy/4Gy, or 1000Gy/100Gy; for these ADs, P+ will be ~0 (TCP~0,NTCP~0) , 1 (TCP~1,NTCP~0), and 0 (TCP~1,NTCP~1), respectively. The goal is to report TCP, NTCP, and P+ using clinical RLT data, and then for a hypothetical optimal treatment, adjust patient cycle 1 administered activity (AA) to demonstrate potential to maximize P+. ***Materials and Methods:*** 18 patients received multiple time-point SPECT/CT-dosimetry after their first cycle of PSMA-617 RLT at University of Michigan. Whole body tumor volume (WBTV) was segmented with a 5Gy threshold applied to the Monte Carlo-generated AD map. Kidneys were segmented via deep learning and biological effective dose (BED) was calculated following Baechler (MedPhys 2008) and scaled assuming 6 cycles. Kidney NTCP was taken from MIRD pamphlet 20. Michigan WBTV absorbed dose (WBTVAD) and corresponding PSA response (50% decline) were combined with Violet et al (JNM 2019) WBTVAD and PSA responses for 47 total observations. Logistic regression was performed to create TCP. The clinical WBTVAD and kidneyBED were used to calculate TCP, NTCP, and P+ . A hypothetical AA was then set to maximize P+ for each patient. Changes between the hypothetical and clinical results are summarized. ***Results:*** For clinical data the avg+-std for TCP, NTCP, P+, WBTVAD, kidneyAD and AA was 0.40+-0.33, 0.06+-0.23, 0.39+-0.34, 13.3+-8.6Gy, 3.3+-2.1Gy and 7.20+-0.16 GBq, respectively. After retrospectively selecting AA to maximize P+ the TCP, NTCP, P+, and AA was 0.70+-0.35, 0.04+-0.05, 0.68+-0.36, and 13.5+-6.0 GBq, respectively. Maximizing P+ increased AA in 17/18 patients. The TCP, NTCP, P+, and AA change was +28%, -2%,+29%, and +85%, respectively. TI did not change as AA scaled assuming no saturation effects. ***Conclusion:*** Maximizing P+ increased AA and TCP and decreased NTCP, while TI remained constant. When designing optimal RLT protocols, complication free tumor control should be considered rather than TI alone. Future work should investigate additional TCP endpoints and include marrow NTCP.

OP-355

Inter-center variability of dosimetry methodology and the impact on reported absorbed dose for [^{177}Lu]Lu-PSMA.

B. Timmermans*[1]*, *B. M. Privé[1,2], R. Hofferber[3], M. Konijnenberg[1,2], G. Flux[4], S. Heskamp[1], J. Nagarajah[1], J. I. Gear[4], W. Jentzen[3], S. M. B. Peters[1];*
[1]RadboudUMC, Nijmegen, NETHERLANDS, [2]Erasmus MC, Rotterdam, NETHERLANDS, [3]Universitätsklinikum Essen, Essen, GERMANY, [4]Royal Marsden Hospital and Institute of Cancer Research, London, UNITED KINGDOM.

Aim/Introduction: As [177Lu]Lu-PSMA is increasingly being used, standardization of dosimetry methodology is crucial to make absorbed dose (AD) outcomes more comparable across institutions and trials. Methodologies to determine AD vary widely. Therefore, we aim to highlight potential variability and identify the main contributing factors. ***Materials and Methods:*** Ten patients with oligometastatic hormone-sensitive prostate cancer underwent 5 timepoint SPECT/CT imaging after administration of 3 GBq [177Lu]Lu-PSMA-617. All data were collected and reconstructed at a single center and shared with two other centers with extensive dosimetry experience. Each center performed dosimetry calculations according to local practice. To compare differences in AD between centers the coefficient of variation (CV) was computed for every patient in each region (kidneys, salivary glands, liver and tumor lesions (n=21)). After harmonizing volumes, activity delineation and time-activity curve (TAC) fitting methods, the change in mean CV between centers was compared to determine the impact on AD variability. ***Results:*** The mean lesion AD across all centers was 13.7 Gy with a mean CV between centers of 63.0% (range: 14.3%-113.6%). The mean AD per center is reported in Table 1. Likewise, for the kidneys, salivary glands and liver the mean AD across all centers was 1.9, 2.2 and 0.4 Gy respectively, the mean CV between centers was 16.9% (range: 8.1%-25.7%), 36.4% (range: 12.2%-52.9%), and 23.5% (range: 9.8%-42.2%) respectively. After homogenizing the organ and lesion volumes across all centers (Table 1), the mean CV decreased to 37.0% for lesions and decreased to 33.8% for the salivary glands. The mean CV between centers remained relatively unchanged for the liver at 23.2%, but increased to 22.0% for the kidneys. Data analysis is in progress for homogenization across centers of activity delineation and TAC fitting methods. ***Conclusion:*** Inter-center variability in AD was highest in tumor lesions, followed by

the salivary glands and liver, while the kidneys showed the most agreement across centers. The variability in lesions and, to a lesser extent, in the salivary glands, is partly explained by challenging volume determination, as volume homogenization resulted in a decrease in CV for these regions. For larger regions, such as the liver and kidney, volume determination does not explain the differences in AD and even resulted in an increase in the mean CV for the kidneys, suggesting that the AD variability in these regions is primarily due to other factors (likely activity delineation and TAC fitting). Evaluation of these factors is currently ongoing.

Evaluation of Different Segmentation Methods for Lesion Dosimetry in mCRPC Patients Treated with ^{177}Lu-PSMA-617: Experience from the Canadian Cancer Trial Group PR.21 Trial (NCT 04663997)

***S. Kurkowska*[1,2]**, *P. L. Esquinas[3], I. Bloise[4], A. Ocampo[5], C. Dellar[6], W. Parulekar[6], F. Saad[7], K. Chi[8], K. Zukotynski[9], J. Beauregard[10], F. Benard[11,3], B. Birkenfeld[1], H. Piwowarska-Bilska[1], C. Uribe[11,3];*
[1]Department of Nuclear Medicine, Pomeranian MedicalUniversity, Szczecin, POLAND, [2]BC Cancer Research Institute, Vancouver, BC, CANADA, [3]BC Cancer, Vancouver, BC, CANADA, [4]IBCC Instituto Brasileiro de Controle do Cancer, Sao Paolo, BRAZIL, [5]Universidad La Gran Colombia, Bogota, COLOMBIA, [6]Canadian Cancer Trials Group, Kingston, ON, CANADA, [7]University of Montreal Hospital Center, Montreal, QC, CANADA, [8]BC Cancer, VANCOUVER, BC, CANADA, [9]Hamilton Health Sciences Centre, Hamilton, ON, CANADA, [10]Université Laval, Quebec City, QC, CANADA, [11]BC Cancer Research Institute, VANCOUVER, BC, CANADA.

Aim/Introduction: Lesion dosimetry in radiopharmaceutical therapies (RPTs) is challenging due to the difficulties in segmentation to determine both the true mass and activity of each lesion. A robust and simple segmentation method is crucial to determine absorbed dose (AD)-response relationships. We aim at finding a method to track dosimetry of qPSMA-determined tumor burden at the per-patient level for tumour dosimetry in 177Lu-PSMA-617 therapies of metastatic castration resistant prostate cancer (mCRPCa) patients. ***Materials and Methods:*** Ten mCRPCa patients treated with 177Lu-PSMA-617 were included in this study, each had prior PET/CT and two post-therapeutic SPECT/CTs. A reference segmentation method (method I) was established using qPSMA segmentation approach based on liver uptake and noise on 68Ga-PSMA-11 PET/CT and refined by manual adjustments by a nuclear medicine physician. The total tumour mass (TTM) was estimated from volume assuming unit density. Activity was quantified for each lesion with partial volume correction using simulated recovery coefficients (RCs). Method II used the same TTM; activity was determined by expanding regions by 1 cm in all directions. Methods III, IV, V were segmented on SPECT; both mass and activity were calculated from same VOIs. Method III used a gradient tool, method IV involved the qPSMA approach on SPECT, method V used threshold above 25% of SUVmax determined for the Whole Body. We performed monoexponential fitting and integration for each lesion to get Time-Integrated Activity coefficients (TIACs) and used OLINDA/EXM with spherical models and mass scaling to estimate ADs. We compared TTM, TIAC, and AD for each method against the reference method using mean square difference (MSD) and assessed their correlation. ***Results:*** Method II gave MSDs of 95.9 for TIAC assessment and 1.8 for AD. Method III showed MSDs of 28090.5 for TTM, 2.6 for TIAC, 3.4 for AD. Method IV gave MSDs of 175560.9 for TTM, 34.4 for TIAC, 3.6 for AD. Method V resulted in MSDs of 1123182.8 for TTM, 22.6 for TIAC, and 2.2 for AD. Method II had the strongest correlation with Method I (the reference) with 0.93, followed by Method III at 0.68, Method IV at 0.6, and Method V at 0.56. ***Conclusion:*** Results suggest that Method II can be reliable for tracking dosimetry of qPSMA-determined tumor burden. This method simplifies the process by eliminating the need for RC measurements and allows to identify more lesions by taking advantage of the diagnostic PET. SPECT-derived methods showed poorer correlation with the reference method.

^{18}F-FDG PET/CT imaging biomarkers in patients with Recurrent/Refractary Multiple Myeloma at baseline and post CAR-T Therapy for predicting clinical outcomes.

M. Romera, *F. Mínguez, V. Betech, A. Basanta, J. Rosales, L. García-Belaustegui, L. Tamariz, M. Panizo, S. Huerga, P. Rodriguez-Otero, J. San-Miguel, F. Pareja del Rio, M. García-Velloso;*
Clínica Universidad de Navarra, Navarra, SPAIN.

Aim/Introduction: To assess the predictive value of 18F-FDG PET/CT imaging biomarkers for patients with recurrent/refractory Multiple Myeloma (RRMM) at pre-CAR-T therapy, and in patient follow-up at 1 and 3-months after the therapy. ***Materials and Methods:*** 69 patients with RRMM treated with Chimeric antigen receptor T-cell (CART-T) therapy from April 2018 to January 2024, were enrolled. Two patients died due to ICANS. Following IMPeTUS criteria, bone marrow (BM) uptake, focal lesions (FL), paramedullary (PMD) and extramedullary disease (EMD) were recorded, considering a Deauville Score (DS) ≥ 4 as positive for any of the mentioned variables. ***Results:*** Tumour burden variables showed impact on progression-free survival (PFS). Patients with positive PET (52 [77.6%]) had significantly inferior PFS (median 8.2 months vs. 27.5; p=0.02). Patients with more than 10 lesions at baseline had significantly inferior PFS (median 7.1 months vs. 22.3; p=0.008) and overall survival (median 23.1 months vs. NR; p=0.003) than those without focal lesions. EMD was associated with worse PFS (median 3.7 months vs. 12; p=0.03). One-month after CAR-T 16/49 (32.7%) patients had complete response by PET (PETCR), and 3-months after CAR-T 15/29 more patients (51.7%) achieved PETCR. Patients without PETCR 1-month after CAR-T had shorter OS (median 13.2 months [95% CI 10.5-15.8] versus NR (p = 0.01); than those with PETCR. Patients without PETCR 3-month after CAR-T had shorter OS (median 7.8 [95% CI 1.2-14.6] versus 25.3 months [95% CI 14-36,6] (p = 0.02); than those with PETCR. Volumetric PET biomarkers MTV >590 and TLG>1640 were associated with lower PFS ([median 3.7 vs. 14.5 months; p=0.02] and [median 3.7 vs. 15.6 months; P=0.005], respectively). ***Conclusion:*** Baseline FDG-PET/CT tumour burden and metabolic response have prognostic value in MMRR patients treated with CAR-T cells. PETCR at 1 and 3 months after CAR-T cells predicts longer OS.

OP-358

Validating novel ^{18}F-FDG PET/CT-based approaches in multiple myeloma

M. Piller[1], *M. Hajiyianni[2], M. Groezinger[1], A. Kopp-Schneider[1], E. K. Mai[2], L. John[2], N. Weinhold[3], S. Sauer[2], M. S. Raab[2], A. Jauch[4], S. Delorme[1], H. Goldschmidt[2], A. Dimitrakopoulou-Strauss[1], C. Sachpekidis[1];*
[1]German Cancer Research Center (DKFZ), Heidelberg, GERMANY, [2]University Hospital Heidelberg and National Center for Tumor Diseases (NCT), Heidelberg, GERMANY, [3]University Hospital Heidelberg, Heidelberg, GERMANY, [4]Institute of Human Genetics, University of Heidelberg, Heidelberg, GERMANY.

Aim/Introduction: To validate novel approaches to 18F-FDG PET/CT evaluation with respect to clinically relevant parameters in MM. ***Materials and Methods:*** 83 MM patients underwent 18F-FGD PET/CT before treatment in the context of a multicentre, randomized, phase 3 trial (GMMG-HD7). PET/CT data analysis was based on the IMPeTUs criteria, which take into account bone marrow (BM) metabolic status based on the 5-point Deauville score (DS), the number and metabolic status of focal 18F-FDG-avid lesions, paramedullary disease, extramedullary disease, number of osteolysis and presence of fractures. Low-dose CT data were further evaluated according to the degree of medullary density in the appendicular skeleton based on two novel approaches: the first approach measured CT values (CTv) over the site with the highest HU in all humeri and femurs. The second approach was based on automatic digital quantification of CT data to determine the proportion of voxels affected by plasma cell infiltration in humeri and femurs (cCTv). Correlation analysis was performed between imaging, histopathological, cytogenetic and clinical data. Results were considered significant for $p<0.05$. ***Results:*** According to IMPeTUs, an increased BM 18F-FDG uptake (DS≥4) was associated with significantly higher BM plasma cell infiltration rate (mean values: 67.5% for DS≥4 vs. 30.1% for DS<4) and plasma levels of β2-microglobulin (mean values: 5.5 mg/L for DS≥4 vs. 2.5 mg/L for DS<4), and lower levels of haemoglobin (mean values: 11.0 g/dL for DS≥4 vs. 12.6 g/dL for DS<4). Moreover, the presence of fractures was associated with significantly higher BM plasma cell infiltration rate (mean values: 48.5% vs. 33.6%), plasma levels of β2-microglobulin levels (mean values: 5.0 mg/L vs. 2.6 mg/L), and Lower levels of haemoglobin (mean values: 11.4 g/dL vs. 12.4 g/dL). CT analysis revealed a significant moderate positive correlation between the quantitative CT parameters, CTv and cCTv, and the degree of BM plasma lell infiltration rate (r= 0.33 and 0.28, respectively), plasma levels of β2-microglobulin (r= 0.33 and 0.27, respectively) as well as a moderate negative correlation with haemoglobin (r= -0.21 and -0.20, respectively). Furthermore, patients with increased BM 18F-FDG uptake (DS≥4) showed significantly higher CTv (mean values: 44.6 HU for DS≥4 vs. 11.8 HU for DS<4) and cCTv (mean values: 5.8 HU for DS≥4 vs. 5.4 HU for DS<4) values. ***Conclusion:*** Novel approaches for the interpretation of 18F-FDG PET/CT data correlate with clinically relevant parameters in MM and may provide a reliable tool towards the optimisation and standardisation of PET/CT interpretation in MM.

OP-359

Assessing the theranostic potential of SSTR imaging in advanced multiple myeloma patients - the SCARLET trial

W. Delbart, *I. Karfis, M. Vercruyssen, S. Vercauteren, Z. Wimana, N. Meuleman, P. Flamen, E. Woff;*
BE0257981101, Anderlecht, BELGIUM.

Aim/Introduction: Established evidence of somatostatin receptor subtype 2 (SSTR2) overexpression in multiple myeloma (MM) patients, demonstrated on SSTR imaging (scintigraphy1 or PET/CT2), led us to design the SCARLET (Somatostatin reCeptors imAging in ReLapsing and rEfractory mulTiple myeloma patients) prospective phase II trial (NCT04379817). This study aims to assess SSTR2 overexpression on 68Ga-DOTATATE PET/CT in symptomatic relapsing and refractory MM (rrMM) patients as a preparatory step before a SSTR-based theranostic trial. ***Materials and Methods:*** Nineteen rrMM patients (10 women and 9 men) have currently been included in this trial (initially planned for 20 patients). All patients had stage II or III disease at the time of diagnosis according to the Durie-Salmon staging system and had received at least three previous lines of treatment at study inclusion. Patients underwent 18F-FDG and 68Ga-DOTATATE PET/CT scans within a maximum interval of 4 weeks with a standardised image acquisition protocol. Target lesions were defined as unequivocal tumoral uptake higher than the femoral bone marrow background uptake. For each radiotracer, a maximum of 15 target lesions were selected. ***Results:*** The median time interval between 18F-FDG and 68Ga-DOTATATE PET/CT was 9 days. Patient-based analysis showed that 16 of the 19 patients had one or more target lesions on 68Ga-DOTATATE PET/CT, with the same proportion of patients having one or more target lesions on 18F-FDG PET/CT. Two patients had no target lesions on either PET scan. The disease was mainly osteomedullary, and six patients had para- and/or extramedullary disease. 68Ga-DOTATATE PET identified more lesions than 18F-FDG in 7 patients, with no 18F-FDG+/68Ga-DOTATATE- lesions. Conversely, 18F-FDG PET/CT identified more lesions than 68Ga-DOTATATE in 7 patients as well. Three patients had a perfect match. Two 68Ga-DOTATATE PET scans were not interpretable due to diffuse uptake. Based on imaging criteria, 10 of the 19 patients could be eligible for peptide receptor radionuclide therapy (PRRT). ***Conclusion:*** In heavily pretreated rrMM patients, 68Ga-DOTATATE PET/CT identified half of the study population as candidates for a SSTR-based theranostic approach. 68Ga-DOTATATE PET/CT could be used as a PET companion diagnostic tool to select patients for 177Lu-PRRT or targeted alpha therapy. ***References:*** 1Agool A et al. OP-360

Application of ^{18}F-FAPI combined with ^{18}F-FDG imaging in assessment of myelofibrosis: a retrospective case series study

J. Zhang, *D. Tian, Y. Zhang, H. Wang, X. Su, J. Sun;*
the First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, Zhejiang Province, CHINA.

Aim/Introduction: Myelofibrosis is a rare hematopoietic stem cell neoplasm characterized by bone marrow (BM) inflammation, marked BM fibrosis (BMF), and inefficient hematopoiesis. The direct and noninvasive methods to assess systemic BMF are still currently unavailable. We aim to evaluate the application of fluorine 18 (18F)-labeled FAP inhibitor (18F-FAPI) PET/MRI combined with 18F-fluorodeoxyglucose (18F-FDG) PET/CT imaging in assessing myelofibrosis. ***Materials and Methods:*** We retrospectively collected 18 patients with myelofibrosis (8 primary

and 10 secondary) from April 2022 to November 2023. The extent and intensity of 18F-FDG or 18F-FAPI accumulation in BM were graded on a 5-level scale and scored by a 12-point scale, in which the whole body was divided into 6 regions and each region had a maximum of 2 points. The spleen volume (SV) and radioactive uptake were measured. The imaging findings, laboratory parameters, and grades of BMF from BM biopsy were analyzed by PASW Statistics 18 software. A P-value <0.05 was considered statistically significant. ***Results:*** 1) The relationship of imaging and histopathology in subgroups with different grades of BMF (Grade 0-1, n=6 vs. Grade 2-3, n=12): The subgroup with grade 2-3 of BMF had a higher grade and score of 18F-FAPI imaging, respectively (P<0.05). No significant differences between subgroups were observed in those of 18F-FDG imaging and laboratory parameters (P>0.05). The grade of BMF was positively correlated with the grade (r=0.739) and score (r=0.553) of 18F-FAPI imaging, respectively (P<0.05). The grade (r=0.518), score (r=0.684), and the SUVmax in the spleen (r=0.757) of 18F-FAPI imaging were positively correlated with the SV, respectively (P<0.05). No significant correlations were shown between the grade of BMF and those of 18F-FDG imaging (P>0.05). 2) The characteristic imaging patterns of 18F-FAPI plus 18F-FDG imaging in myelofibrosis: Three imaging patterns were presented in this series, including (A) mismatch of both BM and spleen (n=11), (B) match of BM and mismatch of spleen (n=3) and (C) match of both BM and spleen (n=4). The grade of 18F-FAPI in pattern C was higher than that in pattern A (P<0.01). The scores of 18F-FAPI in patterns B and C were higher than those of pattern A (P<0.05), respectively. ***Conclusion:*** Our data indicate that the 18F-FAPI imaging can reflect more accurately the grade of BMF than the 18F-FDG imaging in myelofibrosis. The characteristic imaging patterns of 18F-FAPI combined with 18F-FDG imaging may be able to represent the different disease stages of myelofibrosis. Further prospective studies are necessary.

OP-361

Paramedullary disease in Multiple Myeloma after treatment: is there a possible prognostic role of Whole body low dose CT (WBLDCT) vs ^{18}F-FDG-PET/CT?

D. Bezzi[1], *M. Di Franco[2], A. Poletti[3], E. Zamagni[4], M. Talarico[4], K. Mancuso[4], C. Nanni[5];*
[1]Nuclear Medicine Unit, AUSL Romagna, Forli-Cesena, ITALY, [2]Nuclear medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY, [3]DIMEC – Department of Medical and Surgical Science, University of Bologna, Bologna, ITALY, [4]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Istituto di Ematologia "Seràgnoli", Bologna, ITALY, [5]Nuclear Medicine, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.

Aim/Introduction: The post-therapy assessment of paraskeletal plasmacytoma(PM) in multiple myeloma(MM) is still based on lesion persistence and/or its change in size on WBLDCT. Indeed, anatomically evident PM lesions on WBLDCT often persist in ^{18}F-FDG PET/CT(FDG-PET/CT) complete metabolic responders. The aim of this study was to evaluate whether WBLDCT and FDG-PET/CT before and after therapy have prognostic value in this subgroup of patients, in view of future improvements of imaging response criteria. ***Materials and Methods:*** We retrospectively reviewed FDG-PET/CT and low-dose CT(CT) images of patients newly diagnosed with symptomatic MM and carriers of PM lesions, who underwent first-line therapy during the period from October 27,2016 to June 12,2021. In addition, a small subgroup of patients with a diagnosis of solitary plasmacytoma(PSO) was also reviewed. Inclusion criteria were a baseline FDG-PET/CT scan and a subsequent negative FDG-PET/CT scan prior to starting maintenance therapy. Negative FDG-PET/CT was defined applying the Deauville scores(DS) for focal lesions, PM lesions and bone marrow uptake and defining complete metabolic response(CMR) as uptake below liver background(DS <4). FDG-PET/CT parameters reported according to the Italian-Myeloma-Criteria-for-PET-Use(IMPeTUs), CT morphological and technical parameters, and various baseline laboratory data were tested in univariate and multivariate analyses for their impact on clinical outcomes. ***Results:*** We reviewed 42 patients with a median follow-up of 41 months; 39 affected by MM, 3 by PSO. Post-therapy SUVmax of the PM lesions was a significant parameter of adverse PFS and post-therapy Deauville Score 3(DS3) in the PM lesions(PM-DS3) distinguished a subgroup of patients with significantly worse prognosis regarding PFS(medianPFS 27mo vs not reached, HR=3.45, p-value=0.05), confirmed as an independent factor in multivariate analysis; furthermore, there was a trend towards worse OS(medianOS 52mo vs not reached, HR=2.99, p-value 0.16).In patients undergoing autologous stem cell transplantation only (n=32), PM-DS3 was significant in predicting PFS(median 27mo vs 74mo, p-value=0.015) and OS(median 39mo vs not reached, p-value=0.03). CT was not able to stratify patients into prognostic subgroups if we exclude some morphological parameters, as the transverse diameter before maintenance as a numeric variable(PFS, HR=1.86, p-value=0.02), with no significant impact on OS(HR: 1.1, p-value=0.82) and the absence of cortical bone regeneration in the multivariate analysis. ***Conclusion:*** Pre-maintenance PM-DS3 has been shown to be representative of adverse outcomes. Our results demonstrate the added value of FDG-PET/CT when compared to WBLDCT alone, and highlight the possibility of refining future PET monitoring or adapted therapy in this patient population.

OP-362

Prognostic utility of baseline ^{18}F-FDG PET/CT in patients with relapsed and refractory multiple myeloma treated with bispecific monoclonal antibodies.

M. Romera, *F. Mínguez, V. Betech, A. Basanta, J. Rosales, L. García-Belaustegui, L. Tamariz, M. Panizo, S. Huerga, P. Rodriguez-Otero, J. San-Miguel, M. García-Velloso;*
Clínica Universidad de Navarra, Navarra, SPAIN.

Aim/Introduction: To establish the prognostic value of 18F-FDG PET/CT in patients with relapsed/refractory multiple myeloma (RRMM) prior to treatment with bispecific monoclonal antibodies (BsAbs). ***Materials and Methods:*** 116 patients with RRMM eligible for BsAbs treatment underwent 18F-FDG PET/CT from June 8, 2018, to April 5, 2024. Following IMPeTUS criteria, bone marrow (BM) uptake, focal lesions (FL), paramedullary (PMD) and extramedullary (EMD) disease were assessed, considering a Deauville Score (DS) ≥ 4 as positive for any of the mentioned variables. Tumor Metabolic Volume (MTV) and Total Tumor Glycolysis (TLG) were calculated for each lesion. Skeleton was segmented using automatic segmentation software and MTV and TLG were calculated for bone (MTV-B and TLG-B), EM (MTV-E and TLG-E) and total disease (MTV-T and TLG-T). Patient outcome was analyzed using Kaplan-Meier method and Cox regression. ***Results:*** 18F-FDG PET/CT was positive in 101 (87.1%) patients, with diffuse BM uptake with DS≥4 in 59 (5.9%) patients. FL were detected in 88 (75.9%) patients, with DS≥4 in 80 (69.0%); PMD in 57 (49.1%) patients and EMD in 44 (37.9%). Tumour burden variables showed an impact on progression-free survival (PFS). Patients with MTV-T > 336 (26 [27.1%]) had significantly inferior PFS (median 2 months vs. 9; p<0.001). Among EM patients, those with MTV-E > 60 had significantly inferior PFS (median 2 vs. 9 months;

p=0.02). Regarding overall survival (OS) among EM patients, those with MTV-E > 60 and those with MTV-T > 336 had significantly inferior OS (median 4 months vs. 14; p=0.005). ***Conclusion:*** Extramedullary tumor burden prior to BsAbs treatment in RRMM patients significantly reduces PFS and OS. Patients with MTV > 336 also had significantly inferior PFS.

Aim/Introduction: Daratumumab is an anti-CD38 monoclonal antibody currently used for treatment of patients with multiple myeloma (MM). Aim of our prospective study is to determine whether 18F-FDG PET/CT is effective in assessing and predicting early response to daratumumab in patients with relapsed/refractory MM. ***Materials and Methods:*** We selected 54 consecutive patients with relapsed/refractory MM (26M; mean age 70.9 years), scheduled for second- or third-line treatment with daratumumab (in combination with either bortezomib or lenalidomide), and enrolled in an Italian multicentric observational prospective study (DaRMyPET) to perform 18F-FDG PET/CT before (baseline-PET/CT) and after 6 months of treatment (interim-PET/CT). At both baseline and interim PET/CT, the following qualitative and semi-quantitative parameters were analysed: focal active intra-medullary, para-medullary and extra-medullary MM lesions (number and site), SUVmax and SUVmean of the most active lesion, ratio between lesion SUVmax and liver parenchyma or mediastinal blood-pool SUVmean (rSUV-liver and rSUV-med, respectively), summed MTV and TLG of active MM lesions contoured using three different methods (Deauville score ≥ 4; lesion SUVmax > 2.5; lesion SUVmax ≥ 1.5 times than liver SUVmean). Based on an integrated clinical-laboratory evaluation, haematological response was assessed after 6 months of treatment (according to the International Myeloma Working Group criteria). Potential differences in interim and baseline PET/CT parameters between patients with haematological complete or non-complete response (i.e. in partial-response/disease-progression) were statistically analysed (statistical significance set at p<0.05; suggestive association till p<0.10). ***Results:*** Finally, 39/54 patients who performed both baseline and interim PET/CT and with assessable haematological response at 6 months after treatment were analyzed: 26/39 in complete response; 13/39 in non-complete response. From interim PET/CT, significantly higher median SUVmax and rSUV-liver were found in patients with non-complete response than in those with complete response: 3.91 (IQR 3.31-5.20) vs 2.70 (IQR 2.44-3.94) for SUVmax (p=0.03); 2.00 (IQR 1.35-2.62) vs 1.12 (IQR 0.88-1.46) for rSUV-liver (p=0.023); suggestive association with non-complete response was found for higher median SUVmean: 2.26 (IQR 2.04-2.98) in non-complete responders vs 1.77 (IQR 1.46-2.27) in complete responders (p=0.057). From baseline PET/CT, summed MTV using lesion SUVmax > 2.5 was significantly higher in non-complete than in complete responders: 31.10 (IQR 5.47-85.73) vs 2.80 (IQR 0.53-29.59), p=0.04. ***Conclusion:*** Metabolic parameters from 18F-FDG PET/CT are valuable biomarkers for assessing and predicting early haematological response to daratumumab in patients with relapsed/refractory MM.

OP-364

Metabolic Dilemmas of Myeloma; Quandaries Between Laboratory, FDG and FCH

G. Kaya[1], *S. Akın[2], Y. Büyükaşık[3], M. Tuncel[1], M. Bozkurt[1], P. Özgen Kıratlı[1];*
[1]Hacettepe University Medical School Department of Nuclear Medicine, Ankara, TÜRKIYE, [2]Hacettepe University Medical School Department of Medical Oncology, Ankara, TÜRKIYE, [3]Hacettepe University Medical School Department of Haematology, Ankara, TÜRKIYE.

Aim/Introduction: Multiple myeloma(MM), malignancy of the bone and resultant organ damage. The assessment of disease relies on clinical-laboratory findings as well as imaging modalities. FDG PET-CT is a curated choice, although its sensitivity can be limited especially for minimal-residual-disease (MRD). IMPeTUs criteria have been shown to enhance the sensitivity. Recently, preliminary investigations with F^{18}-Fluorocholine (FCH) PET-CT in limited study cohorts have suggested superior diagnostic performance compared to FDG. Our objective is to delineate the diagnostic-efficacy of molecular imaging in MM patients, refine imaging-parameters and correlate these methods with clinicopathological-laboratory findings. ***Materials and Methods:*** Patients aged-18-years and older with myeloma, who have undergone FDG (60th min.) and FCH (10th and 60th min.) PET-CT examinations within 4-weeks were included. In this retrospective-single-center study with ethics-committee-approval; the association between both imaging modalities and clinical-laboratory parameters were investigated. The study entails a comparative analysis of the diagnostic performances of FDG and FCH according to IMPeTUs-criteria. A-total-body semiquantitative analysis was generated similar to SIOPEN method (8-skeletal, 2-soft tissue region multiplied by SUVmax) and was referred as 'hTepe score'. To classify the patients with dual-imaging, NETPET score-alike 5-point MyPET score was calculated as well. Correlations between imaging and clinic-laboratory findings were investigated. ***Results:*** Thirty-five patients (F/M: 13/22) were included to this study. The mean age was 62(±10) years. All, but one patient, had biologically proven active myeloma. Metabolic-active lesions were detected by FDG and FCH in 17(49%) and 32(91%) of the patients, respectively. Median marrow Deauville-Score (DS) was 3(min-max: FDG:2-5; FCH:3-4) in both methods. Median hypermetabolic-focus scores were 1: no-focus (min-max: 1-4) and 4: >10 focus (min-max: 1-4). For skeletal system assessment, FCH demonstrated higher sensitivity in both patient-based and region-based analyses compared to FDG,

exhibiting superior performance; in extramedullary-disease equal performance was observed in both methods, but no patient was MyPET4-5(FDG>FCH)(Table-1). Sensitivity, accuracy, and AUC values for ROC analysis were 50%(CI: 32-67), 51.4%(CI: 34-68), 0.750 for FDG and 94.1 %(CI: 80-99), 94.1 %(CI: 80-99), 0.971 for FCH, respectively. Moderate correlation was seen for hTepe-score, with CD138-marrow-infiltration, hemoglobin, albumin-globulin, secreted-immunoglobulin, lambda-light-chain and proteinuria for FCH; CD138-marrow-infiltration, globulin and proteinuria for FDG. Other laboratory values had no correlation with any of the imaging parameters. ***Conclusion:*** FCH emerges as a viable option in MM, particularly when FDG fails to demonstrate metabolic activity or yields inconclusive results. It excels in detecting MRD and correlation with clinicopathologic-laboratory results.

OP-365

Volumetric histogram-based analysis of standardized uptake values and apparent diffusion coefficients for early immunotherapy assessment in relapsed/refractory multiple myeloma: preliminary results of a PET/MRI study

R. Winzer[1], *K. Epp[2], R. Apolle[1], I. Platzek[3], R. Teipel[2], K. Trautmann[2], S. Raad[1], C. Brogsitter[4], M. Miederer[1];*
[1]Department of Translational Imaging in Oncology, National Center for Tumor Diseases Dresden (NCT/UCC), Dresden, GERMANY, [2] Department of Internal Medicine I, University Hospital Carl Gustav Carus Dresden, Dresden, GERMANY, [3]Institute and Polyclinic for Diagnostic and Interventional Radiology, University Hospital Carl Gustav Carus Dresden, Dresden, GERMANY, [4]Department of Nuclear Medicine, University Hospital Carl Gustav Carus Dresden, Dresden, GERMANY.

Aim/Introduction: This study evaluates histogram-based PET and diffusion-weighted MRI (DWI) parameters derived from volumetric FDG PET/MRI segmentation for differentiating partial (PR) and complete metabolic response (CR) to immunotherapies, specifically Chimeric Antigen Receptor T-cell (CAR-T) therapy and bispecific T-cell engager (TCE) antibodies, in relapsed/refractory multiple myeloma (MM). ***Materials and Methods:*** Between July 2023 and March 2024, eleven MM patients (seven males, mean age 64.6 years, range 59-74 years) underwent FDG PET/MRI scans before and after receiving either CAR-T cell therapy (n=8) or bispecific antibodies (n=3), with a mean interval of 67.5 days. Whole-body DWI was acquired at diffusion weights of 50 and 800 s/mm^2 and ADC maps calculated. Volumes of interest (VOIs) were segmented on baseline DWI (b800) for selected lesions (high signal-to-background ratio, no motion or susceptibility artifacts, no overlap with adjacent structures, n=75, nbone=61) using a semi-automated threshold-based technique. These were transferred to baseline PET and follow-up imaging after deformable registration. Quantitative DWI (ADCmean, ADCkurtosis, ADCskewness) and PET metrics (SUVmax, SUVmean, SUVkurtosis, SUVskewness) were extracted from each lesion and compared between pre- and post-therapeutic scans (absolute change, percent change). Patients were classified into two subgroups, PR and CR, based on the post-therapeutic Deauville score (DS). Diffuse post-therapeutic bone marrow activation was evaluated as not attributable to myeloma (DSx). Group differences (nPR=4, nCR=7) were assessed using Mann-Whitney U test. P-values were adjusted using the Benjamini-Hochberg correction. The effect size was quantified using Cohen's d to evaluate the magnitude of differences between groups, with values of 0.2, 0.5, and 0.8 indicating small, medium, and large effects. Additionally, ROC (Receiver Operating Characteristic) curve analysis was performed to assess the diagnostic performance of each parameter to distinguish subgroups. ***Results:*** The absolute and percent changes in ADCmean demonstrated a good discriminative power for differentiating PR from CR (AUCs = 0.73 and 0.74) with medium to large effect sizes (Cohen's d = 0.75 and 0.65; p-values = 0.0189), highlighting their potential in distinguishing metabolic responses effectively. Absolute ADCskewness showed the largest effect size (Cohen's d = 0.96, p-value = 0.0099) but low discrimination (AUC = 0.23). In contrast, percent changes in SUVskewness had a minimal effect size (Cohen's d = 0.05), indicating limited differentiation capability. ***Conclusion:*** This small patient cohort indicates that ADC measurements may be suited for immunotherapy monitoring relapsed/refractory MM, offering a quantitative tool to potentially assist clinical decision-making.

Critical Role of ^{99m}Tc-SESTAMIBI Scintigraphy with SPECT/CT in expeditious management of PTH dependent severe hypercalcemia

C. Ganapathy[1], *N. Damle[1], K. Mathiazhagan[1], C. Bal[1], G. Priyanka[1], A. Vishnu[1], Y. Dharmshaktu[1], R. Wakankar[1], S. Chumber[2], V. Seenu[2], P. Ranjan[2], K. Kataria[2], G. Puri[2], N. Tandon[3], Y. Gupta[3], P. Namjoshi[3], R. Reddy[3];*
[1]Department of Nuclear Medicine, All India Institute of Medical Sciences (AIIMS), New Delhi, INDIA, [2]Department of Surgical Disciplines, All India Institute of Medical Sciences (AIIMS), New Delhi, INDIA, [3]Department of Endocrinology, Metabolism and Diabetes, All India Institute of Medical Sciences (AIIMS), New Delhi, INDIA.

Aim/Introduction: Severe hypercalcemia (serum Ca2+ levels: >/= 14mg/dl) is a metabolic emergency, frequent cause being sporadic primary hyperparathyroidism (PHPT), due to parathyroid adenomas. While some may be asymptomatic, most show rapid evolution of clinical symptoms that can be potentially fatal. Focussed parathyroidectomy is the cornerstone in managing these patients, yielding excellent short and long-term outcomes. The present study aims to evaluate the role of expeditious 99mTc-SESTAMIBI scintigraphy combined with single-photon emission computed tomography (SPECT/CT) imaging in patients with PTH dependent severe hypercalcemia. ***Materials and Methods:*** Records of patients with severe hypercalcemia (serum Ca2+ - >/=14mg/dl) who underwent 99mTc-SESTAMIBI scintigraphy at our center from January 2016 to March 2024 were retrospectively evaluated. The scintigraphy protocol included intravenous administration of 99mTc-SESTAMIBI, followed by early and late planar imaging at 20 minutes and 2 hours post-injection respectively. Additionally, SPECT/CT

imaging was conducted at 50 minutes post-injection for precise anatomical localization. Imaging findings were correlated with intra-operative findings and pre/post-operative biochemical parameters. ***Results:*** 38 patients (16-men & 22-women, median age: 37 years) with severe hypercalcemia underwent 99mTc-SESTAMIBI scintigraphy for pre-operative localization of parathyroid adenoma at our center, with the most common clinical manifestations being nephrolithiasis, bone pain and fractures. The median parathormone (PTH, normal range:15-65pg/ml) and calcium levels (normal range: 8.5-10.5mg/dl) were 1337pg/ml (152-4352pg/ml) and 15.1mg/dl (14.0-20.3mg/dl) respectively. The ready availability of 99mTc-SESTAMIBI scintigraphy (median waiting time: 3 days) and its ability to rule out ectopic glands reduced the time interval between clinical presentation/diagnosis and surgery (median time: 7 days, range: 1-45 days). Serum calcium levels normalized in all operated patients. 34 patients (89%) had a single parathyroid adenoma, while 4/38 (11%) patients had more than one parathyroid adenoma on scintigraphic evaluation. The median antero-posterior diameter of the adenomas was 2.35cms (0.5-6.7cms). Of the 44 lesions identified overall, 20/44 (45.4%) were right inferior parathyroid adenomas (most common), followed by 13/44 (29.6%) left inferior parathyroid adenomas. 6/44 (13.6%) and 5/44 (11.4%) were right superior and left superior parathyroid adenomas respectively. ***Conclusion:*** In life threatening PTH dependent severe hypercalcemia, expeditious 99mTc-SESTAMIBI scintigraphy with SPECT/CT shortened the time gap between clinical presentation/diagnosis and surgery while accurately localizing the culprit adenoma and ruling out ectopic glands at the same time, thereby enabling timely focussed parathyroidectomies that resulted in in biochemical cure and improvement of clinical outcomes.

OP-368

How [18F]Fluorocholine PET/CT Can Replace Three Preoperative Diagnostics to Localise Parathyroid Adenomas in Patients Suffering from Primary Hyperparathyroidism: A Cost-Effectiveness Analysis

S. van Mossel[1,2], *S. Saing[2], N. M. Appelman-Dijkstra[1], E. Quak[3], A. Schepers[1], F. Smith[1,4], L. de Geus-Oei[1,2,5], D. Vriens[6];*
[1]Leiden University Medical Center, Leiden, NETHERLANDS, [2]University of Twente, Enschede, NETHERLANDS, [3]Centre François Baclesse, Caen, FRANCE, [4]Alrijne Hospital, Leiderdorp, NETHERLANDS, [5]Delft University of Technology, Delft, NETHERLANDS, [6]Radboud University Medical Center, Nijmegen, NETHERLANDS.

Aim/Introduction: We conducted a cost-effectiveness analysis in which we compared a preoperative one-stop-shop imaging strategy based on partial-body (from skull-base to heart-base) [18F]Fluorocholine PET/CT with current best practice in which [18F]Fluorocholine PET/CT is only recommended after negative or inconclusive ultrasonography and [99mTc]Tc-methoxy isobutyl isonitrile SPECT/CT for patients suffering from primary hyperparathyroidism. We investigated whether the one-stop-shop strategy performs as well as current best practice but at lower costs. ***Materials and Methods:*** We developed a cohort-level state transition model to evaluate both imaging strategies while respecting an intraoperative parathyroid hormone-monitored treatment setting as well as a traditional treatment setting without intraoperative parathyroid hormone monitoring. The model reflects patients' hospital journeys after primary referral for biochemically diagnosed hyperparathyroidism. A cycle length of twelve months and a lifetime horizon were used. We conducted probabilistic analyses simulating 50,000 cohorts to assess joint parameter uncertainty. The incremental net monetary benefit and costs for each quality-adjusted life year were estimated. Furthermore, threshold analyses were performed regarding the tariff of partial-body [18F]Fluorocholine PET/CT and the sensitivity of [99mTc]Tc-methoxy isobutyl isonitrile SPECT/CT. ***Results:*** The simulated long-term health effects were similar for both imaging strategies. Accordingly, the one-stop-shop imaging strategy did not result in reduced patient outcomes. A tariff of less than €900 for partial-body [18F]Fluorocholine PET/CT was required to be cost-saving compared to current best practice. These results applied to both treatment settings. The decision to implement either imaging strategy depended on available local resources as well as meeting patient preferences. The one-stop-shop strategy reduced the number of hospital visits, travel times, waiting times, hospital waste and radiation burden, and enabled easy resource capacity allocation. All are fundamentally preferable regarding logistics, environmental impact and interference in patients' lives. ***Conclusion:*** The one-stop-shop imaging strategy based on partial-body [18F]Fluorocholine PET/CT can replace three preoperative diagnostic modalities, and both preoperative strategies can be used interchangeably. Daily clinical practice grounds such as available capacity allocation and patient preferences should inform policy-making on whether a hospital should implement the one-stop-shop imaging strategy.

Crucial elements of parathyroid gland assessment in PET/CT with [11C]-methionine.

M. Kolodziej[1,4], *M. Saracyn[1], A. Lubas[2], M. Dziuk[3,4], A. D. Durma[1], A. Mazurek[3,4], S. Niemczyk[2], G. Kamiński[1];*
[1]Department of Endocrinology and Isotope Therapy, Military Institute of Medicine - National Research Institute, Warsaw, POLAND, [2]Department of Internal Medicine, Nephrology and Dialysis, Military Institute of Medicine - National Research Institute, Warsaw, POLAND, [3]Department of Nuclear Medicine, Military Institute of Medicine - National Research Institute, Warsaw, POLAND, [4]Affidea PET/CT, Warsaw, POLAND.

Aim/Introduction: PET/CT with [11C]MET is one of the useful preoperative diagnostic techniques for patients with tertiary hyperparathyroidism (THP). Some drugs used in dialysis patients may potentially influence the results of this imaging. Lean body mass (LBM) in these patients may change significantly (depending on the time since the last dialysis).The aim of the study was to assess the usefulness of determining SUV in lesions visible in [11C]MET PET/CT for total body weight (TBM) and LBM and to determine the impact of calcimimetics on SUV in [11C]MET PET/CT in the group of patients with THP. ***Materials and Methods:*** We analyzed results of 18 PET/CT performed in patients with THP after administration 5 MBq/kg body weight of [11C]MET using a Discovery 710 GE Medical Systems scanner.In each parathyroid gland found in PET/CT, SUVmax for TBM and LBM was measured, and the tumor/background ratio (TBR) was determined (reference point - the right thyroid lobe. In the analyzed group, 9 patients were treated with calcimimetics, which were not withdraw before PET/CT. ***Results:*** The mean SUVmax in parathyroid gland was 5.85 ± 2.05 and 4.23 ± 1.29 for TBM and LBM respectively, while the TBR for TBM was 2.85 and for LBM 2.87 (p=0.97).There were no statistically significant differences in SUVmax between the groups of patients treated and not treated with calcimimetics.For TBM, the mean SUVmax was 6.76 ± 2.56 in the subgroup with, and 5.91 ± 1.85 without calcimimetics (p=0.51). For LBM, 4.83 ± 1.82 and 4.42 ± 1.25, respectively (p=0.65). ***Conclusion:*** SUV for TBM is sufficient in the quantitative assessment of parathyroid

glands in [11C]MET PET/CT and does not need to be corrected for LBM.Calcimimetics has no impact on [11C]MET uptake in the parathyroid glands, and withdraw such treatment is not necessary before PET/CT in patients with THP.

OP-370

Role of 18F-Fluorocholine PET-CT in the Localization of Ectopic Lesions in Patients with Primary Hyperparathyroidism

Y. Dharmashaktu, *N. Damle, R. Wakankar, C. Bal, S. Chumber, Y. Gupta, D. K, S. Agarwal, P. Ranjan, G. Puri;*
All India Institute of Medical Sciences, Delhi, INDIA.

Aim/Introduction: In primary hyperparathyroidism (PHPT), there are times when a parathyroid adenoma is ectopic in location. In these patients 18F-Fluorocholine PET-CT (18F-FCH PET-CT) is helpful for lesion localisation and this can have a major impact on planning patient management.In the present study we retrospectively evaluated the role of 18F-FCH PET-CT in detection of ectopic parathyroid adenomas in all patients of PHPT that underwent this imaging at our institution from January, 2017 to December, 2021. ***Materials and Methods:*** Data from January, 2017 to December, 2021, of 240 patients that underwent 18F-FCH PET-CT was collected. 28/240 patients with PHPT found to have FCH avid lesions in ectopic locations. The scans were interpreted by a Nuclear Medicine physician and they were graded as positive, suspicious, indeterminate and negative. ***Results:*** In these 28 patients (14 males, 14 females) the mean age was 46.1 years, mean intact parathyroid hormone (iPTH) was 254 pg/mL (±330) and S. Calcium was 11.4 mg/dl (±1.1). 5/28 had prior neck surgery for parathyroid adenoma.Overall, 18F-FCH PET-CT was able to detect 33 lesions (including both positive & suspicious) & 2 lesions that were indeterminate. 6/28 patients had more than 1 lesion and remaining had only a single lesion. 17 culprit lesions were lateralized to right and 16 to left. In relation to thoracic inlet, 11/33 lesions were superior to the inlet and 22/33 were inferior to the inlet. A detailed description of the locations of the ectopic adenomas in given in Table 1. 8/28 patients underwent surgical excision while 20/28 were managed conservatively till last follow up available.In the 8 operated patients, 18F-FCH PET-CT was able to detect a culprit lesion in all patients, with a total of 8 lesions being excised.A per patient analysis demonstrated 18F-FCH PET-CT was able to correctly detect the culprit lesion(s) in 8/8 patients, 4/8 with an adenoma, 3/8 with hyperplasia and 1/8 with parathyroid carcinoma, giving us a lesion detection rate of 100%. ***Conclusion:*** This study helps highlight the role of 18F-FCH PET-CT in localizing ectopic parathyroid lesions in PHPT patients, as demonstrated by us in our cohort of 240 PHPT patients, in whom 18F-FCH PET-CT was able to localize the culprit parathyroid lesions in 28 patients and helped guide surgical management in 8 patients.

OP-371

Evaluation of the Diagnostic Efficacy of [11C] Choline PET/CT in the Detection and Localization of Parathyroid Adenomas in Patients with Clinical Hyperparathyroidism

A. Lazar[1], *G. Matassa[2], U. Pajoro[2], D. Hammami[3], A. Chiti[1,2], R. Maggiore[3], M. Sollini[1,2], L. Antunovic[2];*
[1]Vita-Salute San Raffaele University, Milan, ITALY, [2]Nuclear Medicine Department, IRCCS San Raffaele Hospital, Milan, ITALY, [3]Endocrine Surgery Unit, IRCCS San Raffaele Hospital, Milan, ITALY.

Aim/Introduction: Choline PET/CT is the preferred method for detecting hyperfunctioning parathyroid glands in patients with clinical hyperparathyroidism (cHPT), given its growing accessibility and superior diagnostic performances compared to conventional imaging. The objective of this study was to evaluate the robustness of [11C]Choline PET/CT in accurately identifying and localizing hyperfunctioning parathyroid glands in preoperative settings. ***Materials and Methods:*** This retrospective single-centre study included 110 patients (aged 61.63±11.63 yo) with biochemically proven cHPT who underwent preoperative localization of parathyroid adenomas using [11C]Choline PET/CT between 01/2022 and 03/2023. Information on parathormone (PTH) levels, calcium metabolism, [99mTc]MIBI scintigraphy and neck ultrasound results were collected for each patient; in patients who underwent surgery, histopathological results were noted. Three nuclear medicine physicians conducted qualitative image analysis, evaluating presence and anatomical localization of eventual adenomas, and interobserver agreement was assessed using Fleiss multirater kappa. In cases where a parathyroid was defined as ectopic, the surgical definition was used as the reference standard. Sensitivity was calculated at the patient level based on the surgical definition provided for ectopic cases and on pathology results. ***Results:*** In the cohort, mean PTH, serum calcium and ionized calcium fraction were 130.97±66.38 pg/mL, 2.76±0.94 mmol/L, and 1.56±0.85 mmol/L, respectively. 63 patients (57%) had prior [99mTc]MIBI scintigraphy, with uncertain (n=9) or positive (n=6) results observed in 15 individuals. [11C]Choline PET/CT was positive in 90/110 cases resulting in a detection rate of 82%. In 6 cases (5%), [11C]Choline PET/CT identified more than one parathyroid adenomas. The three reviewers reached moderate interobserver agreement for both parathyroid localisation (Fleiss κ = 0.560, 95% CI: 0.558-0.561) and exam positivity (Fleiss κ =0.643, 95% CI: 0.640-0.646). [11C]Choline PET/CT was deemed positive in 66 cases and negative in 20 cases by all reviewers. In 20/110 patients, the parathyroid gland detected on PET was defined as ectopic by at least one reader (Fleiss κ = -0.016), and 25% were correctly localized according to surgical definition. 22 patients with a positive PET exam underwent surgery, their disease being confirmed by the pathological examination of the excised gland, resulting in sensitivity and positive predictive value of 100%. ***Conclusion:*** Our findings emphasize the diagnostic efficacy of [11C]Choline PET/CT in individuals with cHPT. While the overall detection rate of parathyroid adenomas is promising, the moderate interobserver agreement, particularly related to difficulties in accurately localizing ectopic parathyroids, calls for a refinement of interpretation criteria to improve the accuracy of this imaging technique.

OP-372

A New Promising Tool for Primary Hyperparathyroidism: 68Ga-Trivehexin PET/CT

D. Denizmen[1], *S. Kuyumcu[1], D. Has Simsek[1], A. Poyanli[2], F. Buyukkaya[1], Z. G. Ozkan[1], A. Kubat Uzum[3], E. G. Isik[1], Y. Sanli[1];*
[1]Istanbul University School of Medicine, Department of Nuclear Medicine, Istanbul, TÜRKIYE, [2]Istanbul University School of Medicine, Department of Radiology, Istanbul, TÜRKIYE, [3]Istanbul University School of Medicine, Department of Endocrinology and Metabolic Diseases, Istanbul, TÜRKIYE.

Aim/Introduction: Primary hyperparathyroidism (PHPT) poses a common medical challenge, requiring precise localization of hyperfunctioning lesion/(s) to guide curative surgery. Upregulation of integrin expression by parathyroid hormone-related peptide has been documented (1). However, the relation between integrin expression and parathyroid hyperfunction is not

known. Integrin (αVβ6) targeted imaging using 68Ga-Trivehexin has shown promising results in pancreatic ductal adenocarcinoma and head and neck tumors (2). In this study, we present the first-in-human use of 68Ga-Trivehexin PET/CT for enhancing the diagnostic efficacy of PHPT in comparison to 99mTc-MIBI SPECT-CT (MIBI Scan). ***Materials and Methods:*** Patients diagnosed with PHPT based on biochemical analyses were included. Serum calcium, phosphorus, and parathyroid hormone levels were recorded. Each participant underwent cervical ultrasonography, MIBI Scan, and 68Ga-Trivehexin PET/CT imaging. Additional 4D CT and 18F-Cholin PET/CT were performed in selected patients. The final diagnosis was concluded by either PTH wash-out (WO) or at least two correlated imaging findings. 68Ga-Trivehexin PET/CT and other imaging/WO results were compared. ***Results:*** Ten of 13 patients had sporadic PHPT while 3 patients were diagnosed with MEN-1 syndrome (Table. 1). 10 lesions of 7 patients underwent WO, and the remaining were diagnosed by imaging findings. Of 13 patients, 17 parathyroid lesions were identified. In one patient; cervical USG, 4D CT, MIBI Scan, 18F-Cholin PET/CT, and 68Ga-Trivehexin PET/CT could not localize any lesion. In patient-based analyses; MIBI Scan was positive in 10/13 (77%) patients; while 68Ga-Trivehexin PET/CT yielded 11/13 (85%) patients. Furthermore, 68Ga-Trivehexin PET/CT demonstrated parathyroid lesions in 2 of 3 patients who had negative MIBI Scans and 18F-Cholin PET/CT. In lesion-based analyses; MIBI Scan revealed 10/17 (59%) lesions, while 68Ga-Trivehexin PET/CT identified 16/17 (94%) lesions. Nine of 10 MIBI-positive lesions were positive in 68Ga-Trivehexin PET/CT; only one of them was negative. Of note, 68Ga-Trivehexin PET/CT clearly delineated 4 of the lesions which showed mild MIBI uptake, and identified 7 additional lesions not detected by MIBI Scan. Additionally, 18F-Cholin PET/CT yielded false positive uptake on the cervical lymph nodes of 2 patients which correlated by WO (Table. 2). ***Conclusion:*** 68Ga-Trivehexin PET/CT shows diagnostic superiority in the detection of hyperfunctioning parathyroid tissue justifying further investigation to delineate the clinical utility of this novel imaging modality in PHPT management. ***References:*** 1.Bhatia V,Mula RV,et al.Parathyroid hormone-related protein regulates integrin α6 and β4 levels via transcriptional and post-translational pathways. Pre-operative ^{18}F-Fluorocholine PET/4D-MRI in primary hyperparathyroidism

A. Kaseb[1,2], *S. Aymard[3], N. Poterszman[3], F. Hubele[3], M. Vix[4], A. Imperiale[3];*
[1]University of Jeddah, Jeddah, SAUDI ARABIA, [2]ICANS - Institut de Cancerologie Strasbourg Europe, Strasbourg, FRANCE, [3]ICANS - Institut de Cancerologie Strasbourg Europe, strasbourg, FRANCE, [4]Strasbourg University Hospital, strasbourg, FRANCE.

Aim/Introduction: 18F&#8211Fluorocholine (18F&#8211FCH) PET/CT offers excellent sensitivity in detecting hyperfunctioning parathyroid tissue, leveraging the metabolic information provided by PET and the anatomical localization from CT. Dynamic 4D&#8211MRI does not involve ionizing radiation and provides valuable functional information in addition to high&#8211resolution anatomical imaging. Accordingly, 18F&#8211FCH PET/4D&#8211MRI seems a potentially interesting diagnostic tool for patients with primary hyperparathyroidism (pHPT). Our study aimed to evaluates 18F&#8211FCH PET/4D&#8211MRI in the preoperative work&#8211up of pHPT patients and compare 18F&#8211FCH PET with 4D&#8211MRI. ***Materials and Methods:*** Patients with pHPT underwent 18F&#8211FCH PET/4D&#8211MRI between January 2022 and June 2023 were retrospectively retrieved. 18F&#8211FCH PET (merged with anatomical axial T1&#8211weighting imaging), and 4D&#8211MRI (axial T1&#8211weighted, T2 fat&#8211saturated, diffusion, and dynamic 4D contrast&#8211enhanced T1&#8211weighted) were independently interpreted. 18F&#8211FCH PET/4D&#8211MRI was analyzed jointly by one nuclear medicine physician and one radiologist. For each modality, sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and accuracy, were calculated according to per&#8211gland analysis on surgically treated patients. Histology associated with perioperative PTH blood level decrease was used as a gold standard. ***Results:*** 67 pHPT patients were evaluated by 18F&#8211FCH PET/4D&#8211MRI, and 24 (96 glandes) were surgically treated at time of writing. Sensitivity, specificity, PPV, NPV, and overall accuracy of 18F&#8211FCH PET were 96.2%, 94.7%, 89.3%, 98.5%, and 94.2%, and of 4D&#8211MRI were 73.1%, 100%, 100%, 90.9%, and 88.1%. The integrated use of PET/4D&#8211MRI allowed the right classification of all glands also leading the correction of three peri&#8211thyroid FP and one FN results of 18F&#8211FCH PET. 18F&#8211FCH PET and PET/4D&#8211MRI were more sensitive than 4D&#8211MRI ($p<0.001$). 18F&#8211FCH PET and 18F&#8211FCH PET/4D&#8211MRI performed similarly ($p<0.001$). Analysis of 4D&#8211MRI dynamic parameters revealed a rapid time&#8211to&#8211peak enhancement of parathyroid adenomas (22.0&#1774.6 seconds) and normal thyroid tissue (22.7&#1774.3 seconds) followed by a rapid washout. Parathyroid adenoma showed a statistically significant higher contrast&#8211enhancement than the thyroid parenchyma (&#916Signal Intensity (SI): 4135.6 versus 2919.5, $p<0.001$). Conversely, cervical nodes showed a delayed time&#8211to&#8211peak enhancement (41.6&#17712.4 seconds) and a prolonged gadolinium washout. ***Conclusion:*** 18F&#8211FCH PET/4D&#8211MRI allows precise localization of hyperfunctioning parathyroids adenomas, and the analysis of contrast&#8211enhancement patterns could reduce FP PET results. Despite a lack of significant improvement in diagnostic sensitivity compared to standard 18F&#8211FCH PET/CT, it reduces patient radiation exposure. However, 18F&#8211FCH PET/4D&#8211MRI is not widely available, and the acquisition time is longer, limiting its accessibility compared to standard PET imaging.

OP-374

Imaging Armamentarium of Hyperparathyroidism; New Player FCH PET-CT-US

M. Tuncel, *G. Kaya, M. Caglar, V. Kaynaroglu, O. Cennet, U. Ünlütürk, N. Suslu, G. Guler, O. Ugur;*
Hacettepe University, Ankara, TÜRKIYE.

Aim/Introduction: Hyperparathyroidism(HPTH) is a common endocrinopathy that leads to several morbidities. Therefore, correctly identifying the possible resectable parathyroid disease is crucial. Conventional methods like ultrasound(US) and Tc99m-MIBI scintigraphy(MIBI) may fail to demonstrate the parathyroid pathology. To help these patients, new functional modalities such as F^{18}-Fluorocholine PET-CT (FCH) were introduced. Moreover, FCH combined with the expert US may be synergistic in improving lesion detection. The study aims to assess the performance of FCH PET-CT and additional expert US. ***Materials and Methods:*** Patients with HPTH, equivocal, or negative conventional imaging results who underwent FCH PET-CT imaging were included. The

parathyroid lesion detection rate of FCH PET-CT and additional data obtained with FCH-guided expert USG were analysed. Laboratory, pathology, and follow-up data of the patients were obtained, and the relationship between imaging and clinicopathologic state was assessed. ***Results:*** The study included 119 patients(F/M: 90/29).The median age was 56 (min-max: 13-79 years). Seventy-one patients(n:100,71%) had symptoms related to HPTH; the rest had only hypercalcemia.US and MIBI were negative for 69/119 and 77/119 patients and equivocal for 27/119 and 22/119 patients, respectively.FCH-PET-CT showed parathyroid pathology for 80 (67%) patients, and four had multiglandular disease. The median short-axis and SUVmax of the lesion were 6(3-22) mm and 3.8(1.2-11), respectively. Most lesions were orthotopic (Table 1 66, 55%). CT components of FCH were unremarkable for 52(44%) patients, and FCH-US was able to identify the lesions for 58%(25) of these groups, and the majority were orthotopic. For 12(18%) patients, FCH-US cannot identify the lesions that can be seen on the PET-CT due to ectopic locations (retrosternal, etc.). For 38(37%) patients, FCH-US improved reader confidence or revealed new suspicious lesions. In nine patients, FCH was interpreted as negative, but expert US found true positive parathyroid lesions (mean size-SUVmax: 5.4(±0.6) mm, 3.1(±0.2) respectively), which makes the detection rate of FCH PET-CT-US as 75% (89/119). 56/89 patients were operated, and all of them had revealed parathyroid pathology. The mean follow-up period was 22.4(±1.6) months for these patients(n:51) and 44/51 patients were under remission after 6-months of the operation. ***Conclusion:*** FCH PET-CT-US, operated by the same physician like a one-stop-shop approach, maybe a real problem solver, especially in HPTH patients whose parathyroid lesions could not be found by the conventional modalities. FCH PET-CT-US may surpass any modality used alone to detect the origin of hyperparathyroidism and keep the patients in remission.

Transthyretin V30M Amyloidosis Phenotype Insights through a [^{99m}Tc]Tc-DPD Scintigraphy Perspective

J. Rei da Cruz Escaleira[1,2], *H. Martins[1], A. Campos[2,3,4], J. Bessa Silva[3], L. Costa[1], L. Lobato[2,3,4];*
[1]Nuclear Medicine Department, University Hospital Center of Santo António (CHUdSA), Porto, PORTUGAL, [2]UMIB-Multidisciplinary Unit for Biomedical Research, ICBAS- School of Medicine and Biomedical Sciences, University of Porto (UP), Porto, PORTUGAL, [3]Nephrology Department, University Hospital Center of Santo António (CHUdSA), Porto, PORTUGAL, [4]Corino de Andrade Unit, CHUdSA, Porto, PORTUGAL.

Aim/Introduction: Transthyretin (ATTR) V30M amyloidosis is a rare hereditary disease caused by the systemic deposition of mutated transthyretin. Technetium- 99m-3,3-diphosphono-1,2-propanodicarboxylic acid (DPD) scintigraphy is a widely recognized noninvasive diagnostic method for ATTR cardiac amyloidosis (CA). However, the type of amyloid fibrils appears to influence its sensitivity, including the clinical presentation. This study aims to clarify the genotype-phenotype relationship, unravelling future therapeutic approaches. ***Materials and Methods:*** We conducted a retrospective study of Portuguese patients with V30M mutation observed at nephrology consultations from 2014 to 2024; 104 cases who underwent DPD scintigraphy and echocardiography, with evidence of amyloid deposition or symptoms, were included. Diagnostic criteria for CA: interventricular septal (IVS) thickening ≥13 mm (without other attributable cause) or a Perugini score ≥ 2 (positive DPD) and no plasma cell disease. SPECT/SPECT-CT was performed in 40(54.1%) and 9(75%) Perugini 0 and 1 cases, respectively. Comorbidities present at DPD scintigraphy performance were collected; the Gillmore score was calculated for cardiorenal assessment. ***Results:*** Nearly half of the patients (51) developed CA, counting 18(35%) positive DPD, 10(20%) inconclusive DPD (score 1), and 23(45%) negative DPD cases. The latter two, compassing non-positive DPD CA, developed symptoms in the third decade of life, at median, similarly to patients without CA. Overall, DPD scintigraphy sensitivity for CA was six times lower in patients with early compared to late-onset (›50 years old): 10.3% versus 66.7%. The female/male ratio ranged from 2:1 in non-CA to 1:1 in non-positive DPD CA and 1:6 in positive DPD CA subjects. (p=.025). Neuropathy was universal; non-positive DPD CA patients had higher ocular (p=.038) and gastric (p=.040) involvement and were likely to have previously received liver transplant (p=.003)- table I. Heart failure was more common in positive DPD CA(p=.042), although echocardiographic features of CA differed poorly among the two groups(table II); 17(16.3%) patients died, with a mean follow-up of 40.3 ± 3.5 months. Mortality was five times higher in patients with abnormal Gillmore score - present in 21(63.6%) non-positive DPD CA cases - and 3.5 times higher when IVS hypertrophy, with no significant difference regarding Perugni score. ***Conclusion:*** Our series reinforces the age-dependent sensitivity of DPD scintigraphy in ATTR V30M amyloidosis, possibly related to the null (Perugini score 0) or weak (score 1) uptake by full-length (type B) amyloid fibrils. The existence of different phenotypes, albeit, underlines the influence of a cofactor in tissue amyloid deposition, opening the way for a new staging system.

OP-376

Perugini grade 1 cardiac tracer uptake on [^{99m}Tc] Tc-hydroxydiphosphonate bone scintigraphy in transthyretin variant carriers - diagnostic for cardiac amyloidosis?

H. Tingen, *A. Tubben, P. van der Meer, H. L. A. Nienhuis, R. H. J. A. Slart;*
University Medical Center Groningen, Groningen, NETHERLANDS.

Aim/Introduction: Individuals carrying a pathogenic transthyretin gene variant (TTRv) are at high risk for developing hereditary ATTR (ATTRv) amyloidosis, a progressive protein misfolding disease. Screening for cardiomyopathy (ATTRv-CM) is crucial for early detection of subclinical cardiac amyloidosis and prompt treatment initiation. Perugini grade 2 or 3 cardiac tracer uptake on bone scintigraphy is considered diagnostic for ATTR-CM, provided cardiac light chain amyloidosis is ruled out. In the case of Perugini grade 1 cardiac tracer uptake, additional criteria must be met. However, in a population with a high a priori risk of developing ATTRv amyloidosis, namely TTRv carriers, Perugini grade 1 cardiac tracer uptake might already be diagnostic for ATTRv-CM. To investigate this hypothesis, we analysed our cohort of TTRv carriers. ***Materials and Methods:*** In this retrospective study, we examined our entire cohort of TTRv carriers and ATTRv amyloidosis patients. We collected information on symptoms, cardiac biomarkers, fat biopsy for amyloidosis

deposition, echocardiography, electrocardiography, cardiac magnetic resonance imaging, and bone scintigrams from patient records. A descriptive analysis was conducted to assess potential indicators for ATTRv-CM. ***Results:*** Twelve individuals initially had Perugini grade 1 cardiac tracer uptake on bone scintigraphy. Two individuals already met the additional diagnostic criteria for ATTRv-CM at the time of bone scintigraphy. Over a median follow-up of 2.5 years (range 2-4), four individuals progressed to Perugini grade 2 uptake, confirming ATTRv-CM. Among the remaining six individuals, two had positive fat biopsies and increased wall thickness on echocardiography at the time of bone scintigraphy, strongly suggesting ATTRv-CM. Furthermore, cardiac parameters deteriorated in these patients during a follow-up of 3 years. Among the other four individuals, initially lacking signs of ATTRv-CM, one developed increased wall thickness and positive fat biopsy after 11 years. The remaining three individuals developed potential signs of cardiomyopathy during a median follow-up of 8 years (range 3-8), but the evidence was insufficient to diagnose ATTRv-CM, either due to the absence of a positive fat biopsy or the absence of increased wall thickness on echocardiography. (Table 1) ***Conclusion:*** In conclusion, our study demonstrates that a significant number of individuals with Perugini grade 1 cardiac tracer uptake either have or develop ATTRv-CM within 11 years after bone scintigraphy. Furthermore, cardiac parameters deteriorate in all TTRv carriers with Perugini grade 1 tracer. Our data suggest that grade 1 tracer uptake is diagnostic for early ATTRv-CM in TTRv carriers.

OP-377

Development of a Nomogram for Predicting Positivity in Cardiac Amyloidosis Scintigraphy

A. Kiliçaslan[1], *N. Coskun[2], H. Kafes[3], B. Mecit Demirkan[3], A. Temizhan[3], E. Ozdemir[2];*
[1]University of Health Sciences, Ankara Bilkent City Hospital, Department of Nuclear Medicine, Ankara, TÜRKIYE, [2]Ankara Yildirim Beyazit University, Ankara Bilkent City Hospital, Department of Nuclear Medicine, Ankara, TÜRKIYE, [3]Ankara Bilkent City Hospital, Department of Cardiology, Ankara, TÜRKIYE.

Aim/Introduction: Cardiac ATTR amyloidosis is a disease in which amyloid fibrils accumulate in the heart and cause restrictive type cardiomyopathy. In recent years, scintigraphic imaging with bone agents has become the gold standard imaging in diagnosis. Since clinical findings are nonspecific, there is a need for appropriate patient selection for scintigraphic imaging. This study aims to develop a nomogram that predicts scintigraphy positivity in cases with suspected cardiac ATTR amyloidosis by using clinical, demographic, laboratory and other imaging data. ***Materials and Methods:*** The data of 504 patients who underwent cardiac scintigraphic imaging with Tc99m-PYP between 2019-2024 were retrospectively scanned from the hospital digital archive. Patients with Perugini Grade 2/3 myocardial involvement on scintigraphic imaging were considered positive. The level of difference in clinical, demographic, laboratory and other imaging findings between scintigraphically positive and negative patients was evaluated by T-test and chi-square test. A scoring system was developed using a regression model that included parameters determined to have high predictive power in univariate analysis. A clinical nomogram was developed based on a multivariable logistic regression model using parameters with high predictive value. The contribution of this predictive nomogram to clinical management was evaluated by decision curve analysis. ***Results:*** The average age of 504 patients who met the inclusion criteria was 63±14 years, 274 (54.4%) were male and 230 (45.6%) were female. A total of 32 (6.3%) patients had Grade 2/3 scintigraphic positivity. In the positive patient group, mean age (68.4 vs. 62.4; p=0.018), mean interventricular septal thickness (IVST) (16.4 vs. 14.7 mm; p=0.009) and frequency of carpal tunnel syndrome (CTS) (32.3% vs. 10.4%; p<0.001) was significantly higher. In multivariate logistic regression analysis, age (RR: 1.051; p=0.003), IVST (RR: 1.168; p<0.001) and the presence of CTS (RR: 5.883; p<0.001) were determined as independent predictors for scintigraphy positivity (AUC: 0.722; Table 1). A scoring system was developed using age (18-98 years and score 1-8, respectively), CTS (absent-present and score 0 to 5, respectively) and IVST (8-42 mm and score 2 to 10, respectively) parameters (score 3-18 and probability 0.003%-95%). ***Conclusion:*** According to the study findings, a nomogram-based clinical scoring system was developed that predicts scintigraphy positivity using parameters frequently used in clinical practice such as age, IVST and CTS. If confirmed with larger series, this approach can contribute to development of appropriate patient selection criteria for cardiac amyloidosis scintigraphy.

OP-378

T-Amylo: validation of an artificial intelligence tool as a method for screening and selection of patiens candidate for ^{99m}Tc-DPD scan.

F. Sebastián Palacid, *N. Álvarez Mena, M. García Aragón, R. Zambrano Infantino, B. M. Jaramillo López, J. Gómez Hidalgo, M. Alonso Rodríguez, C. Gamazo Laherrán, B. Pérez López, M. J. González Soto, R. Ruano Pérez;*
Hospital Clínico Universitario Valladolid, Valladolid, SPAIN.

Aim/Introduction: To demonstrate the usefulness of T-AMYLO®, an artificial intelligence (AI)-generated algorithm, as a predictive model of risk in patients who are candidates for cardiac scintigraphy with 99mTc-DPD for suspected transthyretin deposition amyloidosis (TTR-CA). ***Materials and Methods:*** Application of the T-AMYLO® predictive model for TTR-CA to a sample of 232 patients with suspected TTR-CA (60% male; mean age 77.4 ± 9.8 years; 31.4% referred for ventricular hypertrophy) who had undergone 99mTc-DPD scintigraphy between January 2022 and December 2023. T-AMYLO® assesses demographic (age and sex) and clinical variables (interventricular septal thickness, carpal tunnel syndrome or low ECG voltages), assigning a risk for TTR-CA. Three risk groups were obtained: high, intermediate and low. The risk obtained in each patient was correlated with the gammagraphic result. The concordance between tests was calculated (Cohen's Kappa index; KI) and the diagnostic accuracy of the model was checked. ***Results:*** Based on the risk groups according to T-AMYLO®, 59 patients (25.5%) were classified as high risk, 66 (28.4%) as intermediate risk and 107 (46.1%) as low risk. 35.3% of patients (82/232) had a positive 99mTc-DPD scan for TTR-CA. Of these, 63.4% (52/82) were associated with high risk, 24.4% (20/82) with intermediate risk, and 12.2% (10/82) with low risk. The 93.4% of patients (97/104) classified as low risk for TTR-CA had negative scintigraphy, while 83.9% (52/59) with high risk associated positive scintigraphy, obtaining an IK between both tests of 0.78 (good concordance). Regarding the intermediate risk group, 30.3% of patients (20/66) had a positive scintigraphic result. ***Conclusion:*** T-AMYLO® predictive model is a screening tool that improves the selection of patients who are candidates for 99mTc-DPD cardiac scintigraphy, avoiding unnecessary diagnostic tests in patients at low risk of TTR-CA.

OP-379

Multidisciplinary approach for the early detection of amyloid in patients who undergo carpal tunnel syndrome or lumbar stenosis surgery. Results of an ongoing study.

N. Orta[1], *T. Ripoll[2], S. Rubí[1], J. Pons[1], E. Fortuny[1], M. Bosch[1], C. Nadal[3], I. Torralba[3], G. Salvà[3], N. Mora[3], S. Lirola[3], M. Méndez[4], J. Femenias[3], M. Llabrés[3], A. Álvarez[3], B. Barceló[1], V. Daza-Cajigal[1], A. Pérez[1], D. Heine[1], A. Sharma[3], A. Piñar[3], M. Villar[3], C. Peña[1];*
[1]Hospital Universitari Son Espases/IdISBa, Palma, SPAIN, [2]Hospital Universitari Son Llàtzer/IdISBa, Palma, SPAIN, [3]Hospital Universitari Son Espases, Palma, SPAIN, [4]Hospital Sant Joan de Déu, Palma-Inca, SPAIN.

Aim/Introduction: Carpal tunnel syndrome(CTS) and lumbar stenosis(LS) seem to precede the manifestations of cardiac amyloidosis(CA) due to transthyretin amyloidosis(ATTR), so they could represent early markers of CA. CTS is more commonly present in CA due to wild-type ATTR(ATTRwt), although it can also be present in its hereditary variant(ATTRv) and in primary amyloidosis caused by immunoglobulin light chain deposition(AL). Therefore, in this ongoing study, our aim is to evaluate the prevalence of amyloidosis in patients undergoing CTS or LS surgery, in an endemic area of the TTR mutation Val50Met(ATTRv). ***Materials and Methods:*** After recruitment,265/429 patients were included.238/265 were operated(184 CTS,54 LS) in whom an intraoperative biopsy was obtained(ligamentum flavum in LS; synovial tissue/flexor retinaculum in CTS) for histopathological analysis using Congo Red staining for amyloid detection and immunohistochemistry(IHC) or mass spectrometry(MS) for subtyping in amyloid A(AA), kappa, lambda and ATTR. Blood and urine test to rule out a monoclonal component and a cardiac scintigraphy(CS) with 99mTc-DPD to detect myocardial uptake were performed, which analysis was visual by Perugini scale. A cardiac SPECT/CT was performed in cases with a positive planar imaging, according to the ASNC/EANM guidelines. During follow-up of positive patients, clinical data suggesting CA were noted. ***Results:*** Total of 205 biopsies were obtained(155 CTS,50 LS), 16 of them were amyloid positive(8 CTS,8 LS). IHC for AA, kappa and lambda were negative. IHC for ATTR and MS analysis are still pending. 33 operated patients without biopsy(29 CTS,4 LS). 203 laboratory tests and CS have been performed: 5/203 CS were positive(grade 1-3). 4 of them underwent CTS surgery and 3/5 positive-CS had also positive biopsies for amyloid(2/5 without biopsy).In 14/203 laboratory tests, a monoclonal component was detected. 150/178 completed cases have all tests negative). To date, positivity for amyloid has been obtained in 18/238 cases(7.6%) and 18/147(12.2%) if an occupational risk for CTS was excluded: 16 positive biopsies (2/16 with a positive blood test for monoclonal component, 3/16 with positive CS and 11/16 with negative blood/urine test and CS) and 2 positive CS without biopsy and normal blood/urine test. In the follow-up(3.10 years) of patients with positivity, 27.8%(5/18) manifests cardiomyopathy, 4 of them with positive CS, and 88.9%(16/18) have previously other orthopedic manifestations. ***Conclusion:*** The estimated prevalence of amyloidosis in our series of surgically treated patients with CTS or LS is 7.6% and 12.2% if an occupational risk for CTS was excluded. These are preliminary data from an ongoing study.

OP-380

Interobserver agreement viewing planar, SPECT or SPECT/CT scans for suspected transthyretin cardiac amyloidosis: A multicenter study comparing ^{99m}Tc-3,3-diphosphono1,2-propanodicarboxylic acid and ^{99m}Tc-pyrophosphate

Y. Yechiel[1], *S. Ben-Haim[2,3,4], M. Weiler-Sagie[1,5];*
[1]Rambam Health Care Campus, Haifa, ISRAEL, [2]Hadassah Medical Organization, Jerusalem, ISRAEL, [3]Faculty of Medicine, Hebrew University of Jerusalem, Jerusalem, ISRAEL, [4]University College London, London, UNITED KINGDOM, [5]Rappaport Faculty of Medicine, Technion - Israel Institute of Technology, Haifa, ISRAEL.

Aim/Introduction: This study aims to determine the interobserver agreement in interpreting separate planar, SPECT and SPECT/CT images of 99mTc-3,3-diphosphono1,2-propanodicarboxylic acid (99mTc-DPD) and 99mTc-pyrophosphate (99mTc-PYP) scans in patients with suspected transthyretin cardiac amyloidosis (ATTR), and in comparison, to a reference standard: complete study interpretation. Both tracers were included to allow indirect comparison between the two most common tracers used for ATTR scintigraphy. ***Materials and Methods:*** The study cohort comprised 90 patients scanned for suspected ATTR. Planar images from consecutive patients were retrospectively reviewed to include 15 scans with each visual score (VS): 0, 1 and 2 or 3, from both 99mTc-DPD and 99mTc-PYP scans. Readers from six medical centers, reviewed separate components of the scan: planar, SPECT or SPECT/CT images, in 3 separate sessions. The readers assigned VS 0-3 and an interpretation category (INCT): Not suggestive, equivocal or strongly suggestive of ATTR. Consensus interpretation of complete scans, including planar and SPECT/CT images, served as reference standard. The Interobserver agreement was determined using interclass correlation test. Interclass correlation coefficient (ICC) estimates and 95% confidence intervals were calculated. Analyses were conducted to compare the scores given by the 6 readers and the most frequent judgment of the 6 readers (Mode), with reference standards, to assess total agreement (representing accuracy). ***Results:*** Interobserver agreement for VS and INCT was excellent for both 99mTc-DPD and 99mTc-PYP scans for separate components of the imaging protocol (ICC>0.9). The agreement was consistently better for 99mTc-DPD (ICC range 0.975 - 0.987 versus 0.880 - 0.973) but did not reach statistical significance. VS and INCT total agreement of readers with reference standard was consistently higher in 99mTc-DPD (62%-96% and 82%-98%, respectively) compared to 99mTc-PYP (33%-80% and 38%-91%, respectively). The total agreement based on the most frequent rating was significantly worse for 99mTc-PYP VS compared to 99mTc-DPD VS of planar images (p=0.004), and for VS and INCT of SPECT images (p<0.001) but not in SPECT/CT image interpretation. Visual scoring and INCT total agreement were significantly related to scan component only for 99mTc-PYP (p<0.001). ***Conclusion:*** This study demonstrates excellent interobserver agreement for visual interpretation of separate components of the imaging protocol for both 99mTc-DPD and 99mTc- PYP scans. However, compared to reference standard consensus reading of complete exams, 99mTc-PYP underperforms compared to 99mTc-DPD in planar and SPECT but not in SPECT/CT image interpretation. SPECT/CT should be a considered a required component of 99mTc- PYP scans for suspected Cardiac ATTR amyloidosis.

OP-381

Automatic Quantification In Gated-Spect ^{99m}tc-Dpd Studies As A Method For Calculating The Extension Of Affected Myocardium By Transtyretin Cardiac Amyloidosis (Ttr-Ca)

F. Sebastián Palacid, *N. Álvarez Mena, M. García Aragón, R. C. Zambrano Infantino, B. M. Jaramillo López, J. Gómez Hidalgo, B. Pérez López, C. Gamazo Laherrán, R. Ruano Pérez;*
Hospital Clínico Universitario Valladolid, Valladolid, SPAIN.

Aim/Introduction: To establish the percentage of myocardium affected by transthyretin deposits in patients with positive 99mTc-DPD scan for TTR-CA, using automatic quantification tools in gated-SPECT (g-SPECT). ***Materials and Methods:*** Analysis of 60 patients with a gammagraphic diagnosis of TTR-CA (46 males; mean age 83.9 ± 5.8 years; 83% Perugini grade 3) who underwent a g-SPECT-CT study centred on the thorax. Images were processed with Myovation Evolution GE® and QPS/QGS GE® software. Segmented cardiac polar maps were obtained and the "extent of defect" (ED) parameter was calculated. This parameter was derived using a score that calculates the percentage of pixel counts < 2.5 standard deviations. The percentage extent of affected myocardium defined as the inverse of the SD (1-DE) was calculated. Finally, significant differences were sought according to degree of uptake, sex or age. ***Results:*** The average value of affected myocardium was 72.2% ± 20.4 (68.6% ± 23.2 in patients with Perugini grade 2 and 73% ± 20% in patients with Perugini grade 3). 22% (13/60) had myocardial involvement <50%, 30% (18/60) between 51-75%, 22% (13/60) between 76-90% and 26% (16/60) >90%. Statistical differences found were that the smallest extent of myocardium involved (<50%) was more frequent in patients with Perugini grade 2 (40%; p=0.0416). In contrast, greater extent (>90%) was more frequent in women (50%; p=0.0387) and in patients aged <70 years (75%; p=0.0236). ***Conclusion:*** The use of automatic quantification methods in g-SPECT allows an approximate calculation of the percentage of myocardium with 99mTc-DPD deposits (or affected myocardium by TTR-CA). This calculation may be useful in the follow-up of these patients and in monitoring the therapeutic response of the disease.

OP-382

Prognostic implications of quantitative cardiac [^{99m}Tc]-DPD uptake in transthyretin amyloid cardiomyopathy

R. Calabretta, *R. Rettl, F. Duca, C. Kronberger, C. Binder, R. Willixhofer, M. Poledniczek, M. Poledniczek, C. Nitsche, S. Kastl, C. Hengstenberg, R. Badreslam, J. Bergler-Klein, M. Hacker, A. Kammerlander;*
Medical University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: Transthyretin amyloid cardiomyopathy (ATTR-CM) is associated with poor survival, and the prognostic implications of quantitative left ventricular (LV) [99mTc]-3,3 diphosphono-1,2 propanodicarboxylic acid ([99mTc]-DPD) uptake remain poorly understood. We aimed to investigate the relationship between quantitative LV [99mTc]-DPD uptake, cardiac structure and function, and their association with outcomes in patients with ATTR-CM. ***Materials and Methods:*** Eighty-three ATTR-CM patients underwent [99mTc]-DPD single-photon emission computed tomography/computed tomography (SPECT/CT) and two-dimensional speckle-tracking echocardiography. ***Results:*** ATTR-CM patients were divided into two cohorts based on the median of the standardized uptake value (SUV) retention index (low LV uptake: <5.47 mg/dL, n=41; high cardiac uptake: ≥5.47 mg/dL, n=42). We observed significant differences between cohorts in LV global longitudinal strain (LV-GLS: p=0.015), right ventricular longitudinal strain (RV-LS: p=0.026), NT-proBNP (p=0.007), troponin T (p=0.010), 6-minute walk distance (6MWD: p=0.023) and National Amyloidosis Centre (NAC) ATTR stage (I: p=0.021, III: p=0.004). We furthermore observed significant correlations (r, Spearman's correlation coefficient) between the SUV retention index and longitudinal cardiac function (LV-GLS: r=0.369, p<0.001; RV-LS: r=0.251, p=0.029), cardiac biomarkers (NT-proBNP: r=0.330, p=0.002; troponin T: r=0.265, p=0.017), exercise capacity (6MWD: r=-0.249, p=0.028) and disease stage (NAC ATTR stage: r=0.325, p=0.003]. ATTR-CM patients with high SUV retention index experienced adverse outcomes [composite endpoint: all-cause mortality or cardiovascular-related hospitalization, hazard ratio (HR): 1.124, 95% confidence interval (CI): 1.060-1.192, p<0.001]. ***Conclusion:*** In ATTR-CM, quantitative LV [99mTc]-DPD uptake correlates with longitudinal cardiac function, cardiac biomarkers, exercise capacity, disease stage, and enhanced cardiac and is associated with adverse outcomes.

OP-383

Prognostic and Therapeutic Evaluation of Quantitative Right Ventricular Uptake with ^{99m}Tc-DPD SPECT/CT in Transthyretin Cardiac Amyloidosis

M. Zhao[1], *R. Calabretta[2], P. Binder[3], M. Hacker[2], X. Li[2];*
[1]Third Xiangya Hospital of Central South University, Changsha, CHINA, [2]Medical University of Vienna, Vienna, AUSTRIA, [3]raffaella.calabretta@meduniwien.ac.at, Vienna, AUSTRIA.

Aim/Introduction: To characterize right ventricle (RV) uptake derived from quantitative 99mTc-DPD SPECT/CT and evaluate its role in predicting outcomes and evaluating therapeutic effectiveness in transthyretin amyloid cardiomyopathy (ATTR-CA) patients. ***Materials and Methods:*** A total of 53 confirmed ATTR-CA patients were analyzed using quantitative 99mTc-DPD SPECT/CT, to determine maximum standardized uptake values (SUVmax) for the left ventricle (LV) and right ventricle (RV) free wall. SUVmax values were adjusted by dividing them with blood pool uptake, resulting in weighted SUVmax (wSUVmax). RV uptake was categorized as high or low based on the RV wSUVmax. ***Results:*** Patients with high RV uptake demonstrated significantly elevated levels of serum NT-proBNP ($P < 0.05$), IVS thickness ($P < 0.01$), and Gillmore staging ($P < 0.05$) compared to those with Low RV uptake. During a median follow-up of 16 months, multivariable Cox analysis revealed LV and RV wSUVmax as independent predictors of major adverse cardiac events (MACEs) as the primary endpoint. Longitudinal analysis of 20 patients on Tafamidis therapy as a secondary endpoint demonstrated a significant reduction in both LV wSUVmax ($P < 0.01$) and RV wSUVmax ($P < 0.01$) post-therapy. Moreover, patients with lower LV or RV wSUVmax at baseline experienced better treatment outcomes. ***Conclusion:*** High RV uptake quantified by SPECT/CT in ATTR-CA signifies advanced disease burden and worse prognosis. LV and RV wSUVmax emerged as useful imaging markers for monitoring the treatment effectiveness.

Development and validation of ^{18}F-PSMA PET/MR-based radiomics model to predict biochemical recurrence-free survival after radical prostatectomy

T. Li;
The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, CHINA.

Aim/Introduction: Biochemical recurrence (BCR) is a critical indicator of prognosis in patients with prostate cancer undergoing radical prostatectomy (RP). Reliable prediction models are essential to identify patients at risk of BCR and to implement targeted adjuvant therapies. This study aims to develop and validate a clinical-radiomics model based on preoperative ^{18}F-PSMA PET/MR to predict BCR-free survival in prostate cancer patients undergoing RP. ***Materials and Methods:*** This retrospective study was conducted on 221 prostate cancer patients confirmed by histopathology and treated with RP. The cohort was randomly divided into a training set (155 patients) and a validation set (66 patients). All patients undergoing a preoperative ^{18}F-PSMA PET/MR scan. Radiomic features were extracted using the Lifex software from PET, DWI, and T2-weighted images, including 117 features in total. A radiomic signature was developed using the Least Absolute Shrinkage and Selection Operator (LASSO) regression model. The performance of the radiomic signature in predicting BCR-free survival was assessed using Harrell's concordance index (C-index) and incorporated into a multimodal analysis with clinicopathological variables. ***Results:*** The radiomic signature, including five features, demonstrated a C-index of 0.84 (95% CI: 0.76-0.92) in the training cohort and 0.81 (95% CI: 0.71-0.91) in the validation cohort. In multivariate analysis, the radiomic signature remained an independent predictor of BCR-free survival (HR: 3.15, 95% CI: 2.21-5.37, $p < 0.001$). Adding the radiomic signature to a base model including clinicopathological variables significantly enhanced predictive performance (C-index: 0.88, 95% CI: 0.80-0.96, $p < 0.001$). ***Conclusion:*** We developed and validated a novel clinical-radiomics model based on ^{18}F-PSMA PET/MR that can predict BCR-free survival in patients undergoing RP for prostate cancer. This model could help identify patients at higher risk of BCR, thus enabling personalized risk stratification and tailored treatment strategies.

EPS-107

Improving Clinical Progression Prediction in Prostate Cancer: Utilizing Radiomics of Normal Tissue in Negative PSMA PET/CT Scans for Patients with Biochemical Recurrence

F. Yousefirizi[1], *S. Harsini[2], M. Mohebi[3], P. Martineau[4], A. Shariftabrizi[5], D. Wilson[2], F. Bénard[2], C. Uribe[2], A. Rahmim[6];*
[1]Bc Cancer, Vancouver, BC, CANADA, [2]BC Cancer, Vancouver, BC, CANADA, [3]Department of Biomedical Engineering, Tarbiat Modares University, Tehran, IRAN, ISLAMIC REPUBLIC OF, [4]Department of Molecular Imaging and Therapy, BC Cancer, Vancouver, BC, CANADA, [5]University of Iowa Carver College of Medicine, Iowa City, IA, UNITED STATES OF AMERICA, [6]BC Cancer Research Institute, Vancouver, BC, CANADA.

Aim/Introduction: Prostate-specific membrane antigen (PSMA) PET/CT is commonly used for prostate cancer patients with biochemical recurrence (BCR). However, the long-term implications of PET/CT negativity are unclear. Our study evaluates radiomics features of normal tissue in negative [18F]DCFPyL PET/CT scans to predict clinical progression in BCR patients. ***Materials and Methods:*** This subgroup analysis is based on a prospective clinical trial. 95 patients (mean age: 74.16 years) with BCR after primary treatment with curative intent, negative on [18F]DCFPyL PET/CT and followed without active treatment. TotalSegmentator was employed to automatically segment hip bone, liver, lung, sacrum, and prostate bed (without prostatectomy) from 3D CT images . Clinical progression (CP) and clinical progression-free survival (CPFS) after negative PSMA PET/CT were determined based on routine follow-up imaging. Radiomics features, including intensity-based and GLSZM, GLRLM, and GLCM-based features, were extracted using Lifex 7.3.0 [2]. Feature selection methods were LASSO, MRMR, and NCA. Selected features were employed in classification tasks with various ML algorithms: KNNs, Linear Discriminant Analysis, Logistic Regression, ADABoosted, SVMs, kernel-based methods, Neural Network, Random Forest, RUSBoosted Trees, and Subspace KNN. Performance was assessed via 5-fold cross-validation, reporting mean results of 50 iterations for robustness. ***Results:*** Thirty patients (31.8%) experienced CP within various areas on their follow-up scans with a median CPFS of 38.75 months (range: 7.5-71 months). Analysis of negative [18F] DCFPyL PET scans revealed that radiomics features including intensity, GLRLM, and GLSZM from the lung, along with intensity from the hip bone, liver, and prostate bed, and GLSZM of the sacrum, showed the highest predictive power for CP. For instance, the overall performance of Fine KNN with NCA feature selection showed predictive power for CP with an accuracy of (78±2.9)%, F-score of (84±2.2)%, precision of (83±1.8)%, sensitivity of (86±3.6)%, and specificity of (61±4.5)%. We performed multivariate Cox regression to examine the association of the normal tissue radiomics features with CP. The selected features by LASSO i.e. intensity features from the hip bone, liver, and lung, along with GLCM from the hip and liver, and GLSZM from the hip bone were examined. Among these, intensity-based Kurtosis of the lung demonstrated the strongest association with the outcome (hazard ratio=1.21, P-value < 0.001). ***Conclusion:*** This study establishes a radiomics signature from apparently normal tissue in negative [18F]DCFPyL PET/CT scans of BCR patients, predictive of CP. These features offer potential predictive value for CP and CPFS, providing valuable insights that could guide treatment decisions in such cases.

EPS-108

Multicollinearity and redundancy of the PET radiomic feature set

Aim/Introduction: Radiomic feature sets contain many strongly correlating features. The aim of this study was to map this multicollinearity in five [18F]FDG-PET cohorts with different tumour types and identify non-redundant features. ***Materials and Methods:*** Five [18F]FDG-PET radiomic cohorts were analysed:

non-small cell lung carcinomas (N=35), pheochromocytomas and paragangliomas (N=40), head and neck squamous cell carcinomas (N=54), [18F]FDG-positive thyroid nodules with indeterminate cytology (N=84), and gastric carcinomas (N=206). Lesions were delineated and 105 radiomic features were extracted with a fixed bin size of 0.5 or 0.55 g/mL using PyRadiomics. Interpolated voxel sizes were standardised per cohort and ranged from 3.18×3.18×3.00 mm^3 to 4.00×4.00×4.00 mm^3. In all cohorts, Spearman's rank correlation coefficient (ρ) matrices of features were calculated and it was determined which features showed (very) strong (ρ>0.7 and ρ>0.9) correlations with any other feature in all five cohorts. Cluster analysis of an averaged correlation matrix for all cohorts was performed at a threshold of ρ=0.7 and ρ=0.9. For each cluster, a representative, non-redundant feature was selected. ***Results:*** Seventy-two and 90 out of 105 features showed a (very) strong correlation with any other feature in all five cohorts. Cluster analysis resulted in 35 and 15 non-redundant features at thresholds of ρ=0.9 and ρ=0.7, respectively. Non-redundant features at ρ=0.9 are (* marks non-redundancy at ρ=0.7): intensity features energy, kurtosis*, maximum*, and skewness; shape features elongation*, flatness, least axis length, sphericity*, surface-to-volume-ratio*, and volume*; total lesion glycolysis; grey level co-occurrence matrix features cluster shade*, correlation*, inverse difference moment normalized, inverse measure of correlation 1* and 2, inverse variance*; grey level run length matrix features grey level nonuniformity*, long run (high grey level) emphasis, and low grey level zone emphasis; grey level size zone matrix features grey level nonuniformity, high grey level zone emphasis, large area high/low grey level emphasis, low grey level zone emphasis*, size zone nonuniformity (normalized*), and small area (low grey level) emphasis; grey level dependence matrix features large dependence high grey level emphasis* and small dependence low grey level emphasis*; and neighbouring grey tone difference matrix features busyness, contrast, and strength. Seventy or 90 redundant features could be omitted at thresholds of ρ=0.9 and ρ=0.7, respectively. ***Conclusion:*** At least two-third of the radiomic feature set could be omitted, because of strong multicollinearity. More redundant features could be identified using a less conservative threshold. Future research should indicate whether multicollinearity of the radiomic feature set is similar in other modalities.

EPS-109

Radiomic feature variability in response to deep-learning image enhancement algorithms:a phantom and sarcoma patient evaluation.

L. Bonney[1,2], *G. M. Kalisvaart[3], F. H. P. van Velden[3], K. M. Bradley[4], A. B. Hassan[1,2], W. Grootjans[3], D. R. McGowan[5,2];*
[1]Sir William Dunn School of Pathology, University of Oxford, Oxford, UNITED KINGDOM, [2]Oxford University Hospitals NHS Foundation Trust, Oxford, UNITED KINGDOM, [3]Department of Radiology, Leiden University Medical Center, Leiden, NETHERLANDS, [4]4.Wales Research and Diagnostic PET Imaging Centre, University of Cardiff, Cardiff, UNITED KINGDOM, [5]Department of Oncology, University of Oxford, Oxford, UNITED KINGDOM.

Aim/Introduction: PET/CT imaging data contains a wealth of quantitative information that combined with other 'omic data can provide valuable contributions to tumour characterisation. However, the dependence of PET radiomics on reconstruction technique limits reproducibility and generalisability. Here, we characterise the response of radiomic features to two research deep-learning (DL) image enhancement algorithms from a manufacturer in a phantom simulating heterogeneity and sarcoma patient data. Both DL-enhancement algorithms are trained to generate time-of-flight (TOF) block sequential regularisation expectation maximisation (BSREM) like images. The first algorithm, DLT, uses a BSREM-non-TOF image as the input with potential applications in systems with high sensitivity low temporal resolution crystals [1]. The second, DLE, uses a TOF ordered-subset expectation maximisation (OSEM) image as the input, to achieve a BSREM-TOF like image at lower computational cost [2]. ***Materials and Methods:*** A modular heterogeneous phantom was filled with F^{18} [3]. Five repeat acquisitions of the phantom were acquired on a GE Discovery 710 PET/CT scanner. A retrospective sarcoma clinical dataset from the same department was also analysed, with segmentation performed by an experienced nuclear-medicine radiologist (n=15, 17 tumours). First DL-enhanced images were compared to the respective algorithm input images. Then the DL-enhanced images were compared to the gold-standard BSREM-TOF images the algorithms were trained to emulate. Ninety-three radiomic features were extracted (first order and texture features excluding shape, imaging biomarker standardisation initiative compliant). The significance of the difference between images was tested for each radiomic feature ($p<0.05$, Bonferroni-corrected for 93 features). ***Results:*** In phantom data when comparing input to DL-enhanced images a high proportion of features measured as significantly different (DLT:35.6%, DLE:40.8%), this decreased when comparing DL-enhanced images to the gold-standard reconstruction method (DLT:5.5%, DLE:6.7%). In the tumour data a smaller difference was observed (DLT:24.7%, DLE:20.4% vs. DLT:19.4%, DLE:16.1%). Patterns of radiomic feature variability were similar in patient and phantom images; 74.2% of highly variable phantom features (mean percentage difference >15%) also measured as highly variable in tumour data. ***Conclusion:*** In unseen data, DL-enhancement techniques affect radiomic feature values as compared to input images. However, DL-enhanced images behaved, at the quantitative level of radiomic features, similarly to the 'gold-standard' images the algorithms are trained on. These results offer insight into the performance of the DL algorithms, and demonstrate the potential of DL algorithms in harmonisation for radiomics. ***References:*** Mehranian et al. EPS-110

Automated 68Ga-PSMA-PET Total Metabolic Tumor Volume (TMTV) extraction for predicting PSA change in 177Lu-PSMA therapy

R. Eduardo[1,2], *S. David[1], B. Jean Noël[1];*
[1]Creatis, Lyon, FRANCE, [2]Siemens Healthcare, Paris, FRANCE.

Aim/Introduction: An automated method to extract TMTV from 68Ga-PSMA-PET images is proposed. It is used to assess the predictive capability of PET images towards PSA change. ***Materials and Methods:*** 58 patients who completed 1 to 6 cycles of 177Lu-PSMA were analyzed. Patients were categorized into responders and non-responders based on PSA nadir which refers to the difference between the initial PSA and the lowest PSA value observed throughout the course of treatment. Lesional uptake was automatically separated from physiological uptake, followed by a threshold based on the mean uptake in physiological areas, to obtain the Total Metabolic Tumor Volume (TMTV). SUV mean in TMTV regions was plotted against response status for 68Ga-PSMA-PET, ^{18}F-FDG-PET, and 177Lu-PSMA-SPECT imaging (24h after

injection, 1st cycle). A subset analysis focused on bone lesions (TMTVbones). A fully connected multi-layer neural network (NN) model was trained to predict the outcome with TMTV statistical values (mean, max, min, ···) as input. ***Results:*** Statistical analysis revealed significant differences in TMTV between responders and non-responders for 68Ga-PSMA and 177Lu-SPECT (p-value 0.03 and 0.005 respectively). However, ^{18}F-FDG did not demonstrate predictive value, alone or in combination with 68Ga-PSMA. The NN prediction model utilizing 68Ga-PSMA's TMTV statistics achieved the highest performance, with an AUC of 0.76. TMTVbones did not improve the results. ***Conclusion:*** Automated TMTV extraction from 68Ga-PSMA-PET and 177Lu-PSMA-SPECT confirms predictive potential for PSA change with a simple NN model. ^{18}F-FDG did not provide additional predictive value. These findings underscore the importance of pre-treatment imaging modalities in guiding personalized therapy decisions and optimizing patient outcomes. ***References:*** Moazemi S et al. Decision-support for treatment with 177Lu-PSMA: machine learning predicts response with high accuracy based on PSMA-PET/CT and clinical parameters. Ann Transl Med. 2021.

UNIRIV: a French database to identify factors predictive of response and toxicity in the treatment of metastatic prostate cancer with 177Lu-PSMA.

***J. Badel*[1],** *C. Garcia[2], A. Diatchenko[3], N. Varmenot[4], L. Ferrer[4], N. Anizan[5], D. Broggio[6], S. Lamart[6], D. Sarrut[7], T. Baudier[1], A. Giraudet[3];*
[1]Centre Leon-Berard, CREATIS CNRS UMR 5220, INSERM U 1044, Université de Lyon, INSA-Lyon, Lyon Cedex 08, FRANCE, [2]Institut Gustave Roussy, Villejuif, FRANCE, [3]Centre Leon-Berard, Université de Lyon, Lyon Cedex 08, FRANCE, [4]Institut de Cancérologie de l'Ouest, Saint-Herblain, FRANCE, [5]Institut Bergonié, Bordeaux, FRANCE, [6]IRSN, Fontenay-aux-Roses, FRANCE, [7]CREATIS CNRS UMR 5220, INSERM U 1044, Université de Lyon, INSA-Lyon, Lyon Cedex 08, FRANCE.

Aim/Introduction: The UNIRIV project is a French multicenter study aiming to identify predictive factors of response and occurrence of toxicities in the treatment of metastatic prostate cancer with 177Lu-PSMA. A radiomic method is used to search for links between the quantitative parameters of pre-treatment 68Ga-PSMA PET/CT imaging, and the biological, clinical and dosimetric results of post-treatment patients. However, obtaining diagnostic biomarkers requires very large volume of data, which necessitates the centralization of data from several partner centers. The construction of this multimodal and multicenter database constitutes the first step of the UNIRIV project. The UNIRIV project benefits from funding from the French UNIBASE 2 program. ***Materials and Methods:*** The data to be centralized for each patient was identified. The availability of data to be mobilized by partner centers was verified. Data sources and the digital and/or manual means of extraction and transfer used by partner centers were evaluated. Data Protection Impact Assessment (DPIA) was carried out. ***Results:*** Data to be centralized per patient include quantitative parameters extracted from 68Ga-PSMA PET/CT imaging (SUVmax, SUVpeak, SUVmean, total tumor volume, quantification and quality of tumor uptake of 68Ga-PSMA), biological data (PSA tumor marker, Gleason score, white blood cell count, absolute neutrophil count, platelet count, etc.), and clinical data (PCWG3 criteria, improvement of clinical symptoms, analgesic effect of treatment). Eleven centers are participating in the UNIRIV project, and will provide multimodal data. Their data will be hosted and centralized in a secure project space, whose digital infrastructure is currently being built by the data center of the French National Federation of Cancer Centers (UNICANCER). An initial data set is available, and will serve as a test for remote transfer, storage and analysis operations. ***Conclusion:*** Building a multi-modal, multi-center database is a long and difficult process. UNIRIV is the first French nuclear medicine database project to centralize clinical, biological and imaging data.

EPS-112

The utility of textural characteristics derived from ^{18}F-FDG PET-CT in pathological response prediction following neoadjuvant chemotherapy in locally advanced breast cancer patients

K. Bishnoi, *K. Agrawal, S. K. D. Majumdar, P. Mishra, D. K. Muduly, B. Padhy, G. K. Parida;*
All India Institute of Medical Sciences, Bhubaneswar, INDIA.

Aim/Introduction: Breast cancer is the most frequent cancer among women around the world with second highest morbidity. PET-CT is an indispensable tool for staging and assessing response in breast cancer. The radiomics is a new area of research in PET-CT imaging, serving as an additional tool to predict the treatment response of tumor. We have assessed the relevance of textural characteristics derived from ^{18}F-FDG PET-CT scan in predicting the pathological complete tumor response (pCR) following neoadjuvant chemotherapy in patients with locally advanced breast cancer. ***Materials and Methods:*** A total of 83 histopathologically proven locally advanced breast cancer patients underwent baseline ^{18}F-FDG PET-CT. The primary lesion was segmented through semiautomatic mode with 40% SUVmax threshold and textural characteristics were extracted. The patient then received neoadjuvant chemotherapy followed by surgery. Surgical histopathology reports were utilized for pCR assessment. The predictive performance of different radiomic parameters for identifying pCR or non-pCR was evaluated using univariate and multivariate logistic regression. The variable exhibiting a significant p-value (less than 0.05) was analyzed using a receiver operating characteristic (ROC) curve. We additionally analyzed correlation of textural characteristics of the primary tumor with immunohistochemistry markers at dual time point imaging at 1 and 2 hours. ***Results:*** The subjects' mean age was 51 +/- 10.5 years (28-76 years). Most of the patients (41%) were in clinical stage IIIB, and 35% were IIIC. Among the 83 patients, a total of 23/83 (27.7%) patients exhibited pCR. 60/83 (72.3%) patients were categorized as non-pCR. Four parameters, namely approximate volume, Run Length Non-Uniformity, Grey Level Non- Uniformity, and Zone Size Non-Uniformity (ZSN) showed p value <0.05 in univariate logistic regression analysis for prediction of pCR. In ROC curve, ZSN had area under curve of 0.703 at cut-off value of 170.13, with a sensitivity of 66.7% and specificity of 69.6%. for prediction of pCR. In 1-hour data, none of the radiomic parameters showed any significant correlation with immunohistochemistry markers. However, in 2-hour data, significant correlation of many radiomic parameters with ER, PR and Mib-1 index was seen. ***Conclusion:*** This correlation analysis indicates associations between radiomic parameters on PET-CT and pCR as well as immunohistochemistry markers, providing insights into the potential use of these features in understanding tumor characteristics and assessment of treatment outcome.

EPS-113

Clinical Evaluation of Deep Learning Corrected PET Imaging for Lesion Detection and Quantification

S. Xue[1], *H. Chunyu[2], X. Zhang[2], A. Rominger[3], R. Guo[2], B. Li[2], K. Shi[3];*
[1]Medical University of Vienna, Vienna, AUSTRIA, [2]Department of Nuclear Medicine, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA, [3]Department of Nuclear Medicine, University of Bern, Bern, SWITZERLAND.

Aim/Introduction: Ensuring the reliability of AI for clinical use, particularly in AI-generated medical imaging, is a significant concern due to potential false findings. There are currently limited recognized standards or methods for managing and testing medical AI systems, especially those related to AI-generated imaging. Many evaluations focus solely on image-based metrics rather than assessing clinical applicability. Our objective is to develop a systematic clinical evaluation method specifically for AI-generated PET imaging, with a primary focus on lesion detection and quantification. ***Materials and Methods:*** We conducted a clinical evaluation using whole-body PET images from 359 patients administered with 18F-FDG, 18F-PSMA, 68Ga-DOTA-TOC, 68Ga-DOTA-TATE, 68Ga-FAPI, acquired with clinical PET scanners, namely the Biograph Vision (Siemens Healthineers), United Imaging uMI 780 (United Imaging), Discovery MI (General Electric Healthcare) in Shanghai and Bern. PET imaging generated by three deep learning (DL) models (2D, 3D and Decomposition-based [1]) used for attenuation and scatter correction (ASC) were compared with CT-based ASC imaging. Image quality was assessed using a Likert scale across six anatomical regions: head, neck, chest, abdomen, pelvis, and limbs. All lesions were identified and delineated on all datasets to evaluate lesion detectability and alterations in SUVmax values. ***Results:*** Image quality scores indicated that CT ASC-PET images and Decomposition-based DL PET images were comparable ($p<0.05$) across all anatomical regions, whereas 2D and 3D DL PET scores were significantly lower ($p>0.05$). Regarding lesion detectability, both 2D (FPR=0.3%, FNR=5.0%) and 3D (FPR=0.5%, FNR=7.3%) DL ASC PET exhibited false positives and false negatives, whereas only one false positive was observed with Decomposition-based DL ASC PET (FPR=0, FNR=0.06%). The mean absolute percentage deviation (MAPE) calculated between SUVmax values from DL ASC and CT ASC PET revealed that Decomposition-based DL PET achieved the lowest estimation error across all anatomical regions in all datasets. ***Conclusion:*** The systematic comparison of the three groups of DL images demonstrates that Decomposition-based DL PET images outperform 2D and 3D DL PET images in terms of qualitative image quality, lesion detectability, and semi-quantitative evaluations, achieving image quality comparable to CT ASC-PET images. ***References:*** [1] Guo, R. et al., Nat Communications 13, 5882 (2022).

EPS-114

Deep learning-based synthesis of TSPO PET from T1 weighted MRI images only

M. Inglese[1], *M. Ferrante[1], L. Brusaferri [2], M. Loggia[2], N. Toschi[1];*
[1]University of Rome Tor Vergata, Rome, ITALY,
[2]Athinoula A. Martinos Center for Biomedical Imaging, Boston, MA, UNITED STATES OF AMERICA.

Aim/Introduction: Chronic pain-related biomarkers can be found using a specific binding radiotracer called [^{11}C]PBR28 able to target the translocator protein (TSPO), whose expression is increased in activated glia and can be considered as a biomarker for neuroinflammation[1]. However, PET imaging is expensive, requires the use of ionizing radiation and the proximity of a cyclotron. Structural (i.e. T1-w MRI) images may encode information relevant to neuroinflammation because the latter also involves some morphological/structural changes in the glial cells. We here aimed to develop a deep learning model able to synthesize PET images of the brain from T1w MRI only. ***Materials and Methods:*** Our dataset includes 204 patients (28 healthy controls, 87 knee osteoarthritis cases, and 89 chronic lower back pain cases), undergoing simultaneous 3T MRI and [^{11}C]PBR28 (TSPO)-PET imaging. Prior to PET/MR imaging, all subjects were injected with a dose in the range 9-15mCi. T1-weighted MRI and PET images were coregistered, skull-stripped, and normalized using FSL and python. The 3D U-Net architecture was specifically adapted for the task of synthesizing PET images from MRI inputs[2]. The core of the model's design is a depthwise separable convolution-based encoder, which incorporates four layers of downsampling. This minimizes the number of parameters necessary to deal with 3D images without overfitting or generating prohibitive memory footprints. The model is trained with a balanced loss between binary cross-entropy and mean squared error for 50 epochs using the Adam optimizer. ***Results:*** Voxel-wise analysis incorporated the mean squared error (MSE) to gauge reconstruction accuracy, with percentage difference maps highlighting spatial error distribution, the normalized difference and the contrast-to-noise ratio. A low MSE of 0.0034+/-0.0010 for raw synthesized PET indicated minimal voxel-wise intensity error. Smoothing the synthesized PET images further reduces MSE. NormDiff showed a mean close to zero, confirming an unbiased reconstruction of PET intensities. Smoothing the synthesized images further lowered this measure, indicating improved reconstruction accuracy. CNR calculations yielded similar mean values across raw and smoothed synthesized images, demonstrating the preservation of diagnostic characteristics in synthesized PET. ***Conclusion:*** We introduced a novel and non-invasive method to transform current diagnostic and therapeutic strategies for chronic pain conditions offering an opportunity to monitor neuroinflammation in chronic pain patients more frequently with a reduced cost. This facilitates personalized treatment and the acquisition of large-scale studies, potentially leading to a better understanding of the complex mechanisms of chronic pain and to the discovery of new therapeutic targets. ***References:*** [1]Loggia,https://doi.org/10.1093/brain/awu377;[2]Weng,https://doi.org/10.1109/ACCESS.2021.3053408.

EPS-115

CT-less PET by AI-derived synthetic CT trained in a federated learning setup

F. Andersen[1], *K. Jørgensen[1], L. Partin[2], V. Shah[2], M. E. Montgomery[1], A. B. Rodell[3], C. N. Ladefoged[1], R. Askok[4], B. M. Fischer[1], B. Spottiswoode[5];*
[1]Clinical Physiology and Nuclear Medicine, Rigshospitalet, Copenhagen, DENMARK, [2]Siemens Healthineers, Knoxville, TN, UNITED STATES OF AMERICA, [3]Siemens Healthineers, Ballerup, DENMARK, [4]Siemens Healthineers, Erlangen, GERMANY, [5]Siemens healthineers, Knoxville, TN, UNITED STATES OF AMERICA.

Aim/Introduction: With the emergence of long axial field of view (LAFOV) PET/CT scanners, PET sensitivity has increased markedly allowing for reduced radiation dose. The associated attenuation correction (AC) CT scan then becomes the primary source of ionizing radiation. Deep learning synthetic CT (sCT) for AC using non AC emission data (NAC PET) has been demonstrated to achieve excellent results, and even addresses common artifacts due to motion [1]. Developing AI-models which are robust to demographic and site variations is becoming more challenging

with as data privacy regulations evolve. We propose a federated learning (FL) setup where local hardware is used for training and patient data storage, and the model is composed of data from multiple sites. ***Materials and Methods:*** Training: Paired NAC PET and CT images from 515 patients scanned on a LAFOV PET/CT at Rigshospitalet, Copenhagen (RH-cohort). PET (FDG 3MBq/kg) were reconstructed according to clinical protocol (4i5s). NAC PET for training: 4mm filtering, noPSF. PET images for evaluation: full PSF, 2mm filtering. Patients were scanned from vertex to mid-femur (106 cm). Furthermore 25 patients available at Siemens Healthineers (External-cohort) were used in this study. Data was uploaded to the federated learning platform with data storage and permission remaining site-controlled. A GAN-model was trained according to [1], 30 subjects were reserved for independent testing. First, training was performed on the RH cohort using the FL framework. We report mean relative error in selected organs between PET and sCT-AC PET. Secondly, we applied a two-site FL approach by using transfer-learning from the first run, alternating the training between the two sites/cohorts for 25 rounds with 10 epochs per round. To balance the datasets, only 25 subjects were used per location. ***Results:*** Quantitative analysis from the single site evaluation revealed mean relative error of liver, lung, kidney, heart, aorta, spleen, brain, bones of -2.8 ± 3%, 1.5 ± 6.3%, -1.8 ± 4.0, -1.6 ± 5.1%, -1.4 ± 3.5%, -3.5 ± 3.4%, -3.7 ± 3.2.7%, -2.9 ± 2.1% respectively. The two-site training demonstrated proof-of-concept for training an AI-model in a federated setup with local data.. ***Conclusion:*** We present a federated learning setup demonstrating implementation of a GAN-model. The model provides CT-less PET benefitting radiation sensitive cohorts using LAFOV PET scanning below 0.5 mSv. Furthermore, we demonstrated that a federated training setup is feasible with local handling of training and data storage. ***References:*** [1] Montgomery, M.E. , Andersen, F.L., Ladefoged, C.N. Aim/Introduction: Accurate PET-CT co-registration is crucial for accurate and precise attenuation correction in hybrid PET/CT scanners. Schaefferkoetter et al. developed a supervised convolutional neural network(CNN) utilizing elastic registration of anatomical data to mitigate motion artefacts and enhance image quality and quantification of attenuation corrected PET images[1]. However, the generalization ability of this CNN-based method requires validation across a diverse range of radiotracers and different scanner configurations, as the original training dataset was limited to four PET tracers on a single short axial field-of-view(SAFOV) scanner. Therefore, the aim of this study was to evaluate the performance of the CNN-based PET-CT co-registration method for additional PET tracers on a long axial field-of-view(LAFOV) PET/CT scanner. ***Materials and Methods:*** The CNN-based PET-CT co-registration framework employed a dual-network architecture consisting of a shared feature extraction CNN and a deformation vector field(DVF) prediction CNN. The performance of the method was evaluated using multiple datasets acquired with five different PET tracers on a LAFOV PET/CT scanner. PET images used as registration targets were not corrected for attenuation(NAC) and reconstructed by PSFTOF-OSEM, 4 iterations and 5 subsets, and without post-reconstruction filtering. To investigate the impact of the co-registration method on attenuation correction, two sets of attenuation-corrected images were reconstructed using the same reconstruction settings: one set utilized the co-registered CT obtained by applying the co-registration framework, and another used the original CT for attenuation correction(ACCT). ***Results:*** PET images reconstructed using the co-registered CT demonstrated a significant improvement in image quality by reducing the characteristic respiratory "banana artefact" at the liver dome compared with corresponding PET images reconstructed using the original ACCT. PET images with co-registered CT exhibited a more uniform tracer distribution within the whole liver, with a reduction in standard deviation ranging from 18.8% to 35.3% across different tracers. In addition, the co-registration method led to an increase in activity in the liver ranging from 1.9% to 3.7%. Finally, better alignment between tracer distribution and anatomical information was observed. ***Conclusion:*** The CNN-based PET-CT co-registration method appears to be generalizable to different tracers and scanners not included in the original training dataset, demonstrating great potential for improving attenuation correction accuracy and, especially, for reducing respiratory artefacts. However, occasional mismatches of bones were observed, indicating the need for additional registration strategies, such as rigid registration for bones. Nevertheless, the method could potentially be a valuable tool for quantitative PET imaging. ***References:*** [1] Schaefferkoetter, EJNMMI 50,8: 2292-2304 (2023).

^{225}Ac phantom characterization, in vivo mouse imaging, and quantitation on a commercial benchtop imaging system

J. Hesterman[1], *M. Georgiou[2], C. McCutcheon[1], S. Patel[1], R. Schneider[1], Y. Alcaina[1], E. Fysikopoulos[2], E. Lamprou[2], G. Savvidis[2], G. Loudos[2], A. Amor[1];*
[1]Ratio Therapeutics, Boston, MA, UNITED STATES OF AMERICA, [2]Bioemtech, Agia Paraskevi, GREECE.

Aim/Introduction: Targeted alpha therapy (TAT) is an increasingly active area of research and development. Direct imaging of TAT compounds is advantageous for understanding biodistribution and dosimetry but is often challenging due to the complex decay schemes and low administered activities, typical of alpha emitters in TAT. We aimed to evaluate a commercial desktop imaging system equipped with a prototype high-energy, high-sensitivity collimator suitable for in vivo imaging of therapeutic amounts of 225Ac-labeled compounds. ***Materials and Methods:*** A benchtop preclinical imaging system was equipped with a Tungsten prototype high-energy, high-sensitivity collimator. Uniformity and linearity calibrations were performed to enable gamma-imaging of the 225Ac daughters, multiple characteristic x-rays, and a triple energy window (TEW) scatter correction for the 86 keV photopeak. A mouse phantom, consisting of bladder (11 kBq), left kidney (22 kBq), right kidney (37 kBq), and tumor (16 kBq) compartments, was used to assess acquisition and quantitation performance post-calibration. Jax Nu/J female mice were inoculated with 1 million AR42J cells. Mice were administered 185 kBq (5 uCi) of [225Ac]DOTATATE and sacrificed 1h and 4h post-injection (p.i.), respectively. Additional mice were imaged in vivo at 1, 24, 48, and 168h p.i. Whole-body planar image data were acquired for

30-60 minutes in all cases. ***Results:*** Image data were successfully acquired in both the mouse phantom and mice. Qualitative distribution of mouse phantom data was concordant with known activity distribution with all four phantom compartments clearly visualized. Correlation coefficients between estimated and known activities were 0.96, 0.90, and 0.86 for the 86, 218, and 440 keV photopeaks, respectively. Both ex vivo and in vivo mouse imaging show clearly differentiated uptake in kidneys and tumor across multiple time points post-administration, enabling generation of tissue time-activity curves suitable for analysis. ***Conclusion:*** This proof-of-concept study indicates that quantitative 225Ac imaging across multiple photopeaks with a commercial desktop planar imaging system is feasible in mice, using relevant administered activities and practical imaging times. Future work includes optimization of performance for high energy peaks, including TEW scatter correction windows, test-retest studies, and dynamic in vivo mice imaging to assess tissue biodistribution differences across photopeaks.

EPS-118

Comparison of Striatal Binding potentials between a 360°-CZT system and a conventional camera equipped with LEHRS collimators: an anthropomorphic phantom study

***E. Cassol*[1],** *P. Gantet[1], L. Whitfield[2], S. Coutant[2], H. Cristofol[2], B. Nicol[2], P. Payoux[1], P. Blanc[1,2];*
[1]Department of Nuclear Medicine, Toulouse University Hospitals, Toulouse, FRANCE, [2]Department of Nuclear Medicine, Albi General Hospital, Albi, FRANCE.

Aim/Introduction: The 123I-FP-CIT dopamine transporter SPECT imaging is basically performed using a conventional gamma-camera equipped with LEHR collimators. Our objective is to evaluate with a phantom how to perform and optimise this cerebral examination with two recent technologies: LEHRS collimators (0.13 mm septal-thickness) using a conventional Anger-camera and a 360°-CZT camera (12 moving-detectors). ***Materials and Methods:*** A striatal anthropomorphic phantom was filled with 39 MBq of 123I to achieve the following Binding Potentials (BP) with wholebrain excluding striatum as reference: 6.3 for right and left caudate nuclei, 6.3 for the left putamen and 2.5 for the right-one. On 360°-CZT system, acquisitions were performed in non-focus (0F) brain-focus (BF) and striatum-focus (SF) modes in 30 minutes, the list-mode allowing to achieve acquisitions in various time-durations. On Anger-camera with LEHRS, acquisitions were successively performed in 22, 11 and 5 minutes. Iterative reconstructions were performed with different number of iterations, using an iterative resolution recovery algorithm (OSEM-RR) with no additional correction. For 360°-CZT system, we also used reconstructions recommended by the manufacturer. Reconstructed images were qualitatively validated by an experienced nuclear-physician. Quantification was done with a dedicated software based on CT segmentation of the phantom and correcting the partial volume effect. The mean square error (MSE) was calculated between expected and measured BP. ***Results:*** For the 360°-CZT system, image quality is visually acceptable whatever the conditions of acquisition and reconstruction. For LEHRS, image quality is considered not visually acceptable when acquired in 5 min, related to reconstruction parameters in 11 min and always interpretable for 22 min. For the 360°-CZT system, in 0F mode, the maximum MSE is 0.2 and decreases when the number of counts increases (<0.1). In BF mode, the MSE is below 0.1 whatever the acquisition-time. In SF mode, BP are highly increased the MSE is then between 0.3 up to 0.6. For LEHRS, even if MSE varies slightly within iterations and acquisition time, MSE is around 0.16 with a maximum value of 0.23. ***Conclusion:*** Some of our experimental conditions lead to high number of counts that are over the observed range in usual clinical conditions (SF-mode and all data in 22 min). Results in 5- and 11-minutes show that BP in brain compartments can be quantified with good accuracy for the BF mode (corresponding to the lowest MSE) and also in 0F mode and LEHRS. Attenuation correction will be shortly investigated to test its impact on quantification.

EPS-119

Bias and precisionof SPECT-based ^{177}Lu activity-concentration estimation using a ring-configured solid-state versus a dual-headed Anger system

***I. Ceric Andelius*[1,2],** *A. Stenvall[1], E. Nilsson[1], A. Lindvall[3], E. Larsson[1], J. Gustafsson[4];*
[1]Radiation Physics, Department of Haematology, Oncology, and Radiation Physics, Skåne University Hospital, Lund, SWEDEN, [2]Department of Translational Medicine and Wallenberg Centre of Molecular Medicine, Malmö, SWEDEN, [3]Department of Medical Radiation Physics and Nuclear Medicine, Karolinska University Hospital, Stockholm, SWEDEN, [4]Medical Radiation Physics, Lund, Lund University, Lund, SWEDEN.

Aim/Introduction: The aim was to experimentally evaluate 177Lu activity-concentration estimation for a ring-configured CZT gamma-camera system and compare it with a conventional dual-headed Anger system for imaging at 113 keV and 208 keV with respect to bias and precision. ***Materials and Methods:*** Phantom experiments were performed on a dual-headed Anger system with 5/8" NaI(Tl) crystal (MEGP collimator) and a ring-configured CZT system. A NEMA PET body phantom with six spheres (1.2 mL, 2.6 mL, 5.6 mL, 11.5 mL, 26.5 mL, and 113 mL) and an anthropomorphic phantom with a liver insert and two spheres (10 mL and 25 mL) were filled with 177Lu. The NEMA phantom had a non-radioactive background, and the anthropomorphic phantom was imaged both with activity in the spheres and with activity in spheres and liver (ratio 15:1). SPECT projections at 113 keV and 208 keV were acquired for 1 h and divided into six 10-minute timeframes. Tomographic reconstruction was performed using OS-EM (Anger system: 1-40 iterations, 10 subsets, ring-configured system: 2-30 iterations) with compensation for attenuation, scatter (ESSE (Anger system) and window based (ring-configured system)), distance-dependent spatial resolution, and penetration (ring-configured system at 208 keV). Volumes-of-interest following the physical size of the spheres were defined and activity-concentration mean relative errors and coefficients-of-variation (CVs) over timeframes were computed for the different number of iterations. ***Results:*** The two systems showed similar mean relative errors and CVs for 208 keV. For the smallest and largest NEMA-sphere, at 20 iterations the mean relative errors/CVs were -66 %/21% and -19%/1% for the Anger system and -70%/17% and -27%/1% for the ring-configured CTZ-system. At 113 keV, corresponding results for Anger-system were -60%/15% and -20%/0.3% compared to -50%/12% and -8%/1% for the ring-configured system. For the anthropomorphic phantom with non-radioactive background at 208 keV, results for the sphere inserts were -34%/2% and 29%/1% (Anger) and -39%/3% and -32%/0.5% (ring-configured). At 113 keV, results were -34%/2% and -28%/1% (Anger) and -21%/2% and -12%/2% (ring-configured). For radioactive background at 208 keV, results were 38%/3% and -28%/1% (Anger) and -41%/2% and -33%/2% (ring-configured). At 113 keV results were -37%/2% and -28%/2% (Anger) and -24%/5% and -17%/2% (ring-configured). ***Conclusion:*** The ring-configured

CZT system is an alternative to the Anger system for estimation of 177Lu activity concentration. Precisions are similar for the two systems, whilst bias is better for the ring-configured system for imaging at 113 keV.

EPS-120

Kinetic analysis of [18F]MC225 data without arterial sampling

G. Salvi de Souza[1,2], *P. Mossel[1], J. Somsen[1], L. Providencia[1], C. R. G. Furini[2,3], A. A. Lammertsma[1], C. Tsoumpas[1], G. Luurtsema[1];*
[1]Department of Nuclear Medicine and Molecular ImagingUniversity of Groningen, University Medical Center Groningen, Groningen, NETHERLANDS,
[2]School of Medicine, PUCRS, Porto Alegre, BRAZIL,
[3]Laboratory of Cognition and Memory Neurobiology, Brain Institute, PUCRS, Porto Alegre, BRAZIL.

Aim/Introduction: Arterial blood sampling is an invasive and time-intensive procedure. Although non-invasive quantification is available for tracers if a reference region exists, the requirement for arterial sampling remains if no such region is available1. Therefore, the purpose of this study was: (1) to validate the use of a long axial field-of-view (LAFOV) PET scanner to measure the arterial whole blood time-activity curve (BAC), and (2)to assess whether venous rather than arterial samples could be used to measure the plasma-to-whole blood ratio (PBR) and the plasma parent fraction (PPF). The study made use of data from [18F]MC225 PET acquisitions. ***Materials and Methods:*** Four healthy controls and two Parkinson's disease patients underwent 60-minute scans on a LAFOV PET scanner after administration of 162±58 MBq [18F]MC225. Manual blood samples were collected from the radial artery at 5, 10, 20, 30, 40, 50, and 60 minutes after the start of injection. Radioactivity concentration in whole blood samples was determined using a gamma counter. For BAC estimation, in the early time frames, a 14-20 mm circular region-of-interest (ROI) was placed around the aortic arch. Subsequently, a 1 cm^3 spherical volume-of-interest centred at the maximal pixel intensity (VOImax) within each ROI was generated. TACs for each VOImax were compared with the manual samples. To compare venous with arterial manual samples, six healthy controls from the previous [18F]MC225 study were used2. Arterial and venous samples were collected from the radial artery and the antecubital fossa vein, respectively, at 5, 10, 20, 40, and 60 minutes after injection. Radioactivity concentrations in whole blood and plasma were determined using a gamma counter. PPF was determined using thin-layer chromatography analysis. ***Results:*** Across different time points, a mean Spearman correlation coefficient of r=0.98±0.02 was observed between BAC values derived from aortic arch and whole blood concentrations from manual samples, showing higher values than reported in a previous study3. For the comparison between venous and arterial samples, strong Spearman correlations were observed for PBR (r=0.90, p=0.042) and PPF (r=1.00, p=0.0083), consistent with findings for other tracers4-6. ***Conclusion:*** This study shows that an accurate BAC can be obtained using a LAFOV PET and that, for [18F]MC225, arterial samples can be replaced by venous samples, making a [18F]MC225 study more patient-friendly and cost-effective. It should be noted that the use of venous samples should be validated for each tracer separately. ***References:*** 1Volpi, et al.(2023);2Mossel, et al.(2023);3Reed, et al.(2024);4Tomasi, et al.(2019);5Galovic, et al.(2021);6Ng, et al.(2013).

EPS-121

A Rapid Brain Perfusion Analysis Method with ^{18}F-FDG PET by Using Coincidence Event Detection

W. Zhang[1], *Y. Xia[1], Q. Liu[2], Q. Xie[1,3,4], C. Ye[5], B. Li[3];*
[1]Department of Biomedical Engineering, Huazhong University of Science and Technology, Wuhan, CHINA,
[2]Department of Electronic Information Engineering, Nanchang University, Nanchang, CHINA, [3]Institute of Artificial Intelligence, Hefei Comprehensive National Science Center, Hefei, CHINA, [4]Department of Electronic Engineering and Information Science, University of Science and Technology of China, Hefei, CHINA, [5]Department of Neurosurgery, The First Affiliated Hospital of USTC, University of Science and Technology of China, Hefei, CHINA.

Aim/Introduction: The significance of brain perfusion in ischemic stroke has been extensively investigated. Effective tissue reperfusion is a critical determinant for salvage of the ischemic penumbra and subsequent clinical improvement. Among them, time-based perfusion parameters offer advantages over CBF and CBV image in determining ischemic penumbra. However, previous studies predominantly focused on CT and MRI, neglecting the valuable information inherent in the process of brain perfusion with PET. Given the significant advantages of digital PET in sensitivity and count rate, alongside precise dynamic imaging of cerebral blood flow, this study explores a rapid analysis method of 18F-FDG PET brain perfusion using coincidence event detection to derive the brain perfusion parameters. ***Materials and Methods:*** In this study, 12 individuals without vascular injury underwent dynamic 18F-FDG PET scans, including 7 older adults (age > 50 years), and 5 younger adults (age < 50 years). The duration of perfusion data acquisition was 10 minutes, beginning prior to the 18F-FDG injection, with static images reconstructed 50 minutes post-injection. Perfusion time-count curve (TCC) was generated directly by coincidence events from head. Then PET brain perfusion parameters were extracted from TCC using MATLAB software. ***Results:*** PET static image revealed a markedly lower 18F-FDG-uptake in older adults compared to younger adults (SUVmax: 8.95versus 13.05, SUVmean: 3.29 versus 4.74). Following 18F-FDG injection, all PET brain perfusion curves (i.e., TTCs) exhibited three stages: a rapid rise before reaching a peak, a brief and slight decline post-peak, and followed by a gradual long-term increase. Specifically, two groups showed distinctive and characteristic time-count curves across three stages: The time to reach the perfusion peak following tracer injection decreased by 3.77+/-1.21 seconds for younger adults, and the average duration to reach the plateau stage was markedly longer for older adults (45.83+/-7.88 seconds) compared to younger adults (26.25+/-4.72 seconds), whereas the decline rate in older adults coincidence events post-peak (24.67+/-8.22%) was similar to younger adults (21.27+/-15.18%). ***Conclusion:*** PET coincidence event detection facilitates rapid quantitative assessment of brain perfusion without any addition of the standard protocol. Its values may be served as an alternative for brain blood flow analysis when iodinated contrast agents are unavailable. Overall, the dynamic time-count curve of PET brain perfusion exhibits the similarity with the CT perfusion time-intensity curve, enabling the extraction of some main brain perfusion parameters, and the potential extraction of cerebral hemodynamic parameters. This study underlines the additional value of dynamic 18F-FDG-PET coincidence event acquisition.

EPS-122

Digital Biopsy & Network Analysis of dynamic [^{68}Ga] FAPI data in pancreatic cancer patients

M. MacAskill[1], *M. Geisinger[2], H. Buchholz[3], I. von Goetze[3], U. Haberkorn[2], M. Lang[4], U. Heger[4], J. Liermann[5], E. Gutjahr[6], D. E. Newby[1], A. A. S. Tavares[1], M. Schreckenberger[3], M. Röhrich[3,2];*
[1]University of Edinburgh, Edinburgh, UNITED KINGDOM, [2]Heidelberg Nuclear Medicine, Heidelberg, GERMANY, [3]Mainz Nuclear Medicine, Mainz, GERMANY, [4]Heidelberg Surgery, Heidelberg, GERMANY, [5]Heidelberg Radiation Oncology, Heidelberg, GERMANY, [6]Heidelberg Pathology, Heidelberg, GERMANY.

Aim/Introduction: With static [68Ga]FAPI-PET/CT, distinguishing pathologies like pancreatic ductal adenocarcinomas (PDAC), inflammatory lesions of the pancreas (ILP), post-pancreatectomy reactive tissue (PRT) and recurrent-PDAC (RPDAC) is a major challenge due to their marked increase in signal. Dynamic imaging allows full [68Ga]FAPI kinetic profile analysis, highlighting differences between these pathologies. Analysis of such dynamic PET data is challenging. We propose the use of a voxel-level "digital biopsy" approach combined with network analysis and clustering to overcome this challenge. We hypothesise this approach will allow the identification of healthy, non-malignant pathological and malignant pathological kinetic signatures which could aid diagnosis in the future. ***Materials and Methods:*** 47 Patients with unclear pancreatic lesions (26 primary, 17 recurrent setting) underwent dynamic [68Ga]FAPI-PET/CT. Primary cases underwent surgical resection/biopsy after PET imaging. Possible recurrences were classified according to CT and clinical course (minimum 18 months). A digital biopsy consisting of 300 voxels was sampled in each volume of interest (VOI) before being blinded and imported into Graphia V.3.1. Muscle, fat, kidneys, liver and blood were sampled as controls. Voxel networks were created with multiple VOI from a single scan, or VOI combined from multiple scans, with a minimum Pearson correlation value of 0.7. k-NN edge reduction was also applied before Markov clustering. The datasets were then unblinded for interpretation. ***Results:*** A total of 48 individual-networks, and two combined-networks, were created. Within the individual datasets, voxels tended to arrange and cluster within the sampled VOI, with the exception of the left and right kidney which strongly co-clustered. Networks typically arranged into healthy control, elimination organ and pathological (malignant and non-malignant) regions. Pathologies tended to cluster with high purity (>95% from the same VOI), with multiple clusters per VOI indicating heterogeneity within the pathological classification. The combined PDAC (19 cases) and ILP (26 cases) network revealed a central core mainly consisting of PDAC clusters, which had more sustained [68Ga] FAPI signal towards the end of the scan relative to the ILP clusters which tended to be peripheral to this malignant core. A similar pattern was observed in the combined RPDAC (6 cases) and PRT (9 cases) network. Across both combined-networks, clusters almost exclusively clustered within their pathological cluster with minimal co-clustering. ***Conclusion:*** The unique kinetics of [68Ga] FAPI across the different regions, coupled with this sampling and analysis approach, allowed the separation and identification of healthy, non-malignant pathological and malignant pathological clusters and kinetic features, thus warranting further investigation.

EPS-123

Comparison Of Correlations Between ^{18}F And ^{68}Ga PET-CT PSMA Suspected Prostate Cancer Patients To Assess If Increased Bias Is Associated With Either Imaging Agent

B. Sanghera[1], *G. Lowe[2], W. Wong[2];*
[1]St Bart's Hospital NHS Trust, London, UNITED KINGDOM, [2]Paul Strickland Scanner Centre, London, UNITED KINGDOM.

Aim/Introduction: [18F]F-PSMA-1007 and [68Ga]Ga-PSMA-1 are frequently used imaging agents in PET prostate cancer scanning that are sometimes interchanged when tracer supply is compromised. We investigate if greatly increased bias exists through analysing correlations between common parameters found in PET to establish if either radiopharmaceutical imaging agent leads to more reliable results. Results from such studies help establish a framework promoting the case for centrally commissioned funding and approval of a range of PET-CT PSMA imaging agents nationally. ***Materials and Methods:*** 61 68Ga and 72 18F different PSMA subjects were PET-CT scanned using clinical protocols. Each group consisted of 200 suspected lesions including metastatic sites of disease identified and reported by experienced radiologists. Spearmen ranks analysis was used to investigate the strength and direction (ρ) of correlations between height, weight, age, body mass index (bmi), body surface area (bsa), lean body mass (lbm), injected activity, uptake time, suspected lesion SUV with different normalisations, liver SUV with different normalisations, T/B, MTV and TLG for each radiopharmaceutical to investigate if either imaging agent was considerably more biased than the other. $P<0.05$ signified a statistically significant result. Data were analysed by medical physicists with >20 years PET experience each. ***Results:*** Extensive correlation results were visualised as heatmaps that exhibited multiple statistically significant differences for 68Ga and 18F PSMA parameters. In the case of 68Ga 89 correlations were negative, 0 had no correlation and 82 were positive (31 very strong) while 65 were highly significant ($P<0.0001$), 34 significant ($P<0.05$) and 72 not significant ($P\geq0.05$). For ^{18}F 97 correlations were negative, 0 had no correlation and 74 were positive (32 very strong) while 51 were highly significant ($P<0.0001$), 41 significant ($P<0.05$) and 79 not significant ($P\geq0.05$). For both radiopharmaceuticals highly significant strong positive correlations ($p<0.0001$) were seen especially between different lesion SUV normalisations and T/B, MTV, TLG. ***Conclusion:*** Results revealed a relatively similar trend for 68Ga and 18F PSMA with highly significant positive correlations in both especially for T/B, MTV and TLG with lesion SUV normalisations. This is reassuring and indicates analogous bias trends for either radiopharmaceutical so validating use clinically for detecting prostate cancer. Such results further support the case for full regulatory approval/commissioning of different imaging agents in prostate cancer imaging nationally.

EPS-124

Early Ultra-short [^{18F}]FDG Patlak Parametric Imaging May Reduce Patient Uptake Time and Increase Throughput

M. Roya, *J. van Sluis, J. H. van Snick, P. Mohr, Z. Li, L. Providência, S. Mostafapour, A. W. J. M. Glaudemans, C. Tsoumpas;*
University Medical Center Groningen, Groningen, NETHERLANDS.

Aim/Introduction: Parametric Patlak imaging (PPI), unlike static imaging, reveals tracer kinetics and distinguishes between specific and non-specific uptake. Using population-based input functions (PIF) together with dynamic imaging on novel long axial field-

of-view (LAFOV) PET/CT systems facilitates the use of shortened PPI in clinical routine. When applying the Patlak plot on [18F]FDG data, equilibrium between blood and reversible compartment is assumed at 30min post injection (p.i.). Still, patients are typically scanned around 60min p.i. This work investigates the feasibility of 10min PPI at 30min p.i., as well as using early kinetic information to predict static images at around 60min p.i. ***Materials and Methods:*** Twenty patients with suspected lung malignancy received 3 MBq/kg [18F]FDG and underwent 65min of dynamic scan on a LAFOV PET. Using the list mode data, Patlak Ki images from 30-40min p.i. (Ki30) and 55-65min p.i. (Ki55) were reconstructed, as well as a 10min standard static image at 55min p.i., as per local clinical reconstruction settings (CLIN). When applying the Patlak plot, the PIF was scaled to the image-derived input function. In addition, the PIF was used to calculate the reversed Patlak to predict SUV at 55-65min p.i. (SUV55). Ki and SUVmean of different tissues (lesion, brain, liver, spleen and muscle) were compared between images using R2 and Bland-Altman (BA) analysis. Both limited (high sensitivity, HS) and wide (ultra-high sensitivity, UHS) photon acceptance angle settings of the PET system were evaluated. ***Results:*** High correlation was found for both the Ki values between Ki30 and Ki55 (HS: 0.925<R2<0.995, UHS: 0.958<R2<0.999), as well as for the SUV values between CLIN and SUV55 (HS and UHS: 0.979<R2<0.999). BA analysis showed excellent agreement for both Ki (HS: -0.048<LOA<0.026, UHS: -0.068<LOA<0.041) and SUV in HS mode (-0.52<LOA<0.34). Higher, yet acceptable, differences in SUV were observed between CLIN and SUV55 in UHS (-2.104<LOA<1.078), mainly due to differences in lesion SUV. ***Conclusion:*** This work demonstrates the viability of 10min PPI at 30min p.i., resulting in about 30min shorter uptake times, possibly leading to increased patient comfort, higher throughput, and more cost-effective PET/CT scanning. Furthermore, using the PPI data, the calculated SUV at 60min p.i. can be obtained, which can aid in data harmonization with previous and ongoing studies and can still be used as a reference by clinicians for diagnostic purposes. Additionally, this method could be very beneficial in studies with other irreversible radiotracers, such as [18F]F-DOPA, with uptake times generally around 90 min.

Noninvasive Granzyme B PET Imaging of meso-CAR T Intervention for Monitoring Early Tumor Responses to Immunotherapy
X. Lv[1,2], *J. Cao[3], X. Song[1,2], Y. Gai[1,2], D. Jiang[1,2], Y. Zhang[1,2], R. An[1,2], P. Lei[3], X. Lan[1,2];*
[1]Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA, [2]Hubei Province Key Laboratory of Molecular Imaging, Wuhan, CHINA, [3]Department of Immunology, School of Basic Medicine, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA.

Aim/Introduction: The serine protease granzyme B and perforin, acting synergistically upon release, facilitate target cell apoptosis by cytotoxic lymphocytes, indicating granzyme B as a promising biomarker for evaluating the efficacy of immunotherapy. The substrate-based probe 68Ga-NOTA-GZP can specifically bind and longitudinally capture the dynamic changes of granzyme B levels within tumors, providing information about immune cell function and the immune activation status in the tumor. Utilizing the mesothelin-specific targeted nanobody MS3, identified from our preceding study, we have engineered a novel chimeric antigen receptor T cell (meso-CAR T). Moreover, we have delved into the

application of 68Ga-NOTA-GZP PET/CT imaging for evaluating the early tumor responses to CAR T-based cancer immunotherapy. ***Materials and Methods:*** T cells were genetically modified to express CAR with MS3 serving as the targeting recognition domain. As BxPC-3 tumors exhibit moderate to high mesothelin expression levels in immunohistochemical analysis and 68Ga-NOTA-MS3 PET imaging, they are potential candidates for meso-CAR T therapy. 10 days after tumor inoculation, approximately 5 × 106 CAR T or blank T cells were intravenously administered to BxPC-3 tumor-bearing mice on day zero. Granzyme B PET/CT imaging was performed on the day prior to T cells administration and subsequently on day 1, 3, 5, and 7. The mean percentage of injected dose per gram (%ID/g) for tumors were obtained by drawing regions of interest. ***Results:*** Baseline imaging with 68Ga-NOTA-GZP showed extremely low uptake in BxPC-3 tumors (0.17 ± 0.10 %ID/g), denoting minimal background adsorption, which is conducive to the highly sensitive detection of granzyme B within the tumor. After therapy administration, a progressive increase in tumor uptake was observed in CAR T and blank T groups through consecutive granzyme B PET imaging, as T cells accumulated, infiltrated, expanded and activated at tumor sites. Overall, the tumor uptake of 68Ga-NOTA-GZP in the CAR T group consistently exceeded that in the blank T group, despite no statistically significant. This can be attributed to the augmented tumor-targeting capacity of the CAR T cells. Semi-quantitative analysis presented that on day 7 post-treatment, the tumor uptake of 68Ga-NOTA-GZP in the CAR T group was significantly higher than the corresponding baseline levels (0.14±0.01 vs 0.61±0.20, P<0.05). ***Conclusion:*** Our findings preliminarily validate that granzyme B PET imaging can support early response assessment of CAR T therapy in a non-invasive, dynamic, and quantitative manner, holding the potential to guide and enhance the efficacy of CAR T therapy in solid tumors.

OP-407

Noninvasive longitudinal PET imaging of granzyme-B and caspase-3 for monitoring early treatment response to immunotherapy

Y. Feng[1,2,3], *X. Zhang[1,2,3], M. Li[1], Z. Lin[1], W. Hu[1], X. Wang[1], X. Lan[1,2,3];*
[1]Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA, [2]Hubei Key Laboratory of Molecular Imaging, Wuhan, CHINA, [3]Key Laboratory of Biological Targeted Therapy, the Ministry of Education, Wuhan, CHINA.

Aim/Introduction: Early predicting treatment response is important in assessing the course of immunotherapy to minimize deleterious side effects and timely adjust the treatment plan. This study aimed to provide a novel noninvasive method for monitoring early tumor response to immunotherapy using two positron emission tomography (PET) tracers targeting granzyme-B and caspase-3. ***Materials and Methods:*** CT26 murine colon cancer cells were implanted bilaterally on the right shoulder of Balb/c mice. Mouse models in the treatment group received anti-PD-1 on day 1, 4, 7 intraperitoneally. The control group was treated with an equal volume of PBS (vehicle). Tumor growth of the two groups was measured. Two substrate-based probes, [68Ga]Ga-NOTA-GZP targeting granzyme-B and [68Ga]Ga-NOTA-AC3 targeting caspase-3, are employed to compare their efficacy in monitoring the response to immune checkpoint inhibitor treatment in preclinical studies. Changes in granzyme-B activity and caspase-3 activity were assessed using the two PET tracers from baseline and continued every 3 days until day 9. ***Results:*** In the CT26 model immunotherapy group, immune system activation and subsequent tumor apoptosis are well induced, as demonstrated by the granzyme-B and cleaved caspase-3 levels. Tumor uptake of [68Ga]Ga-NOTA-GZP and expression of granzyme-B peaked on day 3 and remained high thereafter. Concurrently, tumor uptake of [68Ga]Ga-NOTA-AC3 and the expression of cleaved caspase-3 gradually increased and peaked at day 9 during the immunotherapy regimen. The signal from [68Ga]Ga-NOTA-GZP on day 3 throughout the regimen enabled early and effective monitoring of the response to immunotherapy in vivo. ***Conclusion:*** [68Ga]Ga-NOTA-GZP PET imaging facilitates early and non-invasive prediction of the early treatment response to immunotherapy. It provides a potential translational paradigm for early monitoring of immune checkpoint inhibitor treatment in a clinical setting.

OP-408

Discovery of [^{68}Ga]Ga-BCY10939, a bicyclic peptide PET ligand for in vivo imaging of tumor PD-L1 status

X. Wang, *Q. Chen, J. Wang, W. Yang, F. Kang, J. Wang;*
Department of Nuclear Medicine, Xijing Hospital, Fourth Military Medical University, Xi'an, CHINA.

Aim/Introduction: In clinical practice, the clinical decision-making of immune checkpoint inhibitors has always relied on assessment of PD-L1 expression using immunohistochemical staining of biopsy tissues, which may not be optimal due to the heterogeneous and dynamic expression of PD-L1 protein. In contrast, positron emission tomography (PET) could noninvasively capture whole-body PD-L1 expression and dynamics, compensating the deficiency of immunohistochemistry. In this study, we described the discovery of [68Ga]Ga-BCY10939, a bicyclic peptide PET ligand for in vivo imaging of tumor PD-L1 status. ***Materials and Methods:*** The bicyclic peptide precursor NOTA-BCY10939 were custom synthesized and radiolabelled with 68GaCl3 to obtain the PET radiotracer [68Ga]Ga-BCY10939. The radiochemical yield and purity, molar activity, partition coefficient as well as in vitro stability of [68Ga]Ga-BCY10939 were characterized. The binding model between [68Ga]Ga-BCY10939 and PD-L1 protein was determined by molecular docking. The cell uptake and binding assays, PET imaging, biodistribution and pharmacokinetics of [68Ga]Ga-BCY10939 were performed in vitro and in vivo using U87 MG, U87MG/PD-L1-/- and their tumor xenograft models. ***Results:*** [68Ga]Ga-BCY10939 was produced with high radiochemical yield, radiochemical purity and molar activity. The hydrophilicity of [68Ga]Ga-BCY10939 was determined with a partition coefficient (Log P) of -1.43 ± 0.25. The stability was verified in saline and serum within 4 h. In silico approach revealed the optimized binding conformation of [natGa]Ga-BCY10939 towards PD-L1 with a binding energy of -9.087 kcal/mol. In vitro assays demonstrated the nanomolar affinity and specificity of [68Ga]Ga-BCY10939. Tumor uptake of [68Ga]Ga-BCY10939 with high contrast was observed by PET imaging in U87MG xenograft models and the in vivo specificity was proved using U87MG/PD-L1-/- tumor xenograft models and blocking study with excess of non-radioactive BCY10939. The biodistribution of [68Ga]Ga-BCY10939 was consistent with the PET results. [68Ga]Ga-BCY10939 displayed the renal excretion and a rapid clearance from blood and other non-specific organs, contributing to high contrast imaging in the clinical time frame. ***Conclusion:*** [68Ga]Ga-BCY10939 is a promising bicyclic peptide-based PET ligand for in vivo imaging of tumor PD-L1 status. Further clinical translation of [68Ga]Ga-BCY10939 in patients is warranted.

OP-409

Granzyme B PET/CT Imaging Evaluates Early Response to Immunotherapy in Gastric Cancer

Q. Liu, *S. Song;*
Department of Nuclear Medicine, Fudan University Shanghai Cancer Center, Fudan University, Shanghai, CHINA.

Aim/Introduction: As few patients could benefit from immune checkpoint inhibitors (ICIs), accurately predicting and monitoring early therapeutic responses to ICIs is essential for precision therapy. Here, we developed a positron emission tomography/computed tomography (PET/ CT) probe targeting granzyme B, [68Ga]Ga-NOTA-GSI, and aimed to investigate whether it could provide a noninvasive and effective method to predict the early response to immunotherapy. ***Materials and Methods:*** A total of 72 patients were performed the interim [68Ga]Ga-DOTA-GSI PET/CT scan. And finally, 40 patients were included for further analysis. The SUVmax of tumor, metastatic lymph nodes (LNs), and normal tissues (liver and blood pool) were measured, and their ratios were denoted as TLRtumor, TBRtumor, TLRLN, and TBRLN, respectively. Two-sample t tests and Wilcoxon rank-sum tests were used to compare the PET/CT parameters between responders and non-responders. Moreover, receiver-operating characteristic (ROC) curve analysis was used to investigate the predictive performance of [68Ga] Ga-DOTA-GSI PET/CT in evaluating the treatment response. Two-tailed $P < 0.05$ was considered statistically significant. ***Results:*** We found that SUVmax-t, TLRtumor, TBRtumor, SUVmax-LN, and TBRLN were higher in responders than in non-responders (2.49 ± 0.58 vs. 1.55 ± 0.48, $p = 0.000$, 2.24 ± 0.48 vs. 1.74 ± 0.67, $p=0.007$, 1.38 ± 0.43 vs. 0.90 ± 0.23, $p = 0.000$, 2.24 ± 0.99 vs. 1.42 ± 0.55, $p = 0.003$, 1.28 ± 0.68 vs. 0.83 ± 0.32, $p =0.012$), respectively. According to ROC curve analysis, the cutoffs for SUVmax-t, TLRtumor, TBRtumor, SUVmax-LN, TLRLN, and TBRLN were 2.05, 2.25, 0.885, 1.65, 0.765, and 1.52, respectively. SUVmax-t and TBRtumor showed satisfying accuracy in distinguishing non-responders and responders. Additionally, multivariate logistic regression indicated that TBRtumor was an independent predictor of treatment response ($p = 0.03$). ***Conclusion:*** Our results indicated that [68Ga] Ga-DOTA-GSI PET/CT is a promising useful tool to predict the early response to combined immunotherapy in patients with GC.

OP-410

Development of a Bispecific Antibody ^{124}I-NB12 for Imaging PD-L1/2 Expression in Tumors

Y. Yao, *N. Li;*
Peking university cancer hospital, Beijing, CHINA.

Aim/Introduction: NB12 is a bispecific antibody that consists of two anti-programmed cell death-ligand 1 (PD-L1) nanobodies and two anti-programmed cell death-ligand 2 (PD-L2) nanobodies. As two ligands of programmed cell death protein 1 (PD-1), PD-L1 and PD-L2 are closely related to the efficacy of ICI therapy (ICI), and therefore this bispecific antibody could be suitable for screening potential beneficiaries. The aim of this study is to design a novel tracer 124I-NB12 targeting PD-L1/2 and perform preclinical evaluation to dynamically monitor PD-L1/2 expression. ***Materials and Methods:*** The bispecific antibody targeting PD-L1 and PD-L2 (NB12) was labeled with the radionuclide 124I at room temperature. An in vitro binding assay was performed to assess the affinity 124I-NB12 to PD-L1 and PD-L2, respectively. In vitro stability in 5% human serum albumin (HSA) and PBS was analyzed using Radio-thin layer chromatography (Radio-TLC).. Cell uptake, pharmacokinetic, and biodistribution experiments were used to evaluate the biological properties. Micro-PET/CT imaging with 124I-NB12 was conducted at different time points. Immunohistochemical and HE staining studies were carried out using tumour tissues from tumour-bearing mice. ***Results:*** The MALDI-TOF-MS results showed that the average molecular weight of NB12 was 108.376 kDa. The radiochemical yield of 124I-NB12 was 84.62±3.90% and the radiochemical purity (RCP) was more than 99%. The tracer incubated in 0.01 M PBS and 5% HSA maintained high stability (RCP>95%). Radio-ELISA showed that 124I-NB12 had a high affinity for the PD-L1 ($Kd = 19.82$ nM, $R2 = 0.95$) and PD-L2 protein ($Kd = 2.52$ nM, $R2 = 0.87$). Cellular uptake experiments confirmed that the uptake of 124I-NB12 in A549-PDL1/2 cells was higher than that in A549 cells at each time point. The half-lives of the distribution phase and elimination phase were 0.26 h and 4.08 h. Micro-PET/CT showed significant uptake in the tumor region of A549-PDL1/2 tumor-bearing mice 24h postinjection of 124I-NB12 compared with A549 group (SUVmax=2.26 ± 0.08, 2.90 ± 0.11 and 0.38 ± 0.07, respectively). HE staining confirmed that the subcutaneous xenograft tumor model A549-PDL1/2 was successfully constructed, and immunohistochemistry showed that A549-PDL1/2 was highly expressed in A549-PDL1/2 mice. ***Conclusion:*** We have constructed 124I-NB12 targeting PD-L1 and PD-L2. On the basis of high yield, radiochemical purity and stability, biological evaluation showed its specificity and affinity for PD-L1/2, and micro-PET/CT imaging confirmed the feasibility of visualizing tumor PD-L1/2 in vivo. It will be a promising method to dynamically monitor PD-L1/2 expression and screen potential beneficiaries of ICI therapy.

OP-411

Development of A New ^{68}Ga-labeled Peptides for PD-L1 Targeted PET Imaging

F. Zhang;
Department of Nuclear Medicine, Fudan University Shanghai Cancer Center, Shanghai, CHINA.

Aim/Introduction: The immune checkpoint protein programmed death-ligand 1 (PD-L1, CD274) serves as a crucial therapeutic target. However, the heterogeneity in PD-L1 expression poses challenges to the accuracy of immunohistochemistry (IHC) results. In order to precisely monitor PD-L1 expression levels throughout the body, we developed novel 68Ga-labeled peptides. These peptides enable specific and selective in vivo imaging of PD-L1, offering a promising avenue for enhanced diagnostic and therapeutic strategies. ***Materials and Methods:*** 68Ga-DOTA-CCC was synthesized and its radiochemical purity was evaluated by Radio-iTLC and Radio-HPLC. Its stability, octanol/water partition coefficient (log P), and biological half-life were also evaluated PET imaging was performed on B16F10, NCL-H292, or A549 tumor-bearing mice. dynamic monitoring of PD-L1 exposure in NCL-H292 tumor-bearing mice for five days after the injection of different doses of atezolizumab. ***Results:*** 68Ga-DOTA-CCC showed favorable radiolabeling efficiency, and the stability of 68Ga-DOTA-CCC in saline and serum remained above 95% in 3 h. The logP of 68Ga-DOTA-CCC was -1.95 ± 0.32 ($n = 5$), which suggests the probe was hydrophilic, and the half life of the probe was 17.5 ± 5.5 min ($n = 5$). PET imaging showed the tumor uptake of B16F10 was 3.20 ± 0.17 %ID/gmax, and NCI-H292 was 1.47 ± 0.06 %ID/gmax ($n = 3$) at 30 min post injection, this was consistent with WB. We will subsequently refine the imaging of the A549 tumor model with low PD-L1 expression. Tumor uptake of 68Ga-DOTA-CCC was significantly reduced at 24 h after injection of atezolizumab and then gradually recovered. ***Conclusion:*** 68Ga-DOTA-CCC was successfully synthesized with high radiochemical purity.

Tumor uptake was related to PD-L1 expression that suggested the specificity of the probe. Dynamic monitoring experiments of PD-L1 exposure demonstrate the potential of probes to advise for antibody therapy in clinic.

OP-412

^{18}F-CFA/FAC-PET Reveals Immune Cell Activation in the Tumor-Draining Lymph Nodes Following Treatment with Immune Checkpoint Inhibitors

C. Philippe[1], *J. Cotton[2], G. D. Bowden[2], S. Pöschel[2], B. Schörg[2], P. Knopf[2], I. Gonzalez-Menendez[2], D. Sonanini[2], L. Flatz[2], M. Allen-Auerbach[3], C. Radu[3], J. Czernin[3], L. Quintanilla de Fend[2], B. Pichler[2], M. Hacker[1], A. Maurer[2], M. Kneilling[2];*
[1]Medizinische Universität Wien, Wien, AUSTRIA,
[2]Eberhard Karls University, Tübingen, GERMANY, [3]UCLA, Los Angeles, CA, UNITED STATES OF AMERICA.

Aim/Introduction: The advent of immunotherapy underscores the need for advanced non-invasive whole-body imaging techniques to facilitate patient stratification and enhance therapy monitoring. Being substrates of the deoxyribonucleoside salvage pathway, the murine radiotracer 1-(2′-Deoxy-2′-18F-fluoro-β-D-arabinofuranosyl)-cytosine (18F-FAC) [1] and the human analog 2-chloro-2′-deoxy-2′-18F-fluoro-9-β-d-arabinofuranosyl-adenine (18F-CFA) [2] allow for the in vivo visualization of immune cell activation within lymphatic organs. ***Materials and Methods:*** 18F-CFA-PET/CT was conducted on two metastatic melanoma patients before and after the onset of immune checkpoint inhibitor therapy (CIT). In a preclinical setting, CIT-sensitive (MC38 and CT26 colon adenocarcinomas) or CIT-resistant (B16F10 melanomas and 4T1 breast cancers) tumor bearing mice underwent a baseline and - after one week of CIT (anti-PD-L1 mAb) - a follow-up 18F-FAC-PET/MRI. Control mice received sham-treatment (isotype mAbs). Ex vivo biodistribution, flow cytometry analyses, immunohistochemistry and in vitro 18F-FAC cell uptake experiments (T cells, macrophages, tumor cell lines) completed our studies. ***Results:*** Melanoma patients revealed CIT-induced enhancement of 18F-CFA uptake in in tumor-draining lymph nodes (TDLNs). In line with this, CIT-induced immune cell activation yielded a significantly increased 18F-FAC uptake in TDLNs of experimental mice when compared to contralateral control lymph nodes (cLNs) and to the TDLNs of sham-treated tumor-bearing mice. Furthermore, enhanced 18F-FAC uptake was observed in primary and secondary lymphoid organs, small intestine, and tumors. Cross-sections of the TDLNs were larger compared to their cLNs, regardless of whether the mice underwent anti-PD-L1 or isotype mAb treatment. Flow cytometry analysis revealed a lower abundance of CD3+ T cells in the TDLNs but not in the cLNs of tumor bearing mice independent of treatment indicating that not the T cell population might be responsible for the enhanced 18F-FAC-uptake within the TDLNs. We determined in the TDLNs of both CIT-resistant tumor models a generally higher relative number of CD11b+ cells when compared to the CIT-sensitive tumor models. In vitro experiments showed significantly elevated 18F-FAC uptake by activated mouse T cells and macrophages, whereas naïve T cells and macrophages showed almost no 18F-FAC-uptake. In addition, all four tumor cell lines exhibited a significant 18F-FAC-uptake. ***Conclusion:*** 18F-FAC- and 18F-CFA-PET enable the identification of CIT-induced immune cell activation in TDNLs, supporting further the essential role of the TDLN in promoting anti-cancer immune response. ***References:*** [1] Radu, C.G. et al. Nat. Med. 14, 783-788 (2008). [2] Shu, C.J. et al. J. Nucl. Med. 51, 1092-1098 (2010).

OP-413

Development and Evaluation of ^{124}I-E6scFv-Fc for Monitoring PD-L2 Expression in Tumors

Y. Yao, *N. Li;*
Peking university cancer hospital, Beijing, CHINA.

Aim/Introduction: Programmed cell death-Ligand 2 (PD-L2), a ligand programmed cell death protein 1 (PD-1), is an immune checkpoint molecule closely related to the efficacy of immune checkpoint inhibitor therapy (ICI). The aim of this study is to design a novel tracer 124I-E6scFv-Fc targeting PD-L2 and perform preclinical evaluation to dynamically monitor PD-L2 expression and screen potential beneficiaries of ICI therapy. ***Materials and Methods:*** A human single-chain fragment variable (scFv) was generated by phage display, using the extracellular domain of recombinant human PD-L2. The E6scFv was reformatted into a bivalent E6scFv-Fc, based on human IgG1-fragment crystallizable (Fc). The E6scFv-Fc was radiolabeledwith 124I by N-Bromosuccinimide (NBS) in PB-buffer at pH 7 (37°C, 60s). The affinity of the 124I-E6scFv-Fc was evaluated using PD-L2 protein by Radio-ELISA. Cellular uptake assays were performed using the transduced PD-L2 expressing lung cancer cell line A549 (A549-PD-L2) and wild-type A549 cells as negative control. Micro-PET/CT imaging was conducted with 124I-E6scFv-Fc and static images were recorded with an acquisition time of 15 min. Immunohistochemical and HE staining studies were carried out using the tumor tissue of tumor-bearing mice. ***Results:*** The radiochemical yields of 124I-E6scFv-Fc were 84.02±4.89% and the radiochemical purity (RCP) of the tracer was more than 99%. Radio-ELISA showed that 124I-E6scFv-Fc had a high affinity for the PD-L2 protein (Kd = 11.17 nM, R2 = 0.92). Cellular uptake experiments confirmed that the uptake of 124I-E6scFv-Fc in A549-PDL2 group was higher than that in A549 group and A549-PDL2-block group at each time point. The half-lives of the distribution phase and elimination phase were 0.18 h and 9.01 h. Micro-PET/CT showed significant uptake in the tumor region of A549-PDL2 tumor-bearing mice (SUVmax = 3.53 ± 0.12 at 40h) compared with other groups. The biodistribution of the at 24h postinjection showed higher tumor uptake in A549-PDL2 mice (20.34±1.09 %ID/g for 124I-E6scFv-Fc in A549-PDL2 mice vs 3.25±0.24 %ID/g for 124I-E6scFv-Fc in A549 mice vs 3.20±0.51 %ID/g for 124I-CKscFv-Fc in A549-PDL2 mice). The dosimetry estimation by using olinda software showed that the effective dose was 7.99E-02 mSv/MBq. Immunohistochemistry showed that A549-PDL2 was highly expressed in A549-PDL2 mice. ***Conclusion:*** 124I-E6scFv-Fc enables easy radiosynthesis and shows excellent in vitro and in vivo PD-L2 targeting characteristics. The high tumor uptake at early imaging time points demonstrate the feasibility of 124I-E6scFv-Fc for imaging of PD-L2 expression in tumors and is encouraging for further clinical applications of screening potential beneficiaries of ICI therapy.

Quantum convolutional neural networks for minimizing training and model complexity - a dual-center prostate cancer study

L. Papp1, *D. Haberl[1], S. Wail[2], M. Hacker[1], B. A. Irene[3], R. Laudicella[4], W. Drexler[1], S. Moradi[1];*
[1]Medical University of Vienna, Vienna, AUSTRIA, [2]Telix Pharmaceuticals, Melbourne, AUSTRALIA, [3]Kantonsspital Baden, Baden, SWITZERLAND, [4]Messina University, Messina, ITALY.

Aim/Introduction: State-of-the-art classic convolutional neural networks (CNN) may have millions of parameters to train; thus, they generalize poorly if trained on small medical data. Quantum computing can encode N voxel values to log2(N) number of qubits, resulting in a simplified search space for artificial intelligence tasks. This allows simplified training and minimizes barren plateaus as well as model complexity [1]. In this work, we aimed to compare the predictive performance of quantum CNNs (qCNN) and state-of-the-art classic CNNs in small medical imaging data. ***Materials and Methods:*** This study relied on 53 [68Ga]Ga-PSMA-11 (PSMA) PET/CT and 30 PSMA PET/MRI prostate cases to form a mixed training set (n=83) from one imaging site. For independent testing 84 PSMA PET/MRI prostate cases collected from an external imaging site were used. The PET/CT cases underwent image-guided biopsy, while all PET/MRI cases had whole-mount histopathology evaluations at both sites. Each case was classified as ISUP ≤ 2 vs. ISUP ≥ 3 to result in a binary label for prediction. Prostate detection with pre-trained deep learning (DL) models in CT and MRI scans was performed. Each PSMA PET was resampled to 2mm isotropic voxel resolution, followed by masking out a 32x32x32 cuboid VOI area around the prostate as defined by the DL detection models. The PSMA cuboid VOI voxels of each case were encoded to log2(32x32x32) = 15 qubits. A qCNN model having 2 convolutional and 5 fully connected layers utilizing the training set was built in the Pennylane quantum simulator. For comparison, a 3D CNN was built as well. Performance evaluation of the qCNN and the CNN models was done on the independent test set with confusion matrix analytics. ***Results:*** The test balanced accuracy was 84% for qCNN, and 41% for the classic CNN. The number of parameters to train was 435 in qCNN and ~11million in the classic CNN. ***Conclusion:*** We demonstrated quantum advantage in qCNNs while relying on a dual-center imaging dataset. Quantum CNNs have the potential to democratize NNs on small data due to their simple model and training schemes while relying on the advantage of classic-quantum encoding. ***References:*** [1] Caro, et al. (2022). DOI: 10.1038/s41467-022-32550-3.

[1]Medical University of Vienna, Vienna, AUSTRIA, [2]Georgia Institute of Technology, Atlanta, GA, UNITED STATES OF AMERICA, [3]LaTIM, INSERM, UMR 1101, Univ Brest, Brest, FRANCE, [4]University of Pécs, Pécs, HUNGARY.

Aim/Introduction: The recently proposed distance-encoding biomorphic-informational neural network (DEBI-NN) has demonstrated to significantly reduce the number of trainable parameters, while preserving predictive performance, compared to traditional neural networks (NN) [1] in various clinical datasets. However, due to the novelty of DEBI-NNs, the optimal choice of hyperparameters and their generalization abilities are unknown. This study aimed to evaluate DEBI-NNs in two small multi-centric medical datasets in an independent train-test setting, over which training highly generalizable deep NNs would not be feasible. ***Materials and Methods:*** The train and independent test sets were taken from the diffuse large b-cell lymphoma (DLBCL) [2] and the HECKTOR [3] ^{18}F-FDG PET/CT datasets to predict 2-year survival and HPV status, respectively. DLBCL had 40-44, while HECKTOR had 340-223 train-test cases. Both datasets contained IBSI-compliant radiomic and clinical-demographics features per patient. Five different network architecture configurations and 20 different hyperparameter configurations were used, resulting in 100 different DEBI-NN configurations overall. The train-test cases were evaluated 10-times in a test-retest scenario (1000 runs overall per cohort) to investigate the effect of any random selection events during training. Test predictive performance was estimated with averaging balanced accuracy (BACC) and 95% confidence interval (CI) values over the test-retest evaluations per configuration. ***Results:*** In DLBCL, networks with 1-2 hidden layers were sufficient to model the data (highest BACC: 79%). In HECKTOR, 3 hidden layers resulted in better overall performance (highest BACC: 72%). The highest-performing DEBI-NN models in both cohorts were with shift-scale optimization and without group norm, weight standardization and spatial dropout. These models yielded 68-73% BACC, 4.17-6.45 CI (DLBCL) and 67-69% BACC, 3.41-7.75 CI (HECKTOR). In contrast, poorly-performing models had 49-66% BACC, 3.75-7.81 CI (DLBCL) and 62-66% BACC, 4.03-7.04 CI (HECKTOR). ***Conclusion:*** DEBI-NNs with minimal to no regularization techniques can result in highly generalizable NN configurations even if the training set is disproportionally small compared to what is generally required for training conventional NNs. This has been hypothesized in [1], but this work provides a rigorous analysis and supporting evidence. This novel network architecture can pave the way to successfully model small, albeit representative nuclear medicine imaging datasets with deep NNs while maintaining minimal training complexity. ***References:*** [1] Papp, L., et al. Generative artificial intelligence improves performance of medical classifiers in low data regimes

D. Haberl[1,2], *K. Kluge[1,2], J. Ning[1,2], K. Kumpf[3], Y. Lutz[4], A. Monaci[5], M. Starace[5], L. Camoni[6], F. Bertagna[6], D. Albano[6], R. Sciagra[5], R. Calabretta[1], C. Nitsche[7], M. Hacker[1], C. P. Spielvogel[1];*
[1]Division of Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA, [2]Christian Doppler Laboratory for Applied Metabolomics, Medical University of Vienna, Vienna, AUSTRIA, [3]IT4Science, Medical University of Vienna, Vienna, AUSTRIA, [4]Division of Nuclear Medicine, Vienna General Hospital, Vienna, AUSTRIA, [5]Department of Experimental and Clinical Biomedical Sciences, Nuclear Medicine Unit, University of Florence, Florence, ITALY, [6]ASST Spedali Civili of Brescia, Università degli Studi di Brescia, Brescia, ITALY, [7]Department of Internal Medicine II, Division of Cardiology, Medical University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: A paradigm shift in medical imaging research has been introduced by the rise of machine learning. Deep neural networks have shown promising results in the detection of diseases and for prediction of patient outcome. This advancement, however, is limited by the availability of large datasets, as substantial volumes of data are required to train effectively. We hypothesize that recent advances in Generative AI can help to alleviate this need by enlarging small medical datasets with

synthetic examples enabling medical image research at a larger scale. ***Materials and Methods:*** A generative adversarial network was trained on bone scintigraphy scans from the Vienna General Hospital to generate synthetic images of patients representing two clinical conditions: (1) cardiac uptake indicative of cardiac amyloidosis and (2) tracer uptake indicative of bone metastases. Two scenarios were created to evaluate the clinical value of the generated synthetic cases. First, we benchmarked the synthetic dataset against real patient data. Second, we investigated the added value of complementing small single-center datasets by adding synthetic data to the training in a downstream classification task. ***Results:*** Overall, 11.997 patients with 12.761 scans from three medical centers were included. A convolutional neural network trained on real patient data revealed an average AUC=1.000 (95% CI=0.999-1.000) across external validation for the detection of cardiac uptake indicative of cardiac amyloidosis. The same model, trained with purely synthetic cases only, performed on par with an average AUC=0.998 (0.996-1.000). For the detection of tracer uptake indicative of bone metastases, an AUC=0.920 (0.906-0.933) and 0.891 (0.875-0.906) was achieved for real and synthetic data models, respectively. Enlarging small single-center datasets with synthetic examples (real/synthetic-data-ratio 1:50) improved the model performance by +10% and +9% AUC in the prediction of the two respective clinical endpoints. ***Conclusion:*** Generative AI enables synthetic image generation representative of realistic clinical characteristics such as prespecified disease entities. These images can be used to create medical classifiers with the same degree of accuracy as real patient data. Complementing small medical datasets by adding synthetic cases to the training, improved model performance significantly. Our findings point to the potential of synthetic data to overcome challenges in data sharing and might be beneficial in addressing fairness in medical classifiers through the adjustment of underrepresented subgroups in the training dataset. The detection of rare diseases by imaging is particularly challenging, and augmenting the training set with synthetic examples may increase detection rates and improve clinical care.

Towards increased prognostic value of FDG PET/CT in non-malignant diseases via healthy digital twins

C. Hinge[1], *K. Jørgensen[1], F. E. Høi-Hansen[1], V. Shah[2], A. B. Rodell[2], B. Spottiswoode[2], S. Zuehlsdorff[2], R. J. F. Loos[3], B. M. Fischer[1], C. N. Ladefoged[1], F. L. Andersen[1];*
[1]Rigshospitalet, Copenhagen University Hospital, Copenhagen, DENMARK, [2]Siemens Healthineers, Knoxville, TN, UNITED STATES OF AMERICA, [3]Novo Nordisk Foundation Center for Basic Metabolic Research, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, DENMARK.

Aim/Introduction: The distribution of fluorodeoxyglucose (FDG) uptake in certain tissues/organs and organs holds promise as a prognostic marker for non-malignant diseases such as diabetes. One challenge is that the prognostic information is often concealed by physiological patient-specific factors such as patient age, weight, and sex, which can greatly influence FDG uptake patterns. While these factors may average out in population-based comparisons, they must be accounted for when prognosing individual patients. Addressing this, we propose a Synthetic Baseline PET (sbPET) model aimed at decoupling physiological from non-physiological FDG uptake. The sbPET image represents a healthy FDG distribution tailored to the patient's characteristics. Abnormal uptake patterns can thus be revealed by comparing the sbPET and the true PET images. We demonstrate the efficacy of the sbPET model in explaining the uptake variance observed in brown adipose tissue (BAT). ***Materials and Methods:*** 3190 Long Axis Field of View (LAFOV) FDG PET/CT studies acquired during clinical routine at Rigshospitalet were used to train a 3D generative AI-model to synthesize a personalized sbPET images conditioned on the accompanying CTs as well as the patient age, sex, weight, FDG dose, and uptake time. Using BAT masks obtained from a separate segmentation model (nnUnet, trained on 150 manually CT-delineated subjects), the average BAT SUV was calculated for 98 independent test patients, yielding a vector of average PET uptakes, yPET. Likewise, ysbPET, was calculated by averaging the BAT SUV in the generated sbPET images. As a baseline, we employed a 3rd order polynomial regression model to predict the BAT SUV based on the aforementioned patient-specific features excluding the CT. The performance of both models was quantified by the explained BAT variance (1- Var[yPET -ysbPET]/ Var[yPET]). ***Results:*** The sbPET and regression models achieved explained variances of 48% and 20%, respectively, indicating that nearly half of the variance in BAT uptake, can be explained by simple patient specific features and anatomical information using a AI-based synthetic baseline PET. ***Conclusion:*** The gap in baseline and sbPET performance emphasizes the value of the CT providing anatomical information and alludes to a complex nonlinear relationship between patient features and FDG uptake. By removing the healthy physiological component in the BAT, one could imagine that uptake patterns of certain diseases would become more distinguishable. Future work could focus on subject with disease labels that could be acquired form electronic patient records or even genetic profiling.

Synthetic Data to Simplify Development of Machine Learning Models in Medical Imaging

L. P. Schilder[1,2], *B. N. Vendel[1], P. H. Hiemstra[2], J. A. Van Dalen[1], G. A. Hakvoort[2], J. D. Van Dijk[1];*
[1]Isala hospital, Zwolle, NETHERLANDS, [2]Windesheim University of Applied Sciences, Zwolle, NETHERLANDS.

Aim/Introduction: Artificial Intelligence (AI) offers promising opportunities for innovating the field of medical imaging, yet its practical implementation remains limited. Two important reasons for this are strict legislation and the unavailability of data, partly due to patient privacy. Synthetic data (SD) could offer a solution to the latter. Synthetic data is a machine-learning (ML) technique that learns the distributions and correlations of a real dataset and generates a synthetic dataset with the same characteristics, without containing real data. Synthetic data could facilitate multi-centre collaborations enabling the training of ML-models with data that are now limited. Our aim was to investigate the effects of replacing real data with synthetic data on ML-model performance using SD-generators for the prediction of metastases on 18F-PSMA-1007 PET/CT using a tabular dataset. ***Materials and Methods:*** We included a cohort of 131 consecutive patients who underwent 18F-PSMA-1007 PET/CT that yielded 289 bone hotspots and 272 lymph node hotspots in whom follow-up from multidisciplinary meetings were available. Several ML-model classifiers were trained to classify hotspots as metastases or aspecific. The ML-models were trained either on real data or synthetic data from three SD-generators (CTGAN, CopulaGAN, TVAE). Four algorithms were used for the classifiers (Random Forest, K-Nearest Neighbor, XGBoost and Logistic Regression). ML-model performance was assessed using five metrics (F1-score, Accuracy, ROC-AUC, Sensitivity and Specificity). The metrics were

determined by comparing the classifiers prediction of a hotspot to the real outcome. ***Results:*** The ML-models trained on synthetic data showed an average F1-score of 0.87 for all generator-model combinations compared to 0.90 for ML-models trained on real data. TVAE showed the highest average score, then CTGAN, followed by CopulaGAN. The generator-model combination with the highest F1-score was TVAE/Random Forest with 0.93. The lowest was 0.75 for CTGAN/XGBoost. For the real data, this range was 0.83 for K-Nearest Neighbor to 0.94 for Random Forest. Although synthetic data performed comparable to real data for most metrics, the specificity showed a large variation ranging from 0.48 to 0.98. ***Conclusion:*** Overall, ML-models trained on synthetic data showed a marginal decrease in performance of predicting metastases on 18F-PSMA-1007 PET/CT, as compared to real data. Although specificity of ML-models trained on synthetic data showed large variation, the performance for the other metrics was comparable to that of real data. Hence, synthetic data could be a viable option for simplifying development of ML-models in medical imaging.

Enhancing Medical Imaging Reporting: a Multimodal Language Model for Automated Bone Scintigraphy Report Generation

H. Lu, *M. Tsai;*
National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Tainan city, TAIWAN.

Aim/Introduction: The rise of large language models enabled computers to hold informative and integrated conversations, presenting far-reaching implications across various domains, including medicine. More recently, language models have progressed to encompass image processing alongside text, known as multimodal language models. We aim to fine-tune and assess a multimodal language model's capability to generate semantic textual reports, focusing specifically on bone scintigraphy within the nuclear medicine domain. ***Materials and Methods:*** We curated a dataset from our own institution consisting of 28571 distinct bone scintigraphy from 9092 patients, with each study containing anterior/posterior planar views and a text report. Our workflow had two stages: A preliminary lesion localizer using the vision transformer (ViT) architecture, and a report generation backbone using Large Language and Vision Assistant (LLaVA). For the purposes of fine-tuning, pseudo-labels were generated from text reports through a large language model. This pseudo-label was used to fine-tune both the first-stage lesion localizer and the second-stage report generation. We evaluated the quality of generated report on image findings using Bilingual Evaluation Understudy (BLEU), Recall-Oriented Understudy for Gisting Evaluation (ROUGE), and Metric for Evaluation of Translation with Explicit Ordering (METEOR) metrics. The generated impression and ground truth impression are both scored by an independent LLM (Google Gemini) to determine the presence of metastasis based on the text; the performance of the system is then evaluated against the score generated from ground truth. ***Results:*** The dataset was split by patient with 80% to training and evaluated on the remaining 20%. Fine-tuning of LLaVA was performed on an A100 with 80G of VRAM for 2 epochs. Our fine-tuned model was able to automatically generate the finding and impression sections of a bone scintigraphy study based on only images. The 1-gram BLEU score, 2-gram BLEU score, ROUGE, and METEOR score of generated image findings were 0.46, 0.33, 0.55, and 0.53, respectively. On the task of determining whether a metastasis is present, we report a F1 score of 0.64, sensitivity of 0.67, and specificity of 0.57. ***Conclusion:*** We demonstrate the feasibility of a two-stage workflow incorporating a multi-modal fine-tuned large language model to generate textual reports for bone scintigraphy. This is an essential first step towards incorporating textual clinical information in addition to images. Our work demonstrates the potential of multi-modal language models in assisting nuclear medicine workflows; however, further research to improve performance and vigilant validation are prudent before its adoption in the clinic.

OP-420

Label extraction from PET/CT reports using Large Language Models

J. Bracci[1,2], *N. Capobianco[1], V. Shah[3], B. Spottiswoode[3], F. Giobergia[2];*
[1]Siemens Healthcare GmbH, Erlangen, GERMANY, [2]Politecnico di Torino, Torino, ITALY, [3]Siemens Medical Solutions USA Inc., Knoxville, TN, UNITED STATES OF AMERICA.

Aim/Introduction: PET/CT clinical reports are typically written in free-text format. Consequently, while they contain a wealth of valuable and reliable information, it is challenging to store and structure this information in a way that it can be searched, modeled and analyzed in a consistent and efficient manner. This study aims to assess the feasibility of extracting structured data from textual reports by employing the latest Large Language Models (LLMs). ***Materials and Methods:*** We reviewed PET/CT reports from 31 patients with confirmed lung cancer. A human reader synthesized these reports into a structured format, categorizing each anatomical location (AL) as either "Presence" or "Absence" of a lesion. We then prompted publicly available LLMs to structure given reports, using Few-Shot (FS) learning [1] with up to 4 shots (reports and expected output fed to the model as examples), to assess the impact on performance. The evaluation was conducted on 27 held-out reports, using the F1-score metric. The dataset's AL distribution included an average of 23.4 ALs for "Absence" (80 unique ALs) with the 5 most frequent being: [bladder: 31, spleen: 31, liver: 29, kidneys: 24, aorta: 22] and 6.9 ALs for "Presence" (143 unique ALs) with the 5 most frequent being: [right-upper-lobe: 4, right-lung-parenchyma: 4, right-lower-lobe: 3, right-middle-lobe: 3, left-upper-lobe: 3]. We evaluated six LLMs: GPT-4-Turbo, Llama3-70B, Llama3-8B, Mistral-7B, Mixtral-8x22B, Mixtral-8x7B. ***Results:*** The results for the "Absence" class showed that Llama3-70B performed best, with an average F1-score of 93.02% when prompted with 4-shots. All models demonstrated a significant increase in performance from 0-shots (i.e., no examples provided) to 1-shot, with an average F1-score increase of 30.12% (from 35.20% to 65.32%). The performance plateaued with 2 or more shots, averaging 80.24% across all models. For the "Presence" class, Mistral-7B had the highest average F1-score of 69.00% with 3 shots. A similar trend was observed with an increase from 0 to 1-shot, with the average F1-score increase of 20.53% (from 35.77% to 56.30%). The performance was also stable with 2 or more shots, with an average F1-score of 57.25% across all models. ***Conclusion:*** The study indicates that LLMs are capable of structuring PET/CT clinical report data effectively, with few-shot learning being a critical factor for achieving high accuracy. Future research should explore additional LLMs for optimal performance and the refinement of the shots used to enhance model performance. ***References:*** [1] Brown T B et al 2020 Language models are few-shot learners (arXiv:2005.14165).

OP-421

Semantic Neuro-Symbolic AI: Pairing Large Language Models with Expert System Oversight for accountable and compliant automated Clinical Studies

***G. Prenosil*[1],** *T. K. Weitzel*[2], *S. C. Bello*[3], *C. Mingels*[1], *K. Shi*[1], *A. Rominger*[1], *A. Afshar-Oromieh*[1];
[1]*Department of Nuclear Medicine, Inselspital, Bern University Hospital and University of Bern, Bern, SWITZERLAND,* [2]*Scientific Consulting, Computing and Engineering GmbH, Herrenschwanden BE, SWITZERLAND,* [3]*Zentit GmbH, Muri bei Bern, SWITZERLAND.*

Aim/Introduction: Use of publicly available large language models (LLMs) in healthcare is hindered by compliance, regulatory, and data privacy concerns. Furthermore, low-factuality outputs from these statistical AIs can have adverse clinical implications. Conversely, symbolic AIs, such as expert systems (ESs), adhere strictly to predefined ontologies, but struggle with uncertainties and unstructured data. Our novel approach therefore employs an LLM for solving complex problems and a rule-based ES for managing inputs and validating outputs. We validated this concept, by creating an AI system capable of autonomously compiling unstructured clinical trial data within the boundaries of a human-designed ontology. ***Materials and Methods:*** We integrated GPT-4, our natural language ES, and various application modules into one system. Semantic interoperability between its elements was enabled by our proprietary multi-paradigm software platform. The thereof resulting neuro-symbolic AI combines scalability of neural networks with traceable logic of symbolic systems and real-world data access. We tasked the LLM to structure clinical data from 206 anonymized 68Ga-PSMA PET/CT diagnostic reports, extracting 25 study relevant variables. The ES verified study compliance before passing data to the LLM and checked returning answers for plausibility, reprompting the LLM if needed. We tested the combined system's ability to extract meta-information through three main tasks: Identifying pathological reports, extracting the nearest PSA-value to the PET exam, and recognizing reports from primary tumor staging (PTS) exams to include only follow-up exams in the study. We compared the outputs of LLM-only and LLM-ES collaborative trials against a physician-generated gold standard. ***Results:*** The LLM demonstrated high sensitivity (0.99) but low specificity (0.41) in identifying pathological reports without ES support, with precision at 0.91. When identifying PTS reports, the LLM alone achieved a sensitivity of 0.5, specificity of 0.99, and precision of 0.83. The LLM identified five physician errors in PSA values but committed three errors itself. Although the ontology was incomplete at submission, preliminary results indicate that ES support could eliminate PTS classification errors and significantly enhance the accuracy of pathological report identification. The ES successfully intercepted two datasets that were not properly anonymized. ***Conclusion:*** Our results demonstrate that LLMs, when paired with ES oversight, can effectively undertake tasks typically performed by clinical study personnel, potentially transforming the management of large clinical trials. Given its ability to impart semantic interoperability and handle heterogeneous data types, our system is well-equipped to digitalize a broad range of clinical workflows, while safeguarding data flow and medical confidentiality.

OP-422

Optimizing Contextual Augmentation for Generative AI Performance in Medical Chatbot Responses

***P. Koller*[1,2],** *C. Clement*[3], *A. van Eijk*[2], *K. Shi*[4,3];
[1]*Ludwig-Maximilians-University, Munich, GERMANY,* [2]*ITM Radiopharma, Garching, GERMANY,* [3]*Inselspital, Universitätsspital Bern, Bern, SWITZERLAND,* [4]*Technical University Munich, Munich, GERMANY.*

Aim/Introduction: Chatbots, such as ChatGPT, are currently gaining interest in many fields, including healthcare. Integrating them into medical practice can lead to improved patient engagement, better patient-physician communication, and more efficient dissemination of healthcare information. However, Large Language Models (LLMs), the AI models that power chatbots, often face challenges in specialized domains such as nuclear medicine. This study examines how augmentation techniques like Retrieval Augmented Generation (RAG) can improve the performance of medical chatbots specialized in theranostics and nuclear medicine topics. ***Materials and Methods:*** In our study, we evaluate four LLMs (OpenAI's GPT-4, Cohere's Command R+, Google's Gemini 1.0, and Antrophic's Claude 3 Opus) on 35 clinician-oriented questions translated into English and German. To assess the impact of contextual augmentation, we generate different answer types: 1) no context, where the LLM relies solely on its pre-trained knowledge, and 2) with context, where the LLM can access 198 pre-selected research papers on theranostics and nuclear medicine through RAG techniques. We conduct a user study to evaluate the appropriateness of the answers, complemented by an LLM evaluator, which uses metrics such as clarity, completeness, conciseness, average sentence length, language robustness, and word count to calculate an overall evaluation score. ***Results:*** Initial evaluations of the LLM evaluator indicate that utilizing RAG techniques enhances the efficiency of LLMs when compared to relying solely on pre-trained knowledge (see Table 1). Gemini 1.0 demonstrated the most substantial improvement, followed by Claude 3 Opus and GPT-4. It is worth noting that the performance of Command R+, a model optimized for RAG pipelines, experienced a slight dip when providing context information. ***Conclusion:*** These preliminary results highlight the potential of RAG techniques in enhancing medical chatbot performance. The study reveals differences in performance based on the different LLMs and augmentation methods used. These findings can guide the development of more effective chatbots tailored to the specific needs of theranostics and nuclear medicine, ultimately improving healthcare delivery and patient outcomes. Ongoing work focuses on implementing advanced RAG techniques with additional pre- and postprocessing steps specific to each LLM and evaluating the user study as an additional assessment method.

PSMA-PET and PROMISE re-define stage and risk in prostate cancer patients

***M. Karpinski*[1,2],** *J. Hüsing*[2], *K. Claassen*[2,3], *L. Möller*[2], *H. Kajüter*[2], *F. Oesterling*[2], *V. Grünwald*[4,5], *L. Umutlu*[6], *H. Lanzafame*[1], *T. Telli*[1], *A. Merkel-Jens*[7], *A. Hüsing*[7], *C. Kesch*[8], *K. Herrmann*[1], *A. Stang*[2,7], *B.*

Hadaschik[8], W. P. Fendler[1];
[1]Department of Nuclear Medicine, DKTK and NCT University Hospital Essen, Essen, GERMANY, [2]Cancer Registry NRW, Bochum, GERMANY, [3]Department of Medical Statistics and Epidemiology, Medical School Hamburg, Hamburg, GERMANY, [4]Department of Urology, Pediatric Urology and Urooncology University Hospital Essen, Essen, GERMANY, [5]Department for Medical Oncology, University Hospital Essen, Essen, GERMANY, [6]Department of Radiology University Hospital Essen, Essen, GERMANY, [7]Institute of Medical Informatics, Biometry and Epidemiology, University Hospital Essen, Essen, GERMANY, [8]Department of Urology, Pediatric Urology and Urooncology University Hospital Essen, Essen, Germany, Essen, GERMANY.

Aim/Introduction: Introduction of Prostate Specific Membrane Antigen Positron-Emission-Tomography (PSMA-PET) for prostate cancer staging in 2012 led to stage-shift in nearly all disease stages. However, the prognostic value of PSMA-PET findings remains less clear. Thus, we compare the prognostic value of PSMA-PET assessed in accordance with PROMISE criteria including tumor volume head-to-head to clinical risk scores in a large prostate cancer dataset with overall survival follow-up. ***Materials and Methods:*** Our retrospective analysis includes all prostate cancer patients, who underwent PSMA-PET between October 2014 and December 2021 at the Essen University Hospital. PSMA-PET stage including the molecular imaging TNM system (miTNM), tumor volume, mean standardized uptake value (SUVmean) and overall survival follow-up were collected. We split the dataset into development and validation cohorts (2:1) and created two nomograms based on Cox regression models with LASSO penalty using the development cohort. Performance of the visual and the quantitative nomograms in the validation cohort were measured using C-indices. ROC-curves and C-indices were examined for head-to-head comparison to clinical risk scores separately for each staging group. ***Results:*** Our cohort includes 1,612 prostate cancer patients across all disease stages with 544 (33.7%) recorded deaths. Predictors based on PROMISE criteria included into the quantitative PSMA-PET nomogram were lymph nodes (miN2, Hazard Ratio [HR]=2.71;95%CI 2.18-3.37), distant metastases (miM1a, HR=3.85;3.15-4.72; miM1b pattern, HRuni=2.13;1.47-3.09 or HRoligo=2.89;1.86-4.49 or HRdiss or dmi=11.73;9.31-14.78; miM1c, HR=5.36;4.06-7.08), tumor volume (per liter, HR=3.64;3.25-4.07) and tumor SUVmean (per unit, HR=1.04;1.03-1.05). The visual nomogram includes distant metastases and total tumor lesion count (Reference: 0-5 lesions, HR6-20=5.00;3.80-6.59 or HR>20=15.80;12.41-20.12). Overall C-indices were 0.80 and 0.78 for the quantitative and visual nomogram, respectively. The quantitative PSMA-PET nomogram was superior to STARCAP at initial staging (n=139; AUC: 0.73 vs. 0.54; p=0.02), to EAU risk score at biochemical recurrence (n=412; AUC: 0.69 vs. 0.52; p<0.001), and to NCCN subgroups at any disease stage (n=1534; AUC: 0.81 vs. 0.74; p<0.001). The visual PSMA-PET nomogram was superior to EAU risk score (n=414; AUC: 0.64 vs. 0.52; p<0.001) and NCCN subgroups (n=1544; AUC: 0.79 vs. 0.73 p<0.001). ***Conclusion:*** Both PSMA-PET nomograms based on standardized PROMISE criteria were prognostic and accurate in early and late stages of prostate cancer with higher predictability compared to clinical risk tools. Multi-center validation with long-term follow-up in the PROMISE registry is ongoing.

OP-424

CD13 as a Potential Membrane Marker in PSMA-Negative Prostate Cancer: A Complementary or Superior Alternative to PSMA

Y. Tang[1,2], *L. Xiao[1], J. Yang[1], J. Hou[1], J. Hong[2], A. Rominger[2], K. Shi[2], S. Hu[1];*
[1]Xiangya Hospital Central South University, Changsha, CHINA, [2]Department of Nuclear Medicine, Inselspital, Bern University Hospital, Bern, SWITZERLAND.

Aim/Introduction: Our aimed to discover new marker by analysing the proteomics of PSMA-negative PCa tissue and develope targeted radiolabeled probe to assess its potential for PCa theranostics. ***Materials and Methods:*** In order to identify new membrane protein targets, we analyzed foci and adjacent tissues from 8 PSMA-negative PCa patients and 11 benign prostatic hyperplasia (BPH) tissues using proteomics. Subsequently, a large-scale immunohistochemistry study was conducted on 141 PCa and 100 BPH tissues to validate the differential expression of the novel target. An 18F-labeled peptide PET probe targeting the marker was developed, with its characteristics and uptake in RWPE-1 and PC-3 (PSMA-negative) cells assessed. Biodistribution and micro-PET imaging were conducted in PC-3 xenograft nude mice. Whole-body PET/CT scans were performed on PCa patients to evaluate diagnostic efficacy. Additionally, the toxicity and therapeutic effects of the targeted radionuclide in PC-3 xenograft models were investigated in Vivo. ***Results:*** In PSMA-negative PCa tissues, proteomic quantification analysis revealed 35 significantly elevated proteins, with CD13 emerging as the most promising among them. Immunohistochemistry results demonstrated CD13 positivity rate of 92.9% in PSMA-negative PCa tissues (13/14), 82.7% in PSMA-positive PCa tissues (105/127), 91.7% in ductal adenocarcinoma (11/12), 70% in intraductal carcinoma of the prostate (14/20), and 20% in post-endocrine therapy PCa (8/40). Subsequently, in vitro studies confirmed the affinity and specificity of $^{[18F]}$F-CD13-L, as demonstrated by cellular uptake tests showing binding to PC-3 but not RWPE-1 cells. Micro-PET studies showed exhibited localized uptake of $^{[18F]}$F-CD13-L in PC-3 tumor xenografts, with a tumor-to-background ratio of 8.30±0.28. Biodistribution analysis revealed rapid circulation clearance, with a half-life of 11.1 minutes, and significant renal excretion. The first human trial of this imaging probe demonstrated results consistent with preclinical studies. In PSMA PET negative PCa lesions, the SUVmax of $^{[18F]}$AlF-CD13-L1 PET was found to be 4.3 (1.5-5.8), with a median tumor-to-muscle ratio of 4.6 (1.4-6.1). Survival curve analysis illustrated that treatment with 7.4 MBq of [177Lu] Lu-CD13-L1 substantially extended the survival of tumor-bearing mice compared to the controls (p=0.0027), with median survival periods of 69 days and 33 days, respectively. ***Conclusion:*** CD13 may serve as a potentially valuable marker, even in PSMA-negative PCa. Our CD13-targeting probe has undergone initial validation for detecting PCa in cell, animal, and first-in-human PET/CT imaging trials. Moreover, CD13-targeted radionuclide therapy has demonstrated safety and efficacy against PC-3 xenografts. Further research is necessary to verify the theranostic potential of the CD13 target and its probe in PCa.

OP-425

Feasibility and Diagnostic Performance of PSMA-PET-Guided Prostate Biopsy in PI-RADS Scores 2-3: Preliminary Results from a Prospective Single-Center Study

C. Sgro[1], *L. Bianchi[2], P. Castellucci[3], R. Mei[3], D. Cangemi[2], M. Presutti[2], A. Di Giorgio[1], C. Gaudiano[4], B. Corcioni[4], R. Schiavina[2], E.*

Brunocilla[2], S. Fanti[3,1], A. Farolfi[3];
[1]Nuclear medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY, [2]Division of Urology, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY, [3]Nuclear Medicine, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY, [4]Department of Radiology, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.

Aim/Introduction: Prostate biopsy utilizes multiparametric MRI (mpMRI) guidance. However, MRI may fail to identify clinically significant prostate cancer(csPCa) in a substantial number of cases. This study aimed to determine the feasibility and the diagnostic performance of trans-perineal prostate biopsy guided by PSMA-PET/CT-US fusion in patients with PI-RADS score 2-3 on mpMRI. ***Materials and Methods:*** Prospective single-center study enrolling patients with serum PSA≥4ng/ml, PSA density (dPSA)≥0,1 and mpMRI PI-RADS 2-3.68Ga-PSMA-11 PET-CT images were acquired both 60-and-90-minutes post-injection. Prostate contours on CT and PSMA-positive lesions(ROIs) were manually delineated. Trans-perineal prostate biopsy was performed via real-time PET/CT-US fusion(Esaote-Urofusion). Biopsy cores were obtained from PSMA-positive regions of interest(at least 3 cores) and systematically. Intra-prostatic PSMA activity was assessed using the PRIMARY score. A PRIMARY score≥3 was considered PSMA-positive and contoured. ***Results:*** 22 patients have been included (mean age 65years). At the time of PSMA-PET-CT the median PSA was 14ng/mL and median dPSA was 0,24. On mpMRI, 19/22(86%) patients had PI-RADS 2 lesions while 3/22(14%) had PI-RADS 3. The median time between the PSMA-PET-CT scan and the biopsy was 27 days (IQR 1-70). 12/22 (55%) patients had a PRIMARYscore≥ 3 and underwent trans-perineal PET-fusion biopsies plus systematic biopsies, while 10/22 (45%) were PRIMARY 1-2 and underwent only systematic biopsies. PRIMARYscores were: score 1-2 in 10/22 patients (none positive for csPCa); score 3 in 5/22 (40% csPCa), score 4 in 4/22 (75% csPCa) and score 5 in 3/22 (100% csPCa). 8/22 (36%) patients had csPCa at PET-fusion biopsies. Median SUVmax of the lesions (PRIMARY score ≥ 3) was 7,9(IQR 3 - 42,5) 60' post-injection and 8,2(IQR 4-45,9) 90' post-injection. Overall, combining PET-guided and systematic biopsies we had 12/22 PCa detected by biospy: 8/22 (36%) patients had a csPCa (3 ISUP 2, 3 ISUP 3, 1 ISUP 4, 1 ISUP 5), while 4 /22 was ISUP 1 (18%). PET-fusion only biopsy sensitivity, PPV and accuracy for csPCa were 85%(95%CI 65-96%), 37%(95%CI 33-41%) and 34%(95%CI 23-47%), respectively. Combining systematic with PET-fusion biopsy, sensitivity, specificity, NPV, PPV and accuracy for csPCa were 85%(95%CI 65-96%), 86%(95%CI 81-90%), 98%(95%CI 96-100%), 37%(95%CI 29-45%) and 86%(95%CI 81-89%), respectively. ***Conclusion:*** Transperineal PSMA-PET-guided biopsy is feasible. Our preliminary results suggest that adding PSMA-PET-guidance to systematic biopsies in patients with suspicious of PCa and PI-RADS 2-3 on mpMRI increased csPCa detection. The PRIMARY score correlates with csPCa. Further studies are warranted to elucidate the role of PET-guided biopsies in patients with PI-RADS 2-3 lesions.

OP-426

Clinical impact of changes in tumor uptake on PSMA-PET/CT during 177Lu-PSMA radioligand therapy in metastatic castration-resistant prostate cancer

L. Djaileb[1,2], *A. Farolfi[3], I. Rauscher[4], W. Fendler[5], B. Hadaschik[5], S. Rowe[6], K. Herrmann[5], L. Solnes[6], M. Rettig[7], M. Weber[5], J. Czernin[2], J. Calais[2], M. Benz[2], M. Eiber[4];*

Morgan Department of Radiology and Radiological Science, Johns Hopkins University School of Medicine, Baltimore, MD, UNITED STATES OF AMERICA, [7]Department of Medicine and Urology, David Geffen School of Medicine, Los Angeles, CA, UNITED STATES OF AMERICA.

Aim/Introduction: To investigate the prognostic value of changes in tumor uptake on PSMA-PET/CT during 177Lu-PSMA radioligand therapy in metastatic castration-resistant prostate cancer ***Materials and Methods:*** This multicenter retrospective study at three academic centers included adults who received 177Lu-PSMA-617 or 177Lu-PSMA-I&T between December 2014 and July 2019. PSMA PET/CT images performed at baseline and after 2 cycles (12 weeks) were evaluated by two nuclear medicine specialists for changes in tumor SUVmax at a region-based level. Whole-body tumor SUVmax, SUVmean, and total tumor volume were calculated using qPSMA software. Changes in tumor SUVmax (whole-body and region-based; ΔSUVmax), whole-body SUVmean (ΔSUVmean), total tumor volume (ΔTTV) and occurrence of new lesions were determined. Region-based analysis was stratified as bone, lymph node and visceral disease. Primary outcomes were the associations of ΔSUVmax, ΔSUVmean, ΔTTV, and occurrence of new lesions with PSA progression-free survival (PSA-PFS) and overall survival (OS) by Cox regression analyses. ***Results:*** A total of 124 adults (median age, 73 years [IQR, 67-76 years]) were included. 114/124 (92%), 101/124 (81%), 32/124 (26%) patients had bone, lymph node, and visceral disease at baseline. In patient-based analysis, median (IQR) ΔSUVmax, ΔSUVmean were -33.5% (-13.3 to -52.0%) and -24.3% (-8.6 to -35.2%), respectively. In region-based analysis, median ΔSUVmax for bone, lymph node and visceral disease were -24% (-7% to -51%), -35% (-17 to -63%), -24% (-6% to -55%). ΔTTV and occurrence of new lesions were significantly associated with PSA-PFS (P<0.001) and OS (P<0.001). In patient-based analysis, ΔSUVmax and ΔSUVmean ,were not associated with outcome. In region-based analysis, only ΔSUVmax in visceral lesion was significantly associated with PSA-PFS (p = 0.007) but not with OS. ***Conclusion:*** Changes in tumor uptake on interim PSMA-PET imaging during 177Lu-PSMA radioligand therapy were not associated with survival outcome. In contrast, change in total tumor volume and occurrence of new lesions provide significant prognostic value and should be considered when evaluating treatment response.

OP-427

Non-invasive stratification of men with clinically suspected prostate cancer but negative-/equivocal-magnetic resonance imaging: a biparametric PSMA PET/CT-based model

Y. Li, *Y. Tang, S. Hu;*
Xiangya Hospital, Central South University, Changsha, CHINA.

Aim/Introduction: Multiparametric magnetic resonance imaging (mpMRI) combined with prostate-specific membrane antigen positron emission tomography (PSMA-PET) has been demonstrated as a highly sensitive diagnostic approach to detect clinically significant prostate cancer (csPCa). Therefore, additional

PSMA-PET scan will enable some MRI-negative/-equivocal men to safely avoid prostate biopsy while ensuring csPCa detection. We aimed to develop a diagnostic model to further improve the diagnostic accuracy of csPCa in such cases. ***Materials and Methods:*** The study included 151 clinically suspected and MRI-negative/-equivocal men (112 from a prospective database, ClinicalTrials.gov identifier NCT05073653), who underwent ultrasound/mpMRI/PET fusion-guided biopsies, into retrospective analysis. PRIMARY-scores on 68Ga-PSMA-617 PET/CT scans were prospectively evaluated and visual assessments based on imaging reports were retrospectively recorded. A diagnostic model was developed using PRIMARY-score, SUVmax and serum free prostate-specific antigen (PSA)/PSA (fPSA/tPSA). The discriminative performance and clinical utility were compared with other methods. The 5-fold cross-validation with 1000 iterations was used for internal validation. ***Results:*** In this cohort of MRI-negative/-equivocal men, for diagnosis of csPCa, area-under-the-curve (AUC) for PRIMARY-score (3-5 vs 2-1), SUVmax (cut off, 6.5) and PSMA PET/CT reports was limited to 0.796 (95% CI, 0.738-0.853), 0.807 (95% CI, 0.740-0.873) and 0.806 (95% CI, 0.742-0.870), respectively, owing to benign prostate diseases (BPD)-related expressions of PSMA, shown as both false-positive rates of 75.0% (15/20) and 46.2% (18/39) for PRIMARY 3 and 4, respectively, and a wide range of overlap of SUVmax between non-csPCa and csPCa. The diagnostic model comprising PRIMARY-score, SUVmax and fPSA/tPSA exhibited a significantly highest AUC of 0.906 (95% CI, 0.851-0.961) compared to visual assessments or single-parameter-based PSMA approach (P≤0.001) and extremely significantly higher than conventional strategies based on PSAD and/or PI-RADS (P<0.001). The internal validation showed that the average 5-fold cross-validated AUC with 1000 iterations was 0.878 (95% CI, 0.876-0.879). The model with a threshold of 21.6% could have prevented 78% of unnecessary biopsies while merely missing 7.8% of csPCa cases in this cohort. ***Conclusion:*** A novel diagnostic model based on PRIMARY-score, SUVmax on 68Ga-PSMA-617 PET/CT and fPSA/tPSA was developed and validated. The model assists clinical decision-making by providing a diagnostic tool with higher accuracy that maximizes PSMA information use and potentially reduces considerable unnecessary biopsy procedures in MRI-negative/-equivocal cases. This approach also facilitates personalized decision-making, especially in challenging cases where additional PSMA-PET scans are considered for men with inconclusive MRI findings.

OP-428

COBRA: Assessment of safety and efficacy of ^{64}Cu-SAR-bisPSMA in patients with biochemical recurrence of prostate cancer following definitive prostate cancer therapy

E. Lengyelova[1], *L. Nordquist[2], D. Saltzstein[3], D. Josephson[4], G. E. Franklin[5], G. Morrish[1], O. Gervasio[1], M. Parker[6], R. Miller[1], N. Shore[7];*
[1]Clarity Pharmaceuticals, Eveleigh, AUSTRALIA, [2]XCancer, Omaha, NE, UNITED STATES OF AMERICA, [3]Urology San Antonio, San Antonio, TX, UNITED STATES OF AMERICA, [4]Tower Urology, Los Angeles, CA, UNITED STATES OF AMERICA, [5]New Mexico Cancer Center, Albuquerque, NM, UNITED STATES OF AMERICA, [6]Clarity Pharmaceuticals, New South Wales, Eveleigh, AUSTRALIA, [7]Carolina Urologic Research Center, Myrtle Beach, SC, UNITED STATES OF AMERICA.

Aim/Introduction: Prostate-specific membrane antigen (PSMA) is a transcellular antigen used as an imaging target in prostate cancer (PC). 64Cu-SAR-bisPSMA may offer several advantages over the currently approved PSMA PET agents due to the bivalent structure of SAR-bisPSMA and longer half-life of 64Cu (t1/2=12.7h), compared to monovalent agents utilizing 18F and 68Ga (t1/2<2h). Clinical evidence showed 2-3x higher tumour uptake and detection of additional lesions using 64Cu-SAR-bisPSMA compared to approved PSMA PET agents. ***Materials and Methods:*** COBRA is a Phase I/II study assessing the safety/efficacy of 64Cu-SAR-bisPSMA (200 MBq) in PC patients with biochemical recurrence (BCR) and negative/equivocal standard of care (SOC) imaging (NCT05249127). Patients underwent PET/CT on Day 0 and Day 1 (1-4h and 24±6h post-dose, respectively). Efficacy endpoints included detection rate (DR), correct detection rate (CDR), maximum standardised uptake value (SUVmax), tumour-to-background ratio (TBR) and lesion size. Results were expressed as the ranges among readers. PET results were assessed against a Reference Standard (histopathology, SOC imaging and/or prostate specific antigen levels) that was determined by an independent, blinded, central expert panel. ***Results:*** Fifty-two patients were enrolled/imaged (42 evaluable for efficacy endpoints). One adverse event was related to 64Cu-SAR-bisPSMA (Grade 2 worsening of type II diabetes, resolved). The Day 0 DR was 44-58% (95% CI:30-71.8), increasing on Day 1 to 58-80% (95% CI:43.2-90). CDR on Day 0 was 21.4-28.6% (95% CI:0.3-44.6), increasing to 28.6-38.1% (95% CI:15.7-54.4) on Day 1. CDR results were substantially impacted by the number of lesions that were detected but were unable to be biopsied in conjunction with the low sensitivity of the SOC scans. The number of lesions identified increased from Day 0, 53-80 to Day 1, 82-153. Mean SUVmax and TBR increased 87% and 4.8x, respectively, on next-day imaging (Day 0 and Day 1, respectively: SUVmax 13.9-14.0 and 22.2-33.4; TBR 23.2-25.4 and 118.1-181.7). 64Cu-SAR-bisPSMA was able to identify lesions of <5mm in diameter (2mm range). ***Conclusion:*** The COBRA study demonstrates that 64Cu-SAR-bisPSMA is safe and effective in detecting lesions in patients with BCR. In patients with a negative/equivocal entry SOC scan, 64Cu-SAR-bisPSMA identified lesions on same-day imaging (53-80 lesions), with a higher proportion of positive scans and more lesions detected on the following day (82-153 lesions). Notably, lesions as small as 2mm were detected. These findings are significant as disease localisation and detection of additional lesions can inform optimal treatment pathways in patients with BCR.

OP-429

PSMA PET/CT improves overall survival in men with biochemical recurrent prostate cancer who are treated with salvage radiotherapy; A national cohort study

A. Mogensen[1,2], *C. Torp-Pedersen[3,4], M. Nørgaard[5,6], L. Petersen[1,2], M. Kempel[7], H. Zacho[1,8];*
[1]Department of Nuclear Medicine, Aalborg University Hospital, Aalborg, DENMARK, [2]Department of Clinical Medicine, Aalborg University Hospital, Aalborg, DENMARK, [3]Department of Public Health, University of Copenhagen, Copenhagen, DENMARK, [4]Department of Cardiology, Nordsjaellands Hospital, Hillerød, DENMARK, [5]Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, DENMARK, [6]Department of Clinical Medicine, Aarhus University Hospital, Aarhus, DENMARK, [7]Department of Oncology and Clinical Cancer Research Center, Aalborg University Hospital, Aalborg, DENMARK, [8]Department of Clinical Medicine, Aalborg University Hospital, Aalborg, DENMARK.

Aim/Introduction: Salvage radiotherapy (sRT) is recommended for potential curative treatment in patients with biochemical recurrence (BCR) after radical prostatectomy (RP). PSMA PET/CT is diagnostically superior to other PET tracers in BCR at low PSA

values, where it can be used in patient selection for sRT. The aim was to evaluate if the use of pre-sRT PSMA PET/CT improves overall survival in patients with BCR following RP undergoing sRT. This was done in a national cohort with free (tax-paid) and equal access to PSMA PET/CT. ***Materials and Methods:*** A Danish nationwide cohort study, using real-world data from the national registries. Using the unique identification number of every Danish citizen and health-care registries, we identified all patients who underwent sRT due to BCR after RP since 2015. Patients were excluded if PSA >1.0 ng/mL at the time of sRT. The cohort was stratified into two groups: 1) patients undergoing PSMA PET/CT before sRT or 2) patients with no PSMA PET/CT before sRT. We applied the Kaplan-Meier method to estimate overall survival for both groups of patients. ***Results:*** We identified 808 patients receiving sRT between January 1, 2015, and July 1, 2023, of whom 300 (37.2%) underwent PSMA PET/CT before sRT, and 508 (62.8%) did not. Preoperative risk class was assessed according to the European Association of Urology (EAU) risk classification. There were no differences among the two groups regarding EAU risk class, age, comorbidities, time since RP, R0/R1 status at RP and N0/N1 status at RP. Median follow-up after sRT was shorter in the PSMA PET/CT group, 28.9 months [IQR: 13.9, 46.9] versus 66.1 months [IQR: 38.1, 82.3] for non-PSMA patients. In the PSMA PET/CT group the 1- and 4-year year overall survival rates were 100% (95% CI: 100-100) and 99.1% (95% CI: 97.4-100), respectively compared to 98.8% (95% CI 97.8-99.8), and 94.7% (95% CI 92.6-96.9) in the non-PSMA group. ***Conclusion:*** The patient group selected to sRT after undergoing PSMA PET/CT had higher survival indicating that PSMA PET/CT is useful in the selection process for sRT. Overall, the four-year survival rate among all patients undergoing sRT was above 94%.

OP-430

Imaging shapes the long-term oncological outcome of oligorecurrent prostate cancer patients submitted to metastasis-directed therapy (the PRECISE-MDT study)

F. Lanfranchi[1], *D. Albano[2,3], F. Linguanti[4,5], L. Urso[6], A. Rizzo[7], F. Dondi[2,3], E. Abenavoli[4], L. Vaggelli[4], N. Ortolan[6], F. Garrou[8], S. Grimaldi[8], P. Ghedini[9], A. Iudicello[9], G. Rovera[8], F. Pazienza[8], M. Salgarello[10], M. Racca[7], M. Bartolomei[6], S. Panareo[9], F. Bertagna[2,3], S. Morbelli[8], G. Sambuceti[1,11], M. Bauckneht[1,11], PRECISE-MDT Collaborators;*

[1]Nuclear Medicine, Department of Health Sciences (DISSAL), University of Genoa, Genova, ITALY, [2]Nuclear Medicine, ASST Spedali Civili di Brescia, Brescia, ITALY, [3]University of Brescia, Brescia, ITALY, [4]Nuclear Medicine, Careggi University Hospital, Florence, ITALY, [5]Nuclear Medicine, Ospedale San Donato, Arezzo, ITALY, [6]Nuclear Medicine, Oncological Medical and Specialist Department, University Hospital of Ferrara, Ferrara, ITALY, [7]Nuclear Medicine, Candiolo Cancer Institute, FPO–IRCCS, Turin, ITALY, [8]Nuclear Medicine, AOU Città della Salute e della Scienza di Torino, University of Turin, Turin, ITALY, [9]Nuclear Medicine, Oncology and Haematology Department, University Hospital of Modena, Modena, ITALY, [10]Nuclear Medicine, IRCCS Ospedale Sacro Cuore Don Calabria, Negrar, ITALY, [11]IRCCS Ospedale Policlinico San Martino, Genova, ITALY.

Aim/Introduction: Clinical trials showed metastasis-directed therapy (MDT) as an effective treatment for oligorecurrent prostate cancer (PCa). However, there is an ongoing debate regarding the impact of using different imaging techniques interchangeably for defining lesions and guiding MDT within clinical trials. Thus, we aimed to assess the impact of different imaging tools in guiding MDT and their effects on oncological outcomes in oligorecurrent PCa patients. ***Materials and Methods:*** We retrospectively analysed hormone-sensitive or castration-resistant oligorecurrent PCa patients who underwent $^{[18F]}$F-Fluorocholine, [68Ga]Ga-PSMA-11 or $^{[18F]}$F-PSMA-1007 PET/CT-guided MDT across eight Italian tertiary-level cancer centers between July 2012 and May 2023. Inclusion criteria were: (i) histologically confirmed PCa, (ii) ≤5 nodal, bone or visceral metastases at choline or PSMA PET/CT, (iii) MDT through stereotactic body radiation therapy with or without systemic therapy, and (iv) ≥6 months clinical follow-up. To compare treatment groups, we calculated a propensity score using multivariable logistic models, including PET tracers used as independent variables, and well-known prognostic factors as dependent variables: International Society of Urological Pathology grade at baseline, and, at the time of MDT, castration-resistant status, PSA level, concurrent systemic treatment, and number of metastases. Propensity-matched cohorts on a one-to-one basis with a 0.01 calibration were then created. Through Cox-regression and Kaplan-Meier analyses, imaging guiding MDT was assessed as Progression-Free Survival (PFS), time to systemic treatment change due to polymetastatic conversion (PFS2), and Overall Survival (OS) predictor. The Inverse Probability of Treatment Weighting (IPTW) approach was employed as a sensitivity analysis. ***Results:*** Out of 402 patients, 232 (57.7%) and 170 (42.3%) were submitted to MDT guided by $^{[18F]}$F-Fluorocholine and PSMA PET/CT, respectively. Matched and unmatched variables across the two groups were superimposable. After propensity score matching, PSMA PET/CT was associated with significantly longer PFS (HR=0.49, 95%CI=0.36-0.67; p<0.0001), PFS2 (HR=0.42, 95%CI=0.28-0.63; p<0.0001) and OS (HR=0.39, 95%CI=0.15-0.99; p<0.05) compared to choline PET/CT-guided MDT. We then matched patients submitted to [68Ga]Ga-PSMA-11 vs. $^{[18F]}$F-PSMA-1007 PET/CT, showing that MDT based on the former provides higher PFS and PFS2 compared to the latter (HR=0.51, 95%CI=0.26-1.00 and HR=0.24, 95%CI=0.09-0.60, respectively; p<0.05 and p<0.005, respectively). In the whole sample of unmatched patients, IPTW-based sensitivity analyses confirmed all these findings. ***Conclusion:*** Diverse PET/CT methods influence the long-term oncological outcome in a real-world, multi-institutional, propensity score-matched sample of patients with oligometastatic PCa undergoing MDT. Additional studies with prospective and randomised designs are necessary to provide more evidence for the practical implementation of the obtained findings.

OP-431

Long-Term Outcomes of PSMA PET/CT-Guided Radiotherapy in Biochemical Recurrence Patients Post-Radical Prostatectomy: a 5-Year Follow-Up Analysis.

A. Di Giorgio[1], *F. Serani[2], C. Malizia[3], P. Castellucci[4], S. Fanti[1,4], A. Farolfi[4];*

[1]Nuclear Medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY, [2]"Spirito Santo" Hospital, Nuclear Medicine, Pescara, ITALY, [3]PET Radiopharmacy Unit, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY, [4]Nuclear Medicine, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.

Aim/Introduction: PSMA PET/CT imaging is increasingly used to guide salvage radiotherapy (sRT), the main potentially curative option for biochemical recurrence (BCR) after radical prostatectomy (RP) in clinically localized prostate cancer (PCa). Our purpose is to evaluate the role of PSMA PET/CT guided salvage radiotherapy (sRT) in improving long-term biochemical recurrence free-survival in these patients. ***Materials and Methods:*** we retrospectively screened 240 patients, with 100 meeting inclusion criteria: PSMA PET/CT performed for biochemical persistence (PERS) or BCR after

RP; ≥4 years of follow-up; PSMA PET/CT-guided sRT; availability of PSA values and clinical data. All PSMA PET/CT scans were performed using [68Ga]Ga-PSMA-11. The study endpoint was biochemical recurrence free survival (PSA ≤ 0.2 ng/ml) after PSMA PET/CT guided sRT. ***Results:*** Sixty-tree/100 patients underwent PSMA PET/CT for BCR and thirty-seven for PERS. Fifteen patients had PSA pre-RT<0.5 while seventy-five had PSA pre-RT≥0.5. sRT was performed according to EAU guidelines. PSMA PET/CT was positive in 52/100 cases. BCR patients were more often PET-negative or, if positive, exhibited a higher frequency of local recurrence (21%BCR vs 8%PERS); with 65%receiving RT as the only treatment. PERS patients were more often PSMA PET/CT positive with nodal involvement (54%PERS vs 21%BCR; p <0,001). Patients with PERS received RT and androgen deprivation treatment (ADT) in 21/37 cases (57%). The hazard ratio (HR) of RT-treatment failure between patients with PSA pre-RT≥0.5 and patients with PSA pre-RT<0.5 was statistically significant (2.2; p<0.039). Answering to our main aim, the overall median time of follow-up was 59mo (IQR 50-67mo) and the median PSA at last follow-up was 0,01ng/ml (0,01 -0,03ng/ml). We assessed a RT-treatment failure in 36/100 patients (36%) with a median time from RT of 33mo (18-47mo) without statistically significant differences between BCR and PERS (38%BCR vs 32%PERS); all of them underwent a second PSMA PET/CT. Among all patients who had RT-treatment failure, 23/36 (64%) were PET positive and 14/36 (39%) received a new PSMA PET/CT-based RT. All patients were alive at the last analysis. ***Conclusion:*** PSMA PET/CT-guided radiotherapy demonstrates significant long-term efficacy in patients experiencing biochemical recurrence or persistence post-RP, eliciting a substantial PSA response over time and serving as a valuable tool in treatment management.

Impact of radioactive iodine treatment on long-term overall- and relative-survival in patients with differentiated thyroid cancer: A SEER based cohort study

***H. Weis*[1]**, *M. Hellmich*[2], *A. Drzezga*[1], *M. Schmidt*[1];
[1]*Department of Nuclear Medicine, Faculty of Medicine and University Hospital of Cologne, University of Cologne, Cologne, GERMANY,* [2]*Institute of Medical Statistics and Computational Biology, Faculty of Medicine and University Hospital of Cologne, University of Cologne, Cologne, GERMANY.*

Aim/Introduction: In patients with differentiated thyroid cancer (DTC, i.e. papillary- and follicular thyroid cancer (PTC, FTC)) the American Thyroid Association (ATA) established a risk stratification system based on i.a. TNM and histology, which is currently adopted in the planned German S3 guideline. Only in high-risk patients ATA generally recommends radioiodine therapy (RAI). However, adjuvant RAI remains a matter of controversial debate. A single prospective study showed that treatment avoiding RAI was non-inferior for selected low risk patients, yet follow-up time was short (three years). We present long-term data based on the large Surveillance, Epidemiology, and End Results Program database (SEER). ***Materials and Methods:*** We retrospectively compared long term overall survival (OS) and survival relative to the proportion of expected survivors in a comparable set of cancer free individuals (RS) in patients treated with and without RAI using SEER. The years 2000 to 2020 were analyzed (n=187915 patients). Patient were subdivided based on histology (PTC, aggressive PTC, FTC including minimal invasive FTC and angioinvasive FTC). These cohorts were stratified into very low risk [pT1a, N0], low risk [(pT1b, pT2), N0, M0], intermediate risk [(pT3, N0, M0) or (pT1-3, N1, M0)] and high risk [(pT3, pT4, N1 or any M1]]. OS and RS were determined for each subgroup. Statistics included a 1:1 z-test. ***Results:*** OS and RS were improved or tended to be improved in the majority of subgroups undergoing RAI. Preliminary results show that even in low risk subgroups ten-year survival may relevantly be increased after RAI: In minimally invasive FTC, OS was increased by 5.5% and RS by 1.9%. For intermediate risk, even in less aggressive classical PTC, OS was increased by 3.1% and RS by 1.7% after RAI. In high-risk patients, RS was improved by 32.4 % and OS by 25.2% for FTCs after RAI. Notably, without RAI, RS was decreased to ~20%. For high-risk classical PTC OS was improved by 12.9% and RS by 12.7% after RAI. RAI did not impair OS and RS in any subgroup after ten years. ***Conclusion:*** In patients with DTC, subgroup analysis defining cohorts of low, intermediate and high-risk of recurrence according to the planned German S3 guideline undergoing surgery and RAI have a benefit in OS compared to patients with surgery alone, especially in the presence of lymph node and distant metastases. Benefit of RAI was most pronounced in cohorts of high risk of recurrence.

OP-433

Effects of radioiodine treatment on fertility indicators in men with differentiated thyroid cancer: A cohort study

A. Aghaee, *S. Soltani, S. Kasaeian Naeini, M. Emadzadeh, S. Zakavi;*
Nuclear medicine research center, Mashhad University of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Following thyroidectomy, radioiodine therapy is the standard management of differentiated thyroid cancer. The effects of such treatment on testicular function remained a concern for cases and clinicians. We aimed to observe changes in fertility indicators in men treated with ablation. ***Materials and Methods:*** In this prospective cohort study, 18 men with differentiated thyroid cancer from June to December 2020 underwent thyroidectomy plus radioiodine therapy. Participants were grouped based on iodine dose (8 men with 30 mCi vs. 10 men with ≥ 150 mCi). Baseline values (VB) of the follicular stimulating hormone, luteinizing hormone, testosterone, and sperm analyses were measured 3 wk before iodine ablation and repeated 3 (V3) and 12 (V12) months later. They were analyzed once as a whole and once based on their groups via ANOVA and Friedman's tests where appropriate. ***Results:*** The mean age of participants was 35.61 ± 9.74 yr. Follicular stimulating hormone levels showed a significant trend among all participants (VB : 12.51 ± 1.72, V3 : 13.54 ± 1.41, and V12: 13.10 ± 1.67 IU/mL; p < 0.001). Luteinizing hormone showed a similar pattern (VB : 4.98 ± 1.27, V3 : 5.65 ± 1.29, and V12: 5.21 ± 0.95 IU/mL; p < 0.001). Testosterone levels did not differ significantly from baseline. Sperm count decreased at the first checkpoint and returned to normal after 12 months (VB : 38.22 ± 19.40, V3 : 32.05 ± 17.96, and V12: 36.66 ± 18.81 million/mL; p < 0.001). Sperm motility and morphology did

not change significantly. ***Conclusion:*** Our research showed that even less than 5 GBq irradiation could induce a transient testicular dysfunction in the first 3 months of therapy, but it was mostly reversible after 12 months.

OP-434

INSPIRE - A multi-centre clinical trial to investigate the radiation dosimetry of radioiodine therapy for thyroid cancer

G. Flux, *J. Taprogge, H. Sharman, Y. Fox-Miller, S. Yusuf, S. Patel, K. Wong, K. Newbold;*
Royal Marsden NHS Trust & Institute of Cancer Research, Sutton Surrey, UNITED KINGDOM.

Aim/Introduction: The aim of this study is to investigate the range of absorbed doses delivered to thyroid remnants, whole-body and salivary glands in patients undergoing radioiodine treatment for low, intermediate or high risk thyroid cancer and to determine the feasibility of conducting clinical dosimetry-based trials in a multi-centre setting. ***Materials and Methods:*** A prospective observational dosimetry study, INSPIRE (NCT04391244), has been set up with a recruitment target of 150 patients across 10 UK sites. Sites were prepared for quantitative imaging following procedures developed for previous UK and European multicentre clinical trials (1,2). Data acquisition protocols were designed to have sufficient flexibility with imaging timepoints to allow for local logistics and constraints. Imaging and patient-specific data are acquired and uploaded to a core dosimetry hub for centralised processing. ***Results:*** To date 49 patients have been recruited (median age: 47, range 18-84, M:F 17:34, 37 papillary, 15 follicular carcinoma). Initial results indicate a wide range of radiation doses delivered to thyroid remnants (median: 9.1 Gy, range 1 - 691 Gy), whole-body (mean: 0.13 Gy, range 0.03 - 0.33 Gy) and salivary glands (median: 0.3 Gy, range 0.1 - 1.7 Gy) that have shown transient toxicity in some patients. ***Conclusion:*** INSPIRE builds on previous clinical studies (SELIMETRY and MEDIRAD) to demonstrate that investigator-led multicentre dosimetry trials are feasible, permitting clinical questions to be addressed. Standardised imaging and centralised data processing for patient dosimetry supports widespread multicentre participation. Further work will investigate associations between delivered radiation doses and clinical outcome. It is envisaged that the results of this study will inform a subsequent interventional trial, particularly focussed on personalised dosimetry-based treatments. ***References:*** 1. OP-435

Radioactive iodine therapy, response-related factors and survival analysis in lung metastatic differentiated thyroid cancer.

T. Bilgüglü, *G. Uçmak, B. Demirel;*
Dr. Abdurrahman Yurtaslan Ankara Oncology Training and Research Hospital, Ankara, TÜRKIYE.

Aim/Introduction: The aim of our study is to analyze the clinicopathological characteristics and survival-related factors in adults with lung metastatic differentiated tyroid cancer (DTC) who received Radioactive Iodine Therapy (RAI). ***Materials and Methods:*** The study included patients diagnosed with DTC who underwent bilateral total thyroidectomy (BTT) between 1986 and 2017, were found to have lung metastases (LM) at diagnosis or during follow-up, and received RAI at least once (1-7). The patients' pathology results, type of iodine uptake in LM, cumulative doses, RAI response classification, progression-free survival (PFS), and overall survival (OS) were recorded. ***Results:*** 112 patients [mean age at diagnosis 46.8 ± 14.4 (19-81) years] were included in the study. The clinicopathological/demographic characteristics of patients are shown in Table 1. 92 patients (82%) had a cumulative dose of >500 mCi with no complications related to RAI. LM were detected by iodine uptake at diagnosis in 81 (72%) patients and during follow-up in 6 (6%); iodine-negative LM 25 (22%) patients were detected by FDG PET/CT at diagnosis or during follow-up. After RAI, 55 (49%) patients were iodine responsive [32 complete, 18 biochemical incomplete response (disease-free follow-up), 5 anatomical and biochemical partial response], while 57 (%51) were iodine non-responsive (41 iodine positive, 16 iodine negative refractory). The median PFS was 112.0±85.5 months (95% CI 9-418) and OS 10.3±6.7 years (95% CI 2-33). PFS was significantly higher in patients of female gender and <45 years (p=0.02, p<0.001 respectively). Papillary type was associated with longer PFS 228.7±23.3 months (95% CI 182.9-274.4) and OS 22.5±1.8 years (95% CI 19.0-26.1). Additionally, diffuse iodine uptake was associated with longer PFS [294±40 months (95% CI 214-373)], compared to iodine negativity [98±14 months (95% CI 70-125)] and macronodular type [155±18 months (95% CI 120-190)] (p<0.001). Patients with LM at diagnosis had a significantly longer PFS [215±22 months (95% CI 170-259)] compared with concomitant bone metastases at diagnosis [44±10 months (95% CI 23-65)] (p<0.001). Despite the PFS of patients with LM detected during follow-up [120±17 months (95% CI 85-154)] was clinically lower than those with at diagnosis [193±20 months (95% CI 153-234)], it was not statistically significant (p=0.19). ***Conclusion:*** Long-term follow-up in adults with LM DTC revealed that male gender, ≥45 years, poorly differentiated/folicular/oncocytic type, iodine-negative or macronodular pattern, iodine refractoriness, and concomitant bone metastases at diagnosis were associated with shorter PFS, while age ≥45 years, poorly differentiated/folicular/oncocytic type and iodine refractoriness were associated with shorter OS.

OP-436

Short-term re-differentiation in patients with radioiodine refractory metastatic differentiated thyroid carcinoma

J. von Hinten, *O. Viering, C. H. Pfob, M. Kircher, R. A. Bundschuh, H. Wengenmair, C. Lapa;*
Nuclear Medicine, Faculty of Medicine, University of Augsburg, Augsburg, GERMANY.

Aim/Introduction: Differentiated thyroid carcinomas exhibit a favorable prognosis attributed to their typically slow tumor growth, good resectability and possibility of radioactive iodine treatment (RAIT). However, 60-70% of patients with metastatic disease are already radioiodine refractory (RAIR) at diagnosis or become RAIR during the course of the disease, resulting in a significant reduction in overall survival. In these patients, attempts to restore iodine uptake in thyroid carcinoma lesions by inhibition of the MAP kinase pathway with appropriate kinase inhibitors (KI) have been reported. ***Materials and Methods:*** Eight patients with histopathologically confirmed, progressive metastatic differentiated thyroid carcinoma, previously diagnosed as RAIR, underwent re-differentiation therapy. The patients received either a combination of trametinib and dabrafenib (in the presence of a BRAF mutation) or trametinib alone (in all other MAPK pathway mutations or in cases without driver mutations). Success of re-differentiation therapy was assessed after 10 and 20 days of kinase

inhibitor treatment using 123I-scintigraphy. In case of sufficient restoration of iodine uptake, high dose RAIT was performed. Pre-interventional glycolytic activity derived from $^{[18F]}$-2-fluoro-2-deoxy-D-glucose (FDG) - positron emission tomography/computed tomography (PET/CT), the histological tumor subtype and mutation status were correlated with re-differentiation success. Response to RAIT was evaluated using RECIST 1.1 and thyroglobulin marker assessment. ***Results:*** Re-differentiation after only 10 days of daily KI intake was achieved in 2/8 patients (25%), both of whom had BRAF-wild type in the genetic analysis. One of the two patients had an additional NRAS p.Q61K mutation. No sufficient re-differentiation occurred in 4 of the remaining patients who underwent continued KI treatment for another 10 days. Two patients refused further KI treatment after the first iodine re-staging due to adverse effects (pleural effusion and peripheral edema). No significant difference in glycolytic activity could be detected between the patients with and without successful redifferentiation. Following RAIT with 9.9GBq or 11.7GBq of 131I, both patients achieved a stable disease at radiologic assessment and a significant decrease in thyroglobulin levels with 90% and 50%, respectively. ***Conclusion:*** Short-term re-differentiation in metastatic RAIR thyroid carcinoma after only 10 days of daily KI intake is feasible, reducing side effects and overall costs. Additional treatment for another 10 days did not enhance tumor NIS expression. Further prospective trials in larger patient cohorts are warranted.

OP-437

Use of bRAF/Mek Inhibitors to Enhance the Efficacy of Repeated Adjuvant RAI Therapy in Recurrent bRAFV600E-positive Papillary Thyroid Cancers s/p Re-operation

D. Shen[1,2], *H. Chan[1], F. Tsai[1], Y. Chiu[1], T. Liang[1], Y. She[1], S. Li[1];*
[1]Kaohsiung Veterans General Hospital, Kaohsiung, TAIWAN, [2]Tri-Service General Hospital, Taipei, TAIWAN.

Aim/Introduction: The loco-regional recurrence or persistence of intermediate- to high-risk papillary thyroid cancers (PTCs) post thyroidectomy is usually treated with re-do surgical intervention. After reoperation, some patients might receive empirical use of radioiodine (RAI) therapy especially when there is no evidence of structural disease but still detectable serum thyroglobulin (Tg) and anti-Tg antibodies (ATA). However post-therapy scans (RxWBS) usually demonstrate little RAI-avid lesion and thus the usefulness of empirical RAI therapy become controversial. In our study we proposed to use anti-bRAF treatment before repeated empirical RAI therapy after reoperation for recurrent PTCs harboring bRAFV600E mutation. We intend to investigate whether combined use of anti-bRAF and RAI treatments might assist to visualize those occult lesions. ***Materials and Methods:*** We recruited 14 bRAFV600E-positive PTC patients (female=10, age: 21-67 year old) who had received reoperation for cervical recurrence, referred for RAI therapies due to serum Tg- or ATA-positive but without structural disease shown by FDG PET/CT or CT. Pretreatment with bRAF and MEK inhibitors for 12~16 weeks followed by RAI therapy was done and RxWBS were examined for any I-131 avid lesions. The change of serum tumor markers was followed for > 1 year and compared with RxWBS. ***Results:*** 10/14 patients showed RAI avid lesions on RxWBS, including neck lesions only (n=6), neck plus lung metastases (n=2), lung metastases only (n=1) and mediastinal metastasis (n=1). Interestingly, two extra-cervical metastases were noticed in absence of neck lesions. As compared with the change of serum tumor marker, there appears to be greater decrease of Tg or ATA level in patients with positive I-131 avid lesions. ***Conclusion:*** For bRAFV600E-positive PTCs, with bRAF/MEK inhibitor treatment, RAI-avid lesions seem to be more prone to be visualized on RxWBS. Significantly decreased serum Tg/ATA as correlated with the presence of I-131 avid lesion after RAI therapy indicates the efficacy of repeated adjuvant RAI therapy following reoperation therapy. Also accidental notation of extra-cervical RAI-avid lesions gives the impact to change the therapeutic approach. Our preliminary results suggest the possible use of anti-bRAF pretreatment to augment empirical RAI therapy in such settings.

OP-438

Regaining radioiodine avidity following PRRT in four radioiodine-refractory thyroid cancer patients: a revolutionary re-differentiation strategy?

A. Aghaee, *B. Hadad;*
Nuclear Medicine Research Center, Mashhad University of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: About 10% of DTCs are metastatic, of which two-thirds lose their radioiodine (RAI) uptake and finally become RAI-refractory (RAIR-DTC), heralding a worse prognosis (1, 2). Multiple re-differentiation strategies have been proposed, including tyrosine kinase inhibitors (TKI) and retinoic acid administration (3). A proportion of RAIR-DTCs also fall into the thyroglobulin (Tg)-elevated negative iodine scan (TENIS) category. These patients are candidates for a variety of imaging modalities (4). We report 4 cases of TENIS syndrome, suprisingly regaining its RAI uptake following PRRT. ***Materials and Methods:*** four women with a history of follicular in one case and papillary thyroid carcinoma in three cases who were referred to our nuclear medicine department following a total thyroidectomy, were under active follow-up after first radio iodine therapy. During follow-up, they developed TENIS syndrome, short interval doubling seum Tg levels with negative therapeutic WBIS. Ga68-DOTAtate and Tc99m-octerotate scans showed tracer avidity in the metastatic locations. ***Results:*** After being discussed in the tumor board meeting, they were deemed eligible for PRRT, and two cycles of 177Lu-DOTA-TATE were administered(200 mCi each). Post-treatment PRRT SPECT/CT scans depicted increased radiotracer uptake in the metastatic areas (figure 3). Following PRRT, clinical symptoms improved, and serum suppressed-Tg level were reduced . On this account, we decided to withhold additional cycles requesting a diagnostic WBIS. Surprisingly, the WBIS showed significant iodine avidity in all metastatic foci. The patients received 200 mCi 131I, and the post-treatment whole-body scan confirmed the regaining RAI uptake in all of the metastatic foci found in the SSTR PET/CT study . The interval between this WBIS and the previous negative study were between 40-70 months. Despite doing a thorough literature search, we could not find any hypothetical mechanism for re-differentiation following PRRT. Indeed, data in this research domain is still limited, as fewer than 200 cases of RAIR-DTC have been treated with PRRT in the literature. Regaining radioiodine uptake in theses cases were really happened because of PRRT-induced irradiation to the tumoral cells and this needs to be elucidated in future studies ***Conclusion:*** We report four cases of RAIR-DTC that showed re-differentiation and gained RAI uptake capacity after PRRT. This hypothesis may be a ray of hope. It may propose PRRT as a possible re-differentiation strategy in patients with RAIR-DTC who have lost their RAI avidity if repeated and confirmed by future studies.

OP-439

Redifferentiation of radioiodine-refractory differentiated thyroid cancer to warrant I-131 therapy using lenvatinib: results of the RESET trial

M. Dotinga[1,2], *E. Kapiteijn[1], F. H. P. van Velden[1], M. K. Stam[1], P. Dibbets-Schneider[1], M. Pool[1], F. Smit[1,3], L. F. de Geus-Oei[1,4,5], D. Vriens[6];*
[1]Leiden University Medical Center, Leiden, NETHERLANDS, [2]Netherlands Cancer Institute, Amsterdam, NETHERLANDS, [3]Alrijne Hospital, Leiderdorp, NETHERLANDS, [4]University of Twente, Enschede, NETHERLANDS, [5]Delft University of Technology, Delft, NETHERLANDS, [6]Radboud University Medical Center, Nijmegen, NETHERLANDS.

Aim/Introduction: In patients with radioiodine-refractory differentiated thyroid cancer (RAI-R DTC), I-131 therapy is deemed ineffective. In a part of these patients, the disease is characterized by a loss of radioiodine uptake and accumulation. Prior studies show that short-term treatment using (selective) tyrosine kinase inhibitor (TKIs) can reinduce radioiodine uptake and warrant I-131 therapy. This study (NTC04858867) investigated the potential of standard-of-care multitargeted-TKI lenvatinib to reinduce radioiodine uptake and subsequent eligibility for I-131 therapy in RAI-R DTC patients. ***Materials and Methods:*** 9 RAI-R DTC patients starting lenvatinib treatment were included and underwent rhTSH-stimulated I-124 dosimetric procedures at baseline, week 6 (N=7) and week 12 (N=8).[1] At all timepoints, the maximum tolerable activity (MTA)[2] and fraction of patients eligible for I-131 therapy was assessed. Patients were considered eligible if at least one target lesion showed an expected mean absorbed dose >20 Gy when administering 7.4 GBq (or MTA if ≤7.4 GBq) I-131. In total, 23 target lesions were selected for dosimetry. Lesions were segmented on I-124 PET/CT, volumes estimated using low-dose CTs and recovery correction was applied to the measured mean activity concentration at each timepoint. Tumor dosimetry was performed following the MIRD methodology using a mono-exponential fit and S-values from IDAC-Dose2.1. MTA, mean absorbed lesion dose per administered I-131 activity (LDpA), residence time and uptake 24 hours post-administration in target lesions were assessed and compared between time points. ***Results:*** In all patients, a morphological therapy response due to lenvatinib was observed at week 6 and 12. By our definition, none of the patients were found eligible for I-131 therapy at any timepoint. Median LDpA was 0.08 (IQR: 0.04-0.17), 0.18 (IQR: 0.08-0.36) and 0.17 (IQR: 0.09-0.37) Gy/GBq at baseline, week 6 and 12, respectively. No significant increase in mean LDpA was observed at both timepoints on-lenvatinib (p=0.3 and p=0.06, respectively). LDpA showed an increase in 12/17 (71%) lesions at week 6 and 15/20 (75%) lesions at week 12 compared to baseline. MTA, 24h-lesion uptake and residence time were comparable between time points (p>0.2). ***Conclusion:*** Redifferentiation of RAI-R DTC to reinduce radioiodine uptake to a level that warrants I-131 therapy cannot be established by short-term lenvatinib treatment. Based on a predefined futility stopping criterion, the study was preliminary terminated after 9 patients completed all dosimetric procedures. Multitargeted-TKIs may not be as potent as selective-TKIs in reinducing clinically meaningful radioiodine retention. ***References:*** [1] Dotinga et al. Diagnostics (2023) [2] Lassmann et al. EJNMMI (2008).

Results of the phase I "Lumed " study: Dose escalation of ^{177}Lu-PP-F11N in patients with medullary thyroid carcinoma.

C. Rottenburger[1], *M. Hentschel[1], L. McDougall[1], F. Kaul[1], R. Mansi[2], M. Fani[2], H. A. Vija[3], R. Schibli[4], S. Geistlich[4], M. Behe[4], E. R. Christ[5], D. Wild[1];*
[1]Division of Nuclear Medicine, University Hospital Basel, Basel, SWITZERLAND, [2]Division of Radiopharmaceutical Chemistry, University Hospital Basel, Basel, SWITZERLAND, [3]Molecular Imaging, Siemens Medical Solutions USA, Inc, Hoffman Estates, IL, UNITED STATES OF AMERICA, [4]Center for Radiopharmaceutical Sciences, Paul Scherrer Institute, Villigen, SWITZERLAND, [5]Division of Endocrinology, Diabetology and Metabolism, University Hospital Basel, Basel, SWITZERLAND.

Aim/Introduction: Targeting the cholecystokinin 2 receptor (CCK2R) with radiolabeled compounds for therapy of malignancies such as medullary thyroid carcinoma (MTC) is an attractive approach. Recently, we demonstrated that the administration of the CCK2R agonist [177Lu-DOTA-(DGlu)6-Ala-Tyr-Gly-Trp-Nle-Asp-PheNH2] (177Lu-PP-F11N) in patients is safe and enables visualization and dosimetry of metastasized disease in MTC patients. This subsequent prospective phase 1 single-center dose escalation study (ClinicalTrials.gov: NCT02088645) aims to the determination of the maximum tolerated dose of 177Lu-PP-F11N. We present the recent data of two dose levels in patients. ***Materials and Methods:*** Main inclusion criteria were histologically confirmed MTC with or without thyroidectomy and elevated levels of calcitonin (> 100 pg/mL) and/or a calcitonin doubling time of less than 24 months. Depending on the escalation cohort, patients received up to 4 infusions of 177Lu-PP-F11N in an interval of 8-10 weeks. Planar whole-body scintigraphy and quantitative SPECT/CT acquisitions of neck/thorax/abdomen/pelvis were acquired at several time points for tumor and organ dosimetry. For measurement of in-vivo stability, blood samples were taken. Adverse events were recorded and graded according to Common Terminology Criteria for Adverse Events (CTCAE) version 4.03. ***Results:*** In total, 9 patients were recruited for this study and received infusions of 177Lu-PP-F11N between October 2018 and March 2024. Six patients received all planned activity doses according to the dose escalation protocol. Of these, 3 patients received each 3 infusions of 6.0-6.6 GBq (median: 6.3) within the first, and further 3 patients each 4 infusions of 7.8-8.5 (median: 8.2) GBq 177Lu-PP-F11N within the second escalation cohort. Follow-up was performed for (current status, depending on the date of patient recruitment) from 2 months up to 5 years after the last infusion. In all of these 6 patients, no dose limiting toxicity occurred. Patients only suffered temporary adverse reactions related to the pharmacological effects of the substance not higher than CTCAE grade 2. Of the remaining 3 patients, 2 cancelled study participation after the first infusion due to visually low tracer accumulation of metastases in the posttreatment scan and one patient after the second infusion due to noncompliance with the imaging procedures. ***Conclusion:*** In the two escalation cohorts with 3 x 6 GBq and 4 x 8 GBq 177Lu-PP-F11N, no patient suffered any dose limiting toxicity. Therefore, activity doses of at least 4 x 8 GBq 177Lu-PP-F11N can be considered as a safe activity dose in future therapy trials or in clinical application. ***References:*** J Nucl Med. 2020 Apr;61(4):520-526.

Aim/Introduction: This study aims to provide an overview of SIRT dosimetry planning practices with Yttrium-90 (Y-90) resin μspheres in Europe. The project attempts to answer the following question: are dosimetric practices comparable and consistent across Europe? In particular, does the dose prescribed delivered to the tumor depend on center-specific practice? ***Materials and Methods:*** A phantom case and two anonymized clinical cases were provided to participants. The phantom case was composed of 99mTc-SPECT/CT images of an anthropomorphic phantom with an inserted sphere to mimic tumor in liver. The dosimetric challenge was to calculate the activity of Y-90 to deliver 120 Gy into the sphere. The two anonymized clinical cases consisted of a radiation segmentectomy for the treatment of mCRC (case A) and a case of SIRT retreatment of HCC (case B). Patient characteristic, tumor description, clinical data, diagnostic images and 99mTc-MAA SPECT/CT were provided to participants. The dosimetric challenge was to perform the dosimetry planning workflow, from segmentation of volumes of interest to absorbed dose calculations according to the individual clinical practice of the participating centers. Data collected included lung-shunt-fraction (LSF), volumes data (type, segmentation method, volume value, DICOM RTSTRUCT), dosimetric data (calculation method, absorbed doses, DICOM RTDOSE) and calculated Y-90 activity for treatment. Additionally centers reported their methodology by a standardized online questionnaire. Inter-center variability in segmented structures, absorbed doses, LSF, and Y-90 activity was analyzed using the quartile coefficient of dispersion. ***Results:*** In total, 55 Europeans centers participated. Forty-eight percent use voxel-based dosimetric method, with 72.9% of those using a commercial software. In the interim analysis of clinical case A, the quartile coefficients of dispersion (QCD) of calculated yttrium-90 activity and LSF value are 29.5% and 82.9%, respectively. The QCD of absorbed doses for liver, tumor, perfused volume and normal liver are 31.9%, 35.8%, 22.1% and 38.5%, respectively. Results for the phantom case and clinical case B are currently underway. ***Conclusion:*** The interim findings offer valuable insights into the variability in dosimetry planning associated with Y-90 resin μspheres across Europe. This study holds the potential to provide a comprehensive overview in used dosimetric workup procedures, laying the groundwork for the formulation of recommendations and towards the standardization of practices.

In-situ ^{90}Y Microdosimetry and Biological Effects at Microscopic Level after Transarterial Radioembolization
A. Kirov, *L. Carter, O. Talarico, A. Teplov, E. Vakiani, D. Lafontaine, H. Kunin, E. Chan, M. Nehmeh, M. P. Dimopoulos, V. S. Sotirchos, C. Samson, E. Petre, P. Zanzonico, A. Kesner, Y. Yagi, J. L. Humm, C. S. Sofocleous;*
Memorial Sloan Kettering Cancer Center, New York, NY, UNITED STATES OF AMERICA.

Aim/Introduction: To investigate microscopic level correlations between tissue absorbed dose and microsphere distribution with resulting pathologic changes determined by immunohistochemistry (IHC) on the same tissue sample obtained through PET/CT-guided biopsies. ***Materials and Methods:*** The distribution of microspheres was investigated in N = 27 18G

core needle biopsy specimens obtained from the tumor and surrounding liver parenchyma (margins) at day 0 (T0) and 3 ± 1 weeks (T3) post-radioembolization from 7 patients consented to an IRB-approved prospective research protocol and treated by transarterial radioembolization (TARE) using glass and resin 90Y-loaded microspheres. High-resolution micro-CT (voxel dimensions of several microns) and autoradiography were used to determine the number and location of microspheres in each specimen. The absorbed dose distribution within each specimen was determined using a hybrid image-based approach that separated the dose contributions into two components: the internal dose from microspheres within the specimen and the external dose from microspheres in the surrounding tissue. For the internal dose, Monte Carlo particle transport simulations were employed, utilizing the 90Y activity distribution derived from microCT and autoradiographic images of each specimen. The external dose was estimated by multiplying the macroscopic dose, as obtained from 90Y-PET images, by a scaling factor that accounted for the spill-in effect of dose from a uniform-activity background into the specimen volume. The high-resolution dose maps obtained by summing the internal and external dose components are registered with IHC micrographs with submillimeter precision. The correlations of the biological effects (double strand DNA breaks (DSB), cellular viability, apoptosis, necrosis, proliferation and immune infiltration/inflammation) with local dose in the specimens are currently being investigated. ***Results:*** For specimens containing high activity, the mean dose to the specimen exceeds substantially the mean dose derived from the PET images. The initial dose rate and the total treatment dose may exceed 10 Gy/h and 1000 Gy respectively at distances of up to few hundred microns from clusters of glass microspheres. Preliminary results from two specimens showed increased inflammatory infiltration and activation of DSB at T0 in the immediate vicinity of resin microspheres. The dependence of the biological effects on local dose at the two time points will be presented for the current cohort. ***Conclusion:*** Investigating dose response effects in the submillimeter vicinity of the microspheres may help advance our understanding of the processes underlying response to TARE by revealing effects not observable at the whole specimen level or with standard response assessment criteria.

EPS-129

Dosiomics and Dose Volume Histogram Analysis for Early Prediction of Tumor Response in ^{90}Y-SIRT

Z. Mansouri, *Y. Salimi, G. Hajianfar, L. Knappe, N. Bianchetto Wolf, G. Xhepa, A. Gleyzolle, A. Ricoeur, V. Garibotto, I. Mainta, H. Zaidi;*
Geneva University Hospital, Geneva, SWITZERLAND.

Aim/Introduction: The aim of this work was to develop an AI model based on extracted dose volume histogram (DVH) and dosiomic features for early prediction of tumor response in patients undergoing personalized 90Y-SIRT. ***Materials and Methods:*** This retrospective study involved 25 liver cancer patients treated with 90Y-glass microspheres through personalized planning. Treatment response was assessed at three months using m-RECIST criteria, classifying patients into Responders (R) and non-responders (NR) groups. Dosimetry calculations were conducted using 99mTc-MAA SPECT/CT. Voxel-wise dosimetry was performed using the MIRD local energy deposition method. Additionally, biological effective dose (BED) maps were calculated for lesions, normal perfused liver (NPL), and whole normal liver (WNL). 126 dose-volume constraint (DVC) parameters were extracted from physical and BED-related DVHs. Dosiomic features, including first-order, shape, and texture, were extracted from dose maps for all structures. Three strategies, including Dose, BED, and BED+Dose, were adopted for both DVH and dosiomics analysis. The Kruskal feature selection method was used, combined with the Logistic Regression machine learning algorithm for model development. Three-fold nested cross-validation and bootstrapping methods were adopted to avoid overfitting. Model performance was evaluated using area under the ROC curve (AUC), Accuracy (ACC), Sensitivity (SEN), and Specificity (SPE) metrics. ***Results:*** Fourteen cases were NRs, whereas eleven cases were categorized as Rs, with only one case of complete response (mean absorbed dose = 233.45 and mean BED = 378.08 Gy from 90Y). No statistically significant differences existed between mean absorbed doses in NR and R groups (p-value > 0.05). Multiple features were involved in response prediction. Most-frequently selected DVCs were V400(%)-tumor, V20(%)- NPL and V20(%)-BED-WNL, tumor-dose homogeneity index(D5%/D95%), tumor to normal ratio, WNL-Volume, D50-NPL and minimum-dose-NPL. Corresponding dosiomic features were shape-maximum 2D and 3D diameter-WNL and different tumor-GLCM features. The achieved AUCs were 0.52, 0.71, 0.59, 0.78, 0.85, and 0.75 for DVH-BED, DVH-BED-Dose, DVH-Dose, Dosiomics-BED, Dosiomics-Dose, and Dosiomics-BED-Dose, respectively. Corresponding values for ACC were 0.52, 0.72, 0.60, 0.79, 0.84, and 0.76, SEN were 0.50, 0.78, 0.64, 0.92, 0.71, and 0.78, and values for SPE were 0.54, 0.63, 0.54, 0.63, 1, and 0.72, respectively. ***Conclusion:*** This study is a step towards precise and informed 90Y-SIRT therapy. Our findings indicate that dosiomic models outperformed conventional DVH-based models. Moreover, incorporating BED dosimetry features into the DVH approach resulted in improved model performance comparable with dosiomic models. Notably, factors other than mean absorbed dose were more significant in tumor response prediction.

EPS-130

Dosimetric study of Liver and Metastases in Treatments with [^{166}]Ho-PLLA: Dead Time Effects and Prediction Power

L. Miseo[1,2], *S. Ungania[1], M. D'Andrea[1], F. Murtas[2], M. Pacilio[3], M. Bottero[4], D. Maccora[5], R. Sciuto[5], G. E. Vallati[6], A. Soriani[1], G. Iaccarino[1], B. Cassano[1];*
[1]Medical Physics Dept., IRCCS Regina Elena National Cancer Institute, Rome, ITALY, [2]Post Graduation School of Medical Physics Tor Vergata, Rome, ITALY, [3]Medical Physics Department, AOU Policlinico Umberto I, Rome, ITALY, [4]Radiotherapy Unit, IRCCS Regina Elena National Cancer Institute, Rome, ITALY, [5]Nuclear Medicine Unit, IRCCS Regina Elena National Cancer Institute, Rome, ITALY, [6]Interventional Radiology Unit, IRCCS Regina Elena National Cancer Institute, Rome, ITALY.

Aim/Introduction: [166]Ho-PLLA microspheres has been recently introduced into clinical practice for radioembolization in the treatment of liver tumors and metastases. The use of the same microspheres both in pre-therapy simulation (SA) and in therapeutic administration (TA), and the possibility of acquiring SPECT/CT images (81 keV peak), should lead to improved predictive power of absorbed dose estimation (AD) from SA to TA (ADSA and ADTA, respectively). However, TA can exceed 10 GBq, so SPECT/CT image acquisitions (generally performed 2 days after TA) are affected by dead time effects (DTe). The aim of this study is to evaluate the predictive power of SA on TA in terms of mean AD and AD distribution, assessing the impact of DTe. ***Materials and Methods:*** A recovery coefficient curve for DTe was obtained by acquiring SPECT/CT images of a phantom over one week, with

activity ranging from 1.9 GBq to 83 MBq. Fifteen patients with various liver diseases and a single lesion were retrospectively analyzed in this study. ADSA and ADTA were calculated using the local energy deposition method. ADTA was then evaluated using three methods: M1, where no correction for DT was applied, M2, where the entire AD distribution was corrected for DTe, and M3, where only the AD within the tumor contour was corrected. Percentage differences (ΔD%) and linear correlations between the calculated mean ADSA and ADTA were performed, for the three methods. Finally, registering ADSA and ADTA distributions, a gamma index analysis was performed, with Dose Difference equal to 10% and Distance to Agreement equal to 10 mm as pass rate criteria. ***Results:*** DTe result negligible for activities below 250 MBq. The mean AD presents a strong linear correlation in both liver and tumor, using the three different methods. ΔD% values ranged, for the liver contour, between (median[min;max]) -8.6[-21.0;0.6]% (M1), 21.5[3.3;48.2]% (M2) and 8.2[-9.0;24.8]% (M3), and between -20.1[-41.8;-8.8]% (M1) and 0[-19.6;18.5]% (M2) for the tumor ROI. The best result of the gamma analysis was obtained with M3, achieving a pass rate range 92[71;100]% for the whole liver and 87[69;98]% for the tumor contour. ***Conclusion:*** Considering that SPECT/CT images are generally acquired when the therapeutic activity is above 250 MBq, dead time correction is necessary for an accurate estimation of ADTA. The best results from M3 also demonstrate that the correction should be localized to the areas with the highest uptake, achieving high predictive power both in terms of mean and distribution of AD.

EPS-131

Is the 30Gy lung absorbed dose limit still appropriate in Y90 resin microsphere radioembolization with 3D Voxel-Based dosimetry?

V. Betech-Antar[1], *F. Pareja del Río[1], F. Minguez[1], M. Romera[1], J. Bastidas[2], M. Iñarrairaegui[1], A. Martínez de la Cuesta[1], L. Sancho[3], B. Sangro[1], E. Prieto[1], M. Rodríguez-Fraile[1];*
[1]Clínica Universidad de Navarra, Pamplona, SPAIN, [2]Fundación Jiménez Díaz, Madrid, SPAIN, [3]Clínica Universidad de Navarra, Madrid, SPAIN.

Aim/Introduction: To assess the actual absorbed dose by lungs (ADL) in the Y90-PET-voxel-based analysis that is related to the eventual occurrence of radiation pneumonitis. Moreover, to compare ADL and lung shunt fractions (LSF) from planar MAA imaging and MAA-SPECT-CT-voxel-based analysis with the final values derived from Y90-PET. ***Materials and Methods:*** Patients who underwent Y90-resin-microspheres radioembolization (RE) between 2018-2023 were retrospectively analysed. Inclusion criteria comprised same MAA and Y90 injection site/s and >3 month-follow-up period. Commercially available software was used to calculate LSF with MAA-SPECT-CT and Y90-PET and to prevent liver counts from overlapping with lung counts, a boolean operation excluding manual delineation of a 1%-threshold of maximal activity in the liver from automatic lung volume segmentation was employed. Additionally, ADL mean and other parameters related to voxel-based dosimetry [V70V30,D40···] were obtained. ADLmean from planar images were calculated using partition model formula. To evaluate the agreement between planar and MAA-SPECT-CT values with the actual ones in Y90-PET, Lin coefficient correlation (CCC) was utilized. The potential correlation between dosimetry parameters and the presence of pneumonitis was also studied. ***Results:*** Sixty-six patients were included: 48 men; 64±8.5 years; 81% primary liver tumors; RE procedures: 6% bilobar, 53% lobar/lobar-extended, 38% segmental or selective. Median admininistered activity 1GBq (CI:1-2). Median LSF for planar, MAA-SPECT-CT and Y90-PET were 5% (95% confidence interval [CI]:4-7), 2% (CI:1-3) and 1% (CI:1-2), respectively. Median ADLmean were: 4Gy(CI:2-6) for planar, 1.2Gy (CI:0.6-2.4) for MAA-SPECT-CT and 1.3Gy (CI:0.77-2.2) for Y90-PET. A poor correlation between planar and Y90-PET was observed for LSF and ADLmean: CCC=0.23 (CI:0.11-0.33) and 0.37 (CI:0.2-0.52) respectively, being moderate between MAA-SPECT-CT and Y90-PET for LSF (CCC=0.46; CI:0.25-0.62) and ADLmean (CCC=0.5; CI:0.33-0.65). An strong correlation for V70 (volume of lung receiving more than 70 Gy) between MAA-SPECT-CT and Y90-PET was obtained(CCC=0.85; CI:0.76-0.91). One patient developed radiation pneumonitis (ADLmean of 25Gy in Y90-PET, 15Gy in planar and 11Gy in MAA-SPECT-CT; V70 of 3% in both MAA-SPECT-CT and Y90-PET). Median [maximum and minimum values] ADLmean for the remaining patients were 3.5 Gy [0-15) for planar, 1.2 Gy [0.3-8.4] for MAA-SPECT-CT and 1.3Gy [0.37-20.5] for Y90-PET, with V70 of 0%[0-0.8]in MAA-SPECT-CT and 0%[0-1.5] in Y90-PET. ***Conclusion:*** This series challenges the conventional 30Gy limit for ADLmean in planar images, showing that with voxel-based dosimetry, radiation pneumonitis can occur with values of 25 Gy in Y90-PET and 11 Gy in MAA-SPECT. Additionally, parameters from MAA-SPECT-CT-voxel-based dosimetry (V70 >3%), can potentially help to reduce pneumonitis risk.

EPS-132

Radiobiologic considerations in ^{90}Y resin microspheres radioembolization of Hepatocellular Carcinoma: Tumor response prediction with PET/CT and Cone Beam CT-based mean absorbed dose and equivalent uniform dose

M. Olivieri[1,2], *A. Savi[1], E. di Gaeta[1], C. Canevari[1], P. Magnani[1], G. Matassa[1], F. Calabrese[1,2], S. Gusmini[1], A. Casadei-Gardini[1,2], L. Aldrighetti[1,2], F. De Cobelli[1,2], A. Chiti[1,2];*
[1]IRCCS San Raffaele Scientific Institute, Milan, ITALY,
[2]Vita-Salute San Raffaele University, Milan, ITALY.

Aim/Introduction: The aim of the study was to implement radiobiologic models for tumor control probability (TCP) in patients treated with 90Y-resin microsphere using mean absorbed dose (Dmean) and Equivalent Uniform Dose (EUD) metrics derived from post-embolization 90Y PET/CT. ***Materials and Methods:*** 24 patients with hepatocellular carcinoma (HCC) who underwent transarterial radioembolization (TARE) from 2020 to 2024 were retrospectively considered in the study. Tumor volumes (TVs) delineated on the early arterial phase Cone-Beam CT (CBCT) were rigidly coregistered and manually adjusted in the post-TARE 90Y PET/CT. Tumor Dmean was calculated using 90Y PET/CT for all patients with voxel dosimetry-based model. The tumor response evaluation was performed on follow up (FU) contrast enhanced CT at 3 months post-TARE according to modified Response Evaluation Criteria in Solid Tumors (mRECIST) and divided in two groups: partial/complete response versus no response/stable disease. To take into account the biological effects and the dose non-uniformity, the EUD on 90Y PET/CT was calculated as EUD=-(1/α) ln(∑iexp(-αDi)/nvoxel). The radiosensitivity α (Gy-1) was established by simplified linear quadratic model for tumor control via least mean square minimization method. A logistic regression model based on 90Y PET/CT dose distribution was performed to predict the TCP using tumor Dmean, EUD, mRECIST. The area under the curve (AUC) of the receiver-operating characteristic (ROC) curves of the Dmean and the EUD were used to assess the dose values able to determine the tumor treatment response with 85.7% specificity. ***Results:*** A total of 32 lesions were assessed; partial/complete response was seen in 75% (24/32) of lesions.

The overall median Dmean and EUD were 282 Gy and 187.43 Gy respectively.Best-fit value of α parameter was: 0.015 Gy-1.Ninety % TCP corresponded to 315 Gy for Dmean and 200 Gy according to EUD metric.The Dmean and EUD values able to determine the tumor response were 280 Gy and 166 Gy respectively (AUC of 0.9). ***Conclusion:*** TCP model showed a strong association between Dmean, EUD metrics and the response probability. However, EUD should be preferred since it allows to consider the heterogeneity of the dose distribution.

EPS-133

A Recovery Coefficient Model for Resolution Characterization, Harmonization, and Shape-Specific Partial Volume Correction

H. Marquis[1], *C. R. Schmidtlein[1], R. de Nijs[2], P. Mínguez Gabiña[3], J. R. Gustafsson[4], J. C. Ocampo Ramos[1], G. Kayal[1], L. M. Carter[1], D. L. Bailey[5], A. L. Kesner[1];*
[1]Memorial Sloan Kettering Cancer Center, New York, NY, UNITED STATES OF AMERICA, [2]Department of Clinical Physiology and Nuclear Medicine, Copenhagen University Hospital, Copenhagen, DENMARK, [3]Department of Medical Physics and Radiation Protection, Gurutzeta-Cruces University Hospital/Biocruces Bizkaia Health Research Institute, Barakaldo, SPAIN, [4]Medical Radiation Physics, Lund University, Lund, SWEDEN, [5]Department of Nuclear Medicine, Royal North Shore Hospital, Sydney, AUSTRALIA.

Aim/Introduction: Recovery coefficient (RC) based partial volume correction (PVC) is one of the simpler methods used to correct for partial volume losses impacting uptake measurements. However, while RC-PVC is routinely performed, the process is not well standardized and is often sub-optimally implemented. As part of the MIRDsoft community dosimetry tools project, we have developed an empirical RC model with potential applications to resolution characterization, SUV harmonization, and shape-specific PVC. In this work we validate our empirical model with experimental phantom data and demonstrate its utility for PVC. ***Materials and Methods:*** Recovery coefficients for spheres and prolate/oblate spheroids were simulated in python and an empirical model was developed to describe the partial volume losses of these shapes. Our model, "MIRD Resolution Equivalent Recovery Coefficient" (MIRD-RERC), facilitates the conversion between RCs and spatial resolution estimates. The model is a function of volume, sphericity, and spatial resolution, as well as 3 empirical fit parameters. For validation, RCs were measured from IEC phantom experiments containing 99mTc and 177Lu; the RCs were used to generate a conventional two-parameter logistic function RC-curve such as that described in the EANM dosimetry committee guidance document on uncertainty analysis [3], and an RC-curve generated with the MIRD-RERC model. The two models were then used to perform PVC on 3D-printed spheroid phantom data, consisting of 3 large spheres, 9 prolate, and 9 oblate spheroids. The PVC data was compared to the reference values. ***Results:*** The model demonstrates agreement with both experimental and simulated RCs for the various objects and is consistent with previous findings [1,2]. The PVC results, shown in Table 1, demonstrates that in our comparison the MIRD-RERC model outperforms the conventional RC-curve approach. ***Conclusion:*** We have developed a MIRD-model for recovery coefficients of differently shaped objects. The MIRD-RERC methodology is undergoing further validation and may facilitate new approaches to resolution characterization, algorithm optimization & harmonization, and shape-specific PVC. Furthermore, this model will form the basis of MIRDpvc, a MIRDsoft effort currently in development which aims to incorporate these advancements in RC-based PVC methodology accessible and easy to implement in the wider community. ***References:*** [1] Mínguez Gabiña P, et al. Bone Marrow Dosimetry Exploratory Analysis from the Phase 3 SIERRA Trial of ^{131}I-apamistamab Prior to HCT in Relapsed/Refractory Acute Myeloid Leukemia

N. Pandit-Taskar[1], *M. Natwa[2], M. Chen[3], E. Leung[4], J. Spross[5], K. Li[5], A. Desai[5], P. Brodin[5], R. Wahl[6];*
[1]Molecular Imaging and Therapy, Memorial Sloan Kettering Cancer Center, New York, NY, UNITED STATES OF AMERICA, [2]NYU Langone Health, New York, NY, UNITED STATES OF AMERICA, [3]Yale New Haven Hospital, New Haven, CT, UNITED STATES OF AMERICA, [4]The Ottawa Hospital, Ottawa, ON, CANADA, [5]Actinium Pharmaceuticals, New York, NY, UNITED STATES OF AMERICA,[6] Washington University St. Louis, St. Louis, MO, UNITED STATES OF AMERICA.

Aim/Introduction: 131I-apamistamab, an anti-CD45 radioimmunoconjugate, delivers targeted radiation to hematopoietic cells allowing for induction and conditioning. The safety and efficacy of this targeted radiation therapy has been demonstrated in the SIERRA randomized controlled Phase 3 study prior to allogeneic hematopoietic cell transplant (HCT). The main target organ of this treatment is the bone marrow, to achieve successful myeloablation leading to induction and conditioning prior to transplant. ***Materials and Methods:*** Patients 55 years or older with active relapsed/refractory AML were randomized (1:1) to receive 131I-apamistamab with fludarabine and total body irradiation (2 Gy) followed by HCT or conventional care (CC), with the potential to proceed to HCT if achieving CR. Patients not achieving CR on the CC arm were eligible to cross over to 131I-apamistamab. Organ-specific absorbed dose estimates were calculated for each patient and the prescribed activity of 131I-apamistamab was determined individually by limiting the absorbed dose to liver to 24 Gy. Bone marrow dosimetry was performed using the sacral scintigraphy method1 and associations of various patient demographics and estimated dose to marrow are presented in this analysis. ***Results:*** 153 patients were enrolled in SIERRA, 76 in the 131I-apamistamab arm and 77 in the conventional care arm. The primary endpoint of 6-month durable complete remission (dCR) was met with 22% in the 131I-apamistamab arm vs. 0% for CC ($p<0.0001$). 131I-apamistamab followed by HCT was well tolerated with lower rates of sepsis compared to CC (6.1% vs. 28.6%), and respectively 43.9% vs. 50% febrile neutropenia and 15.2% vs. 21.4% mucositis. The median estimated dose to bone marrow was 16.0 Gy (range: 4.6 - 44.6 Gy), Table 1 shows the bone marrow dose estimates stratified by several patient factors. No significant differences were found in dose to marrow by age ($p=0.30$), sex ($p=0.31$), BMI ($p=0.46$) or performance status ($p=0.09$), indicating that myeloablative bone marrow doses were achievable irrespective of patient characteristics. ***Conclusion:*** 131I-apamistamab based induction and conditioning followed by HCT resulted in statistically significant improvement in primary endpoint dCR at 6 months as a result of targeted radiation delivery with excellent safety. High doses of targeted radiation to the diseased marrow, greater than what would be achievable using total body irradiation, were safely delivered irrespective of age, performance status, sex and BMI. ***References:*** 1. Siegel et al. 1989. Sacral scintigraphy for bone marrow dosimetry in radioimmunotherapy. IJRAI. Nuclear Medicine and Biology, 16, 553-559.

EPS-135

GPU-Accelerated Monte Carlo Enables Generation of Patient-Specific Recovery Coefficients for Accurate Partial Volume Correction and Radiopharmaceutical Dosimetry

T. Rydén[1], *J. Grudzinski[2], P. Bernhardt[1];*
[1]Gothenburg University, Gothenburg, SWEDEN, [2]University of Wisconsin, Madison, WI, UNITED STATES OF AMERICA.

Aim/Introduction: The limited spatial resolution of SPECT imaging can lead to inaccurate measurements of radiopharmaceutical (RPT) treatment delivered to patients. Current methods rely on generic recovery coefficients (RCs) based on simplified phantoms, which can be inaccurate due to variations in patient anatomy and activity distribution. ***Materials and Methods:*** SPECT/CT (D0, D1, D2, D7) from patients (n=5) treated with 177Lu-DOTATATE were used as input data for this study. Using an inhouse automatic segmentation algorithm, VOIs were created at each time point for each kidney and five bone marrow regions within the lumbar spine. Patient-specific RCs were calculated using Monte Carlo simulation (1000 photons per voxel) of the SPECT scanner and VOIs. Three scenarios were investigated which used the same VOIs but varied the activity within and around the VOIs:1) Uniform activity within VOIs and no activity outside of VOIs, 2) true 177Lu-DOTATATE activity distribution inside of VOIs, no activity outside of VOIs, and 3) true 177Lu-DOTATATE activity distribution inside and outside of VOIs. The calculated RCs for each VOI (5 patients x 4 time points = 20 data points) were compared for each scenario. A similar investigation was repeated assuming 225Ac-DOTATATE. The effect of varying the collimator (e.g., HEGP, MEGP, MELP, LEHR) was also investigated. ***Results:*** Results showed that the most realistic scenario (activity inside and outside ROIs) produced the most consistent RCs, regardless of ROI size. Bone marrow ROIs showed the most significant variation across scenarios. The type of collimator used in the SPECT scanner also affected the RCs. For 177Lu the mean RCs for L1 were 0.760, 0.527, and 0.979 for scenarios 1-3, respectively; and, for 225Ac, the mean RCs for L1 were 0.641, 0.361, and 0.966 for scenarios 1-3, respectively. For 177Lu of scenario 1 and 2, the largest RC was for the right kidney whose mean was 0.853 ± 0.016 and 0.887 ± 0.015, respectively. For scenario 3, the largest RC was L3 whose mean was 1.002 ± 0.089. The LEHR and MEGP had the largest RCs for 177Lu (0.8268 ± 0.03923) and 225Ac (0.7723 ± 0.01953), respectively, while the HEGP (0.7629 ± 0.05637) and LEHR (0.6614 ± 0.09046) had the smallest RCs for 177Lu and 225Ac, respectively. ***Conclusion:*** This research demonstrates a promising new approach for generating patient-specific RCs, potentially improving the accuracy of RPT dosimetry in SPECT imaging. Future work will compare this method to traditional phantom-based methods for even greater accuracy.

EPS-136

Development of a skin dosimetry model for assessing normal tissue dosimetry following CD44v6 therapy: a comparison between ^{177}Lu and ^{161}Tb

J. Hemmingsson[1], *M. Nestor[2], A. Lundgren Mortensen[3,2], J. Svensson[4], P. Bernhardt[1];*
[1]Department of medical radiation sciences, University of Gothenburg, Gothenburg, SWEDEN, [2]Department of Immunology, Genetics and Pathology, Science for Life Laboratory (SciLifeLab), Uppsala University, Uppsala, SWEDEN, [3]Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, SWEDEN, [4]Department of Oncology, Sahlgrenska University Hospital, Gothenburg, SWEDEN.

Aim/Introduction: The cell surface antigen CD44v6 is a promising targeting agent for several cancers, demonstrating favorable in vivo attributes in terms of affinity and biodistribution. Normal tissue typically has limited expression of CD44v6; however, it is abundantly present in skin keratinocytes. When coupled with a radionuclide, this increases the potential for skin toxicity, emphasizing the need for a dedicated skin dosimetry model. In this study, we compared the energy deposition of 177Lu or 161Tb in various skin structures under different radionuclide distributions. ***Materials and Methods:*** Sequential H&E-stained histological sections of normal skin biopsies were segmented using MATLAB. The dermis region was subdivided into blood vessels, sebaceous glands, sweat glands, hair follicles, and remaining tissue. The epidermis, primarily composed of keratinocytes without a direct blood supply, was divided into the upper epidermis and the basal layer. This thin layer, which forms the boundary between the dermis and epidermis, harbors several skin stem cell populations and is likely of particular importance for skin toxicity assessment. To quantify radiation exiting the skin, the air outside of the epidermis was also included. Simulations in the voxelized skin model were performed using event-by-event tracking in the Monte Carlo program PENELOPE. ***Results:*** The complete model size was 0.2x0.3x0.2 cm with 3.6 µm voxel sides. Ten million decays of either 177-Lu or 161-Tb were simulated in the following source regions: blood, the basal layer, and the upper epidermis. When activity was distributed in the basal layer and upper epidermis, the self-dose from 161-Tb was 59 and 15 keV/decay, respectively, compared to 28 and 13 keV/decay for 177-Lu. For the blood activity distribution in the dermis region, the regional variations were particularly large for 161-Tb, averaging 101 keV/decay in self-dose and 3.9 keV/decay to the basal layer. For 177-Lu, the corresponding measures were 79 and 3.4 keV/decay. ***Conclusion:*** Our results demonstrate increased energy deposition to all skin regions for 161-Tb compared to 177-Lu across all distributions of activity. When activity was solely distributed in the stem cell populations of the basal layer, a two-fold higher energy deposition was observed for 161-Tb.

EPS-137

Post-Therapeutic Dosimetric Evaluation of ^{166}Ho Hepatic Radioembolization: Software Impact on Tumor and Liver Doses

R. Albergueiro[1,2], *R. Silva[3], J. Santos[2,3];*
[1]Unidade Local de Saúde de São João, E.P.E, Porto, PORTUGAL, [2]Portuguese Oncology Institute of Porto/Porto Comprehensive Cancer Center, Porto, PORTUGAL, [3]Unidade Local de Saúde de Santo António, Porto, PORTUGAL.

Aim/Introduction: Transarterial radioembolization with 166Ho-microspheres (166Ho-TARE) is a promising therapy for primary and secondary liver malignancies, sparking interest in precise dosimetric evaluations using quantitative Single Photon Emission Computed Tomography (SPECT/CT)1. This study aimed to estimate post-treatment liver and tumor absorbed doses using two state-of-the-art software platforms. ***Materials and Methods:*** Patients selected for 166Ho-TARE underwent a scout procedure and SPECT/CT images to assess tumor dose coverage and microsphere extrahepatic leakages. Treatment was given two weeks later, followed by a post-treatment SPECT/CT. Whole liver and tumor mean doses were estimated using Hermia Voxel dosimetry™ 1.1 and Q-Suite™ 2.1, and dose coverage was evaluated at three points using (D50, D70 e D85) dose-volume histograms. Results were compared using Bland-Altman analysis

and Wilcoxon tests. ***Results:*** The study included 15 patients with an average age of 60 years, predominantly female (77%), and mostly diagnosed with hepatocellular carcinoma (77%). Hermia Voxel dosimetry showed mean liver and tumor doses of (12±4) Gy and (58±23) Gy, respectively, while Q-Suite reported (44±9) Gy and (209±83) Gy. D50, D70 and D85 values were (55±21) Gy, (41±19) Gy and (29±16) Gy for Voxel dosimetry and (201±78) Gy, (149±67) Gy and (108±59) Gy for Q-Suite, respectively. Significant differences were observed in mean doses (p=0.002 for liver, p<0.001 for tumor), with wide limits of agreement in Bland-Altman analysis. To address these differences, a patient/activity-specific CF was applied, rather than a general CF obtained with low activity, to correct the Voxel dosimetry dose maps. This CF was determined based on the gamma camera's response curve, assuming a direct correlation between camera's sensitivity and CF. The revised mean doses were (42±6) Gy for liver and (196±17) Gy for tumor, aligning closely with Q-Suite results (p=0.69 for liver, p=0.64 for tumor). ***Conclusion:*** Voxel dosimetry initially underestimated doses compared to Q-Suite, likely due to the short time interval between therapy administration and imaging. However, with a new patient-specific CF, the corrected dose maps showed valid results, aligning with Q-Suite outcomes. The CF plays a key role in generating the activity map for accurate dose distribution in 166Ho-TARE using these software, highlighting the importance of proper calibration and timing. ***References:*** 1. Impact of Tissue Density on Dosimetric Accuracy in ^{166}Ho-TARE: A Comparative Analysis Using Local Energy Deposition, Voxel S-Values, and Monte Carlo Simulations

***A. Capotosti*[1],** *M. De Spirito[1,2], L. Indovina[1], G. Iaccarino[3], L. Miseo[3,4], R. Moretti[1], I. Moretti[2], M. Pacilio[5], R. Sciuto[6], A. Soriani[3], S. Ungania[3], B. Cassano[3];*
[1]Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, ITALY, [2]Dipartimento di Neuroscienze, Università Cattolica del Sacro Cuore, Rome, ITALY, [3]Medical Physics Dept., IRCCS Regina Elena National Cancer Institute, Rome, ITALY, [4]Post Graduation School of Medical Physics "Tor Vergata", Rome, ITALY, [5]Medical Physics Department, AOU Policlinico Umberto I, Rome, ITALY, [6]Nuclear Medicine Unit, IRCCS Regina Elena National Cancer Institute, Rome, ITALY.

Aim/Introduction: Radioembolization therapy with 166Ho microspheres needs accurate dosimetric assessments to ensure therapeutic efficacy and minimize potential toxicity. The complexities of absorbed dose (AD) distribution within and around heterogeneous tissues, particularly the liver and lungs, challenge traditional dosimetric methods that rely on homogeneous water-equivalent assumptions. This can lead to significant inaccuracies in AD estimation, potentially affecting clinical outcomes. This study aims to compare the dosimetric differences between the Local Energy Deposition (LED) and Voxel S-Values (VSV) with Monte Carlo (MC) simulations. ***Materials and Methods:*** A retrospective cohort of 10 patients with primary (hepatocellular carcinoma, colorectal carcinoma) and secondary (metastatic) liver malignancies treated with 166Ho microspheres was analyzed. Dosimetric calculations were conducted using data from patient SPECT/CT scans acquired after injecting 166Ho microspheres. A dedicated software was used for LED and VSV AD calculations, while another dedicated one, implementing GPU-accelerated MC algorithm, provided MC absorbed dose values. AD estimations obtained from the LED and VSV methods were compared against those provided by MC simulations (considered as reference values), focusing on the liver and lungs. Absolute and relative AD differences were assessed. ***Results:*** Mean AD percentage differences between LED and MC in the liver region ranged from 0.3% to 4.7% (absolute AD differences from 0.1 Gy to 1.7 Gy). In the lungs, these differences ranged from -97.1% to -100% (absolute AD differences from 3.4 Gy to 10.5 Gy), and with density correction applied, they ranged from -91.8% to -99.9% (absolute AD differences from 3.3 Gy to 10.5 Gy). Mean AD percentage differences between VSV and MC in the liver region ranged from 5.3% to 9.6% (absolute AD differences from 0.9 Gy to 3.4 Gy). In the lungs, these ranged from -73.4% to -77.9% (absolute AD differences from 2.5 Gy to 8.2 Gy), and with density correction applied, they ranged from -25.4% to -37.9% (absolute AD differences from 0.9 Gy to 4 Gy). ***Conclusion:*** Both LED and VSV approaches, compared with MC simulations, showed significant AD underestimations, particularly in regions with air-equivalent densities. These preliminary results highlight the sensitivity and potential inaccuracies in dosimetric calculations when non-MC methods are employed in regions with variable densities. Further research is recommended to explore improvements in dosimetric methods and their impact on clinical efficacy and safety.

Streamlining Parameter Dimensionality in a PBPK Model for [^{177}Lu]Lu-PSMA I&T Radioligand Therapy using Bayesian Parameter Estimation

***C. Orlov*[1],** *E. Yousefzadeh-Nowshahr[1], N. J. Begum[1], V. Vasic[1], A. J. Beer[1], G. Glatting[1], M. Eiber[2];*
[1]University Hospital Of Ulm, Ulm, GERMANY,
[2]Klinikum Rechts der Isar, Munich, GERMANY.

Aim/Introduction: Physiologically based pharmacokinetic (PBPK) models mathematically describe the absorption, distribution, metabolisation and excretion of chemical substances in humans and animals. Compartments within the models represent organs or tissues connected via blood flow. A system of differential equations enables calculating the concentration of substance in each compartment, relying on knowledge of parameter values. Precise parameter estimation can be challenging due to an often-large number of unknown parameters and high computational costs. One method to reduce parameter dimensionality is Bayesian parameter estimation, explored in this work using a whole-body PBPK Model for [177Lu]Lu-PSMA I&T radioligand therapy (RLT). ***Materials and Methods:*** Data from 13 patients who underwent one diagnostic PET scan and one cycle of [177Lu]Lu-PSMA I&T RLT were used to fit 17 parameters of a recently-developed whole-body PBPK model through minimisation of an objective function implementing Bayesian information. To determine which parameters could be fixed, 9 iterations were performed where the Bayesian mean and standard deviation for each patient were updated with the population average of the estimated parameter from the previous iteration. A parameter could be fixed when the average Bayesian relative standard deviation is less than 0.001%. The Time-Activity Curves (TACs) and the Time-Integrated Activity Coefficients (TIACs) of the total body, kidneys, liver, salivary glands and tumour lesions were compared when fitting 17 and 9 parameters. ***Results:*** In 13 patients, after 9 iterations, the Bayes parameters converged, and 8 out of 17 parameters had a standard deviation of less than 0.001%. The modelled TACs for all investigated organs and tumours appeared almost identical when fitting 17 parameters after 9 iterations and 9 parameters after

fixing 8, with the difference in the TIACs being less than 0.01%. Due to their importance in treatment safety and efficacy, the TIACs of the kidneys and tumour lesions are considered. While fitting 17 parameters after the first iteration, these are 0.086±0.019 min and 1.267±0.758 minl-1, respectively. The corresponding TIACs after the 9th iteration and after fitting 9 parameters are identical with results 0.087±0.019 min and 1.257±0.783 minl-1, respectively. The total body and the parotid glands demonstrate the largest differences in the TIACs between the 1st and 9th iteration. ***Conclusion:*** Bayesian parameter estimation has effectively determined the number of adjustable parameters that could be fit in a population, resulting in almost identical TAC results. This reduces user dependence when using a PBPK model for [177Lu] Lu-PSMA I&T RLT without compromising the results.

EPS-140

Plausibility of ^{225}Ac-DOTATATE dosimetry estimation based on the biodistribution of ^{177}Lu-DOTATATE

***U. Olgac*[1],** *G. Birindelli*[1], *L. Blumenstein*[1], *B. Schoeberl*[2], *F. Hourcade-Potelleret*[1], *S. Gaudet*[2];
[1]*Novartis Biomedical Research, Basel, SWITZERLAND,*
[2]*Novartis Biomedical Research, Cambridge, MA, UNITED STATES OF AMERICA.*

Aim/Introduction: Actinium-225 (225Ac) has increasingly been used in targeted alpha therapy, however, its dosimetry estimation poses several challenges. In this work, we investigate the accuracy of human dosimetry estimation for 225Ac-DOTATATE based on the biodistribution (BioD) of 177Lu-DOTATATE collected in NETTER-1 trial [1]. We then compare the results of model extrapolation to the observed dosimetry data for 225Ac-DOTATATE obtained in Part-1 of the ACTION-1 trial [2]. ***Materials and Methods:*** We first reproduced the 177Lu-DOTATATE absorbed doses for each organ and tumor for the 20 patients in the NETTER-1 dosimetry sub-study [1]. We then calculated the number of disintegrations for 225Ac-DOTATATE assuming a similar decay-corrected BioD to 177Lu-DOTATATE. Finally, we calculated the absorbed doses for 225Ac-DOTATATE in OLINDA/EXM v2.2.3, assuming all daughter radioisotopes of 225Ac decay in the same organ/tissue as the 225Ac-parent. We used a relative biological effectiveness (RBE) of 5 for all alpha-emissions similar to ACTION-1 trial [2]. ***Results:*** Estimated (mean ± SD) organ absorbed doses for 225Ac-DOTATATE for the 20 patients from the NETTER-1 trial for spleen, kidneys, liver, and red marrow are 0.97±1.01, 0.69±0.31, 0.28±0.20 and 0.058±0.055 SvRBE5/MBq, respectively. In comparison, in Part 1 of the ACTION-1 trial, mean weighted absorbed doses for 225Ac-DOTATATE for spleen, kidneys, liver, and red marrow in Cycle 1 were 0.88, 0.52, 0.45, and 0.029 SvRBE5/MBq, respectively [2], demonstrating a 10.2%, 32.7%, and 100.0% overprediction for spleen, kidney, and red marrow, respectively, and a 37.8% underprediction for liver. Tumor absorbed doses for 225Ac-DOTATATE are estimated to be 9.7±13.4 SvRBE5/MBq for the 20 patients from NETTER-1, whereas mean tumor absorbed dose was 3.3 (range 1.0-8.8) SvRBE5/MBq in ACTION-1 trial [2]. The discrepancy in red marrow and tumor absorbed doses might be explained by the differences between NETTER-1 and ACTION-1 trials in red marrow dosimetry estimation methods and in pre-treatment with 177Lu-labelled somatostatin analogues, respectively. ***Conclusion:*** Estimating 225Ac dosimetry based on BioD of 177Lu-labelled compounds is a plausible approach, which may be used as a first approximation in cases where no clinical data is yet available. For 225Ac-DOTATATE, other than in red marrow, the estimated absorbed doses in organs compared well to the observed dosimetry in ACTION-1 trial [2]. ***References:*** [1] Strosberg J, et al. Lancet Oncol. 2021, 22(12):1752-1763. [2] Sgouros G, et al., J Nucl Med. 2023, 64:P129.

EPS-141

Reproducibility of SPECT-based MTV for patients treated with Lu-177-PSMA

***V. Nuttens*[1],** *D. Ooms*[1], *S. Vermeulen*[1], *P. De Bondt*[1], *M. Koole*[2];
[1]*OLVZ, Aalst, BELGIUM,* [2]*KU Leuven, Leuven, BELGIUM.*

Aim/Introduction: Recent studies showed that Metabolic Tumor Volume (MTV) from Lu-177-SPECT-imaging can serve as a prognostic marker to determine whether Lu-177-PSMA therapy should be continued. [1,2] These studies use a semi-automatic delineation method with an empirical SUV-threshold of 3. However, this approach has not been validated nor evaluated in terms of reproducibility. This study compares the reproducibility of MTV using a threshold-based semi-automatic approach with values obtained with a gradient-based manual approach. ***Materials and Methods:*** Patients with variable tumour load underwent a full cycle of Lu-177-PSMA therapy consisting of four administrations. Each patient underwent a quantitative Lu-177-SPECT/CT-scan 12 hours after each administration, and one intermediate F18-PSMA PET/CT-scan three weeks after the second administration. First, tumoral lesions on the PET/CT were manually selected and segmented by two expert physicians using a gradient-based contouring approach in addition to a semi-automatic approach with a fixed SUV-threshold of 2, 3 and 4. Next, lesions on SPECT/CT were segmented by each expert, again first manually using a gradient-based contouring approach, in addition to a semi-automatic approach with fixed SUV-threshold of 0.5, 1, 2, 3 and 4. Time per segmentation was recorded while the reproducibility of the different methods amongst the two expert readers was evaluated using the relative percentage difference. ***Results:*** The time for manual segmentations by the readers ranged from under two minutes up to 18 minutes for a patient with high tumour burden. Meanwhile, all semi-automatic segmentations took less than 2 minutes, independent of the tumour burden. For each expert reader, MTV values using semi-automatic segmentations with an SUV-threshold of 2 were closest to the MTV-values from manual segmentations. For the MTV from manual segmentations, the relative difference between expert readers ranged from 5.2% up to 60% while for the MTV of semi-automatic segmentations with an SUV-threshold of 2, the relative difference between expert readers was lower than 2.6%. ***Conclusion:*** An SUV-threshold of 2 instead of 3 better aligned SPECT-based MTV using a semi-automatic threshold-based approach with a manual gradient-based approach. In addition, the semi-automatic threshold-based highly increased MTV reproducibility amongst expert readers compared to manual contouring. ***References:*** [1] John, N.: (177)Lu-PSMA SPECT quantitation at 6 weeks predicts short Progression-Free survival for patients undergoing (177)Lu-PSMA-I&T therapy. EPS-142

Effect of Absorbed Dose on Toxicity and Tumor Response in Patients With Gastroenteropancreatico Neuroendocrine Tumors Treated with Lu-177-DOTATATE in Combination with Olaparib: Preliminary Results

F. Lin, *I. Shamis, J. Zou, J. Carrasquillo, R. Maass-Moreno, M. Cedo, J. Carreon, P. Eclarinal, B. Turkbey, E. Mena, L. Lindenberg, C. Chen, C. Millo, P. Herscovitch, K. Pacak, J. del Rivero;*
National Institutes of Health, UNITED STATES OF AMERICA, Bethesda, MD, UNITED STATES OF AMERICA.

Aim/Introduction: Gastroenteropancreatic neuroendocrine tumors (GEP-NETs) are somatostatin receptor (SSTR) expressing tumors treated with Lu-177-DOTATATE. Olaparib is a poly-ADP-ribose polymerase inhibitor that blocks single-stranded DNA repair which may synergize with Lu-177-DOTATATE for both efficacy and toxicity. We present in-progress dosimetry results of a phase 1/2 trial testing this combination in metastatic GEP-NET. ***Materials and Methods:*** Three quantitative SPECT/CT scans (4, 24, 48 hours post-infusion) are performed in NCT04086485, a 3+3 dose escalation phase 1/2 study evaluating Lu-177-DOTATATE + olaparib. Lu-177-DOTATATE is given at fixed 200 mCi x 4 cycles while olaparib is escalated from 50mg to 100mg, 200mg, and 300mg bid. Dosimetry was performed using MIM's SurePlan MRT workflow. Regions of interest (ROIs) are drawn around all major organs and select tumors by an experienced Nuclear Medicine physician using MIM's automatic segmentation and PET Edge tool. Integrated time activity curves were obtained using both MIM's fitting functions and trapezoidal integration. The latter data and the voxel S-value convolution method in SurePlan was used to calculate absorbed doses. CT scans obtained at baseline, post 2-cycles, and post 4-cycles were used for RECIST tumor measurements. ***Results:*** By April 2024, 11 patients were treated (6 patients with 4 cycles, 3 with 3 cycles, and 2 with 1 cycle). Absorbed doses calculated with trapezoidal integration yielded results that were on average 34% higher than best fit method. For the 6 patients who completed therapy, 62 tumors lesions were contoured, of which 23 were official RECIST measurable lesions. For these 62 tumors, absorbed dose over all 4 cycles averaged 51.86 Gy (range: 0.77 to 248.85 Gy) per lesion. Per cycle average dose decreased over time (Cycles 1-4: 15.91, 13.57, 12.36, 11.29 Gy, respectively). No correlation was found between total absorbed dose or olaparib dose with change in RECIST diameter at studied re-staging time points. For toxicity, 3/9 (33%) evaluable patients had grade 1 creatinine elevation with average absorbed doses of 13.35 Gy (left) and 11.91 Gy (right) to kidneys, compared to 12.79 Gy and 11.02 Gy in the other 6 patients. One patient (11%) had grade 1 transaminase elevation with 5.85 Gy to the liver, compared to 25.14 Gy (range: 5.85 to 53.13 Gy) in others. ***Conclusion:*** Preliminary data suggests that absorbed doses calculated via 3 time-point dosimetry do not correlate with tumor response or organ toxicity after 2 or 4 cycles in patients treated with Lu-177-DOTATATE and olaparib.

EPS-143

Investigation of [^{177}Lu]Lu-PSMA-617 therapy minimum cycle interval with [^{68}Ga]Ga-PSMA-11 PET/CT

G. Costa[1,2], *E. Yousefzadeh-Nowshahr[1,2], C. Orlov[1], K. Fitzpatrick[3], K. Frey[3], A. Beer[1], Y. Dewaraja[3], G. Glatting[1,2];*
[1]Uniklinik Ulm, Ulm, GERMANY, [2]Univesität Ulm, Ulm, GERMANY, [3]University of Michigan, Ann Arbor, MI, UNITED STATES OF AMERICA.

Aim/Introduction: [177Lu]Lu-PSMA therapy is typically performed with up to four infusions of 7.4 GBq 6 weeks apart. However, short intervals may help to avoid tumour resistance, which has been associated with poor patient response at late therapy cycles. The tumour uptake is limited to the number of receptors on the cell surfaces. Once saturated, the remaining free drug in the blood pool irradiates the non-tumoral tissue, reducing the therapeutic index. Therefore, the occupancy of receptors by radiopharmaceutical and how long it takes for the receptors to be free again (recovery time) constitute essential information to help define a minimum interval cycle. Here, we use a physiologically-based pharmacokinetic (PBPK) model with pre- and peri-therapy PET/CT images to investigate receptor occupancy and recovery time. ***Materials and Methods:*** Three patients were imaged with approximately 190 MBq of [68Ga]Ga-PSMA-11 one month before the therapy (baseline) and between 30 min and 120 min after the first cycle of 177Lu-PSMA-617 therapy. Pre and post-infusion images were acquired one hour after 68Ga-PSMA-11 injection. A PSMA whole-body PBPK model was developed in SimBiology (MATLAB) to simulate [68Ga]Ga-PSMA-11 biokinetics in patients before and after the therapy infusion. The model was adjusted for each patient based on age, weight, organ masses, injected and measured activities, kidney and tumour receptor densities, and blood flow to tumour. The PBPK model was used to calculate the receptor occupancy and the time needed for 90% of receptors to be free again. ***Results:*** After the therapeutic infusion, 68Ga-PSMA-11 uptake for tumours was 34%, 72%, and 49% lower than the baseline for patients 1, 2, and 3, respectively, suggesting PSMA receptor saturation. Likewise, kidney uptake was 77%, 68%, and 74% lower. Tumour receptor occupancy in simulations reached 75%, 81%, and 71%, and it took 1.8, 4.2, and 1.2 days to recover for patients 1, 2, and 3. Similarly, on kidneys, 51%, 92%, and 73% of receptors were occupied, and it took 1.3, 5.9, and 1.2 days to recover. ***Conclusion:*** Reducing the interval between therapy cycles depends on the time needed for targeted cells to recover the initial number of free receptors. A subsequent infusion might be ineffective if administered before this time. A minimal cycle interval of 1.8, 4.2, and 1.2 days for the patients would allow for reaching the maximum tumour uptake with the current injected substance amount. In addition, the large interpatient variation reinforces the need for dosimetry for optimal individualised therapy.

EPS-144

Impact of total-body PET/CT Scan Duration and Reconstruction Parameters on Absorbed Doses in Y-90 Radioembolisation Patients derived from Dose Maps generated with a Monte-Carlo simulated Dose Kernel

P. M. Linder[1], *E. Körner[1], J. Brosch-Lenz[2], H. Dittmann[1], C. la Fougère[1,3], F. P. Schmidt[1,3,4];*
[1]Department of Nuclear Medicine and Clinical Molecular Imaging University Hospital Tuebingen, Tuebingen, GERMANY, [2]Institute of Nuclear Medicine, Bethesda, MD, UNITED STATES OF AMERICA, [3]Cluster of Excellence iFIT (EXC 2180) "Image Guided and Functionally Instructed Tumor Therapies", University of Tuebingen, Tuebingen, GERMANY, [4]Werner Siemens Imaging Center, Department of Preclinical Imaging and Radiopharmacy, Eberhard-Karls University Tuebingen, Tuebingen, GERMANY.

Aim/Introduction: The high sensitivity of total-body PET/CT scanners can compensate the low branching ratio of Y-90, enabling precise voxel-based dosimetry for Y-90 liver radioembolisation. Building on our previous work on optimization of Y-90 imaging [1], we implemented an advanced dosimetric approach and evaluated the impact of image reconstruction

parameters and scan duration on absorbed doses (AD) in radioembolisation patients. ***Materials and Methods:*** Evaluation was performed for 7 patients (2 CRC, 3 NET, 1 ICC, 1 breast cancer) with 11 radioembolisations who underwent a 30min total-body PET/CT scan up to 48h post radioembolisation with Y-90 microspheres. PET images were reconstructed using OP-OSEM with 2 iterations and 5 subsets (2i5s)/3i5s/4i5s, 0-mm/2-mm/4-mm post-reconstruction Gaussian filters and rebinned list-mode data of 20min. Subsequently, 3D AD maps were generated by convolution of the PET activity images with a dose kernel (ICRP soft tissue) obtained from Monte-Carlo simulations using GATE. Delineation of tumor and non-tumorous compartment (NTC) was performed to determine AD values Dmean and Dmax and compared with the reference reconstruction (30 min, 2i5s, 4-mm filter [1]) and pretherapeutic therapy planning. ***Results:*** Increasing the number of iterations to 4i5s resulted in an increase in Dmean by 2.0%±1.0/0.6±1.1% and Dmax by 9.6±4.4%/9.2±5.3% for tumor/NTC, respectively. Reducing the filter size to 0-mm resulted in an increase in Dmean by 1.2±0.7%/0.3±0.7% and Dmax by 9.0±4.4%/4.5±2.9% for tumor/NTC, respectively. Shortening the acquisition time to 20 min did not impact Dmean with an average change of 0.7±0.6%/1.0±1.5% (tumor/NTC) and maximum change of 4.0% (25 Gy to 26 Gy). Dmax increased by 3.0±3.7%/3.6±4.1% (tumor/NTC), with maximum change of 10.6% (123 Gy to 136 Gy, tumor) and 12.4% (145 Gy to 163 Gy, NTC). In comparison to pretherapeutic planning, determined Dmean values ranged from a close match 0.3%/6.5% to variations up to 50.0%/56.1% for tumor/NTC, respectively. ***Conclusion:*** The impact of reconstruction parameters on Dmean for tumor and liver was negligible and consistent down to 20min scan duration. However, Dmax is susceptible to reduction of filter size with an average increase of 9%/4.5% (tumor/NTC) and increase of iterations with an average increase of 9.6%/9.2%. The discrepancy observed in absorbed dose between pretherapeutic planning and therapy for some patients is likely to be related to differences in catheter position and therapy administration. As next step, we aim to validate the accuracy of the 3D AD maps obtained with the dose kernel with patient-individual Monte Carlo simulation. ***References:*** [1]Linder et al, Diagnostics 2023, doi:10.3390/diagnostics13223418

EPS-145

Influence of patient motion on image-based dosimetry for ^{177}Lu-PSMA therapy

S. Resch[1], *M. Rumiantcev[1], G. Liubchenko[1], M. Brendel[1,2,3], S. I. Ziegler[1], G. Böning[1], A. Delker[1];*
[1]LMU Klinikum Großhadern, München, GERMANY, [2]SyNergy, University of Munich, Munich, GERMANY, [3]DZNE - German Center for Neurodegenerative Diseases, Munich, GERMANY.

Aim/Introduction: 177Lu-PSMA patients often have progressive bone metastases that cause pain and make it difficult to lie still during post-therapeutic SPECT scans. Thus, they may perform sudden movements that distort quantification and dosimetry. The aim of this study was to investigate the effect of small patient movements on the lesions' and kidneys' activity quantification and time-integrated activity (TIA). ***Materials and Methods:*** SPECT/CT projections of a realistic patient phantom including 2 kidneys (k) and 20 lesions (l) with 25ml were simulated using Simind. In addition to a baseline position, shifted positions of the phantom were simulated with shifts of ±(5, 10 and 20)mm in the transverse plane. These projections were stacked and reconstructed to create motion affected tomographic image data. It was assumed that the patient stays in the translated position until the next movement. To compare the effects of short (5s) and long (15s) scan times per projection the following motion patterns were examined: uniform patterns, with movements occurring every 1 or 4min and patterns with linearly increasing occurrence of movement over time (max. 2 movements/min). For both scan times and all motion patterns, 20 SPECT scans with randomly selected movements were generated. Activity deviations from the baseline (without motion and 15s per projection) were determined and used for generating time-activity-curves (24, 48, 72, 168h p.i.) where each data point was assigned with a deviation corresponding to the results of the motion simulation. The corresponding TIA errors were estimated. ***Results:*** For the linearly increasing motion scenarios, 15s and 5s scan times showed similar results with mean activity deviations of -31±10% (l), -17±6% (k) and -29±19% (l), -19±13% (k). The corresponding TIA errors were -30±7% (l), -17±3% (k) for 15s and -27±15% (l), -17±8% (k) for 5s. For the 1min uniform patterns, the deviations are smaller for the shorter scan time per projection of 5s with -30±18% (l), -17±10% (k) than for 15s with -38±8% (l), -21±6% (k). The same holds for the 4min uniform patterns with deviations of -10±10% (l), 7±8% (k) for 5s and -34±17% (l), -20±11% (k) for 15s. These deviations result in TIA deviations of -10±7 (l), -7±5% (k) for 5s and -32±15% (l), -19±7% (k) for 15s. ***Conclusion:*** This preliminary study shows that small and only few motions during 177Lu-PSMA SPECT/CT scans can lead to significant errors in measured activities, TIAs and hence dosimetry. These results motivate optimization of current 177Lu-PSMA SPECT/CT dosimetry protocols.

EPS-146

Evaluation of automated γ-H2AX+53BP1 foci detection in ex vivo irradiated PBMCs

N. Zindler[1], *H. Scherthan[2], S. Schumann[1], J. Müller[2], M. Lassmann[1], U. Eberlein[1];*
[1]Departement of Nuclear Medicine University Hospital Würzburg, Würzburg, GERMANY, [2]Bundeswehr Institute of Radiobiology affiliated to the University of Ulm, Munich, GERMANY.

Aim/Introduction: This study aimed to establish and test the automated co-localized γ-H2AX+53BP1 DNA double-strand-break foci detection software "AutoFoci"[1] after low dose internal ex vivo irradiation of peripheral blood mononuclear cells (PBMCs) and to compare the results to our gold-standard "manual counting". ***Materials and Methods:*** Blood samples from 3 healthy volunteers were irradiated internally with 50mGy of [177Lu]LuCl2. Time points 0h, 3h, 6h and 24h after irradiation were used to analyse focus induction and DNA repair after automated scanning of extended focus images using Metafer 4. Automated foci analysis was performed using the following software adjustments: First, the ImageJ plugin "Cellect" was used to create single cell images. The maximum cell area of Cellect was adapted to 650µm2 to adjust to PBMCs and to adjust the pixel size to our settings(0.29µm). A manual check of the generated images was performed to discard artefacts. Secondly, AutoFoci was used with its published parameters to determine the number of co-localized γ-H2AX+53BP1 foci per cell. The results of the automated count were compared to the foci per cell values obtained by manual counting 100 cells of each sample by an experienced observer. ***Results:*** In average 471 cells per sample were detected and analysed with Autofoci. The radiation induced foci (RIF) values were calculated to compare the different volunteers with each other. For the different time points, the mean AutoFoci RIF values are: (1.01, range:0.551-1.296, t=0h), (0.43, range:0.067-0.883, t=3h), (0.65, range:0.231-1.292, t=6h), (0.12, range:-0.086-0.379, t=24h post irradiation). The manually counted mean RIF values are: (0.84, range:0.78-0.92, t=0h), (0.4, range:0.38-0.44, t=3h), (0.34,

range:0.28-0.45, t=6h), (0.07, range:-0.03-0.2, t=24h). The values show that the results of the automatic counting are subject to a high degree of scatter relative to the manually obtained values. Nevertheless, it is possible to distinguish between irradiated and non-irradiated samples. To evaluate the results of AutoFoci, the correlations to the gold-standard were determined. The first test person showed a very good correlation of R=0.96. For the second, 0.37 because of outliers at 3h and 24h. The third showed a correlation of 0.79 despite an outlier at 6h. Pooling all data of the volunteers revealed a correlation of 0.68. ***Conclusion:*** A first application of AutoFoci analysis provides meaningful results in the low dose range. More datasets have to be analysed and the software needs further adaptation to our experimental setup to achieve a better correlation and a lower degree of scatter. ***References:*** [1]Lengert et al., SciRep2018

Reconstruction of Time-Activity Curves in MRT Therapy Using Bayesian Unfolding

F. Nicolanti[1], *M. carlo[1], S. Morganti[2], R. Mirabelli[1], E. Solfaroli[3], R. Faccini[1], F. Collamati[2];*
[1]La Sapienza, Rome, ITALY, [2]INFN, Rome, ITALY, [3]National Center for Radiation Protection and Computational Physics, Italian National Institute of Health, Rome, ITALY.

Aim/Introduction: The precise estimation of dose absorbed by the tumor and healthy organs is essential to increase therapeutic effectiveness and optimize the treatment planning in Molecular Radiotherapy (MRT). To address this requirement, we proposed WIDMApp (Wearable Individual Dose Monitoring Apparatus), a multi-channel radiation detector and data processing system for in vivo patient measurement and collection of radiopharmaceutical biokinetic data [1,2]. The two key software components of WIDMApp are a Monte Carlo simulation and a deconvolution algorithm. ***Materials and Methods:*** We employed a Geant4 simulation with a male anthropomorphic ICRP110 phantom to model photon propagation in a patient undergoing Lu-177 prostate therapy. Six organs, including the prostate and four at-risk organs (liver, kidneys, spleen), were activated as radiation sources. Following the WIDMApp approach, a sensor was strategically placed near each organ to collect radiation counts over time. We developed a Bayesian deconvolution algorithm capable of estimating time-activity curves (TAC) in each organ from the signals detected by these sensors without assuming specific functional forms. To assess the algorithm robustness, we simulated four prototype patients with different organ biokinetic profiles, including single, double, triple exponentials, and mixed trends derived from prior literature. We studied the deviations of the reconstructed cumulative activity from the true values as a function of the algorithm initialization priors and the percentage of uniform noise affecting the detected signals. ***Results:*** This study demonstrates that by analyzing the time-dependent counts recorded by various detectors placed at specific locations on the patient's body, the Bayesian algorithm enables the reconstruction of cumulative organ activity for each of the four prototype patients. Notably, the algorithm achieved a 4% accuracy in cumulative activity reconstruction, even with 40% fluctuations on the measured signals. ***Conclusion:*** This study presents a novel Bayesian unfolding approach for reconstructing organ-specific time-activity curves, offering potential enhancements to personalized dosimetry in MRT compared to current methods. The algorithm's flexibility and robustness make it applicable to a wide range of clinical scenarios. ***References:*** [1] S. TEPS-001

Benefit of using an allergen-free diet to optimize gastric emptying scintigraphy

M. Cabanillas Perez[1], *P. Zaragoza-Ballester[2], S. Ruiz Solis[1], I. González Martin[1], M. Tabuenca Mateo[1];*
[1]Hospital Universitario12 de Octubre, Madrid, SPAIN, [2]Hospital Universitario 12 Octubre, Madrid, SPAIN.

Aim/Introduction: The objective of the study is to establish normal values for gastric emptying scintigraphy of a hypoallergenic food that can be used in all patients, by verifying that the protocol used in our service, based on the latest consensus guide published by the SNM (Society of Nuclear Medicine) from a solid diet, had a high percentage of food intolerances and allergies. ***Materials and Methods:*** When retrospectively reviewing gastric emptying since the implementation of the protocol of a solid diet composed of: 120 g pasteurized egg marked with 99m Tc-DTPA, 2 slices of white bread, 30 g of jam, 10 g of margarine and 200 ml of juice and acquisition of periodic images after ingestion at 0, 30, 60, 120, 180 and 240 minutes. We present a research project carried out in our service, based on a prospective and observational study in volunteers (good health, without gastrointestinal diseases). Gastric emptying of a new hypoallergenic meal was evaluated by scintigraphy at 0, 30, 60, 110, 120, 130, 180, 230, 240 and 250 minutes, in a SPECT-CT gamma camera, acquiring static images for one minute in anterior projection. and later, in a standing position (or sitting in specific cases), using a 128x128 matrix after ingestion. Diet composition: 100 g of pasteurized egg marked with 2 mCi of 99 mTc-DTPA, 100 g of cooked potato, 50 g of white rice, 16 ml of olive oil and 120 ml of water. The preparation consists of fasting for 6 hours. ***Results:*** Of the 84 patients reviewed since the implementation of the solid diet: 46 patients were able to complete the procedure without incident (54.8%), 11 of the patients were unable to complete the complete diet (13.1%) and 27 had food intolerances or allergies (32.1%): 17 intolerances (82% lactose, 18% gluten) and 10 allergies (60% fruit). That is why we started this study with the new diet, which included 50 healthy volunteers (age range 26-69), 29 women and 21 men), in order to obtain a normality curve for our service. ***Conclusion:*** The current diet that we use for gastric emptying, based on the latest consensus guide, has a high percentage of food intolerances and allergies (32.1%). For this reason, a multidisciplinary research project has been initiated in our service that has the objective is the standardization of a solid, allergen-free diet.

TEPS-002

The Benefits of SPECT/CT over whole body acquisition in bone imaging

M. Pohjolainen[1], *J. Toikka[2], J. Heikkinen[1];*
[1]The wellbeing services county of South Savo, Mikkeli, FINLAND, [2]The wellbeing services county of Kanta-Häme, Hämeenlinna, FINLAND.

Aim/Introduction: The frequency of tomography imaging of the skeletal accumulation of radiotracers has increased in Finland. Planar imaging of the bone has been performed usually as a whole body aqcuisition. As well known the underlying objects disturb the evaluation of the accumulations. Since the overall development of data processing has given the possibility to calculate tomographic images faster. Nowadays the acquisition and processing of the tomographig data takes only few minutes. Our department took SPECT/CT acquisition method in use two years ago. The aim of this study is to determine the benefits of SPECT/CT over conventional whole body acquisition. ***Materials and Methods:*** Fourteen patients were imaged with both whole body and SPECT/CT methods. An experieced nuclear medicine physician evaluated first whole body images. Later he took SPECT/CT-images under evaluation. Accumulations from whole body images were compared to the ones from SPECT/CT-images. Their clinical conclusions were compared, as well. ***Results:*** Two patients had normal accumulation in both acquisitions. Two patients had metastase suspected accumulations all over the skeleton. Four patients had degenerative type of accumulations. Totally in eight cases there were no significant new findings in SPECT/CT-images. With six patients unsure accumulations in whole body confirmed to appear bening type after SPECT/CT. ***Conclusion:*** Accumulations in neck or lower part of the lumbar spine were easier to define as degenerative type when evaluating from SPECT/CT-images. In one case SPECT/CT confirmed the accumulation to be in ureter rather than skeleton at all. Once the summation disturbed whole body images. And once spine accumulation was confirmed to be in skull after SPECT/CT evaluation. These results indicate that SPECT/CT is better method than planar whole body for bone imaging.

TEPS-003

Continuous SPECT acquisition mode provides faster scan time with comparable or better image quality to step-and-shoot for detection of reduced tracer uptake

R. Kappel[1], *L. G. Kristensen[1], P. C. Holdgaard[1], N. A. Bebbington[2];*
[1]Department of Nuclear Medicine, Lillebaelt Hospital - University Hospital of Southern Denmark, Vejle, DENMARK, [2]Siemens Healthcare A/S, Runevej 2, Aarhus, DENMARK.

Aim/Introduction: Step-and-shoot (SS) and continuous SPECT acquisition modes are available. SS acquires data only when detectors are stationary in each projection, using additional scan time for detector movement between projections. With continuous mode, detectors acquire data whilst moving continuously throughout the acquisition, hence no additional detector movement time is used, thereby reducing acquisition time compared with SS. Greater reductions in total scan time could be made in lung ventilation/perfusion imaging with two SPECT acquisitions. The aim was to determine whether continuous mode provides comparable image quality to SS, for faster imaging of reduced uptake. ***Materials and Methods:*** The NEMA image quality phantom was imaged with a hot background (111MBq Tc-99m-pertechnetate) and cold spheres. Six SPECT acquisitions were made on a conventional dual-headed SPECT-CT system, with low energy high resolution (LEHR) collimator. Acquisitions were made with 120 projections, with continuous and SS acquisition modes, at 5, 10 and 20 minutes sampling time, and acquisition times decay-corrected to the start of the first acquisition. Reconstructions were made with 16 updates, resolution recovery and CT-based attenuation correction. Volumes-of-interest were assigned to the four largest spheres (≥17mm, relevant to sizes of lung perfusion defects) and the background. Contrast-to-noise ratio (CNR) was calculated for each sphere in each dataset and compared between acquisition modes at each sampling time. ***Results:*** Using SS mode resulted in an additional 3:18 mins scan time for equivalent sampling time, as compared with continuous. CNR values, although dependent on sphere size and sampling time, were comparable between continuous and SS modes at 5 mins sampling, with CNR measured in 17-37mm spheres at 14.9-18.1 and 14.8-17.9, for continuous and SS respectively. At longer sampling times, image quality was better for continuous as compared with SS, with CNR measured at 21.6-24.7 vs. 18.0-22.4 for 10 mins, and 27.4-33.2 vs 24.3-31.1 for 20 mins sampling. ***Conclusion:*** Continuous mode provides >3 mins reduction in scan time per SPECT acquisition, for image quality comparable to or better than SS, when imaging reduced uptake. This allows a total scan time reduction of >6.5 mins for lung ventilation/perfusion SPECT comprising two acquisitions, making this examination more tolerable for patients who may have difficulty breathing and lying flat. Since differences in resolution would be more likely detected with the LEHR collimator, it can be inferred that continuous mode could also be used with lower resolution collimators, for same scan time reduction and comparable image quality to SS.

TEPS-004

Optimizing image quality and scan time for DatScan studies on CZT -based 3D digital SPECT-CT - comparison to current clinical protocol on conventional SPECT-CT

A. Keinänen, *S. Halttunen, H. Gröhn, M. Hakulinen;*
Pohjois-Savon hyvinvointialue, Kuopio University Hospital, Kuopio, FINLAND.

Aim/Introduction: We scan approximately 200 DatScan patients per year, and availability of this study is 1-2 months. Current clinical protocol uses conventional SPECT-CT with an acquisition time of 35min, which can be challenging for this patient group. To scan more patients per day and increase patient comfort, we explored options to shorten scan time by using our 3D digital SPECT-CT (3D-CZT).The aim was to find optimal reconstruction for our protocol and see if we can achieve equal or better image quality with shorter scan time using 3D-CZT compared to current clinical protocol. We also wanted to study if EARL reference database could be used with 3D-CZT data. ***Materials and Methods:*** Twelve patients referred to 123I DatScan study were scanned on 3D-CZT and on conventional SPECT-CT. Scans were performed 3-4h after injection with 20min acquisition time on 3D-CZT and according to clinical protocol on conventional SPECT-CT. To optimize scan time, 15min and 10min scans were rebinned from 20min 3D-CZT data. Data was reconstructed with OSEM with and without PSF correction. Image quality was evaluated based on contrast, noise and visually by experienced nuclear medicine physician, rating best image or equal image quality. For EARL database analysis we also scanned DatScan-phantom. ***Results:*** Preliminary results from five patients are presented. Based on visual evaluation of the data, physician rated image quality on 3D-CZT better or equal

in all cases. When decreasing scan time small average change of 6.0% in contrast was observed whereas noise level increased as expected, on average 44.6%. By visual evaluation PSF improved image quality which was also seen in as average increase of 17.9% in contrast. Possibility to use EARL reference database with 3D-CZT data will be further evaluated in ongoing data analysis of phantom and patient data. ***Conclusion:*** By using 3D-CZT we can shorten scan time from current 35min to 15min or even to 10min, if needed. This would be significant improvement to patient comfort, and it would allow us to increase number of scans per day. Based on preliminary analysis, image quality is equal or better compared to our current clinical protocol, but we are still looking to optimize PSF reconstruction which improves contrast further.

TEPS-005

Challenges Imaging Transposition of the Great Arteries on a Dedicated Cardiac Single Photon Emission Computed Tomography Camera - A Case Report

K. Aktemel[1], *R. McDade[2];*
[1]Department of Nuclear Medicine, Gartnavel General Hospital, Glasgow, UNITED KINGDOM, [2]Department of Nuclear Cardiology, Glasgow Royal Infirmary, Glasgow, UNITED KINGDOM.

Aim/Introduction: Transposition of the great arteries (TGA) is a congenital cardiac defect as a result of embryological discordances between the pulmonary trunk and aorta1. In Nuclear Cardiology, imaging TGA is rare. Myocardial Perfusion Imaging (MPI) can evaluate myocardial viability as a result of coronary disease1. Patient X has a complex cardiac history, diagnosed with congenitally corrected (cc)-TGA at birth; the left atrium is connected to the right ventricle (RV), and the left ventricle (LV) connected to the right atrium1. They had continuous chest pain over recent years, resulting in the requested MPI to evaluate myocardium viability. This case report aims to discuss challenges Technologists/Radiographers face when imaging a rare heart disease e.g. cc-TGA on a dedicated cardiac cadmium zinc telluride (CZT) Single Photon Emission Computed Tomography (SPECT) camera. ***Materials and Methods:*** The patient underwent Technologist lead Regadenoson stress. At one minute of arm lifts Regadenoson was given and TL201- Thallous Chloride, 30 seconds later. Images were acquired less than 20 minutes post-injection to visualise stress due to TL201 time sensitivity as it actively redistributes. Positioning the patient on the camera presented as a challenge. The patient was centred more over the LV which was morphologically the RV. There was initial confusion on what exactly was the LV. The duty physicist was called, and in conversation it was decided to acquire over the morphological RV. ***Results:*** Two consultant cardiologist with support for a consultant clinical scientist reported this images based on the morphological RV. It summarised that the morphological RV which lies in the LV position had reduced perfusion mid-basal anteriorly and inferiorly. There was no significant improvement on redistribution imaging at 3 hours 11 minutes. There is a limited view of the morphological LV in the RV position. No evidence of reversible ischaemia. ***Conclusion:*** Imaging cc-TGA patients on a dedicated cardiac CZT-SPECT using TL201 presents difficult time sensitive challenges with positioning. Awareness of how to image patients with rarer heart diseases, where positioning on the scanner may differ from what is typically done, must be considered before imaging. Furthermore, multidisciplinary team involvement for rarer heart conditions prior to imaging is essential to ensure the correct data is acquired. ***References:*** 1. Kumar TKS. Congenitally Corrected Transposition of the Great Arteries. J Thorac Dis [Internet]. 2020 [cited 20 April 2024]; 12(3): 1213-1218. TEPS-006

Correlation of Inflammatory Markers with ^{18}F FDG PET/CT Imaging in Patients with Pyrexia of Unknown Origin

A. Jaiswal, *C. Ganapathy, N. Damle, A. Venugopal, M. Gupta, S. K. Velliangiri, L. Goriparti, J. Krishna P, C. Bal, M. Tripathi, G. Arora, P. Kumar;*
Department of Nuclear Medicine, All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: Pyrexia of Unknown Origin (PUO) is defined as fever >38.3 degree Celsius on at least two occasions with duration of more than 3 weeks in immunocompetent patients, post extensive baseline evaluation.The aim of our study is to investigate the correlation between different inflammatory markers in blood with the ratio of standardized uptake value (SUVmax) of spleen to liver in 18F FDG PET/CT in the patients with pyrexia of unknown origin (PUO). ***Materials and Methods:*** Data of consecutive patients, clinically suspected/diagnosed with PUO, who underwent 18F FDG PET/CT at our center from April 2023 to March 2024, was retrospectively reviewed. The spleen to liver SUVmax ratio was correlated with inflammatory markers-erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), and lactate dehydrogenase (LDH). Quantitative variables were checked for normality using Shapiro-Wilk test and the relationship between the variables was evaluated using Pearson's correlation. ***Results:*** 164 patients with Pyrexia of Unknown Origin (PUO), comprising 81 females and 83 males (median age: 46.5 years), underwent 18F FDG PET/CT evaluation at our center. Of the 110 patients in whom ESR levels (mean: 41.46 mm/hr) were obtained within 72 hours of PET/CT, the spleen to liver SUVmax ratio (mean: 1.14), showed a positive correlation with plasma ESR levels ($r=0.585$, $p<0.001$). In the 46 patients in whom LDH levels were obtained 72 hours within PET/CT study, a positive correlation was noted ($r=0.545$, $p=0.022$) between LDH levels (mean: 486U/L) and spleen to liver SUVmax ratio (mean: 1.22). Among the 33 patients with documented CRP levels (mean: 35.47 mg/L) within 72 hours of PET/CT study, a significant correlation ($r=0.517$, $p<0.01$) was observed with spleen to liver SUVmax ratio (mean: 1.13). ***Conclusion:*** The study findings suggest that spleen to liver SUVmax ratio can be used as an indirect functional marker of the degree of inflammation in patients with PUO and it correlates with inflammatory markers such as ESR, CRP and LDH. Further studies may help in ascertaining if such PET parameters can potentially point towards the etiology of PUO.

TEPS-007

BMI-Based Myocardial Perfusion Imaging: Reducing Patient Exposure by Optimizing the Administered Activity

A. Martins[1,2], *I. Rodrigues[1,2], M. Vieira[1], P. Almeida[1,3], S. Carmona[1], T. Martins[1], A. Alvernaz[1], L. Oliveira[1];*
[1]Joaquim Chaves Saúde, Lisbon, PORTUGAL, [2]Cross I&D Lisbon Research Center, Portuguese Red Cross Health School, Lisbon, PORTUGAL, [3]Universidade de Lisboa, Faculdade de Ciências, Instituto de Biofísica e Engenharia Biomédica, Lisbon, PORTUGAL.

Aim/Introduction: This study evaluates the differences of using Body Mass Index (BMI) or Patient Weight to calculate the administered activity on Myocardial Perfusion Imaging (MPI) and its potential implications on radiation dose optimization. ***Materials and Methods:*** Mastrocola LE et al. (2020) described that the injected activities can be adjusted using BMI: 8 mCi for BMI

<25; 9 mCi for BMI [25-30[; 10 mCi for BMI [30-35[; 12 mCi for BMI >35 for 1-day MPI protocols.We have adjusted linear, logarithmic and exponential models and performed a least-squared analysis to the BMI points previously described, creating a BMI Model. The exponential model had the best fit to the curve with an R2=0.9822 for y = 4.0833e0.0264(BMI). We have determined the theoretical activity for the stress and rest injection by this BMI Model and using a model based on weight [Activity(mCi) = (patient weightx10)/70] for a sample of 103 patients [average weight of 75.39±14.50kg, average height of 1.65±0.10m, and corresponding BMI of 27.64±3.88] who underwent an 1-day stress-rest protocol. We also calculated the total effective dose for the two activities administered for each patient based on ICRP 128. The mean differences between the two methods for theoretical administered activities (1st and 2ndinjection) and total effective dose were compared by pared-samples t-test (SPSS25®). ***Results:*** For all the selected patients, the activities administered were based on the BMI model and good diagnostic accuracy images were assured by a Nuclear Medicine Physician. For first injection, average activities calculated were 8.52±0.88 mCi (315.24±32.56 MBq) by the BMI method and 10.77±2.03 mCi (396.48±75.11 MBq) for the weight method. For the second injection average activities calculated were 25.54±2.64 mCi (944.98±97.68 MBq) by the BMI method and 32.20±6.09 mCi (1195.1±225.33 MBq) for the weight method. Differences between the two methods were -2.25±1.53 mCi (-83.25±56.61 MBq) in the 1st injection and -6.76±4.58 mCi (-250.12±169.46 MBq) in the 2nd injection. For all paired sample test results, statistically significant differences were observed between the BMI and weight methods (p=.000). The total effective dose showed a reduction of -2.22±1.85 mSv in the case of the BMI method when compared to the weight-based method. ***Conclusion:*** The BMI method, according to the formula y = 4.0833e0.0264(BMI), allowed a better optimization of administered activity in 1-day MPI protocols, resulting in a lower effective dose for the patient compared to the previously used method based only on a patient weight factor.

TEPS-008

^{18}F-FDG PET/CT examinations in patients with Li-Fraumeni Syndrome

D. Mouhi, *M. Stokkel, E. Aalbersberg;*
NKI-AVL, Amsterdam, NETHERLANDS.

Aim/Introduction: Li-Fraumeni Syndrome (LFS) is a hereditary cancer predisposition syndrome in which cellular tumor antigen p53 is mutated. Patients with LFS who receive radiation are more susceptible to radiation exposure effects. In order to minimize stochastic and deterministic effects of radiation in patients with LFS who undergo [18F]FDG PET/CT examinations, protocols need to be adjusted for this specific patient group. The aim of this study is to share knowledge about LFS so involved parties can prevent an (unnecessarily) high exposure by taking precautionary dosimetric measures. ***Materials and Methods:*** To reduce radiation dose to LFS patients, the following changes were made to standard [18F]FDG PET/CT protocols: lowering of administered activity (3.5 MBq/kg standard protocol vs 120 MBq activity in dose-reduced protocol), a doubling of time per bed position (BP) in PET (4 minutes/BP instead of 2 minutes/BP), LD-CT dose reduction measures (25 mAs instead of 43 mAs), and hydration measures (use of urinal catheter on indication and diuretics to lower the time of exposure to the urogenital system). With the installment of a LAFOV PET/CT scanner, the administered activity for patients with LFS is lowered from 1.5 MBq/kg to 0.3 MBq/kg (with a minimum activity of 15 MBq) with a quadrupling of time/BP (20 minutes instead of 5 minutes). ***Results:*** In a retrospective period of 13 years, 17 LFS patients (6 male, 11 female) received a total of 35 dose-reductive [18F]FDG PET/CT scans. The most common indications for [18F]FDG PET/CT in LFS patients was breast cancer (33%) followed by lung cancer (17%). The scan quality is comparable to [18F]FDG PET/CT scans using a regular acquisition protocol and regular patient preparation protocol. The dose-reductive protocol has been edited in the past 10 years to facilitate for newer models PET/CT-scanners in which use of lower mAs on LD-CT provides comparable image quality. ***Conclusion:*** 17 LFS patients received a total of 35 [18F]FDG PET/CT scans being scanned according to dose-reductive protocol. The scan quality is comparable to [18F]FDG PET/CT scans using a regular acquisition- and patient preparation protocol. Dose-reductive protocols are successfully used in LFS patients, providing images of good quality and an ALARA radiation dose for LFS patients.

TEPS-009

Validation of reduced patient dose for [18F]FDG PET/CT brain examinations through list-mode reconstruction

M. Rode, *P. Holdgaard, P. Dolliner;*
Lillebaelt Hospital, University Hospital of Southern Denmark, Vejle, DENMARK.

Aim/Introduction: As part of our efforts to fulfill the ALARA principle, we wanted to reduce our administered fixed dose of 200 MBq [18F]fluoro-2-deoxy-D-glucose (FDG) to brain PET CT examinations. The EANM recently recommend an administered dose of 150 MBq or even lower. The aim of this study was to validate image and diagnostic quality with reduced patient dose without changes in acquisition time. The hypothesis was that assessing PET images at different acquisition time frames would be a useful method to evaluate PET images with different administered doses. ***Materials and Methods:*** Forty dedicated brain PET CT scans were acquired on a LSO PET/CT system with a time-of-flight (TOF) of 214 ps. Acquired datasets were reconstructed list-mode by using a five and a ten minutes acquisition dataset. Datasets were processed and displayed in an imaging software system used routinely. An experienced nuclear medicine physician assessed the qualitative pattern of each dataset by using visual criteria only. Furthermore, the diagnostic PET pattern was evaluated and it was assessed whether the diagnostic outcome was identical regardless of acquisition time. ***Results:*** Forty examinations were included in the study, resulting in 80 datasets. Comparing the five and ten minutes datasets showed that all examinations were of the same qualitative PET pattern. There was one examination with visually lower uptake in the five-minute acquisition, however the PET pattern was identical, hence the diagnostic outcome for all 40 patients was the same, regardless of acquisition time. With a 50% reduction in acquisition time, our goal was to reduce the administered dose by 50% as well. The EANM Guidelines recommends a factor 2 dose reduction for digital systems with TOF < 400 ps. However, brain PET CT scans are performed on two systems, one with TOF < 400 ps. and one with TOF > 400 ps. Therefore, we were not able to directly transfer the results to both systems, leading to a fixed dose of 150 MBq for all patients. ***Conclusion:*** As images from the five and ten minutes acquisition times were of equal diagnostic quality, the administered patient dose was reduced by 25% to 150 MBq. List-mode reconstructed datasets of PET brain scans are a simple and useful method to simulate dose reduction by reviewing examinations at different time of acquired frames. Performing this study on the digital PET/CT system with TOF > 400 ps., could lead to a further reduction in patient dose.

TEPS-010

Positronium lifetime measurements in patients with a commercial long axial field-of-view PET/CT

A. Cardoso[1], *L. Mercolli[1], W. Steinberger[2], A. Afshar-Oromieh[1], F. Caobelli[1], M. Conti[3], C. Mingels[1], T. Pyka[1], A. Rominger[1], H. Sari[4], R. Seifert[1], K. Shi[1], M. Viscione[1];*
[1]Department of Nuclear Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, SWITZERLAND, [2]Siemens Medical Solutions USA, Inc, Knoxville, TN, UNITED STATES OF AMERICA, [3]Siemens Medical Solutions USA, Inc., Knoxville, TN, UNITED STATES OF AMERICA, [4]Siemens Healthineers International AG, Zürich, SWITZERLAND.

Aim/Introduction: Before a positron annihilates with an electron from the surrounding tissue, it often forms a bound state with an electron. This metastable electron-positron bound state is called positronium. The lifetime of positronium depends on the size of intramolecular spaces and on the concentration of oxygen. Therefore, measuring the positronium's lifetime in patients could provide additional information about the local tissue composition, which is possibly of diagnostic value. We report the first in vivo positronium lifetime measurements with a commercial long axial field-of-view (LAFOV) PET/CT scanner. ***Materials and Methods:*** Three subjects (m 58y, f 39y, m 39y) underwent a standard PET/CT scan with [68Ga]Ga-PSMA-11, [68Ga]Ga-DOTATOC and [82Rb]Cl. In addition, the subjects were scanned using a special acquisition mode which saves the single-crystal interactions, i.e. in the so-called singles mode. We explain why we can only measure positronium lifetimes with radionuclides that emit positrons together with prompt photons. In addition, we discuss the selection of triplet events, i.e. the detection of a prompt photon and two annihilation photons that originate from the same nuclear decay, and the data processing that is required for the determination of positronium lifetimes. ***Results:*** We illustrate the practical operation of the singles mode on a commercial LAFOV PET/CT system and how a singles mode scan is performed and analysed. The positronium lifetimes measured in different organs of the three patients are reported. Most interestingly, the ortho positronium lifetimes in the left and right heart chambers (combining atria and ventricles) of the [82Rb]Cl patient are 1.38 ± 0.12 ns and 1.66 ± 0.15 ns, respectively. This may hint towards the different blood oxygenation levels in the two heart chambers. ***Conclusion:*** Positronium lifetime measurements in organs are feasible on a commercial LAFOV PET/CT system and may provide additional diagnostic information to the clinicians in the future.

TEPS-011

Can Delayed Pelvic PET/CT with [^{68}Ga]Ga-PSMA-11 Improve Prostate Cancer Detection?

N. Fernandes, *T. Hussain, B. Sanghera, C. Pacheco, B. Ribeiro, M. Krishnamurthy;*
Barts Health NHS Trust, London, UNITED KINGDOM.

Aim/Introduction: [68Ga]Ga-PSMA-11 PET/CT is a non-invasive diagnostic technique to image prostate cancer with increased PSMA expression. Due to its urinary excretion, high residual activity in the urinary system may lead to halo artefacts, and activity in the ureters may lead to false positive findings. Late imaging may be useful to identify lesions in close proximity to the ureter/bladder.The aim of this study is to evaluate the utility of additional delayed pelvic imaging by comparing lesion detection rate, diagnostic confidence, relative image quality and lesion SUV measurements. ***Materials and Methods:*** 99 continuous [68Ga]Ga-PSMA-11 patients who met the EANM guideline PSMA imaging criteria regarding uptake time (50 - 100 min. WB p.i.) and dose administered (1.8 - 2.2 MBq/kg), were included. The patient protocol consists of skull base to mid-thigh imaging (5 minutes pelvic bed) followed by a localised 1 bed 5-minute pelvic image. Patients micturated before each image was acquired. The pelvic area of whole-body scan (WB) was initially reviewed followed by delayed post-micturition pelvic imaging. Two experienced consultants analysed the images for location and number of lesions detected. Where there were differences, consensus was obtained. Images were evaluated regarding lesion count, location, readers' confidence score, image quality and to see if there was a change in patient outcome using the extra pelvic view. Scanner followed recommended QA programmes to ensure accurate SUV measurements. ***Results:*** WB [68Ga]Ga-PSMA-11 PET-CT and Delayed pelvic imaging detected PSMA avid pelvic lesions in 70 patients. The post-micturating pelvic imaging detected no additional lesions. Between WB and post micturating pelvic imaging there was a median increase of 6.6% in SUVmax ($p = 0.009$) and a 0.3% median decrease in SUVpeak ($p = 0.008$). Reader's confidence score was changed in 3 patients after evaluating post-micturating pelvis imaging. Image quality was better on pelvis imaging on 4 patients. In total, the readers found the additional pelvic imaging did not change patient's management in the total of 99 patients evaluated. ***Conclusion:*** Additional post micturition pelvic image did not show an increase in lesion detection. Post micturition pelvic imaging slightly improves diagnostic confidence and image quality. For all patients, eliminating post-micturation pelvic imaging would not alter patient management, however, it would enhance patient throughput and satisfaction. ***References:*** Wolfgang P. Fendler et al. (2017). 68Ga-PSMA PET/CT: Joint EANM and SNMMI procedure guideline for prostate cancer imaging: version 1.0. Eur J Nucl Med Mol Imaging, 11

TEPS-012

Optimising CT scan direction for different PET-CT examinations at anatomical high/low attenuation boundaries when using large CT detector width

K. Christensen[1], *N. A. Bebbington[2], L. L. Østergård[1], P. C. Holdgaard[1];*
[1]Lillebaelt University Hospital, Vejle, Vejle, DENMARK, [2]Siemens Healthcare A/S, Aarhus, DENMARK.

Aim/Introduction: Tube current modulation (TCM) is standard practice for optimising radiation dose and image quality (IQ) across the CT scan range. However, TCM can present challenges for IQ at boundaries of low and high attenuation (e.g. neck/shoulder) with wide detectors, which can cover low and high density regions in the same rotation. Thus, scan direction affects TCM. The aim was to study the differences in whole-body mAs profiles between craniocaudal and caudocranial scan directions on a 128-slice system, and determine which direction is most suitable for the different types of PET-CT exams without contrast enhancement. ***Materials and Methods:*** CT scans of an anthropomorphic whole-body-phantom were made in standard and obese configurations with arms up (whole-body scan), and arms down (head and neck scan) using a 128-slice system, with craniocaudal and caudocranial scan directions. Delivered mAs was recorded in each slice and mAs profiles plotted in the Z-direction, for each scan. The ratio of delivered mAs was calculated between the two scan directions for each slice (highest/lowest) to detect anatomical areas with large relative difference in delivered mAs. It was then determined which scan direction is optimal for different PET-CT exams, according to which direction gives the highest mAs in the prioritised anatomical regions. ***Results:*** Scanning in the direction of low-to-high attenuation provided

the highest mAs at low/high density boundaries. For the standard phantom/arms-up, craniocaudal provided higher mAs at the boundaries of the vertex/arms (maximum mAs ratio 3.8), neck/shoulder (2.5), lung/liver (1.5) and abdomen/pelvis (1.9). With arms-down, a higher ratio was seen at the neck/shoulder (4.6). Caudocranial provided highest mAs at the skull-base/elbows (3.4), thorax/shoulder boundary (2.9), mid-liver (1.4) and femur/pelvis boundary (1.8). Similar findings were made with obese configuration, except that caudocranial delivered higher mAs at the pelvis/abdomen boundary (1.6). The offset in mAs profiles was consistent with detector width, suggesting that the TCM profile is based on the position of the first detector in the direction of travel. ***Conclusion:*** Large differences in delivered mAs were seen between scan directions at a given location. However, knowledge of important anatomical locations for given scan types allows scan direction to be optimised according to PET-CT exam, using the whole-body mAs profiles generated in this study. Craniocaudal appears optimal for parathyroid imaging (prioritising thyroid bed IQ), whilst caudocranial is preferred for PSMA (priortising prostate), whilst for FDG oncology examinations it depends on the specific clinical indication and expected disease sites.

TEPS-013

Evaluation of the effect of data-driven motion correction on $^{13}NH_3$ myocardial perfusion PET/CT

K. Haring[1], *R. J. J. Knol[1], O. I. Mendoza-Ibanez[2], F. M. van der Zant[1], S. V. Lazarenko[1];*
[1]Northwest Clinics, Alkmaar, NETHERLANDS, [2]University Medical Centre Groningen, Groningen, NETHERLANDS.

Aim/Introduction: Myocardial bloodflow (MBF) measurements on dynamic myocardial perfusion PET/CT are frequently hampered by errors produced by patient movement, and errors up to 500% have been described. Data-driven motion correction (DDMC) algorithms can be used to improve both image quality and quantitative MBF measurements in cardiac PET imaging studies. For the present study, a prototype DDMC algorithm, able to track and correct movement, was applied to dynamic myocardial perfusion PET/CT data. This study aimed to assess the prototype algorithm's impact on MBF measurements and generic scan quality parameters of 13NH3 myocardial perfusion PET/CT scans. ***Materials and Methods:*** Datasets of 28 patients who were referred for 13NH3 PET/CT between January 2020 and November 2022, were retrospectively included in this study. The prototype DDMC algorithm was used to correct for patient movement and then the data was further reconstructed. Next, a comparison was made between both regional MBF measurements of motion corrected versus non-motion corrected dynamic datasets and analyzed using paired t-tests ($p < 0.05$ was considered significant). Also, the effects of the DDMC algorithm on the automatic myocardial contour detection was assessed by two experienced readers (KH, SL), as well the effects on interference of extracardiac 13NH3 uptake on dynamic PET/CT data. ***Results:*** Significant differences in MBF were detected between data driven motion corrected versus uncorrected datasets in the RCA perfusion territory in both stress (p 0.016) and rest (p 0.009), and in the LCX territory in stress (p 0.048) and rest (p 0.006). Measurements of the LAD territory showed no significant differences between corrected versus uncorrected scans for both stress (p 0.210) and rest (p 0.485). Upon visual inspection, the original dynamic images showed an incorrect contour detection of the myocardium in 3.6% of the rest scans and 14.3% in stress. After motion correction, contour detection was flawless in all datasets. In the uncorrected data, extra-cardiac uptake of 13NH3 obscuring the inferior wall was present in 32.1% of the dynamic rest datasets and 39.3% in stress. After motion correction this was reduced to 3.6% of the rest and 17.9% of the stress datasets. All scans with remaining interference of extracardiac uptake on the myocardial 13NH3 uptake, did improve visually after correction by the DDMC algorithm. ***Conclusion:*** Application of DDMC to 13NH3 myocardial perfusion PET/CT scans optimizes MBF quantification, facilitates automatic contour detection and decreases interference of extracardiac 13NH3 activity on visualization of myocardium.

TEPS-014

Residual Activities in Lu-177 Molecular Radiotherapy - How Much is Left Out of the Patient Dose?

A. Acheva, *M. Ladev, S. Rajala, H. Ryyppö, M. Salomaa, V. Ahtiainen, K. Nousiainen, V. Reijonen;*
HUS Comprehensive Cancer Center, Molecular Radiotherapy Unit, Helsinki, FINLAND.

Aim/Introduction: In this study, we aimed to evaluate whether residual activity forms a significant part of the dose prescribed to the patient - and how much this varies - in Lu-177-DOTATATE (dodecane tetraacetic acid-octreotate) and Lu-177-PSMA (prostate specific membrane antigen) treatments. Therefore, we made measurements to determine the residual activities in syringes, tubings, and IV (intravenous) administration sets collected post-administrations. ***Materials and Methods:*** We evaluated the residual activity in the drug administration equipment of 32 Lu-177-DOTATATE (5.5 GBq or 7.4 GBq diluted in 100 ml saline and administered as 30 min infusion) and 37 Lu-177-PSMA (5.5 GBq or 7.4 GBq administered as 1-5 min injection) treated patients. We measured the residual activities in the glass bottles or syringes and 3-way stopcocks with a radionuclide calibrator (same Lu-177 setting for all). The IV infusion set activities were evaluated using SPECT-CT imaging. The residual activities were then subtracted from the initially measured activity of the radiopharmaceutical with decay correction, and the resulting administered activity was compared with the prescribed activity. ***Results:*** For Lu-177-DOTATATE, the mean difference between the administered and prescribed activity was -1.2% (standard deviation 1.7%, range -5.2 to +1.58%). The IV-lines contained significantly smaller amounts of activity (M=13.1 MBq, SD=5.3) compared to the bottles (66.0 MBq, SD=13.6, $p<0.0001$). In PSMA treatment, the administered activity differed from the prescribed activity by -1.8% (SD=2.7%, range -9.0% to 2.8%). There were no significant differences between 5.5 and 7.4 GBq target activities. In a few of the studied patient cases, the disparity exceeded 5% (six in total, comprising one DOTATATE and five PSMA treatments). The absolute difference between administered and prescribed activities was smaller for Lu-177-DOTATATE (M=1.6%, SD=1.5%) than for Lu177-PSMA (M=2.4%, SD=2.1%); $t(67)=2.0$, $p=0.05$, which is probably due to the different flushing technique. ***Conclusion:*** Upon analyzing the residual activities in the radiopharmaceutical administration equipment, we found out that the mean difference between the prescribed and administered activities was well within our tolerance range of ±5% for both Lu-177-DOTATATE infusions and Lu-177-PSMA injections. Thorough flushing in the end of the treatment is encouraged. The administration set material (glass bottles versus plastic syringes) and dilution of the radiopharmaceutical may influence outcomes.

TEPS-015

Efficacy of adenosine vasodilatation in Rubidium PET perfusion for risk stratification prior to renal transplantation

A. Tsvetanova, *J. Hidalgo, S. Townrow, B. Ribeiro, T. Hussain, L. Menezes;*
Barts Health NHS Trust - Nuclear Medicine, London, UNITED KINGDOM.

Aim/Introduction: Vasodilator nuclear stress testing is frequently requested for risk stratification prior to kidney transplantation. However, Adenosine receptor expression is reduced in end stage renal failure (1), which may affect the efficacy of vasodilatation, rendering the scan less reliable.This quality improvement project sought to demonstrate the efficacy of adenosine vasodilatation in candidates for renal transplantation undergoing Rubidium PET perfusion. ***Materials and Methods:*** A retrospective search of the department database between January 2020 and February 2023 to identify patients referred for risk assessment prior to renal transplantation.The haemodynamic effects of adenosine, visual reduction splenic counts during stress compared to rest, global myocardial flow reserve (MFR), and normalcy rates were recorded. ***Results:*** 154 patients were identified who had been referred for Rubidium imaging as part of the renal transplant pathway. 87 of these were male (56.5%), 67 were female (43.5%) with an average age of 54.3 ± 11.7 years. 81 patients (52.6%) included a calcium score as part of their procedure; i.e.: had no known coronary artery disease. 148 patients received adenosine at 140 µg/kg/min. One of these patients required a second infusion at 210 µg/kg/min due to inadequate reduction in splenic activity initially. 6 patients required the higher infusion rate of 210 µg/kg/min due to caffeine consumption beforehand. All of the patients completed both the rest and stress imaging. All patients were adequately stressed, according to a combination of haemodynamic change, splenic reduction of counts on stress, and global myocardial flow reserve, 153/154 after their original adenosine infusion and 1/1 after infusing at a higher rate. ***Conclusion:*** Adenosine administration at the usual concentration achieves satisfactory vasodilation and clinical results in Rubidium PET perfusion. The higher dose also attenuates the effect of caffeine.Despite the theoretical risk with reduced adenosine receptor expression in end stage renal failure, adenosine achieves effective vasodilatation in all patients undergoing MPS for risk assessment prior to renal transplantation. ***References:*** 1) Carrega L, Fenouillet E, Giaime P, Charavil A, Mercier L, Gerolami V, Berge-Lefranc JL, Berland Y, Ruf J, Saadjian A, Dussol B. TEPS-016

Pilot study on the technical fusion of 3D ultrasound and SPECT/CT data sets in thyroid imaging

J. Heute;
Nuklearmedizin Telfs, Telfs, AUSTRIA.

Aim/Introduction: Hybrid imaging in nuclear medicine has become an increasingly important part of diagnostics, but ultrasound imaging has received little attention in the fusion process so far. The aim of this pilot study is the technical fusion of 3D ultrasound data sets and single photon emission computed tomography/computed tomography (SPECT/CT) data sets on an external workstation using the latest technology in nuclear medicine. Instead of being limited to separate SPECT, CT and ultrasound data sets this study uses combined SPECT/CT data sets from one and the same hybrid device. The CT images were used as the basis for the fusion of CT and ultrasound data sets. The fused US/SPECT data subsequently served both as a result and as an optical quality control. ***Materials and Methods:*** The methodology was chosen based on technical scientific documentation. As part of the pilot study 14 data sets (from 7 patients) were fused. The existing data, consisting of the 3D ultrasound and the SPECT/CT, were analysed and fused in a fusion software. ***Results:*** As a result, a process method for the fusion procedure was developed. Additionally, 13 landmarks selected and tested, serving as anatomical reference points for fusion. The outcome was an average deviation of 4.91 mm and an average fusion time of 6.17 min. ***Conclusion:*** It is possible to fuse data using offline fusion without any limitations in time. Although there still is a need for further research on using this fusion on a regular basis, it is evident that this type of fusion of data sets could be an important tool for diagnosing, planning treatments and monitoring various thyroid diseases in the future.

TEPS-017

Developing communication support for information-sharing to patients in conjunction with an ^{18}F-FDG-PET/CT examination

C. Andersson[1], *B. Möller-Christensen[2];*
[1]Dept. of Surgical Sciences, Uppsala University, Uppsala, SWEDEN, [2]Dept. of Natural Science and Biomedicine, Jönköping University, Jönköping, SWEDEN.

Aim/Introduction: An 18F-FDG-PET/CT examination requires the patient to follow instructions before and during the examination procedure to ensure a high image quality. There is thus a need to develop ways to ensure that patients absorb the information given in connection with the examination. Aim To develop communication support for information sharing related to an 18F-FDG-PET/CT examination. ***Materials and Methods:*** The study has a qualitative design adapting a multiphase structure. A prototype of the communication support consisting of illustrations and text related to an 18F-FDG-PET/CT examination was developed. Interviews were conducted with patients scheduled for an 18F-FDG-PET/CT examination for the first time and questionnaires were collected from healthcare professionals with experience of 18F-FDG-PET/CT. The communication support was revised until consensus about the material. ***Results:*** The results are based on interviews with patients (n=10) and questionnaires collected from healthcare professionals (n=9). The overall theme revealed that information in conjunction with the 18F-FDG-PET/CT examination is a balancing act between text and illustrations. The analysis showed two categories; "illustrations as a complement" and "easy to understand lay-out". ***Conclusion:*** The participants strengthened the development of the communication-support by bringing in valuable viewpoints from various perspectives. The results support a person-centered approach, where the information in conjunction with an ^{18}F-FDG-PET/CT examination can be adapted to each patient's needs as a balancing act between text and illustrations.

TEPS-018

The role of the technologist - a case study

M. Attard;
Meander Medisch Centrum, Amersfoort, NETHERLANDS.

Aim/Introduction: To ensure a patient centered approach, technologists work in close collaboration to Nuclear Medicine Physicians in a Nuclear Medicine Department. In most situations,

the Nuclear Medicine Physician does not see the patient but needs to submit an interpretation of the examination put forward by the technologist. He/she needs to rely solely on what the technologist has described, performed and accomplished the examination in question. ***Materials and Methods:*** In this presentation, a couple of case studies will be put forward and discussed. The session will be interactive, and it will involve recent studies of some patients presented with different ailments and symptoms, together with their relevant complications. The technologist's role and the findings and/or results. Scenario's such as a female patient referred for PET/CT with possible lung malignancy. However the scan had to be terminated after 5 minutes because she felt unwell and had an acute headache - how would the technologist handle this and go about it? Another example is a young pregnant patient presented with dyspnoe referred for V/Q scan - what is the role of the technologist here? Another example is whether the technologist knows which organs should be visible according to the radiopharmaceutical being injected and what to do in the case when something odd is seen and is not supposed to be there. ***Results:*** All of the examples discussed in this presentation demonstrate a possible impact on the imaging to be performed, which will then determine on how to proceed with the image interpretation and the management of the patient. ***Conclusion:*** At the end of the presentation, there will be some take home messages that the technologist could put into practice back home.

TEPS-019

Creating a modern workforce: standardising and certifying Clinical Technologist competence

T. Mcdade, *C. Kelly, C. Paterson;*
Glasgow Royal Infirmary, Glasgow, UNITED KINGDOM.

Aim/Introduction: Technological advancements in Nuclear Medicine (NM) outstripped a co-ordinated response in guidance, standards and provision of suitable education to skill the Clinical Technologist workforce to meet current & future requirements. Hybrid techniques rapidly redefined working practice over the last decade. [1-3] ***Materials and Methods:*** The Institute of Physics and Engineering in Medicine (IPEM) is the UK's largest trainer of Clinical Technologists. Their Professional Standards Council (PSC) engaged the workforce to produce a curriculum[4] in addition to the Register of Clinical Technologists (RCT) scope of practice. Coupled with new standardised national plans and pro-forma portfolios (2023) documenting: knowledge, skills and experience. Candidates practice is examined in-situ via external examiners and a final viva is performed. PSC have been working with Higher Education Institutes (HEI) to gain academic recognition for the IPEM Diploma. Resulting in a training programme that certifies skills and provides education satisfying relevant Education Career Frameworks (ECF). [5] This presentation will draw from experience of leading a national training scheme combined with evidence and reflection from current candidates. ***Results:*** The IPEM Diploma meets National Occupation Standards (NOS), relevant ECF and adapts to meet workforce needs through standardised national training plans and portfolios documenting candidate's knowledge and skill base. 2024 IPEM launched an innovative IV contrast online work-shop, giving training centres and candidates a framework to acquire the required knowledge and skill base. ***Conclusion:*** IPEM has successfully updated its training model; certifying Technologists skill base while meeting the educational requirements of the modern NM environment. It is an organised national collegial network of expertise with innovative resources in training and assessment. It could serve as a model for European wide standardisation of education, training and certification of Clinical Technologists. ***References:*** Marc Griffiths (2015) "Creating the Hybrid Workforce: Challenges and Opportunities" Journal of Medical Imaging and Radiation Sciences, 2-15-09-01, Volume 46, Issue 3, Pages 262-272; Society of Radiographers (2016) Computerised Tomography (CT) scanners in Nuclear Medicine facilities; use by nuclear medicine practitioners from both radiographic and technologist backgrounds; Marcel and Owers, E.C. TEPS-020

Assessment of Somatostatin Receptor Expression in Normal Prostate Tissue: Insights from ^{68}Ga-DOTANOC PET/CT Imaging

I. Rodrigues[1,2], *A. Martins[1,2], M. J. Vieira[1], J. Oliveira[1], S. Carmona[1], A. Alvernaz[1], L. Oliveira[1];*
[1]Joaquim Chaves Saúde, Lisbon, PORTUGAL,
[2]Cross I&D Lisbon Research Center, Portuguese Red Cross Health School, Lisbon, PORTUGAL.

Aim/Introduction: Prostate gland physiological uptake is documented in 68Ga-DOTANOC PET/CT studies. This study pretends to characterize somatostatin receptor expression in normal prostate gland by calculating its maximum and mean standardized uptake value (SUVmax and SUVmean) as well as prostate/liver and prostate/mediastinum ratios using 68Ga-DOTANOC PET/CT. ***Materials and Methods:*** A prospective study was performed with 48 men (60.18±17.06 yrs; 26 - 85 yrs) who underwent a 68Ga-DOTANOC PET/CT for NET assessment. Oncological prostate disease and octreotide interference were excluded. Qualitative 3-point visual score was performed to compare normal prostate (P) to mediastinum (M) and liver (L) uptake (0≤mediastinum; 1≤liver; 2>liver). SUVmax and SUVmean were measured and SUVmax P/L, SUVmean P/L, SUVmax P/M and SUVmean P/M ratios were also calculated. Prostate volume was estimated based on CT measures to create subgroup 1 with normal volumes (<30cc) and subgroup 2 with enlarged volumes (≥30cc). Statistical analysis was performed (ANOVA and Pearson Correlation) using SPSS25®. ***Results:*** Visual score demonstrated a weak correlation with SUVmax P/L (R2=0.231 p=0.000) and with SUVmax P/M (R2=0.296 p=0.046) and had no correlation with SUVmean P/L and SUVmean P/M. Mean 68Ga-DOTANOC SUVmax values in prostate were 6.12±1.95, in liver 7.56±2.36 and in the mediastinum 2.83±0.72 while mean SUVmean was 3.29±0.99; 4.26±1.44 and 1.09±0.19, respectively. Aging was related to an increase in prostate 68Ga-DOTANOC uptake, when considering SUVmax (Pearson's correlation 0.349 p=0.015), SUVmean (Pearson's 0.365 p=0.011), SUVmax P/L (p=0.001), SUVmean P/L (p=0.000) and SUVmax P/M (p=0.013). No correlation was observed with SUVmean P/M (p=0.083). Prostate enlargement was also related to an increase in 68Ga-DOTANOC uptake when considering all measured parameters (p<0.05). Subgroup 2 registered a 32.71% 68Ga-DOTANOC increase uptake for mean SUVmax and a 46.53%

increase for mean SUVmean when compared with subgroup 1. Between the ratios analyzed, SUVmax P/L seems the most robust measure to study normal prostate uptake (variance 0.077). ***Conclusion:*** Prostate physiological uptake in 68Ga-DOTANOC PET/CT is higher compared with the mediastinum and lower than the liver. Moreover, it appears to increase with age and prostate volume. SUVmax and SUVmean P/M and P/L ratios tend to provide more valuable insights for assessing normal prostate behavior, particularly the SUVmax P/L ratio. Therefore, visual assessment alone should not replace semiquantitative parameters.

OP-445

Revision of the ICRP reference dose coefficients in diagnostic nuclear medicine

A. Giussani;
BfS - Federal Office for Radiation Protection, Oberschleißheim, GERMANY.

Aim/Introduction: The current reference dose coefficients for patients in diagnostic nuclear medicine published by ICRP [1] are still based on the dosimetric assumptions of the 1990 recommendations [2]. In the last year the ICRP Task Group (TG) 36 has been working on a revision of the dose coefficients for radiopharmaceuticals using the dosimetry methodology of the 2007 recommendations [3], including the new adult and paediatric reference voxel phantoms and updated nuclear decay data. ***Materials and Methods:*** The descriptive biokinetic models used in [1] were replaced by more physiologically based compartmental models. Recycling structures with a central exchange blood compartment were set up based on the available biodistribution data. For urinary bladder, a dynamic bladder model that allows to consider realistic voiding schemes, and changes in the urinary bladder volume and geometry due to filling and emptying was used. The Specific Absorbed Fractions (SAFs) calculated with the ICRP anthropomorphic adult and paediatric reference voxel phantoms were employed. For urinary bladder, the dynamic bladder model was used to calculate the volume-dependent SAFs. A computer code developed within the Task group was used as the reference benchmark and validated using three other available software codes for quality assurance purposes. ***Results:*** Compartmental models for about one hundred radiopharmaceuticals used in diagnostic nuclear models were developed and the corresponding dose coefficients calculated for reference patients of different age and sex,As far as reasonable, a harmonisation of biokinetic and dosimetric models with those developed for occupational and public exposures was sought. For some specific patient groups, for which the concept of effective dose cannot be applied, detriment-weighted dose coefficients were provided instead. The new report also includes revised recommendations in case of extravasation as well as on breastfeeding interruptions for lactating patients. The draft document was reviewed by the members of ICRP Committees 2 and 3. ***Conclusion:*** The revised document tabulates reference dose coefficients computed following the current state-of-the-art in internal dosimetry for diagnostic substances. After clearance from the Main Commission, the document will be released for public consulation to collect valuable comments from relevant stakeholders before its final publication. ***References:*** [1] ICRP Publication 128. Ann. ICRP 44(2S), 2015. [2] ICRP Publication 60. Ann. ICRP 21 (1-3), 1991. [3] ICRP Publication 103. Ann. ICRP 37 (2-4), 2007.

Intensive care staff radiation exposure during [18F]FDG PET/CT procedures in critically ill patients

B. van Leer[1], *C. van Stee[1], J. van Snick[2], M. Nijsten[3], A. Glaudemans[2], R. Slart[2], A. Willemsen[2], J. Pillay[3];*
[1]Departments of Critical Care and Nuclear Medicine and Molecular Imaging, University Medical Center Groningen, University of Groningen, Groningen, The Netherlands, Groningen, NETHERLANDS, [2]Department of Nuclear Medicine and Molecular Imaging, University Medical Center Groningen, University of Groningen, Groningen, The Netherlands, Groningen, NETHERLANDS, [3]Department of Critical Care, University Medical Center Groningen, University of Groningen, Groningen, The Netherlands, Groningen, NETHERLANDS.

Aim/Introduction: The accessibility of [18F]FDG PET/CT scans for critically ill patients has significantly improved with the introduction of long axial field of view PET/CT scanners. This leads to new diagnostic opportunities, and an increase of scans performed in ICU patients. Since these patients require constant monitoring and frequent care, maintaining a sufficient physical distance between the staff and the patient during [18F]FDG PET/CT procedure is challenging. For the procedure a strict scan protocol was developed including staff radiation safety based on the 'as low as reasonably achievable' principle. The objective of this study was to measure the radiation dose received by ICU staff during a [18F]FDG PET/CT procedure while using this protocol. ***Materials and Methods:*** Staff radiation dose was measured during all [18F] FDG PET/CT procedures performed within our center for 1.5 years. A procedure was defined as tracer administration at the ICU department, transport to the scan facility, and the remaining decay time of 4 hours (equalling 2 half-life times) after returning at the ICU. During the procedure staff were advised to limit patient contact and to stay at a reasonable distance from the patient. To facilitate this, a checklist was provided encompassing transport preparation and patient care. Procedures had to be evenly divided between colleagues, only necessary staff was allowed to participate. A electronic personal dosimeter (EPD) was provided to the participating nurse en physician to measure the received radiation doses. The EPD was carried ventral on top of the clothing at thoracic hight. The EPD was transferred between staff when shifts ended. Four hours after administration of [18F]FDG, readings were taken from the EPD. ***Results:*** In total 18 [18F]FDG PET/CT procedures were performed in 16 patients. Three procedures were excluded due to incorrect use of the EPD, resulting in 15 procedures in 13 patients. The mean (±SD) administered dose was 155 MBq [18F]FDG (±2 MBq/kg). The radiation dose received by nurses and physicians was respectively 15 µSv (SD± 7) and 8 µSv (SD± 4). For one physician the received dose was relatively high (20 µSv). This physician was present during the CT-scan as a precaution because of the presence of a cardiac assist device. The legal upper limit for additional radiation dose for ICU personnel in the Netherlands is 1 mSv. ***Conclusion:*** The received radiation dose for ICU nurses and physicians during a [18F]FDG PET/CT procedure was acceptable and well below recommended limits for hospital staff.

OP-447

Implementing Ultra-low-dose CT in Molecular Imaging: Impact of CT Artefacts on Attenuation-corrected SPECT and PET Reconstructions

***N. Bebbington*[1]**, *P. C. Holdgaard*[2], *I. S. Armstrong*[3];
[1]Siemens Healthcare A/S, Ballerup, DENMARK, [2]Lillebaelt University Hospital, Vejle, DENMARK, [3]Manchester University Hospitals NHS Foundation Trust, Manchester, UNITED KINGDOM.

Aim/Introduction: Ultra-low-dose CT scans can be used for attenuation correction (AC) of PET and SPECT images but may exhibit artefacts with reduced Hounsfield Units (HU) around very dense structures, which may limit how low the CT exposure settings can be. Time-of-flight (TOF) PET is more robust to data inconsistencies, and PET timing resolution has been markedly improved in recent years. The aim of this study was to assess the impact of artefact-induced reduction in CT HU on signal intensity in SPECT and PET reconstructions made with CT-based AC. ***Materials and Methods:*** Cylindrical uniformity phantoms of water-equivalent density containing Tc-99m and Ge-68 were imaged using a SPECT-CT system and a PET-CT system with 214 ps timing resolution, respectively. High-density objects were placed either side of the phantom to induce CT beam hardening (BH) artefacts. One high-count PET/SPECT acquisition was made, along with three CT acquisitions at different exposure settings generating different BH severities, and PET/SPECT reconstructions made using each of their three respective CT reconstructions for AC. At each CT exposure setting, absolute difference in CT HU was measured between BH-affected and unaffected regions of the phantom and plotted against the corresponding percentage differences in measured PET/SPECT activity concentration. Linear fits were applied to establish the relationship between the artefact's absolute difference in CT HU (x) and percentage difference in SPECT, TOF PET and non-TOF PET signal intensity (y). ***Results:*** Non-TOF PET reconstruction was most impacted by artefact-induced reduction in CT HU (y=0.069x+2.04), followed by SPECT (y=0.052x+2.26), whilst TOF PET was least affected (y=0.009x+0.52). Thus, with artefactual reduction of 200 HU, signal intensities would be reduced by 1%, 8% and 12% for TOF PET, SPECT and non-TOF PET respectively. If a limit of ≤2% effect on PET or SPECT signal intensity were demanded with ultra-low-dose CT for AC, artefacts with reduction of just ≤60 and ≤80 HU could be tolerated for non-TOF PET and SPECT respectively, whilst a ≤285HU reduction can be tolerated for TOF PET with state-of-art timing performance. ***Conclusion:*** TOF PET AC reconstruction is most robust to CT artefacts, followed by SPECT and non-TOF PET. Hence, exposure settings and thus radiation dose for CTAC could potentially be more greatly reduced for TOF PET, as compared with SPECT and non-TOF PET. This study allows determination of how much difference in CT HU can be tolerated for a given percentage difference in PET or SPECT signal intensity.

OP-448

Harmonizing $CTDI_{vol}$ Values of Auxiliary CT for Lung Perfusion (^{99m}Tc-MAA) Scintigraphy: Validation of a Phantom-Based Scaling Method to Adjust Patient Data between CT Protocols

M. Salas Ramirez*, S. Schlögl, S. Seifert, P. Hartrampf, M. Lassmann, J. Tran-Gia;
Department of Nuclear Medicine, University Hospital Würzburg, Würzburg, GERMANY.*

Aim/Introduction: Current nuclear medicine guidelines for lung perfusion scintigraphy provide limited information on the acquisition parameters for auxiliary CT as it is typically acquired for attenuation correction in SPECT/CT [1, 2]. The publication of national diagnostic reference levels (NDRLs) for auxiliary CT in SPECT/CT lung studies (CTDIvol of 2.9mGy in Nordic countries [3] and 2.0mGy in Germany [4]) shows the readiness for optimization. This study proposes a scaling method to identify optimal combinations of kilovoltage (kVp) and quality reference mAs (QRM) for lung auxiliary CT scans, with the aim of achieving compliance with NDRLs. ***Materials and Methods:*** An anthropomorphic thoracic phantom (ATP) equipped with lung inserts, a removable soft tissue layer, and removable arms was scanned using a (SPECT/)CT system. CTDIvol was measured over four phantom geometries at 110kVp with QRMs of 20, 25, 30, and 35mAs: ATP, ATP plus soft tissue layer, ATP plus arms, and ATP with soft tissue layer and arms. Water equivalent diameters for each geometry were calculated using 35mAs images. Linear relationships between water equivalent diameter and CTDIvol were calculated for each QRM. For validation, the water equivalent diameter was calculated for 2 groups of 21 patients each acquired with different clinical protocols: Protocol1 (110kVp, 35mAs) and Protocol2 (110kVp, 25mAs). CTDIvol values from Protocol1 were rescaled to match the (110kVp, 25mAs) setting based on the scaling factor from the phantom studies. In addition, CTDIvol from both patient groups were scaled to the same imaging parameters (110kVp, 20mAs) for further comparison with published NDRLs. The third quartile of CTDIvol was calculated for all patient data (real and scaled). ***Results:*** Statistical comparison between Protocol1, rescaled to (110kVp, 25mAs), and Protocol2 (110kVp and 25mAs) showed no statistically significant difference between the datasets (p-value = 0.56). CTDIvol third quartiles were 3.5mGy for rescaled Protocol1 and 3.1mGy for Protocol2. When both protocols were rescaled to the same imaging parameters (110kVp, 20mAs), there was also no statistically significant difference (p-value = 0.54). CTDIvol third quartiles for Protocol1 and Protocol2 under these conditions were 2.7mGy and 2.5mGy, respectively. ***Conclusion:*** This study provides a method for identifying the optimal combination of kilovoltage (kVp) and quality reference mAs (QRM) for lung auxiliary CT used for attenuation correction to harmonize the CTDIvol third quartiles for compliance with NDRLs. ***References:*** [1] Bajc M., et al. OP-449

Optimization of Iterative Reconstruction Safire CT protocol to reduce patient's effective dose in PET/CT studies

A. Ferretti, *S. Chondrogiannis, J. Peretto, A. M. Maffione, P. Bartoletti, N. Ortolan, M. Gava, M. C. Marzola;
Ospedale S.Maria della Misericordia, Rovigo, ITALY.*

Aim/Introduction: To implement the use of the Safire CT Iterative Reconstruction (IR) protocol, available on our PET/CT tomograph, instead of the standard filtered backprojection (FBP) reconstruction, in order to reduce the CT component's effective dose of the PET/CT scans, preserving both image quality and SUV accuracy, according to the principle of radiation protection optimization. ***Materials and Methods:*** a) Alderson-Rando anthropomorphic phantom was used to assess the CT image quality, using Safire IR protocol at level 3 with five decreasing values of the modulation parameter CareDose4D Quality-ref-mAs (100, 80, 70, 60 and 50 mAs, respectively); b) the NEMA IQ PET phantom (equipped with 6 hot spheres with ^{18}F-FDG at a nominal contrast

of 8:1) was used to evaluate the SUV reproducibility and accuracy with the progressively reduced CT dose; c) clinical evaluation on 25 PET/CT scans using the optimized safire CT protocol was performed by comparing whole body PET/CT with standard CT FBP reconstruction, with additional late segmental PET/CT acquisition with the optimized iterative Safire protocol and dose reduced of 30%. ***Results:*** a) applying the Safire level 3 IR protocol on the anthropomorphic phantom, a CT dose reduction between 20% and 40% didn't worsen the image quality in any anatomical district; b) comparing Safire IR vs FBP standard protocols on NEMA IQ phantom with five decreased CT doses, SUV values didn't show significant variation (deviations <0.4%); c) nuclear medicine physician clinical evaluation showed in all patients the non-inferiority of PET/CT image quality with 30% CT dose reduction and Safire level 3 IR protocol compared to the standard CT full dose with FBP reconstruction. By the means of this new reconstruction protocol the average total effective dose to the patient in a whole body PET/CT scan would be reduced from 10.8 to 8.8 mSv (-18%). ***Conclusion:*** the use of the Safire IR Protocol at level 3 in whole body PET/CT studies allowed an overall reduction of patient's effective dose of about 2 mSv, without any worsening neither of the image nor in the SUV accuracy calculation.

OP-450

CT Radiation Dose Reduction with Tin Filter for PET-CT Quantitative Analysis in a Whole-body Patient Phantom for Bone, Lung and Soft Tissue

N. Bebbington[1], *K. B. Christensen[2], L. L. Østergård[2], P. C. Holdgaard[2];*
[1]Siemens Healthcare A/S, Ballerup, DENMARK,
[2]Lillebaelt University Hospital, Vejle, DENMARK.

Aim/Introduction: A CT tin filter has demonstrated large radiation dose reductions in some standalone CT examinations providing diagnostic image quality without contrast media. PET-CT on the other hand, often uses 'low-dose' CT exposure settings for lesion localisation and/or characterisation, where a higher noise level is tolerated. Hence, different relative dose reductions with tin filter may be appropriate for localisation/characterisation level CT. The aim was to determine how much CT dose reduction is afforded by the tin filter for comparable image quality to using standard filtration in localisation/characterisation level CT, determined by quantitative image quality analysis. ***Materials and Methods:*** A whole-body CT phantom was scanned in standard and obese configurations. Scans were made with tube current modulation, with two sets of exposure settings without tin filter, representing standard practice for localisation/characterisation CT (120kV/20mAs-ref, 120kV/40mAs-ref), and with a range of mAs settings with tin filter applied at Sn100kV (25, 50, 100, 150, 200, 250, 300, 350 and 400mAs-ref) and Sn140kV (7, 12, 25, 50 and 100mAs-ref). Regions of interest (ROIs) were drawn in uniform areas of the brain, lung, bone, liver, kidney and fat. Mean and standard deviation HU were recorded, together with dose length product (DLP). Contrast-to-noise-ratio (CNR) of brain, lung, bone, liver and kidney ROIs were calculated relative to fat. Plots of DLP versus CNR were generated for each tissue, and linear regressions applied to Sn100kV and Sn140kV datapoints. These were used to calculate the percentage dose reduction with tin filter for equivalent CNR to standard filtration scans. ***Results:*** The dose reduction afforded by the tin filter for comparable CNR was dependent on tube voltage, tissue, phantom configuration, and exposure settings of the non-tin filter reference dataset. Using Sn100kV afforded dose reductions in all conditions, whilst Sn140kV only provided dose reduction in the lung compared with the 120kV/40mAs-ref standard filtration reference. Dose savings with Sn100kV ranged from 8-43% in brain, 27-51% in lung, 50-76% in bone, 36-61% in liver and 32-52% in kidney. ***Conclusion:*** These findings suggest that large CT dose reductions can be afforded by the tin filter using Sn100kV, for comparable image quality to CT without tin filter, in bone, lung and soft tissues, relevant to a wide range of PET-CT examinations. The marked CT dose reductions for bone imaging could help justify transition to whole-body cross-sectional imaging from planar radionuclide scintigraphy where CT dose has previously been a limitation.

OP-451

An ultra-low dose CT protocol does not affect $^{[18F]}$FDG PET image quality

S. Mostafapour, *A. Brouwers, W. Noordzij, G. Stormezand, J. van Snick, R. Dierckx, J. van Sluis, A. Lammertsma, C. Tsoumpas;*
UMCG, Groningen, NETHERLANDS.

Aim/Introduction: While CT is an integral part of PET/CT for anatomical mapping and attenuation correction, its use increases radiation exposure. The purpose of this clinical study was to evaluate PET image quality while reducing CT radiation doses by incorporating a tin filter1. ***Materials and Methods:*** Twenty-nine oncological patients undergoing follow-up were scanned with whole-body $^{[18F]}$FDG PET/CT, each receiving a low-dose (LD) CT with standard settings for clinical care and an experimental ultra-LD (ULD) CT employing a tin filter and reducing the tube current to 6 mAs. Multiple volumes of interest were delineated for five healthy tissues (brain, heart, lung, liver, and subcutaneous fat) and for confirmed lesions in 10 patients. Parameters such as standardized uptake value (SUV), coefficient of variation, and signal-to-noise ratio were assessed in healthy tissues. Lesions were assessed for SUVmean, SUVmax, and tumor-to-background ratio (TBR). Three nuclear medicine physicians independently rated PET images, reconstructed using both LD-CT and ULD-CT for attenuation correction, on a 5-point Likert scale, considering image noise, lesion margin demarcation, and overall image quality. Physicians independently evaluated the number and location of lesions in 10 patient datasets, while the images were randomly divided between two scoring rounds (three-week interval). Intra- and inter-observer variability were analyzed using the Two-Way Mixed-Effects Model and intraclass correlation coefficient (ICC). ***Results:*** ULD-CT resulted in a remarkable 97% reduction in CT-related radiation dose (0.059±0.03 mSv) compared with LD-CT (1.932±0.61 mSv). Across five different healthy tissues, SUVs exhibited minimal relative variances between both reconstructions. SUVmean, SUVmax, and TBR results underscored the negligible absolute disparities between the two attenuation-corrected image types. The 5-point Likert scale scores remained consistent across both cohorts. Evaluation of physician reports revealed an impressive level of agreement regarding lesion detection between both types of reconstructions (intra-observer ICC values: 0.85, 0.96, and 0.99) and good agreement regarding the inter-observer variability between physician reports (0.69 and 0.66 for LD-CT and ULD-CT attenuation corrected images, respectively). ***Conclusion:*** $^{[18F]}$FDG PET image quality and quantification remain unaffected when using a 33-fold lower-dose CT protocol in a long Axial field-of-view scanner. This means that in cases where anatomical detail is not critical, and PET imaging alone can provide sufficient diagnostic information, the radiation exposure can be further reduced using the proposed ULD-CT protocol. High intra-observer agreement in lesion detection supports the clinical viability of ULD-CT protocols based on the incorporation of a tin filter. ***References:*** 1. Radiation protection considerations with [^{89}Zr]Zr-girentuximab PET/CT experience in France

C. Morgat[1,2], *C. Bailly[3];*
[1]Department of Nuclear Medicine, University Hospital of Bordeaux, F-33076 Bordeaux, FRANCE, [2]University of Bordeaux, UMR CNRS 5287, INCIA, F-33400 Talence, FRANCE, [3]Nantes Université, Inserm, CNRS, Université d'Angers, CRCI2NA, Nantes, FRANCE.

Aim/Introduction: The recent ZIRCON trial endorsed the use of [89Zr]Zr-girentuximab PET/CT imaging in patients with indeterminate renal masses suspect of clear cell renal cell carcinoma scheduled for partial or radical nephrectomy. 89Zr is emerging as a popular radionuclide for imaging; however, safety procedures for healthcare providers working with the radionuclide have not been well established. We took radiation dose rate measurements from the drug vial, syringe, and patients to aid in the assessment of the radiation risk and necessary control procedures. ***Materials and Methods:*** A ZIRCON trial site in France measured radiation dose rates from a vial and syringe containing 12 mL [89Zr]Zr-girentuximab with and without shielding . Radiation doses were measured at 1 metre from 28 patients enrolled in the ZIRCON trial on Day 0, Hour 1, Hour 2, and on the day of imaging, which ranged from 3-7 days with a median of 5 days. Radiation doses were also measured during surgery for the surgical assistant's hands, eyes, and whole body at 0.8 metres. ***Results:*** Radiation dose rates from a vial of [89Zr]Zr-girentuximab at 0 and 1 metre was 15.6 and 0.32 µSv/hr/MBq, respectively, with no shielding, and 4.2 and 0.05 µSv/hr/MBq, respectively, with shielding. A syringe containing [89Zr]Zr-girentuximab at 0 and 0.3 metre had a dose rate of 111.11 and 2.74 µSv/hr/MBq, respectively, with no shielding, and 11.28 and 1.79 µSv/hr/MBq, respectively, with shielding. The mean dose rate (SD) from patients enrolled in the ZIRCON trial was 11.7 (3.6) µSv/hr on Day 0, 10.0 (2.4) µSv/hr on Hour 1, 10.3 (3.4) µSv/hr on Hour 2, and 3.9 (1.2) µSv/hr on the day of imaging. Radiation doses were measured at a surgical assistant's hands, eyes, and whole body, which received 21, 3, and 5 µSv/hr, respectively. Surgery ranged from 5-89 days after infusion with mean 14.2 days and median 6 days after injection with patient surgery occurring 20.5±20.1 days (mean ± SD) after administration in the ZIRCON study. ***Conclusion:*** Our results demonstrate low radiation exposure levels associated with [89Zr]Zr-girentuximab administration, imaging, and subsequent surgery. Given the short delay observed between [89Zr]Zr-girentuximab administration and surgery, our on-site measurements represent the upper end of the range of expected dose to staff. With recent positive Phase 3 trial results and potential integration of [89Zr]Zr-girentuximab into clinical practice, appropriate radiation protection procedures are needed. Dose rate measurements such as those presented here can help guide development of best practices.

OP-453

Dose Rates and Patient Contact Restrictions Following Zirconium-89 (Zr89) Positron Emission Tomography (PET) Studies

G. Wright[1], *E. Papadopoulos[1], A. Saleem[2,1];*
[1]Hull University Teaching Hospitals NHS Trust, Cottingham, UNITED KINGDOM, [2]Hull York Medical School, Hull, UNITED KINGDOM.

Aim/Introduction: Unlike short-lived radioisotopes (Fluorine-18, Gallium-68), Zirconium-89 is less often used in diagnostic PET. The longer half-life of Zr89 (78.4h) is ideal for imaging tissue pharmacokinetics of longer half-life biologicals but means longer radiation exposure to subject contacts , potentially necessitating subject contact time restrictions . However, data on contact radiation exposure from subjects receiving Zr89 is scanty. This ongoing study aims to clarify restrictions required to ensure radiation exposure remains within typical dose constraints. ***Materials and Methods:*** Following administration of 37MBq±20% of Zr89-Crefmirmilab-bedroxam (PRETZCEL study; NCT05744128) , dose rates were measured at 0.1m, 0.3m, 0.5m and 1m anteriorly and posteriorly at chest height for 6 patient studies (3 patients studied twice). Dose rates at 2m were estimated using the IAEA method [1]. Dose rates at 3m and 5m were estimated using the inverse square law. Effective doses were estimated based on contact patterns for adult partners and children living at home with the subject [2] and for babies [3], as described previously [4]. The time duration subjects were required to avoid contacts at distances of 1m or less to keep doses to 0.3mSv, 0.5mSv or 1mSv were calculated using the maximum encountered dose rate for each distance. ***Results:*** Maximum dose rates at 0.1m, 0.3m, 0.5m, 1m, 2m, 3m, and 5m were 67.5, 22.9, 12.9, 4.5, 1.6, 0.5, and 0.2 µSv/h, respectively. For a dose constraint of 0.3mSv, close contact restrictions of 88h, 56h, and 260h are needed for adults, children and babies respectively. For 0.5mSv the restriction times are 21h, 0h, and 202h. For 1mSv contact restrictions are only needed for babies (124 hours). ***Conclusion:*** Advice on contact with others should be provided to patients administered with Zr89. To comply with a 0.3mSv constraint, restrictions (<1m) are required for adults (88h), children (56h) and babies (260h). For 1mSv, contact restrictions are only needed for babies (124h). ***References:*** [1] IAEA, "Release of Patients After Radionuclide Therapy Safety Reports Series No. 63," 2009. [2] M. L. How rapidly does the FAPI-PET signal reverse following therapy?
Z. Varasteh[1], *A. Hosseini[2], E. Haj-Yahia[3], M. Cantore[4], K. Ferenz[4], K. Herrmann[2], T. Rassaf[3], U. Hendgen-Cotta[3], W. Weber[1]; [1]Klinikum rechts der Isar der TUM, Munich, GERMANY, [2]Department of Nuclear Medicine, University Hospital Essen, Essen, GERMANY, [3]Department of Cardiology & Vascular Medicine, University Hospital Essen, Essen, GERMANY, [4]Institut of Physiology, University Hospital Essen, Essen, GERMANY.*

Aim/Introduction: Reactive fibrosis is a complex response to a variety of chronic insults that contribute to the onset and progression of heart failure (HF). FAPI-PET has shown potential in differentiating active fibrosis from established fibrosis. Though anti-fibrotic therapies hold potential for enhancing left ventricular (LV) function in preclinical settings, their clinical translation is hindered by the absence of established non-invasive imaging methods for assessing fibrosis regression following treatment. We aimed to assess the potential of the FAPI-PET to determine

the speed of transition of active fibroblasts to a dormant state in response to therapy. ***Materials and Methods:*** Male C57BL/6 mice were implanted subcutaneously with Alzet mini-osmotic pumps (2006), infused with Ang-II/PE (Dose: 1.5/50 mg/kg/D) for up to 6 weeks, and scanned with 68Ga-FAPI-46 (480-500 pmol, 8-10 MBq) PET/CT longitudinally for up to 8 weeks. Mini-pumps in control animals were filled with saline. Structural and functional changes of LV was assessed by echocardiography. Tissue fibrosis was assessed through histological analysis, while FAP expression was evaluated using immunofluorescence staining. ***Results:*** Compared to control mice, a significant 68Ga-FAPI uptake in the myocardium peaked at W1 (0.06±0.01 %ID/g vs 0.23±0.08 %ID/g). An increase of 68Ga-FAPI uptake was also observed in the liver. Liver uptake peaked at W3 (0.84±0.12 %ID/g) and decreased significantly at W4 (0.18±0.16 %ID/g). Withdrawal of the Ang-II/PE at W1 and W2 resulted in PET signal decline to indiscernible level in the heart (from 0.23±0.08 %ID/g on Day 7 to 0.06±0.01 %ID/g on Day 10) and liver (from 0.77±0.27 %ID/g at W2 to 0.11±0.03 %ID/g at W3). Co-injection of mice with an excess of unlabeled FAPI (30 nmol/mouse) resulted in a 53±5% reduction in liver and heart uptake. Despite a significant increase in the thickness of the LV anterior and posterior walls at W1 (the peak of FAPI-PET signal in the myocardium), the ejection fraction (EF) remained stable (Base: 58±2 % vs W1: 50±5 %). ***Conclusion:*** Rapid reversibility of the PET signal after Ang-II/PE withdrawal demonstrated that 68Ga-FAPI can visualize dynamic changes in FAP expression and is suitable for rapid assessment of treatment response aimed at eliminating activated fibroblasts. Cardiac cirrhosis is a well-known complication of HF and FAPI may also be able to visualize the complications of HF. The cardiac FAPI signal emerges prior to functional alterations in the myocardium, suggesting that FAPI-PET could serve as a valuable tool for visualizing the initial phases of fibrosis in HF.

OP-467

[18F]AlF-NOTA-FAPI-04 PET/CT can predict treatment response and survival in patients esophageal squamous cell carcinoma treated with concurrent chemoradiotherapy.

X. Hu, *J. Yu, Y. Wei;*
Shandong Cancer Hospital and Institute, Jinan, CHINA.

Aim/Introduction: The prospective study investigated whether uptake of [18F] AlF-NOTA-FAPI-04 on positron emission tomography/computed tomography (PET/CT) could predict short-term response and survival in patients with locally advanced esophageal squamous cell carcinoma (LA-ESCC). ***Materials and Methods:*** 33 patients with LA-ESCC who underwent baseline [18F] AlF-NOTA-FAPI-04 PET/CT before concurrent chemoradiotherapy (CCRT) were included in this study. The maximum, mean and peak standard uptake values (SUVmax, SUVmean and SUVpeak), FAPI -avid tumor volume, and total lesion FAP expression of the primary tumor were evaluated on PET images. Additionally, the SUVmax of the primary tumor and SUVmean of blood were measured, and their ratios were denoted as target-to-background ratios (TBRblood). Correlations between baseline PET parameters and clinical variables were assessed with Spearman's rank test. Receiver operating characteristic curve analysis was used to define the optimal cut-off value. Cox regression and Kaplan-Meier methods were used to examine associations between progression-free survival (PFS) and overall survival (OS) with baseline clinical/PET parameters. ***Results:*** Median follow-up time, PFS and OS were 30.23, 19.83 and 24.57 months, respectively. The SUVmax (P=0.010), TBRblood (P=0.040) were significantly higher in non-responders than in responders. In multivariate analysis, high baseline TBRblood on [18F] AlF-NOTA-FAPI-04 scans was associated with poor PFS (hazard ratio [HR]=1.096, 95%CI 1.017-1.181, P=0.016) and OS (HR=1.101, 95%CI 1.010-1.201, P=0.029). Kaplan-Meier analysis showed that the baseline TBRblood on [18F] AlF-NOTA-FAPI-04 scans can predict PFS (cut-off 11.60; P=0.009) and OS (cut-off 14.25, P=0.010). ***Conclusion:*** High baseline TBRblood on [18F] AlF-NOTA-FAPI-04 scans was associated with poor short-term response, PFS, and OS for CCRT treatment in LA-ESCC patient, which may help optimize their treatment.

OP-468

Predictive Value of ^{68}Ga-FAPI-04 Micro PET/CT Imaging in Abdominal Aortic Aneurysm Growth in Rats

X. Bi[1], *J. Liu[1], L. Cao[2], H. Liu[1], T. Ma[1], B. Wang[2], W. Guo[2], R. Wang[1], B. Xu[1];*
[1]Department of Nuclear Medicine, the First Medical Centre, Chinese PLA General Hospital, Beijing, CHINA, [2]The First Medical Centre, Chinese PLA General Hospital, Beijing, CHINA.

Aim/Introduction: In the pathogenesis of abdominal aortic aneurysm (AAA), fibroblast-like differentiation plays a dominant role expressing fibroblast activation protein (FAP) molecules. Utilizing 68Ga-FAPI-04 PET/CT imaging might unveil fibroblast activation in the arterial wall. This study aims to investigate whether FAP promotes AAA formation or merely coexists in AAA lesions. ***Materials and Methods:*** ApoE-/- mice aged 12 weeks were used to induce aortic aneurysm model by continuous subcutaneous infusion of AngII (1000 ng/kg/min) with Alzet (2004 model) sustained release pump for 28 days. There were 6 model mice and 6 normal control mice. 68Ga-FAPI-04 Micro PET imaging was performed on all the mice at different time periods (3, 7, 14, 28 days), and the diameter of abdominal aorta was measured by B-ultrasound. Anatomical ROI was plotted around the aortic region of the superior kidney, and TBR (Target-to-background ratio) PET parameters were obtained. The rank sum test was used to compare the TBR between the 28-day AAA group and the normal control group. Immunofluorescence staining was used to detect the expression and localization of FAP in the tissue sections of mice with abdominal aortic aneurysm. The protein level of FAP was detected by Western blot. ***Results:*** FAP upregulation was observed in AAA mice. Enhanced FAPI uptake preceded substantial aortic expansion. FAP-positive mice displayed aortic enlargement from day 3 of AngII infusion through days 7 to 28, contrasting with FAP-negative and control mice. The 28-day AAA group exhibited higher TBR compared to the control group (2.27±0.25 vs. 1.87±0.14, P<0.05). ***Conclusion:*** This study unveils FAP as a potential mediator and novel pathological characteristic of AAA, emphasizing the significant value of FAP changes in the abdominal aorta observed through PET/CT imaging for predicting the onset and progression of abdominal aortic aneurysm. ***References:*** Kosmala A, Serfling SE, Michalski K, et al. Molecular imaging of arterial fibroblast activation protein: association with calcified plaque burden and cardiovascular risk factors. Eur J Nucl Med Mol Imaging. 2023 Aug;50(10):3011-3021.

Comprehensive Preclinical Evaluation of the dimeric FAP Inhibitor DOTAGA.Glu(FAPi)$_2$ labeled with gallium-68 and lutetium-177. Exploring its Potential for Theranostic Applications

A. Bilinska[1], *E. Menéndez[1], E. Pilatis[1], M. Marcel[2], T. Läppchen[1], F. Rösch[2], A. Rominger[1], E. Gourni[1];*
[1]Department of Nuclear Medicine, Inselspital, Bern University Hospital, Bern, SWITZERLAND, [2]Department of Chemistry—TRIGA site, Johannes Gutenberg University, Mainz, GERMANY.

Aim/Introduction: The development of radiotheranostics targeting tumor stroma through Fibroblast Activation Protein (FAP) is a promising approach for diagnosis and treatment of various types of cancers. This study aims at evaluating the dimeric FAP inhibitor DOTAGA.Glu.(FAPi)2, labeled with gallium-68 and lutetium-177, with the potential to be used for theranostic applications of FAP-positive tumors. ***Materials and Methods:*** DOTAGA.Glu(FAPi)2 was labeled with gallium-68 and lutetium-177. Both [68Ga]Ga-DOTAGA.Glu(FAPi)2 and [177Lu]Lu-DOTAGA.Glu(FAPi)2 were evaluated in vitro (lipophilicity, protein binding, saturation, and internalization studies) on immortalized FAP+ CAFs. In vivo studies (PET/SPECT/CT imaging, metabolic stability, biodistribution, autoradiography) were performed on PC3 xenografts. ***Results:*** Both tracers were prepared in >98% radiochemical purity with molar activites of 17-22 MBq/nmol for [68Ga]Ga-DOTAGA.Glu(FAPi)2 and up to 30 MBq/nmol for [177Lu]Lu-DOTAGA.Glu(FAPi)2, exhibiting a hydrophilic profile with logDoctanol/PBS values of -2.9±0.1 and -3.0±0.1 respectively. About 9% of the activity was found to be bound to proteins after 30 min of incubation with human serum for both radiotracers. Their affinity for FAP was high, with Kd values of 0.7±0.1 and 0.9±0.3 nM. Both tracers were rapidly internalized, with a maximum of about 35% of the total cell associated activity being internalized. Metabolic studies 10 min after their injection to mice revealed only intact radiotracer in blood. Biodistribution studies for [68Ga]Ga-DOTAGA.Glu(FAPi)2 demonstrated a specific tumor uptake of 16.6±2.3 %IA/g at 1h p.i., preserved at a high level of 18.4±2.1 %IA/g at 3h p.i., while blood uptake maintained a low level of 3.2±0.5 and 2.5±0.1 %IA/g at 1 and 3h, respectively. In the case of [177Lu]Lu-DOTAGA.Glu(FAPi)2, the tumor uptake of 33±5% IA/g at 4h p.i. slowly decreased over time, reaching 10.4±0.2 IA/g and 4.4±0.3 %IA/g at 48 and 96 h p.i., respectively. The activity in blood decreased from 4.2±0.2 at 1h p.i to 0.4±0.1 and 0.1±0.01 % IA/g at 48 and 96 h p.i.. Both tracers exhibited high tumor-to-background ratios at all tested time points. These findings are well illustrated by PET/SPECT/CT imaging. In vivo autoradiography exposed the distribution and specificity of [177Lu]Lu-DOTAGA.Glu(FAPi)2 in PC3 xenografts across all examined time intervals. ***Conclusion:*** The favorable characteristics of [68Ga]Ga-DOTAGA.Glu(FAPi)2 as a PET probe for tumor stroma imaging, coupled with the therapeutic potential demonstrated by [177Lu]Lu-DOTAGA.Glu(FAPi)2, render these radiotracers a promising theranostic pair for targeting of FAP-positive tumors.

OP-470

Investigating the Efficacy and Mechanism of FAP-targeted Radioligand Therapy Combined with Immune Checkpoint Blockade: A Translational Study

L. Zhao[1], *Y. Pang[1], J. Zhang[2], X. Chen[2], H. Chen[1];*
[1]The First Affiliated Hospital of Xiamen University, Xiamen, CHINA, [2]National University of Singapore, Singapore, SINGAPORE.

Aim/Introduction: Radiotherapy combined with immune checkpoint blockade holds great promise for synergistic antitumor efficacy. Targeted radionuclide therapy delivers radiation directly to tumor sites. LNC1004 is a fibroblast activation protein (FAP)-targeting vector conjugated with the albumin binder Evans Blue for enhanced tumor uptake and retention. Combining radionuclide-targeted therapy against pancancer targets with immunotherapy may be a promising treatment strategy for certain advanced tumors. Moreover, single-cell RNA-sequencing (scRNA-seq) technology offers a comprehensive view of cellular and molecular interactions at an unprecedented resolution. However, to date, no studies have reported the application of scRNA-seq in radionuclide-targeted or combined immunotherapies. ***Materials and Methods:*** We investigated the therapeutic efficacy of 177Lu-LNC1004 in combination with PD-L1 in a preclinical setting. We pioneered the use of scRNA-seq for analyzing the changes within the TME and elucidated the underlying mechanisms of action of this combination treatment. Additionally, we assessed the safety and efficacy of 177Lu- LNC1004 in a small cohort of patients (clinical trial: NCT05963386) with various cancer types and analyzed the abundance of immune cell types among peripheral blood mononuclear cells (PBMCs) pre- and posttreatment. ***Results:*** 177Lu-LNC1004 stimulation increased tumor PD-L1 expression both in vitro and in vivo. We further explored the antitumor efficacy of a combination treatment including anti-PD-L1 antibody and 177Lu-LNC1004 radioligand therapy. Combination therapy led to complete eradication of all tumors in MC38/NIH3T3-FAP mixed tumor xenografts, with mice showing 100 % tumor rejection upon rechallenge. The combination therapy reprogrammed the tumor microenvironment in mice to foster antitumor immunity by suppressing malignant progression and increasing cell-to-cell communication, CD8+ T-cell activation and expansion, M1 macrophage counts, antitumor activity of neutrophils, and TCR diversity. A preliminary clinical study demonstrated that 177Lu-LNC1004 was well-tolerated and effective in patients with refractory cancers, resulting in an increase in antigen processing and presentation juxtaposed with T-cell inactivation. ***Conclusion:*** In conclusion, our preclinical data suggested that 177Lu-LNC1004 can amplify the antitumor efficacy of ICB. Furthermore, preliminary clinical data indicated that 177Lu-LNC1004 is a safe and well-tolerated therapeutic regimen with encouraging antitumor activity. Our data foster further exploration of the synergy between 177Lu-LNC1004 and immunotherapy in patients with advanced and refractory disease, particularly in those with FAP-positive tumors.

OP-471

Feasibility of [68Ga]DATA.SA.FAPi-PET/MRI for locoregional staging in bladder cancer: preliminary results of prospective, comparative study

D. Muin;
Medizinische Universität Wien, Wien, AUSTRIA.

Aim/Introduction: Fibroblast activation protein (FAP) targeting cancer-associated fibroblasts is frequently overexpressed in various tumor types. This study aimed to compare the diagnostic accuracy of [68Ga]DATA.SA.FAPi PET/MR and $^{[18F]}$-FDG PET/CT imaging in predicting locoregional tumor stages in patients with muscle-invasive bladder cancer (MIBC). ***Materials and Methods:*** In this prospective, comparative study, MIBC patients planned for radical cystectomy (RC) with or without prior neoadjuvant chemotherapy (NAC) were enrolled. Prior to RC, patients underwent [68Ga] DATA.SA.FAPi-PET/MRI and $^{[18F]}$-FDG-PET/CT. Patients receiving NAC underwent [68Ga]DATA.SA.FAPi-PET/MRI and $^{[18F]}$-FDG-PET/

CT before and after treatment with chemotherapy, mainly with Gemcitabin und Cisplatin. The primary outcome of interest was the diagnostic accuracy of [68Ga]DATA.SA.FAPi-PET/MRI (mean time PET-RC (days) - 28.7 (± 25.3)) and [18F]-FDG-PET/CT (mean time PET-RC (days) - 20.61 (± 20.20)) for local and nodal staging in MIBC patients with pathology results serving as the reference test. ***Results:*** Nineteen MIBC patients (67.26 (± 11.91) years, 74% male) were included, with 42% (8/19) receiving NAC. Sensitivity and specificity for [18F]-FDG PET/CT and [68Ga]DATA.SA.FAPi-PET/MRI in histologically positive primary tumors were identical with 58.3% and 71.4%, respectively. For the prediction of histologically positive lymph nodes, [18F]-FDG PET/CT exhibited superior performance with a sensitivity, specificity, PPV and NPV of 75.0%, 100%, 100% and 90.9% versus 50.0%, 90.0%, 66.7% and 81.8%, respectively, for [68Ga]DATA.SA.FAPi-PET/MRI. ***Conclusion:*** Preliminary findings suggest inferiority of diagnostic accuracy of [68Ga]DATA.SA.FAPi-PET/MRI compared to [18F]-FDG PET/CT. While the detection of cancer lesions in the bladder wall was similar for both modalities, [18F]-FDG-PET/CT showed better results for lymph node staging compared to [68Ga]DATA.SA.FAPi-PET/MRI.

OP-473

Preclinical evaluation and first-in-human imaging of [203/212Pb]Pb-PSV359, a novel cyclic peptide targeting fibroblast activation protein-alpha (FAP)

B. Cagle[1], *N. J. Baumhover[1], P. Thakral[2], D. Malik[2], I. N. Vance[1], D. Liu[1], S. N. Rodman[1], A. L. Kalen[1], S. Kapoor[1], E. A. Sagastume[1], F. L. Johnson[1], M. K. Schultz[1], I. B. Sen[2], M. Li[1];*
[1]Perspective Therapeutics, Coralville, IA, UNITED STATES OF AMERICA, [2]Fortis Memorial Research Institute, Gurugram, INDIA.

Aim/Introduction: Alpha particle radionuclide therapy for cancer is a promising treatment that delivers alpha radiation specifically to tumor sites. Lead-212 (212Pb; alpha-particle therapy; half-life 11 h) and 203Pb (SPECT imaging; half-life 52 h) are an elementally identical isotope pair for image-guided targeted-alpha-particle therapy. Fibroblast activation protein-alpha (FAP) is overexpressed in a variety of cancers making it a favorable target for radiopharmaceuticals. High-throughput screening of approximately 3 billion amino acid sequences and affinity maturation identified PSV359, a cyclic peptide targeting FAP. This study details the in vitro and in vivo evaluation and first-in-human SPECT/CT imaging of [203Pb]Pb-PSV359. ***Materials and Methods:*** Radiolabeling was accomplished using in-house protocols. Surface plasmon resonance (SPR) and enzyme inhibition assays determined binding specificity and affinity. In vivo biodistribution (n=3), planar imaging (n=2), and efficacy studies (n=9-10) were carried out using female athymic nude mice bearing either HT1080-hFAP or U87MG xenografts. Fractionated dosing (5-7 MBq [212Pb]Pb-PSV359) was chosen for efficacy studies. For first-in-human imaging, three patients with FAP expressing cancers received 259-266 MBq [203Pb]Pb-PSV359, and SPECT/CT images were acquired at 1, 4, and 18h post venous administration. ***Results:*** PSV359 exhibits strong binding affinity (Kd=1.8 nM, Ki=0.4 nM) and selectivity for hFAP. Preclinical biodistribution and imaging studies revealed strong tumor uptake of PSV359 with fast renal clearance and low background in off-target tissues. In the HT1080-FAP model (in which FAP is expressed on the cancer cells), the tumor uptake was 20% ID/g at 1.5 h, and 14% ID/g at 24 h. For the U87MG model, which is expected to express mFAP in the mouse stroma and a low level of hFAP on the cancer cells, high tumor uptake was observed (2 h: 11% ID/g, 6 h: 15% ID/g). 100% survival and 80% tumor remission were observed in the treated cohort during a 90-day therapy study in HT1080-hFAP bearing nude mice. A 60-day efficacy study with U87MG bearing nude mice revealed an 89% survival rate. First-in-human SPECT/CT images of [203Pb]Pb-PSV359 were performed in three patients with FAP expressing cancers (chrondoblastic osteosarcoma, neuroendocrine, and lung adenocarcinoma). Strong tumor uptake, fast clearance through the renal system, low accumulation in normal organs, and long tumor retention were observed in all three patients. ***Conclusion:*** A novel radiopharmaceutical targeting FAP, PSV359, exhibits superior binding affinity, binding specificity, and in vivo tumor targeting in preclinical and clinical settings. Strong anti-tumor efficacy of [212Pb]Pb-PSV359 was found in both HT1080-hFAP and U87MG xenograft models.

PSMA PET/CT radiomics: Assessment of Adverse Pathological Risk and Proteomic Biomarker Correlations in Prostate Cancer

Y. Tang[1,2], *L. Xiao[1], J. Yang[1], J. Hou[1], J. Hong[2], A. Rominger[2], K. Shi[2], S. Hu[1];*
[1]Xiangya Hospital Central South University, Changsha, CHINA, [2]Department of Nuclear Medicine, Inselspital, Bern University Hospital, Bern, SWITZERLAND.

Aim/Introduction: Prostate cancer (PCa) is a highly heterogeneous malignant disease, making it essential to explore markers that can aid in the early detection of adverse pathological characteristics of PCa and ultimately enhance patient prognosis. In this study, we utilized radiomics machine learning models to predict the aggressiveness of PCa, pinpoint quantitative radiomic features, and discover protein biomarkers linked to unfavorable pathological traits. The objective of the study was to build a multi-omics marker model to refine clinical risk stratification. ***Materials and Methods:*** This was a retrospective study on 191 patients who were diagnosed with PCa or benign prostatic hyperplasia (BPH) and were pathologically confirmed after undergoing 68Ga-PSMA-617 PET/CT scan. CT imaging was utilized for anatomical localization, while PET/CT scans were employed for image fusion and manual contouring of the prostate gland was performed. Radiomic features were then extracted from the contours to analyze the imaging characteristics. Six machine learning algorithms were applied to construct radiomics models for predicting malignancies and combinations of adverse pathological features (Gleason score (GS), ISUP group, pathological stage (pT), lymph node infiltration (LNI), and perineural invasion (PNI). Two methods, minimum redundancy maximum relevance (mRMR) and LASSO, were utilized conduct feature selection and identify quantitative radiomic features with high predictive ability. Moreover, proteomics analyses were performed on 39 patients to identify protein biomarkers associated with adverse pathological features at the molecular level in PCa. Correlation analysis was performed to determine the association of quantitative radiomic features with protein biomarkers. ***Results:*** The optimal radiomics model constructed using machine learning methods showed an area under the curve (AUC) of 0.938 (95% CI: 0.893 to 0.983) for

predicting malignant prostate lesions and an AUC of 0.916 (95% CI: 0.854 to 0.977) for adverse pathological feature combinations in the test set. Results of the validation set obtained AUC values of 0.918 (95% CI: 0.848 to 0.989) for predicting malignancy and 0.855 (95% CI: 0.728 to 0.983) for adverse feature combinations. Three quantitative radiomic features and ten protein molecules associated with adverse pathological characteristics were identified. Moreover, a significant correlation was observed between quantitative radiomic features and protein biomarkers. The radioproteomic analysis demonstrated that molecular changes in protein molecules could affect the imaging biomarkers. ***Conclusion:*** The machine learning models constructed based on 68Ga-PSMA-617 PET/CT radiomic features demonstrated strong performance in stratifying patients.This can aid in clinical risk stratification and reveal significant connections between quantitative radiomic characteristics and protein biomarkers.

OP-475

Can PET Quantitative Differences Between ^{18}F And ^{68}Ga PSMA Suspected Prostate Cancer Patients Impact On Clinical Trial Therapy Cohort Selection?

B. Sanghera[1], *G. Lowe[2], W. Wong[2];*
[1]Barts Health NHS Trust, London, UNITED KINGDOM, [2]Paul Strickland Scanner Centre, London, UNITED KINGDOM.

Aim/Introduction: We characterize SUV using various lesion and liver normalizations, tumour/liver background (T/B), lesion metabolic volume estimates (MTV and TLG) and %COV between [18F]F-PSMA-1007 and [68Ga]Ga-PSMA-11 tracers in suspected prostate cancer patients. We discuss how this influences decision making in clinical trials where parameters like T/B thresholds are used to select patients for therapy e.g. VISION study. This study can help validate a framework for centrally commissioned funding and approval of suitable PET PSMA imaging agents nationally. ***Materials and Methods:*** 61 68Ga and 72 18F different PSMA subjects were PET-CT scanned using clinical protocols and analyzed as 2 separate radiopharmaceutical imaging cohorts. Each group consisted of 200 suspected lesions including metastatic disease identified and reported by experienced radiologists. Lesion and liver SUV were normalized to weight as standard, lean body mass (lbm) and body surface area (bsa) for comparison while vendor software was used to estimate MTV and TLG. Data were analyzed by medical physicists with >20 years PET experience each. ***Results:*** Sig differences were recorded between 68Ga and 18F PSMA for: Lesion SUVmax ($p = 0.0004$), SUVpeak ($p = 0.0017$) and SUVmean ($p = 0.0007$), SUVlbm ($p = 0.0002$) and SUVbsa ($p = 0.0005$) with higher mean and median 68Ga PSMA values. Liver SUVmax ($p < 0.0001$), SUVpeak ($p < 0.0001$) and SUVmean ($p < 0.0001$) with higher mean and median 18F PSMA values. T/B ratio ($p<0.0001$) with higher median and lower mean 68Ga PSMA values. % COV showed greater variability for 68Ga PSMA in all lesion SUV, liver SUVmean and T/B. Greater variability was seen for 18F PSMA in other liver SUV, MTV and TLG volume estimations. ***Conclusion:*** Significant differences with some arising from biodistribution effects in prostate cancer were seen between [18F]F-PSMA-1007 and [68Ga]Ga-PSMA-11 PSMA PET imaging parameters e.g. lesion SUV, liver SUV, %COV, T/B and TLG. Caution is required when using different radiopharmaceuticals as significantly higher T/B seen in 68Ga PSMA may not be suitable for 18F PSMA as a discriminator for patient therapy selection in clinical trials like the VISION study. Results presented further increase knowledge with caveats when using multiple radiopharmaceuticals and support potential for regulatory approval/commissioning of current and new imaging agents in prostate cancer imaging. ***References:*** Cook GJR, Wong WL, Sanghera B, et al. Eligibility for 177Lu-PSMA Therapy Depends on the Choice of Companion Diagnostic Tracer: A Comparison of 68Ga-PSMA-11 and 99mTc-MIP-1404 in Metastatic Castration-Resistant Prostate Cancer. OP-476

Identifying corresponding lesions in longitudinal PET/CT scans using a hierarchical descriptor and adaptive overlap framework

A. Soliman[1], *H. Yerebakan[2], G. Platsch[3], N. Varghese[4], V. Shah[1], G. Valadez[2], B. Spottiswoode[1];*
[1]Siemens Medical Solutions USA, Inc., Knoxville, TN, UNITED STATES OF AMERICA, [2]Siemens Medical Solutions USA, Inc., Malvern, PA, UNITED STATES OF AMERICA, [3]Siemens Healthineers AG, Erlangen, GERMANY, [4]Siemens Healthcare Private Limited, Bangalore, INDIA.

Aim/Introduction: Interpretation of PET/CT images to assess oncological disease progression or therapy response routinely involves comparing a current scan with one or more prior scans. In cases with multiple metastases it is impractical to manually quantify individual lesion changes over time. This study aims to develop an automated framework to identify corresponding lesions in longitudinal PET/CT studies. ***Materials and Methods:*** Under an approved IRB, 18F-FDG data was collected from 30 patients diagnosed with different types of cancer and scanned on multiple PET/CT systems. Each patient underwent imaging at least twice (min=2, max=12, avg=4.3). Linking was performed between each two consecutive timepoints, resulting in 61 scan pairs and a total of 915 lesions. These lesions were segmented from the PET images and mapped across consecutive timepoints by a nuclear medicine physician. The lesion linking framework comprises two main steps: (1) Fast point matching is applied on the CT images to efficiently map lesion centroids across time points. (2) An adaptive overlap algorithm is employed, commencing from the mapped centroid and searching for the corresponding lesion label for each voxel within an adaptive search space at another time point. This search space evolves spherically until a maximum predefined diameter is reached or a lesion label is found based on overlapping voxels. The linking framework handles disappearing, one-to-one, splitting, merging, and new lesions. Classification accuracy was used to evaluate the matching scenario for each lesion. True positives, false positives, false negatives, precision, recall, and F1-score were utilized to assess the linkage between each pair of lesions. ***Results:*** Setting the tuning hyperparameters to 5mm search radius and 15% minimum overlap for establishing correspondence between lesions, the accuracy of the lesion classification for the disappearing, one-to-one, splitting, merging, and new lesions are as follows: 99.6%(278/279), 96.9%(281/290), 100%(7/7), 100%(4/4), and 99.4%(333/335), respectively. For linking evaluation, the number of true positives, false positives and false negatives was 158, 5 and 1, respectively, and the precision, recall and F1-score was 96.9%, 99.4% and 98.1%, respectively. A single linking correction is thus only required once every 10 scan pairs for this cohort. ***Conclusion:*** This work presents a method to achieve fast and highly accurate linking of corresponding lesions across time, elegantly handling complex mappings (splitting, merging, etc.) and eliminating the need for a computationally demanding image registration step. This approach facilitates longitudinal quantification at the lesion level, which could potentially be used for more precise patient management.

OP-477

Automatic diagnosis of obstruction in Tc99m-EC renal scanning by aid of deep learning

A. Aghaee[1], *S. Soltani[1], E. Askari[1], S. Bagheri[1], H. Zeidi[2];*
[1]Nuclear medicine research center, Mashhad University of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF, [2]2.Division of Nuclear Medicine and Molecular Imaging, Geneva University Hospital, Geneva, Switzerland, Geneva, Switzerland, SWITZERLAND.

Aim/Introduction: Deep learning, a subset of artificial intelligence (1), has emerged as a powerful tool in various fields of medicine (2,3). In the context of renal disease, accurate diagnosis of complications associated with hydronephrosis is crucial for timely intervention and improved patient outcomes. This research endeavor aims to develop and apply a deep learning algorithm to detect obstructive processes and differentiate them from non-obstructive diseases in Tc-99m ethylene dicysteine (EC) scans. By leveraging the power of deep learning, early detection of these complications could be achieved, leading to more effective and prompt treatment strategies for patients. ***Materials and Methods:*** Participating in this research were 317 patients who had undergone EC renal scans (173 patients with abnormality). Image acquisition was performed after administering 4 to 7 mCi of Tc-99m EC intravenously gamma camera in two phases. The image had a matrix dimension of 128 x 128. Flow phase data was collected for one minute (60 frames), while second phase data was collected for thirty to sixty minutes (thirty to sixty frames). Figure 1 shows example of a normal and abnormal patients. To standardize and normalize each phase for individual patients, we scaled them to their maximum values across all frames. Following this, 60 frames were added to the uptake phase, and the flow and uptake phases were concatenated to create a single 120-frame frame. The patients were divided into two distinct groups including training (75%), and test (25%). Fifteen percent of the training dataset was selected for validation. The InceptionResNet model was utilized for backbone of deep learning. We implemented two 128 dense layers and sigmoid dense layer for final layer. For model training, 2 batch size and 300 epochs were utilized. As performance metrics, the area under the curve (AUC), recall, f1 score, precision, and accuracy were utilized to assess the model's performance on the test data. ***Results:*** The accuracy and AUC were 0.67 and 0.69 for the InceptionResNet model. Using InceptionResNet, recall (0.58 and 0.66), precision (0.58and 0.66), and f1-score (0.58 and 0.66) were resulted for obstructive and normal patterns, respectively (Figure 2). ***Conclusion:*** The findings of this inquiry suggest that deep learning models may have utility in identifying and diagnosing irregularities occurring in renal abnormalities. Nevertheless, it is feasible to attain superior outcomes through the implementation of alternative filtering, using other artificial intelligence algorithms, and augmenting the data set.

Use of Peptide Receptor Radionuclide Therapy in Neuroendocrine Tumour Patients in Germany - A Retrospective Evaluation Based on Chart Review Data

K. Herrmann[1], *H. Lanzafame[1], L. M. Unterrainer[2], A. Buck[3], C. la Fougère[4], E. Winter[5], M. Heuschkel[6], C. Rischpler[7], A. Rinke[8], H. Kulas[9], Y. Hashlamun[10];*
[1]Universitätsklinikum Essen, Essen, GERMANY, [2]Ludwig-Maximilians-Universitätsklinikum München, Munich, GERMANY, [3]Universitätsklinikum Würzburg, Würzburg, GERMANY, [4]Universitätsklinikum Tübingen, Tübingen, GERMANY, [5]Universitätsklinikum Heidelberg, Heidelberg, GERMANY, [6]Universitätsmedizin Rostock, Rostock, GERMANY, [7]Klinikum Stuttgart, Stuttgart, GERMANY, [8]Universitätsklinikum Marburg, Marburg, GERMANY, [9]IGES Institut GmbH, Berlin, GERMANY, [10]Novartis Pharma GmbH, Nuremberg, GERMANY.

Aim/Introduction: Gastroenteropancreatic neuroendocrine tumours (GEP-NET) are a rare disease with an incidence of approximately 1.33-4.76/100.000 patients per year in Europe. A current treatment option - which is recommended by various clinical guidelines - is the peptide receptor radionuclide therapy (PRRT). PRRT is available as Lutetium (177Lu) radiolabeled somatostatin analogues manufactured on a per-patient basis by hospitals (locally compounded preparation, LCP) but also as EMA approved product, both targeting non-resectable or metastatic, progressive, well differentiated somatostatin receptor-positive (G1, G2) GEP-NETs in adults. Currently, only limited data are available on the use of PRRT regarding patient population and treatment pattern in routine care in Germany. This study therefore addressed this information gap by analysing data of patients being treated with both LCP (177Lu-DOTATATE/DOTATOC) and the approved product (177Lu-oxodotreotide). ***Materials and Methods:*** This non-interventional study was conducted via a retrospective chart review using patient data from 7 participating medical centres. Data of adult GEP-NET patients in Germany receiving their first cycle of primary PRRT between 01st July 2020 and 30th June 2021 were included. The analyses focused on patient characteristics, medical history and treatment patterns. Clinical outcomes were assessed descriptively. ***Results:*** In total, data of 117 patients fulfilling all criteria were included in the analysis set. The majority of the patients were male (60.7%) and aged between 51-75 years (72.6%) with a progressive tumour (87.2%). The patients mainly received PRRT as second line therapy (77.8%). Mean time from initial diagnosis to initiation of primary PRRT was approximately 4 years. Administration of PRRT (dosage, treatment interval, co-medication) mostly corresponded to guideline and treatment recommendations. Among the study population, 45 patients (38.5%) received LCP, 63 (53.8%) were treated with the approved product and 9 (7.7%) switched substance within the PRRT cycles. No clinically relevant differences were observed between the PRRT alternatives regarding clinical outcomes. Also, both therapies were well tolerated, corresponding to established safety profile. Three months after completion of last PRRT, the disease control rate (DCR) was 74.6%. ***Conclusion:*** The results of the study indicate that PRRT is used in accordance with guideline recommendations regarding target population and administration. The results support the relevance of PRRT in treating GEP-NET patients with high DCR and good tolerability. This real world data as well as upcoming new comparative data on efficacy and safety (NETTER-2) might lead to PRRT becoming an integral part of treatment.

OP-479

Deep Learning-Based Acceleration of Monte Carlo-Based Dosimetry at Voxel Level

A. Gehring, *J. Bao, M. Salas-Ramirez, P. Hartrampf, M. Laßmann, J. Leube, J. Tran-Gia;*
University Hospital Würzburg, Würzburg, GERMANY.

Aim/Introduction: High time and computational effort, among other things, currently prevent the application of patient-specific Monte Carlo (MC) simulations for estimating absorbed doses in radiopharmaceutical therapies. In this study, we propose a new method to reduce the number of simulated nuclear transformations required in MC-based voxel-level dosimetry. This

is achieved by a u-shaped convolutional neural network (u-net) that transforms fast simulated, low-statistic dose-rate images into high-statistic dose-rate images. ***Materials and Methods:*** The dataset consisted of 220 SPECT/CTs obtained from 87 patients one day after receiving [177Lu]Lu-PSMA-I&T therapy at our hospital. Imaging was performed on one clinical SPECT/CT system (quantitative OSCGM reconstruction, matrix size: 256×256, voxel size: 1.95mm). Dose-rate maps were obtained using the DoseActor scoring tool of the GATE MC simulation toolkit (version 9.3 [1], based on Geant4 version 11.1.0). Simulations of 2·109 nuclear transformations were defined as ground-truth dose-rate maps. Four lower-statistic dose-rate maps were simulated using fewer nuclear transformations (1.4·106/5.2·106/1.0·107/5.0·107) , corresponding to accelerations of about 1,400/400/200/40. For each statistic, a separate 2D u-net was trained (50 epochs, L1 loss function). The dataset was divided in 160/30/30 for training/validation/testing. For each training step, the input consisted of a total of nine 2D images: CT, SPECT and one of the lower-statistic dose-rate maps for three adjacent axial slices. The ground-truth dose-rate map of the central slice was used as target. For each dataset, input and target were advanced slice by slice to cover the entire SPECT/CT scan. Performance of the four u-nets was evaluated using SSIM, NRMSE, and volume activity accuracy (VAA) [2] between output and target dose-rate maps for the test data. ***Results:*** In general, the performance measures (SSIM/NRMSE/VAA) with regards to the ground-truth dose-rate maps decreased with increasing acceleration: 0.990/0.32%/17.0% (40-fold acceleration), 0.955/0.71%/7.5% (200-fold acceleration), 0.916/1.00%/5.2% (400-fold acceleration), and 0.754/1.98%/2.2% (1,400-fold acceleration). After application of the u-nets the same trend was maintained with performances of 0.998/0.17%/42.7% (40-fold acceleration), 0.994/0.26%/37.5% (200-fold acceleration), 0.993/0.28%/35.1% (400-fold acceleration), and 0.988/0.37%/23.4% (1,400-fold acceleration). In all cases, the application of the u-net resulted in a clear improvement in performance. ***Conclusion:*** Our study shows that deep learning reduces the number of simulated nuclear transformations required for 177Lu SPECT/CT-based dosimetry. Our method considerably cuts the time and computational effort required for voxel-based absorbed dose-rate calculations, paving the way for real-time calculation of patient-specific dosimetry. ***References:*** [1] Jan S et al. PET/CT radiomics combined with clinical features in predicting sarcopenia and prognosis of diffuse large B-cell lymphoma

F. Wang[1], *Y. Chen[1], X. Han[2], L. Jiang[1];*
[1]Guangdong Provincial People's Hospital, Guangzhou, CHINA, [2]Southern Medical University, Guangzhou, CHINA.

Aim/Introduction: To assess the role of 18F-FDG PET/CT radiomics combined with clinical features using machine learning (ML) in predicting sarcopenia and prognosis of patients with diffuse large B-cell lymphoma (DLBCL). ***Materials and Methods:*** A total of 178 DLBCL patients (118 and 60 applied for training and test sets, respectively) underwent pretreatment 18F-FDG PET/CT were retrospectively enrolled. Clinical characteristics and PET/CT radiomics features were analyzed, and feature selection was performed using univariate logistic regression and correlation analysis. Sarcopenia prediction models were built by ML algorithms and evaluated. Besides, prognostic models were also developed, and their associations with progression-free survival (PFS) and overall survival (OS) were identified. ***Results:*** Fourteen features were finally selected to build sarcopenia prediction and prognosis models, including 2 clinical (SUVmax of muscle and BMI), 9 PET (7 gray-level and 2 first-order) and 3 CT (3 gray-level) radiomics features. Among sarcopenia prediction models, combined clinical-PET/CT radiomics features models outperformed other models; especially the support vector machine (SVM) algorithm achieved the highest area under curve (AUC) of 0.862, with the sensitivity, specificity and accuracy of 79.2%, 83.3% and 78.3% in the test set. Furthermore, the consistency index based on the prognostic models were 0.753 and 0.807 for PFS and OS, respectively. The enrolled patients were subsequently divided into high-risk and low-risk groups with significant differences, regardless of PFS or OS (P<0.05). ***Conclusion:*** ML models incorporating clinical and PET/CT radiomics features could effectively predict the presence of sarcopenia and assess the prognosis in patients with DLBCL.

Survival prediction of glioblastoma patients at initial diagnosis using multimodal radiomics analyses

L. Kaiser[1], *S. Quach[2], A. J. Zounek[1], A. Zatcepin[1], A. Holzgreve[1], S. Kirchleitner[2], V. C. Ruf[3], M. Brendel[1], N. Thon[2], J. Herms[3], M. J. Riemenschneider[4], S. Stöcklein[5], M. Niyazi[6], R. Rupprecht[7], J. Tonn[2], P. Bartenstein[1], S. Ziegler[1], L. von Baumgarten[2], N. L. Albert[1];*
[1]Department of Nuclear Medicine, LMU University Hospital, LMU Munich, Munich, GERMANY, [2]Department of Neurosurgery, LMU University Hospital, LMU Munich, Munich, GERMANY, [3]Faculty of Medicine, LMU München, Institute of Neuropathology, Munich, GERMANY, [4]Department of Neuropathology, University Hospital Regensburg, Regensburg, GERMANY, [5]Department of Radiology, LMU University Hospital, LMU Munich, Munich, GERMANY, [6]Department of Radiation Oncology, LMU University Hospital, LMU Munich, Munich, GERMANY, [7]Department of Psychiatry and Psychotherapy, University of Regensburg, Munich, GERMANY.

Aim/Introduction: Patients with glioblastoma continue to have a poor prognosis even with multimodal therapy. Therefore, enhancing diagnosis, patient stratification, and treatment planning is crucial. In this regard, noninvasive medical imaging plays a vital role in the ongoing monitoring of tumor progression. This study aimed to assess and compare the prognostic value of radiomic analyses from various imaging techniques - FET-PET, TSPO-PET, and MRI - in patients newly diagnosed with glioblastoma. ***Materials and Methods:*** We included 40 glioblastoma patients at initial diagnosis undergoing multimodal imaging prior to radiation therapy. The following images were included: 5-15 and 20-40 min p.i. FET-PET, 60-80 min p.i. TSPO-PET, contrast-enhanced (CE) T1-MRI, and T2-MRI. Furthermore, dynamic FET-PET data were described using time-to-peak and slope images. MRI volumes were determined using the BraTS Toolkit, while PET volumes were defined using a threshold of 1.6 times the background level. We employed Cox's proportional hazards model with an elastic net penalty to predict overall survival, evaluating model performance using the C-index from nested cross-validation with five folds and five repeats. ***Results:*** Multivariate analysis of individual modalities revealed a higher CI for the TSPO model (0.75±0.17) compared to the other modalities (FET20-40 0.67±0.15; CE T1 0.64±0.12; T2 0.55±0.13). Multimodal multivariate analysis did not outperform the model trained on features from TSPO-PET alone. ***Conclusion:*** The findings have significant implications for the field of neuro-oncology, as they underscore the superior prognostic value of TSPO-PET radiomics. These results need to be validated in larger and more diverse cohorts, especially with respect to the prognostic value of a combination of different modalities.

Bicentric Validation of a [^{68}Ga]Ga-PSMA-11 PET Based radiomics Signature for Primary Prostate Cancer Characterization

S. Ghezzo[1,2], *P. Gurunath Bharathi[3], H. Duan[3], P. Mapelli[1,2], G. Davidzon[3], C. Bezzi[1,2], B. Chung[4], A. Samanes Gajate[2], A. Thong[4], T. Russo[1,5], G. Brembilla[1,5], A. Loening[6], P. Ghanouni[6], A. Briganti[1,7,8], F. De Cobelli[1,5], G. Sonn[4], A. Chiti[1,2], A. Iagaru[3], F. Moradi[3], M. Picchio[1,2];*
[1]Vita-Salute San Raffaele University, Milan, ITALY, [2]Department of Nuclear Medicine, IRCCS San Raffaele Scientific Institute, Milan, ITALY, [3]Division of Nuclear Medicine and Molecular Imaging, Department of Radiology, Stanford University, Stanford, CA, UNITED STATES OF AMERICA, [4]Department of Urology, Stanford University, Stanford, CA, UNITED STATES OF AMERICA, [5]Department of Radiology, IRCCS San Raffaele Scientific Institute, Milan, ITALY, [6]Division of Body MRI, Department of Radiology, Stanford University, Stanford, CA, UNITED STATES OF AMERICA, [7]Department of Urology, IRCCS San Raffaele Scientific Institute, Milan, ITALY, [8]Division of Experimental Oncology, URI, Urological Research Institute, Milan, ITALY.

Aim/Introduction: While numerous studies assessed the role of radiomics in prostate cancer (PCa), scarce attention has been focused towards validating existing radiomics signatures. This gap hinders the ability to draw conclusions regarding results' generalizability. This study aims to validate a radiomics signature identified in a preliminary investigation across a larger cohort within our institution and an external cohort from a separate centre. ***Materials and Methods:*** One hundred and twenty-seven PCa patients were retrospectively enrolled across two independent hospitals. The first centre included 62 [68Ga]Ga-PSMA-11 PET scans, with 20 patients classified as class 0 (ISUP grade<4) and 42 as class 1 (ISUP grade≥4). The second centre provided 65 [68Ga]Ga-PSMA-11 PET scans, with 49 patients labelled as class 0 and 16 as class 1. Manual segmentation of the entire prostate was performed; images were discretised, resampled, normalized, and 102 Image Biomarker Standardization Initiative compliant radiomics features were extracted. Feature selection was based on a prior study, identifying two relevant features: GLSZMZone Entropy and Shape-Least Axis Length. Machine learning (ML) models were trained and tested using 100-fold Monte Carlo cross-validation (70-30% train-test split) at both Centre 1 and Centre 2 independently. Subsequently, ML models were trained in one centre and tested in the other, and vice versa. Finally, data from both centres were combined for training and testing using Monte Carlo cross-validation. Synthetic oversampling of the minority class was used to address class imbalance in the training folds. Accuracy (ACC), sensitivity (SN), specificity (SP), positive predictive value (PPV), negative predictive value (NPV), and area under the curve (AUC), were computed. ***Results:*** In Centre 1, a logistic regression model achieved AUC of up to 80.9% in the test set, while the radiomics signature did not generalize to Centre 2, where it only reached a maximum AUC of 49.3%. When ML models were trained in Centre 1 and tested on data from Centre 2, a support vector machine obtained an AUC of 63%. Conversely, testing the ML models in Centre 1 resulted in an AUC of 76.5%. Finally, in the last section of this study, the reported AUC reached 72.8%. ***Conclusion:*** The highest performances were reached when testing the radiomics signature in Centre 1, where it was first developed. These results suggest the influence of centre-specific imaging protocols, patient populations, and contextual factors on the models' performance. These findings emphasize the need to consider centre-specific factors and dataset characteristics when conducting radiomics analysis.

Comparison of Different Response Evaluation Criteria at the Interim PET/CT in Diffuse Large B-cell Lymphoma: Is ΔTotalMTV Worth Measure?

G. Babacan[1], *M. Ö. Tamam[1], N. Demirel[2], H. Bilgi[3], I. Mansuroğlu[3];*
[1]Department of Nuclear Medicine, Prof. Dr. Cemil Taşcıoğlu City Hospital, Hamidiye Faculty of Medicine, University of Health Sciences, Istanbul, TÜRKIYE, [2]Department of Haematology, Prof. Dr. Cemil Taşcıoğlu City Hospital, Hamidiye Faculty of Medicine, University of Health Sciences, Istanbul, TÜRKIYE, [3]Department of Pathology, Prof. Dr. Cemil Taşcıoğlu City Hospital, Hamidiye Faculty of Medicine, University of Health Sciences, Istanbul, TÜRKIYE.

Aim/Introduction: We aimed to compare six different treatment response criteria (Lugano, RECIL, Peking, qPET, ΔSUVmax, ΔTotalMTV) on survival prediction at the interim PET (iPET) stage in patients with diffuse large B-cell lymphoma (DLBCL). ***Materials and Methods:*** Patients who received R-CHOP or equivalent treatments for three or four cycles and underwent ^{18}F FDG PET/CT imaging at baseline and interim stages were included. Scans were interpreted in accordance with Lugano, RECIL, Peking, qPET, and ΔSUVmax criteria. Also, the percentage-based change rate was obtained from the change in total MTV between baseline PET (bPET) and iPET and was adjusted as a novel criterion (ΔTotalMTV). ROC curves were drawn for continuous variables based on progression-free survival (PFS) results. Cox regression analysis was performed to compare the predictive value of survival data after the categorical classification of treatment response criteria. Predictive comparisons were made by using Harrell's C-index. The significance alpha value for statistical data was set as p<0.05. ***Results:*** One hundred and two patients were included in this study. Median follow-up was 47(6-90) months for overall survival (OS) and 41.5(3-86) months for the PFS. At the end of follow-up, 34 (33.3%) of the patients had progression and/or death.The relationship between all prognostic markers and survival data is summarised in Table 1. In the time-dependent ROC curve analysis on PFS, the threshold value for ΔTotalMTV percentage was determined as 85.69% (AUC:0.630, p:0.028). In the Cox regression analysis, ΔTotalMTV was statistically significant for PFS (p:0.0171). However, no significant prognostic relationship was found for OS (p:0.0554). In addition, 126.8 cm3 was determined as the threshold value in the ROC curve analysis performed for bPET TotalMTV (AUC:0.676, p:0.004). Cox regression analysis performed on this value revealed a statistically significant relationship between PFS and OS (p:0.0079, p:0.0082). Furthermore, comparative Cox regression analysis revealed that ΔSUVmax was the response evaluation criterion with the highest Harrell's C-Index value for OS and PFS among six criteria (Both p<0.0001)(Table 2). ***Conclusion:*** ΔSUVmax is the criterion with the most predictive value on PFS and OS data among the defined methods in patients with DLBCL. These results suggest that iPET-based treatment management with ΔSUVmax may be beneficial. Although higher initial MTV was predictive for worse survival, ΔTotalMTV was not predictive for OS.

This result suggests that this issue may be solved in the future by the calculation of extranodal disease with better segmentation methods.

OP-484

Prognostic value of interim ^{18}F-PET/CT after immunotherapy-based combinations in extranodal NK/T-cell lymphoma, nasal type

L. Liu, *S. Hao, W. Chen, W. Fan, Y. Zhang;*
Sun Yat-sen University Cancer Center, Guangzhou, CHINA.

Aim/Introduction: The prognostic value of interim 18F-FDG PET/CT for extranodal natural killer/T-cell lymphoma (ENKTL) patients is still uncertain. We aimed to determine the utility of interim PET/CT in ENKTL patients after immunotherapy-based systemic therapy. ***Materials and Methods:*** In this retrospective study, we recruited 133 newly-diagnosed nasal-type ENKTL patients who underwent interim PET/CT scans after 2-4 cycles of immunotherapy-based treatments that contained anti-programmed cell death-1 (PD-1)/programmed cell death-ligand 1 (PD-L1). Interim PET/CT was interpreted by maximum standardized uptake value (SUVmax), Deauville 5-point scale (DS), and early treatment response. The prognostic value of overall survival (OS) and progression-free survival (PFS) was assessed with survival curves generated using Kaplan-Meier analysis and compared using the log-rank test. Univariate and multivariate Cox proportional hazards analysis were performed to evaluate the independent effects for survival. ***Results:*** In the study cohort, 112(84%) patients were early-staged (Ann Arbor I or II). All patients received anti-PD-1/PD-L1 inhibitors in combination with other systemic treatment regimens before interim PET/CT: 24 patients combined with asparaginase-based chemotherapy, 25 patients with targeted therapy, and 84 patients with asparaginase-based chemotherapy plus targeted therapy. Afterwards, 110 patients underwent radiotherapy. Patients with high SUVmax (>9.2), DS of 5, or early treatment response of stable disease (SD) /progressive disease (PD) on interim PET/CT showed significantly unfavorable OS and PFS with the Kaplan-Meier estimate, respectively. All interim PET/CT parameters remained independent predictors for both OS and PFS after univariate and multivariate analysis. We combined interim DS with the prognostic index for natural killer cell lymphoma- Epstein-Barr virus (PINK-E) model as a novel prognostic index and stratified our cohort into 3 risk categories: low-risk (0-2 risk factors), intermediate-risk (3 risk factors), and high-risk (≥4 risk factors), which showed significant stratifications of OS and PFS. ***Conclusion:*** Interim PET/CT after immunotherapy-based systemic treatments showed independent prognostic value for ENKTL, and the model combining interim PET/CT with PINK-E might be an effective prognostic tool for clinical application.

OP-485

PET Radiomics Signature Construction by Automatic Machine Learning for Treatment Outcome Prediction in Diffuse Large B-cell lymphoma: A Multicenter Study

Z. Zhang, *C. Jiang, R. Tian;*
Department of Nuclear Medicine, West China Hospital of Sichuan University, Chengdu, CHINA.

Aim/Introduction: To develop and validate PET radiomics signatures (RadSig) using automatic machine learning (AutoML) for treatment outcome prediction of diffuse large B-cell lymphoma (DLBCL) patients. ***Materials and Methods:*** A total of 308 DLBCL patients treated with R-CHOP regimen from two medical centers with 1471 lesions were studied. AutoML (AutoGluon) was applied to the baseline PET radiomic features from the training cohort to generate responses heterogeneity-aware RadSigs of lesions. To perform patient-level analysis, the RadSigs of all lesions for each patient were summed and averaged, resulting in the patient's radiomics signature (RadSigpatient).The performance of RadSigpatient for predicting treatment response were validated in external cohort. Furthermore, multi-parametric models were designed, and assessed through calibration curves, receiver operating characteristic(ROC), and decision curve analysis (DCA). The prognostic significance of the RadSigpatient were evaluated by Kaplan-Meier method. ***Results:*** AutoML-generated RadSigs were significantly higher in imcomplete response than that of response group in both training and external validation cohorts (P<0.05). The RadSigpatient for response prediction outperformed metabolic parameters in training (AUC=0.834 for interim and 0.809 for end-of-treatment) and external validation cohorts (AUC=0.745 for interim and 0.707 for end-of-treatment). The multi-parametric prediction models that incorporated RadSigpatient demonstrated superior efficacy and offered more net clinical benefits compared to competing models. The RadSigpatient were significantly associated with progression-free survival (PFS) and overall survival (OS) in both training and validation cohorts (P<0.05). ***Conclusion:*** RadSigpatient generated by AutoML represent valuable biomarker for predicting treatment outcome in DLBCL patients, offering potential assistance in clinical decision-making.

OP-486

Prognostic Value of Visual and Quantitative Parameters of FDG PET/MRI in Diffuse Large B Cell Lymphoma

R. Kalkan, *S. Kucukali, U. Aydos, L. Atay;*
Gazi University, Faculty of medicine, Ankara, TÜRKIYE.

Aim/Introduction: This study aimed to evaluate the prognostic value of visual and quantitative parameters obtained from primary staging and interim FDG PET/MRI in patients with diffuse large B cell lymphoma (DLBCL). ***Materials and Methods:*** The images of 47 adult patients diagnosed with DLBCL, who underwent PET/MRI for primary staging and interim response evaluation in our department were evaluated retrospectively. In quantitative evaluation, the highest SUVmax and the lowest ADCmin of the lesions, and the longest distance between two FDG positive lesions normalized to patient's height (Dmax/height) were obtained from PET/MR images. qPET values and Deauville scores (DS) were obtained from interim images. In addition, the percentage changes of quantitative parameters (ΔSUVmax, ΔADCmin, ΔDmax/height) were calculated. Primary staging PET/MR images and histopathological bone marrow status were considered together to determine disease stages at diagnosis. Progression-free survival (PFS) and overall survival (OS) times of the patients were calculated from the interim imaging date. Cox proportional hazard regression models were used to identify prognostic factors. Survival curves were estimated by using the Kaplan-Meier method. Statistical analyses were performed on SPSS version 23.0. ***Results:*** The median follow-up duration after interim PET/MR imaging was 31 months. During the follow-up period, progression/relaps was observed in 13 patients and mortality was observed in 7 patients. The univariate and multivariate regression analyses with backward stepwise selection demonstrated that primary and interim ADCmin and ΔDmax/height were found as independent predictors for PFS (p=0.02, p=0.007, p=0.043, respectively). The Cox regression analyses also demonstrated that interim SUVmax was the only parameter which was significantly associated with prognosis for OS (p<0.001). When metabolic response evaluation

criteria (DS, qPET, ΔSUVmax) were evaluated together, the qPET was the only parameter showed significant relations with PFS (p=0.003) and OS (p=0.006). The Kaplan-Meier survival analysis showed that higher interim SUVmax (>5.8), higher qPET (>1.6), lower ΔDmax/height (<65%) were significantly associated with lower PFS and OS rates. Additionally, significantly lower PFS rates were observed in patients with lower primary ADCmin (<43.5) and interim ADCmin (<115.5) values; and significantly lower OS rates were observed in the patient group with lower ΔSUVmax (<66%). ***Conclusion:*** FDG PET/MRI quantitative parameters, which reflect the metabolic activity and cellular density of tumors and the level of the lesion spread, may contribute to identify patients with poor prognosis. In our study, it was also found that qPET had a higher relationship with patient prognosis compared to other metabolic response evaluation criteria.

OP-487

The Value of Pretreatment ^{18}F-FDG PET/CT Radiomic Features in the Prognosis Evaluation of Diffuse Large B-cell Lymphoma

X. Meng;
Department of Nuclear Medicine, The First Medical Centre, Chinese PLA General Hospital, Beijing, CHINA.

Aim/Introduction: To investigate the prognostic value of pretreatment 18F-FDG PET/CT radiomic features in predicting Progression-Free Survival (PFS) of patients with Diffuse Large B-cell Lymphoma (DLBCL). A novel combined model was established, and a clinically applicable nomogram was constructed to guide clinical decision. ***Materials and Methods:*** A total of 239 patients with DLBCL were enrolled. Divided the 239 patients into training set (167 patients) and validation set (72 patients) in a 7:3 ratio to build model. SUV threshold segmentation method was used to semi-automatically delineate Region Of Interest (ROI) and extract features. Univariate Cox regression analyses and LASSO regression algorithms were used to select features .Calculating the Radscore for each patient using features's weighted coefficients.Receiver Operating Characteristic (ROC) curve was used to analyze the predictive value of the Radscore for PFS. Univariate and multivariate COX regression analyses were used to select the potential independent prognostic factors.Three models were established, namely clinical model, imaging model and combined model. The predictive efficacy of these models were compared by C-index,timeROC,and decision curve (DCA) . Finally, a nomogram was created based on the model with the best predictive efficiency and validated by the calibration curve. ***Results:*** Radscore determined by 7 radiomics features were signifcantly associated with PFS. The area under the curve (AUC), sensitivity, and specificity of Radscore were 0.843, 0.766, and 0.796. The univariate and multivariate COX regression analysis showed that age,Ann arbor stage,SUVmax ,TLG were independent risk factors for PFS. Three models were established: clinical model, including age and stage; imaging model, including SUVmax, TLG, and Radscore; combined model, including age, stage, SUVmax, TLG, and Radscore.Whether in the training set or validation set, the predictive efficiency of the combined model (training set: 0.807, validation set: 0.737) was better than that of clinical model (0.740, 0.706) and imaging model (0.791, 0.658).And even better than IPI (0.729, 0.663)of the most commonly used model in clinic. The difference in predictive efficacy between the combined model and the other three models was statistically significant (P<0.05). TimeROC shows that AUC of the combined model is best for different time points.DCA shows that the combined model achieves the greatest clinical net benefit. Calibration curves show the predicted values of the combined model are consistent with the actual observed values. ***Conclusion:*** The Radscore could be used as a powerful prognostic indicator for DLBCL. The combined model that integrates clinical and imaging indicators may allow for guiding clinical decision.

OP-488

Higher lesions conspicuity in lymphoma patients with delayed [18F]FDG Total-Body PET/CT - a prospective single center AI-aided study

C. Mingels[1,2], *H. Nalbant[1], K. J. Chung[1], L. K. S. Sundar[3], M. Rokni[1], F. Sen[1], N. S. Esteghamat[4], J. M. Tuscano[4], Y. G. Abdelhafez[1], R. D. Badawi[1], B. A. Spencer[1], L. Nardo[1];*
[1]Department of Radiology, University of California Davis, Sacramento, CA, UNITED STATES OF AMERICA, [2]Department of Nuclear Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, SWITZERLAND, [3]Medical University of Vienna, Vienna, AUSTRIA, [4]Department of Bone Marrow Transplant, University of California Davis, Sacramento, CA, UNITED STATES OF AMERICA.

Aim/Introduction: To evaluate late time point (120 min post-injection) [18F]FDG total-body (TB) PET/CT with regard to lesion and background uptake in lymphoma patients. We hypothesize that 120 min TB imaging may increase diagnostic accuracy. ***Materials and Methods:*** A total of 75 lymphoma patients (male: 46, female: 29) had staging [18F]FDG TB PET/CT imaging PET/CT scan at both 60-and 120-minutes post injection. PET images were automatically segmented using an AI-driven algorithm. Segmentation was scrutinized and edited. Images were read by three nuclear medicine physicians. Lesion uptake was characterized by mean, maximum and peak standardized uptake values (SUVmean/max), metabolic tumor volume (MTV) and total lesion glycolysis (TLG) using a 40%-iso-contour approach. Background uptake was characterized by predefined volumes-of-interest (VOI) in the right liver lobe (30mm diameter) and ascending aorta (10mm diameter). SUVs and standard deviation were used to calculate the coefficient of variation (COV), the tumor-to-background ratio (TBR) and contrast-to-noise ratio (CNR) for each TB PET/CT. Paired t-test was used to assess statistically significant differences (p<0.05). ***Results:*** A total of 977 lesions were identified and analyzed. 60- and 120-minutes PET images showed no significant difference in tumor uptake measured by SUVmax (60min: 3.89±3.43 vs. 120min: 3.65±3.37, p=0.09). MTV and TLG were also not statistically significantly different between the two timepoints. However, liver and blood pool activity were significantly lower in 120min p.i. acquisitions (liver SUVmean 60min: 1.66±0.34 vs. 120min 1.04±0.18, p<0.01). The COV was not significantly different for the background in both acquisition times (60min vs. 120 min liver: 0.14±0.24 vs. 0.10±0.02, p=0.27 and blood pool: 0.15±0.30 vs. 0.10±0.03, p=0.31). Lower liver and blood pool activity and similar lesion SUV values resulted in significantly higher TBR (60min: 3.32±4.54 and 120min 6.40±6.28, p<0.001) and CNR (60min: 13.56±23.07 vs. 120 min: 30.44±41.19, p<0.001) in 120min acquisition. This was confirmed by the visual impression of the late TB PET/CT imaging by three independent nuclear medicine physicians. ***Conclusion:*** [18F]FDG TB PET/CT at 120-minutes post-injection increases lesion conspicuity compared to 60-minutes post-injection due to significantly higher TBR and CNR in late imaging in lymphoma patients. Therefore, late TB PET imaging might be helpful to increase the diagnostic accuracy in lymphoma patients with low disease burden or for therapy response assessment, where lesion detectability can be difficult in standard 60-minutes TB PET imaging.

OP-489

Prognostic value of metabolic indices in baseline ^{18}F-FDG PET/CT for pediatric Burkitt lymphoma

E. Roshdy[1,2], *A. Hamoda[3,2], A. Salah[4,2], E. NasrEldin[4], A. Zaher[5,2], M. Romeih[4,2] , C. Mingels[6];*
[1]Radiotherapy and nuclear medicine department, South Egypt Cancer Institute, Assuit, EGYPT, [2]Children Cancer hospital of Egypt, Cairo, EGYPT, [3]Pediatric oncology department, National Cancer Institute, Cairo, EGYPT, [4]Radiodiagnosis department, Faculty of medicine, Helwan University, Cairo, EGYPT, [5]National Cancer Institute, Cairo-University, Cairo, EGYPT, [6]Department of Nuclear Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, SWITZERLAND.

Aim/Introduction: Burkitt lymphoma (BL) is the most common non-Hodgkin lymphoma (NHL) in children and adolescents accounting for over 40% of NHL in those under the age of 18 (1),The early recognition of patients with poor prognosis and the tailoring therapeutic remediation options to them are undoubtedly key interventions.Our aim is to assess the value of baseline PET metabolic indices [maximum standardized uptake value (SUVmax), mean standardized uptake value (SUVmean), total metabolic tumor volume (TMTV), and total lesion glycolysis (TLG) in predicting treatment response and prognosis in pediatric Burkitt lymphoma. ***Materials and Methods:*** We retrospectively analyzed 98 pediatric patients with BL who underwent baseline and end of treatment ^{18}F-FDG PET/CT from 1st January 2018 to 31 December 2019 with minimum follow up one year up to three years after end of treatment protocol. PET images were analyzed semi-quantitatively by measuring SUVmax, SUVmean, TMTV and TLG. Treatment response groups include Good response (patients with complete remission) and Poor response (patients with partial response or who develop recurrence or progression). Event-free survival (EFS) defined as the duration from start chemotherapy to last contact or first event. Events were defined as death for any reason, progression, or relapse. Overall survival (OS) was defined as the duration from start chemotherapy to last contact or death. Quantitative metabolic indices were analyzed using receiver operating characteristic (ROC) curve and area under curve (AUC) to estimate the optimal cut-of value. EFS and OS curves were constructed using the Kaplan-Meier method and compared with the log-rank test. ***Results:*** SUVmean and SUVmax do not show a statistically significant difference between treatment response groups, TMTV and TLG do exhibit statistically significant differences (p=0.008; p=0.01). After follow-up of three years, TMTV (<570 cm3) and TLG (< 4000) had better 3-year EFS rate compared with those with a high TMTV and high TLG (p=0.001). However, TMTV and TLG were not predictive of OS (p=0.81; p=0.96). ***Conclusion:*** TMTV and TLG could represent potential PET/CT metabolic biomarkers for predicting the response and prognosis of EFS in pediatric Burkitt lymphoma. These results warrant further verification in larger cohorts across multiple institutions. ***References:*** 1: Molyneux EM, Rochford R, Griffin B, et al. Burkitt's lymphoma. Metabolic tumor volume after two cycles of chemotherapy in patients treated for advanced-stage Hodgkin Lymphoma: analysis of the German Hodgkin Study Group phase III HD18 and HD21 trials

C. Kobe[1], *H. Kaul[1], G. Schneider[1], M. Fuchs[1], H. Eich[2], J. Rosenbrock[1], C. Baues[3], K. Roth[1], A. Drzezga[1], L. van Heek[1], M. Dietlein[1], P. Borchmann[1], J. Ferdinandus[1];*
[1]University of Cologne, Cologne, GERMANY, [2]Department of Radiotherapy, University Hospital of Muenster, Muenster, GERMANY, [3]Department of Radiation Oncology, Marienhospital Herne, Ruhr University Bochum, Bochum, GERMANY.

Aim/Introduction: Positron emission tomography (PET) guided treatment is standard of care to treat patients diagnosed with advanced-stage classical Hodgkin Lymphoma (AS-cHL). Currently, Deauville Score (DS) is used to determine remission in PET, but metrics such as residual metabolic tumor volume (MTV) hold promise to quantify response. However, there is still insufficient data to support their use in clinical routine. Our aim was to investigate the role of MTV in response assessment of patients treated for AS-cHL. ***Materials and Methods:*** The investigator-initiated phase III trials HD18 and HD21 randomized patients between 18-60 years with AS-cHL to receive BEACOPP (HD21 standard arm, HD18) or BrECADD (HD21 experimental arm). All patients received two cycles of chemotherapy followed by response assessment after two cycles (PET-2). MTV after two cycles (MTV-2) encompassed all lymphoma tissue with standard uptake value > 4. To exclude confounding of PET-guided treatment, we first measured MTV-2 in all patients treated in the standard arms of HD18 following amendment, of which all patients received 6 cycles of BEACOPP (C6-Cohort). Cox-regression models and Kaplan Meier estimates were used to analyse impact of MTV-2 on progression-free survival (PFS). Findings were then validated in the full ITT cohorts of HD18 and HD21. ***Results:*** A total of 645 patients were included in the C6-Cohort, of these 471 (64.6%) were rated as DS1-3 in PET-2 and 569 (88.2%) had no residual MTV-2. Patients with measurable MTV-2 had significantly inferior PFS (HR 3.62, CI95: 1.94-6.76). Results were not significant for patients without detectable MTV-2 and DS4 (HR 1.65; CI95: 0.8-3.38). In the analyzed ITT cohorts of HD18 (n = 1756) and HD21 (n= 1211), Patients with DS4 but with completely resolved MTV-2 had comparable outcomes to patients with DS1-3 (HD18: HR 1.12, CI95: 0.69-1.80; HD21: HR 1.03, CI95: 0.55-1.95), whereas patients with measurable MTV-2 featured higher risk of progression (HD18: HR 2.98, CI95: 1.92-4.64; HD21: HR 4.44, CI95: 2.78-7.09). Results were similar in both trial arms of HD21 (BEACOPP vs. BrECADD) and frequency of measurable MTV-2 remained was comparable between HD18 post-amendment and HD21. ***Conclusion:*** Complete resolution of MTV after two cycles of BEACOPP/BrECADD first-line chemotherapy for AS-cHL is associated with a favorable prognosis. Approximately 10% had measurable MTV-2 (i.e. any lesion with SUV > 4) and face significantly higher risk of progression. Our results advocate implementation of quantitative biomarkers to refine response assessment in AS-cHL.

OP-491

Comparison of Total Metabolic Tumor Volume Segmentation Methods and Their Prognostic Impact in Follicular Lymphoma

R. Durmo[1], *L. Guerra[2], S. Chauvie[3], F. Bergesio[3], F. Fallanca[4], L. Marcheselli[5], A. Anastasia[6], C. Minoia[7], L. Arcaini[8], M. Federico[9], A. Versari[1], S. Luminari[1];*

Aim/Introduction: Total metabolic tumor volume (TMTV) is

a significant prognostic factor in lymphoma patients, yet the method for calculating TMTV is debated. The main methods used involve three different segmentation workflows: fixed SUV thresholds (SUV≥2.5 or SUV≥4.0) and a 41% threshold of SUVmax. There are no large-scale studies directly comparing the impact of these three methods. This study aims to evaluate how different TMTV segmentation methods influence prognostic outcomes in a large cohort of follicular lymphoma (FL) patients from the FOLL12 trial. ***Materials and Methods:*** FOLL12 trial is a multicenter, randomized, phase III trial that compared standard vs response adapted maintenance therapy in patients with FL. In this study we included patients for whom baseline FDG PET/CT was available and centrally reviewed. The TMTV was obtained from baseline scans by summing the metabolic volumes of all individual nodal and extra nodal lesions, using the fixed SUV thresholds (SUV≥2.5 and SUV≥4.0) and 41% of SUVmax methods. AUC and log-ranks methods were used to determine the best cutoffs for the survival analysis. Hazard ratios (HRs) were calculated for the three TMTV values (TMTV2.5, TMTV4 and TMTV41), and predictive performance was assessed using the c-Harrel index. The study end point was PFS. ***Results:*** A total of 692 patients from the FOLL12 trial population were included in the study. 48% were over 60 years old, 89% had stage III-IV disease, and 40% had a high-risk FLIPI-2 score. The overall 5-year PFS rate was 79% (95% CI, 76-82%). The median TMTV was 242 mL (IQR 446) for TMTV41, 320 mL (IQR 552) for TMTV2.5, and 158 mL (IQR 332) for TMTV4 segmentation method. The optimal prognostic cut-offs for each method were identified as 200 mL for TMTV41, 250 mL for TMTV2.5, and 300 mL for TMTV4. With a cut-off point of >200 mL for TMTV41, the HR was 1.82 (95% CI, 1.39-2.40) and the c-Harrel's concordance index was 0.569. For TMTV2.5 with a cut-off point of >250 mL, the HR was 1.64 (95% CI, 1.25-2.16) and the c-Harrel's index was 0.557. For TMTV4 with a cut-off point of >300 mL, the HR was 1.62 (95% CI, 1.25-2.11) and the c-Harrel's index was 0.558. ***Conclusion:*** Higher TMTV is associated with a worse prognosis in follicular lymphoma, regardless of the measurement method used or cut point. The predictive performance, as measured by the c-Harrel index, was similar across the three methods used for calculating TMTV.

Semiquantitative Approach to DaT SPECT in Scans Without Evidence of Dopaminergic Deficit (SWEDD) in the Era of the Biological Staging of Alpha-synucleinopathies: a PPMI Analysis

G. Rovera[1], *M. Zotta[2], A. Agosti[2], C. Boccalini[3,4], D. Arnaldi[5,6], F. Garrou[2], A. Lesca[2], A. Daverio[2], F. Massa[5,6], B. Orso[6], F. Lanfranchi[7], L. Sofia[7], P. Mattioli[5,6], M. Bauckneht[5,7], S. Raffa[5], M. Pardini[5,6], V. Garibotto[3,4], S. Morbelli[1,2];*
[1]Nuclear Medicine Unit, Department of Medical Sciences, University of Turin, Turin, ITALY, [2]Nuclear Medicine Unit, AOU Città della Salute e della Scienza di Torino, Turin, ITALY, [3]Division of Nuclear Medicine and Molecular Imaging, Geneva University Hospitals, Geneva, SWITZERLAND, [4]Laboratory of Neuroimaging and Innovative Molecular Tracers (NIMTlab), Faculty of Medicine, Geneva University Neurocenter, University of Geneva, Geneva, SWITZERLAND, [5]IRCCS Ospedale Policlinico San Martino, Genoa, ITALY, [6]Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOGMI), University of Genoa, Genoa, ITALY, [7]Nuclear Medicine Unit, Department of Health Sciences, University of Genoa, Genoa, ITALY.

Aim/Introduction: SWEDD are patients clinically diagnosed with Parkinson's disease (PD) but with normal DaT-SPECT. This heterogeneous group deserves renewed attention to increase sensitivity for the identification of patients who will later fit in the new biological staging of alpha-synucleinopathies. In Parkinson's Progression Markers Initiative, SWEDD patients were classified based on visual-reading. We aimed to evaluate the capability of visual- and semiquantitative-analyses of DaT-SPECT to predict the presence of α-synuclein in cerebrospinal fluid (CSF) in SWEDD patients of PPMI. ***Materials and Methods:*** In PPMI, 76/499 patients recruited as PD are classified as SWEDD (median-age 63 years). Baseline Unified Parkinson's Disease Rating Scale (UPDRS_III) and Montreal-Cognitive-Assessment (MoCA) are available for all SWEDD while CSF and 2-years follow-up are available in 51/76. Scans were visually evaluated in our center by 2 experts. Inter-reader-agreement was evaluated (Fleiss Kappa). Semiquantitative-assessment of striatal-binding-ratio (SBR) and z-scores were computed with Datquant® versus 118 healthy-controls. Scans classification based on z-score for striatum, substriatal regions and putamen/caudatus (P/C-ratio) was compared using two z-score cut-offs (ZS -1.3, -2). The predictive value of visual-reading and z-scores for α-synuclein and for the persistence/progression of motor and cognitive impairment was assessed. ***Results:*** Median UPDRS_III and MoCA were 13 [IQR:7-18] and 27 [IQR:26-29] at baseline and 12 [IQR:6-21] and 26 [IQR:24-28] at follow-up. At visual-reading 5 scans were classified as positive, 5 borderline and 40 negative by both experts, leading to an overall fair concordance (Kappa 0.32). As to alpha-synuclein positivity (n = 10), expert-reading achieved the highest accuracy together with P/C-ratio based on -2 ZS (80.4%). Considering positive+borderline categories, a sensitivity of 70% was only reached by the expert-reading (not by semiquantification). P/C ratio of the most affected hemisphere showed the highest correspondence with expert-reading (ROC AUC:0.74) and it was the only parameter able to increase specificity of expert-reading for alpha-synuclein (97.6% for -2 ZS and 92.7% for -1.3 ZS). P/C-ratio also showed a high specificity to predict persistence of motor and cognitive impairment at 2-y-follow-up (100% for UPDRS_III ≥6, MoCA<26 with -2 ZS) however its sensitivity was low. ***Conclusion:*** In most cases SWEDD patients do not reflect an alpha-synucleinopathy. A combined visual-reading and a more conservative quantitative approach (ZS -2) capturing the typical unbalanced reduction of nigro-putaminal versus nigro-caudate deafferentation seems to provide the highest accuracy for the identification of patients with an apparently normal DaT-SPECT which, however, need to find a position in the biological staging of alpha-synucleinopathies.

Spatial covariance of cortical metabolism with multiple metrics of nigrostriatal degeneration in Dementia with Lewy bodies (DLB)

L. Sofia[1], *L. Lombardo[2], F. D'Amico[1], T. Di Raimondo[1], F. Massa[2], D. Arnaldi[2], B. Orso[2], F. Lanfranchi[1], S. Raffa[3], G. Celesti[4], G. Sambuceti[1], M. Bauckneht[1], S. Morbelli[5], M. Pardini[2];*
[1]Nuclear Medicine Unit, Department of Health Sciences (DISSAL), University of Genoa, Genoa, ITALY, [2]Department of Neuroscience,

Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOGMI), University of Genoa, Genoa, ITALY, [3]Nuclear medicine unit, IRCCS Ospedale Policlinico San Martino, Genoa, ITALY, [4]Nuclear Medicine Unit, University of Messina, Messina, ITALY, [5]Nuclear Medicine Unit, University of Turin, Turin, ITALY.

Aim/Introduction: From a biomarker point of view, Dementia with Lewy bodies (DLB) is characterised by a dopamine transporter's (DaT) deficit in the striatum and by specific patterns of cortical hypometabolism, which can be assessed using DaT-SPECT imaging and fluorodeoxyglucose (FDG)-PET, respectively. The relationship between specific features derived from dopaminergic and metabolic neuroimaging is still unclear. Given this background, we aimed to investigate the relationship between dopaminergic deafferentation in different striatal regions (caudate, anterior and posterior putamen) and the presence of specific cortical metabolic patterns. ***Materials and Methods:*** 76 patients with DLB who underwent both Dat-SPECT and FDG-PET were included in the study (27 females, 49 males). The DaT-SPECT scans were analysed using DaTQUANT 2.0 and the striatal binding ratios (SBR) were measured. All FDG PET scans were flipped in order to have the more affected hemisphere on the right side. The correlation between caudate, anterior and posterior putamen SBR and FDG-PET metabolic patterns was assessed by means of standard parametric mapping (SPM12). The analyses were corrected considering age, MMSE and sex as nuisances. P values corrected for family-wise errors (p[FWE])<0.05 at the cluster level were accepted as significant. ***Results:*** SBR reduction in the caudate showed a significant correlation with hypometabolism in the parietal, occipital and lateral temporal cortex, with the most significant cluster located in the lateral temporal cortex (p[FWE]<0.001). The dopaminergic deafferentation of the anterior putamen demonstrated a significant correlation with a less extended cluster of hypometabolism located in the same areas, with the most significant cluster in the angular gyrus of the parietal lobe (p[FWE]<0.005). Posterior putamen SBR values resulted to be significantly associated to the presence of hypometabolism in the occipital cortex and, to a less extent, in the parietal lobule, with the most significant cluster in the inferior occipital gyrus (p[FWE]<0.001). ***Conclusion:*** in DLB patients, the spreading of the dopaminergic deafferentation from the posterior putamen to the anterior putamen and the caudate is associated to a widening of the clusters of cortical hypometabolism. Moreover, the dopaminergic deficit in each different striatal region seems to be linked to the presence of hypometabolism in different specific areas of the cortex.

The Role of [18F]FDG PET in the Early Identification of Psychiatric-Onset Dementia with Lewy Bodies: a Preliminary Analysis

C. Pini[1,2], *G. Ninatti[1,2], S. Caminiti[1,3,4], L. Jonghi-Lavarini[2], M. Mattoli[5,6], L. Bonanni[7], A. Chiti[1,3], D. Perani[1,3];*
[1]Nuclear Medicine Department, IRCCS Ospedale San Raffaele, Milan, ITALY, [2]School of Medicine and Surgery, University of Milano-Bicocca, Monza, ITALY, [3]Vita-Salute San Raffaele University, Milan, ITALY, [4]Department of Brain and Behavioral Sciences, University of Pavia, Pavia, ITALY, [5]Department of Neuroscience, Imaging and Clinical Sciences, University G. D'Annunzio, Chieti, ITALY, [6]Nuclear Medicine, Ospedale Santo Spirito, Pescara, ITALY, [7]Neurology Clinic, Department of Medicine and Aging Sciences, University G. D'Annunzio, Chieti, ITALY.

Aim/Introduction: Delirium/Psychiatric-onset dementia with Lewy bodies (DLB) is one of the possible prodromal manifestations of DLB that typically features a primary psychiatric disorder preceding dementia onset and other neurological signs. The identification of patients presenting with prodromal DLB and its differentiation from primary psychiatric disorders is challenging, possibly resulting in diagnostic delays and unsuccessful pharmacological treatments, interfering with correct patient management. The aim of this study is to describe the possible use of [18F]FDG PET in this complex scenario. ***Materials and Methods:*** We retrospectively selected patients with a final diagnosis of probable psychiatric-onset DLB, according to the research criteria proposed by McKeith et al., who underwent brain [18F]FDG PET/CT between 2020 and 2023, for suspect neurodegenerative disease in an early undiagnosed phase. Data on clinical history, neurological examination, neuropsychological assessment, CSF biomarkers analysis, EEG, and morphological brain imaging were available. Brain hypometabolism on [18F]FDG PET was assessed by means of a voxel-wise approach (SPM software) on each patient, and as a group analysis. ***Results:*** Fourteen patients (M:F = 7:7, median age 72.5, range 62-83) were included. The most common presentations were new-onset psychosis (n=8), major depression and/or anxiety disorder (n=7), delirium and/or delusions (n=8). By the time of PET imaging, seven (50%) patients developed mild symptoms of parkinsonism, seven (50%) patients mild cognitive impairment, while only two (14%) a moderate or severe cognitive impairment. SPM voxel-wise subject analysis revealed occipital lobe hypometabolism in the whole series (n=14), in one case unilateral, occasionally extending to the parietal lobe(s) (n=8), temporal lobe(s) (n=5), and/or frontal lobe(s) (n=3). A group commonality analysis revealed a signature area of hypometabolism involving the inferior occipital lobe, bilaterally. ***Conclusion:*** [18F]FDG PET hypometabolic patterns were supportive of DLB diagnosis, thus representing a possible biomarker in the challenging classification of these patients in the early undiagnosed phase. Of note, the identification of a specific imaging signature of inferior occipital hypometabolism may shed light on the complex interplay between visual and emotional networks, crucial for the pathogenesis of the psychiatric manifestations. This study aims to pave the way for larger prospective investigations, to confirm the potential clinical impact and predictive utility of [18F]FDG PET and its capability to significantly improve the management of this rare clinical entity. ***References:*** McKeith IG, et al.; prodromal DLB Diagnostic Study Group. Research criteria for the diagnosis of prodromal dementia with Lewy bodies. Neurology. 2020 Apr 28;94(17):743-755.

Brain Regional Metabolic Changes in Isolated REM Sleep Behaviour Disorder Progression Stages

L. Lopes[1,2], *J. Ge[3], J. Lu[3], C. Schäfer[4], J. Hong[1], Q. Xu[3], J. Wang[3], J. Wu[5], J. Wang[5], C. Bassetti[6], A. Rominger[1], H. Yu[5], C. Zuo[3], P. Wu[3], K. Shi[1];*
[1]Department of Nuclear Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, SWITZERLAND, [2]Graduate School for Cellular and Biomedical Sciences, University of Bern, Bern, SWITZERLAND, [3]Department of Nuclear Medicine & PET Center, Huashan Hospital, Fudan University, Shanghai, CHINA, [4]Sleep-Wake Epilepsy Center, Department of Neurology, Inselspital, Bern University Hospital, University of Bern, Bern, SWITZERLAND, [5]Department of Neurology, Huashan Hospital, Fudan University, Shanghai, CHINA, [6]Department of Neurology, Inselspital, Bern University Hospital, University of Bern, Bern, SWITZERLAND.

Aim/Introduction: Isolated rapid-eye-movement sleep

behavior disorder (iRBD) is an early stage of neurodegenerative α-synucleinopathies, such as Parkinson's disease (PD), dementia with Lewy bodies, and multiple system atrophy. At present, no biomarkers are clinically available for predicting phenoconversion to α-synucleinopathy. Despite the revealed metabolic patterns of iRBD and PD, the metabolic changes within iRBD disease progression remain unknown. This study aimed to explore regional brain metabolism changes with iRBD disease progression. ***Materials and Methods:*** Sixty-seven FDG PET scans of 19 iRBD patients with mean follow-up ± standard deviation of 5.9±2.4 years (mean age 64.9±5.7 years, 14 male) were included. These patients eventually converted to PD. We divided scans into 3 stages: S0 - more than 6 years before conversion; S1 - less than 6 years before conversion; S4 - conversion to PD. All scans were spatially normalized to the MNI brain space and intensity normalized by the average of the whole brain. Regions of interest (ROI) were obtained using the AAL3 atlas. Mean standardize uptake value ratios (SUVr) were obtained for each ROI. Kruskal-Wallis test was used to assess differences in ROI between stages and Mann-Whitney for pairwise comparisons. ***Results:*** Significant differences were found in the lingual gyrus (p=0.031), lateral (p=0.007) and medial geniculate nucleus (p=0.033) of thalamus, locus coeruleus (p=0.026) and median raphe nucleus (p=0.029) between stages. From S0 to S1, a significant increase in SUVr was detected on lateral geniculate nucleus of thalamus (p=0.011). From S1 to S2, the lingual gyrus mean SUVr significantly decreased (p=0.020) and the locus coeruleus and median raphe nucleus significantly increased (p=0.030 and p=0.029, respectively). From S0 to S2, there was a decrease in lingual gyrus (p=0.016) and increase in lateral (p=0.006) and medial geniculate nucleus (p=0.011) of thalamus, locus coeruleus (p=0.007) and median raphe nucleus (p=0.009). ***Conclusion:*** In this relatively large longitudinal cohort for the rare disease of iRBD, we found several brain regions that suffer metabolic changes with disease progression. Our results align with previous studies on metabolic regional changes, especially in the lingual gyrus. As a novelty, also the thalamus lateral and medial geniculate nucleus, the locus coeruleus and the median raphe nucleus metabolism seem to change with iRBD progression. These findings contribute to understanding of the underlying neurobiological mechanisms involved in the evolution of iRBD towards α-synucleinopathy. Further studies are warranted to validate these findings and potentially establish biomarkers for predicting phenoconversion to α-synucleinopathies in clinical settings.

OP-497

Decreased striatal blood flow after dopamine transporter inhibition

M. Jonasson, *L. Appel, T. Danfors, G. Antoni, M. Lubberink; Uppsala University, Uppsala, SWEDEN.*

Aim/Introduction: 11C-PE2I is a PET ligand with high affinity and selectivity for the dopamine transporter (DAT). In a dual-biomarker approach both DAT availability and relative blood flow can be assessed from the same dynamic scan. In a recent study we found a significant correlation between striatal binding potential (BPND) as a measure of DAT availability and relative tracer delivery (R1) as a measure of relative cerebral blood flow with 11C-PE2I in healthy subjects [1]. Since dopamine can be an inhibitor of neuronal activity, one hypothesis is that higher availability of DAT may implicate less available dopamine, and hence less inhibition of the post synaptic neurons which means they are more active and require a higher blood flow. To test this hypothesis, the aim of the present work was to evaluate whether DAT inhibition results in reduced relative striatal blood flow within individuals. ***Materials and Methods:*** Data from 42 healthy subjects was retrospectively re-analysed. All subjects underwent 80 min dynamic 11C-PE2I PET scans at baseline and at steady-state conditions following once-daily dosing of a dopamine reuptake inhibitor for ten days. Volumes of interest (VOIs) were automatically defined using a probabilistic VOI template and BPND and R1 were calculated using a basis function implementation of the simplified reference tissue model with cerebellum as reference region. Averaged BPND and R1 values were extracted from putamen and caudate and only subjects with more than 10% reduction of BPND in putamen were included in further analysis. The differences between R1 values at baseline and during DAT inhibition were assessed using a paired t-test and correlation between the relative difference of BPND and R1 from both scans were calculated. ***Results:*** Of the 42 includes subjects, 33 had a reduction > 10% of BPND in putamen. A significant reduction of R1 was found between baseline and post-drug scans in both putamen and caudate (p-value < 0.0001 and 0.03 respectively). Mean reductions of BPND and R1 were 24.4% ± 17.7% and 4.0% ± 6.6% in putamen and 27.0% ± 14.4% and 2.3% ± 9.5% in caudate. Correlation between the relative change of R1 and BPND between the two scans was moderate, r = 0.49 and 0.36 for putamen and caudate respectively. ***Conclusion:*** Inhibition of dopamine transporters is associated with reduction of relative striatal blood flow. ***References:*** [1] Jonasson et al., J Cereb Blood Flow Metab., 2023.

OP-498

Dual Biomarker Potential of ^{18}F-PR04.MZ-PET: Assessing Dopaminergic Function and Cerebral Blood Flow in Degenerative Parkinsonian Syndromes.

A. Damian[1], *L. Gutierrez[2], V. Kramer[3], I. Amorin[4], A. Haeger[3], G. Falasco[1], L. Urrutia[1], I. Cordero[1], E. Savio[1], J. R. Higgie[4], A. Lescano[4], T. Arias[2], P. Duarte[1], O. Alonso[1], R. Ferrando[1];*
[1]Uruguayan Centre of Molecular Imaging (CUDIM), Montevideo, URUGUAY, [2]Unidad Académica de Medicina Nuclear e Imagenología Molecular, Hospital de Clínicas, Universidad de la República, Montevideo, URUGUAY, [3]PositronMed, Santiago, CHILE, [4]Instituto de Neurología, Hospital de Clínicas, Universidad de la República, Montevideo, URUGUAY.

Aim/Introduction: 18F-PR04.MZ is a novel dopamine transporter (DAT) radiotracer that exhibits with high affinity and selectivity for this membrane protein. Prior studies involving different radiotracers in dementia and movement disorders have suggested that R1 images derived from compartmental analysis of dynamic studies could serve as an indicator of cerebral blood flow (CBF). This study aims to explore the association between a rough index of CBF obtained from dynamic 18F-PR04.MZ studies (R1) and brain metabolism in patients diagnosed with parkinsonian syndromes. ***Materials and Methods:*** Fourteen patients with degenerative parkinsonisms (11 Parkinson's disease, 3 multiple system atrophy) underwent PET/CT scans with both 18F-FDG and 18PR04.MZ radiotracers within a three-month timeframe. Additionally, 17 healthy controls (HC) examined with 18F-PR04.MZ PET/CT were included. Parametric R1 images were generated via compartmental analysis of dynamic 18F-PR04.MZ studies using the Simplified Reference Tissue Model (SRTM). Specific Uptake Ratios (SUR) were calculated in both patients and HC to assess dopaminergic integrity. Comparative analysis of SUR between patients and HC was conducted, and the correlation between R1 and brain metabolism was explored across cortical and subcortical brain regions using Pearson's correlation (α < 0.05). ***Results:***

Patients with degenerative parkinsonism exhibited lower SUR values (9.0+/-2.6, 5.8+/-4.9 and 1.1+/-0.66 for caudate, putamen and substantia nigra respectively) compared to HC (15.8 +/- 3.2, 20.7 +/- 4.4 and 4.4 +/- 1.7, p < 0.0001). A significant correlation was found in patients between R1 derived from 18F-PR04.MZ studies and brain metabolism in various regions, including the caudate nuclei (p<0.0001, correlation coefficient [CC] 0.86), putamen (p= 0.005, CC 0.70), parietal (p<0.0001, CC 0.79), occipital (p=0.005, CC 0.70), frontal (p=0.01, CC 0.66), and temporal (p=0.018, CC 0.62) cortex. ***Conclusion:*** R1 images derived from dynamic ^{18}F-PR04.MZ studies hold promise in delineating alterations in CBF within cortical and subcortical regions in degenerative parkinsonisms, thereby aiding in the differential diagnosis of these patients.

Age-related high-frequency hearing loss and inhibitory neurotransmission - methodological requirements for working out a connection

P. Deutsch[1,2], *R. Buchert[3], S. Rosemann[4,2], M. Mamach[5,2], D. Weiberg[1], C. Thiel[4,2], T. Ross[1], F. Bengel[1], E. A. Lopez-Poveda[6], G. Klump[7,2], G. Berding[1,2];*
[1]Department of Nuclear Medicine, Hannover Medical School, Hannover, GERMANY, [2]Cluster of Excellence Hearing4all, German Research Foundation, GERMANY, [3]Department of Diagnostic and Interventional Radiology and Nuclear Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, GERMANY, [4]Biological Psychology, Department of Psychology, School of Medicine and Health Sciences, University of Oldenburg, Oldenburg, GERMANY, [5]Department of Radiation Protection and Medical Physics, Hannover Medical School, Hannover, GERMANY, [6]Instituto de Neurociencias de Castilla y León, Universidad de Salamanca, Salamanca, SPAIN, [7]Division of Animal Physiology and Behaviour, Department for Neuroscience, School of Medicine and Health Sciences, University of Oldenburg, Oldenburg, GERMANY.

Aim/Introduction: High-frequency hearing loss (HFHL) is known to occur with increasing age. Furthermore, also age-related changes in inhibitory processing in the brain are observed. The aim of the present study was to describe possible interrelations between age, HFHL and the binding potential (BP) of inhibitory neuroreceptors for Flumazenil. ***Materials and Methods:*** Pure-tone audiograms (500-12,000Hz) and F18-flumazenil PET/CT-examinations were performed in 23 individuals (51±12 years; range 24-69) without hearing loss in need of treatment (i.e. bilateral loss in pure tone average < 20%). F^{18}-flumazenil PET was performed dynamically from the injection of 370MBq over one hour. BPs of the GABA-A receptors were calculated using the simplified reference tissue model with the pons as the reference region for the primary auditory cortex (Heschl-ROI according to the AAL-atlas) using either the mean or the 75th percentile of the BP-values within the ROI (the latter to avoid partial volume effects due to white matter contained in the region). The density of the gray matter (GMD) in the Heschl-ROI was determined from MR-tomograms (MPRAGE). The normal distribution of the variables was tested using the Shapiro-Wilk and Kolmogorov-Smirnov tests, and a Pearson correlation was only calculated in the case of a normal distribution, otherwise a Spearman correlation was calculated. ***Results:*** The HFHL at 12,000Hz correlated significantly with age (r=0.61, p=0.0019). With regard to the BP, significant negative correlations were found for the mean values in the Heschl-area with age bilaterally (r=-0.49, p=0.0190) and the HFHL (r=-0.45, p=0.0317) for the right side. The 75th percentile of the BPs in the Heschl-region showed with age significant correlation only for the right side (r=-0.47, p=0.0221) and with HFHL no significant correlation at all (p≥0.34). GMD correlated negatively with age (r=-0.71, p=0.0001) and HFHL (r=-0.45, p=0.031). ***Conclusion:*** These results suggest that age-related HFHL might be associated with a reduction in inhibitory GABA-A receptor-binding in the primary auditory cortex as a possible counter-regulation. Restricting the correlated BPs to primary cortical sections (75th percentile) could lead to an overestimation of the receptor binding particularly in older patients with atrophy, which would explain the partly loss of significant correlations. In addition, the parallel correlation of GMD with age and HFHL supports the need for an accurate partial volume correction to identify the specific influence of receptor binding.

Metabolic Network Connectivity Disturbances in Parkinson's Disease: A Novel Imaging Biomarker

B. Chen, *Y. Tang, S. Hu;*
Department of Nuclear Medicine, Xiangya Hospital Central South University, Changsha, CHINA.

Aim/Introduction: While 18F-fluorodeoxyglucose (18F-FDG) positron emission tomography (PET) has provided insight into the metabolic abnormalities associated with Parkinson's disease (PD) at systemic levels, the diagnosis and understanding of the underlying network interactions within the metabolic connectome in these patients remain largely unknown and challenging. ***Materials and Methods:*** We performed a retrospective cohort study, analyzing data from 52 PD patients and 82 well-matched healthy controls (HC). An individual metabolic connectome, based on the standard uptake value (SUV) of 18F-FDG PET, was constructed using the Jensen-Shannon Divergence Similarity Estimation (JSSE) method. Then, this approach was utilized to compare the intra- and inter-network connectivity between PD patients and HC. Finally, a random forest (RF) classifier was utilized to determine the neuroimaging characteristics that most effectively differentiate between PD and HC. ***Results:*** This study used 18F-FDG PET imaging data to construct individual metabolic networks based on the JSSE algorithm to investigate the characteristic pattern of interaction effects among brain functional networks in PD patients. Our results indicated that there is a significant increase in inter-network connectivity between the somatomotor network (SMN) and frontoparietal network (FPN) in PD patients when compared to HC. Notably, only the increased inter-network connectivity between SMN and FPN in the PD group was corrected through the multiple comparisons in the 10% and 20% sparsity (p < 0.05, Bonferroni corrected). Among these results, the altered inter-network connectivity in 10% sparsity could be used to distinguish the PD group and HC group with an accuracy of 70.15%, sensitivity of 50.00%, and specificity of 82.93%. In 20% sparsity, the significantly different inter-network connectivity could be used to identify the PD patients with an accuracy of 67.91%, sensitivity of 46.15%, and specificity of 81.71%. This significantly altered connectivity pattern was able to effectively differentiate PD patients from HC. ***Conclusion:*** By using 18F-FDG PET imaging to construct individual metabolic networks, this study identified heightened inter-network connectivity between SMN and FPN in PD patients. This discovery suggests that it could serve as a potential imaging biomarker for the early detection of PD.

The value of ^{18}F-FDG PET/CT in the evaluation of efficacy and prognosis of gastric cancer patients with peritoneal metastases
Y. Peng[1], *M. Shi[2], D. Xiong[3], S. Lu[4], C. Yan[4], Z. Zhu[4], B. Li[1], Z. Yang[4],* ***J. Hu[1];***
[1]Department of Nuclear Medicine, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA, [2]Department of Oncology, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA, [3]Department of Nuclear Medicine, Baoshan People's Hospital, Yunnan, CHINA, [4]Department of General Surgery, Shanghai Institute of Digestive Surgery, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA.

Aim/Introduction: Conversion therapy and conversion surgery (CS) can improve the prognosis of gastric cancer (GC) patients with peritoneal metastasis (PM). However, patients benefit differently. There is no way to confirm the prognostic benefit non-invasively and early. This retrospective study aimed to evaluate the performance of 18F-FDG PET/CT in predicting the conversion therapy outcome and prognosis of GC patients with PM. ***Materials and Methods:*** 104 GC patients with PM were enrolled, undergoing 121 18F-FDG PET/CT scans. 43 scans were before conversion therapy, 56 were after conversion therapy, and 22 were after CS. Maximum standardised uptake value (SUVmax), mean standardised uptake value (SUVmean), metabolic tumour volume (MTV), total lesion glycolysis (TLG), and tumor-to-background ratio (TBR)of primary and peritoneal lesions, anastomotic and recurrent metastatic lesions were recorded to evaluate their association with the conversion therapy outcome and prognosis. ***Results:*** In assessing the conversion therapy outcome, the TBR of primary and peritoneal lesions after conversion therapy could guide the completion of CS. The TBR of the peritoneal lesion to the mediastinal blood pool SUVmax (TBRAmaxp) was the best predictor (cutoff=0.705, specificity 83.3%, sensitivity 79.2%, AUC 0.843, P<0.001). In terms of prognostic evaluation, the TBR of the peritoneal lesion to the hepatic blood pool SUVmax (TBRLmaxp) before conversion therapy was the best predictor of 12 and 18 months survival(cutoff=1.605, OS=12 months, AUC 0.706, P=0.01; OS=18 months, AUC 0.722, P=0.014), the SUVmax of the peritoneal lesion after conversion therapy (SUVmaxp) was the best predictor of 20 and 24 months survival (OS=20 months, cutoff=1.646, AUC 0.838, P=0.001; OS=24 months, cutoff=1.475, AUC 0.803, P=0.004). Metabolic parameters of peritoneal lesions before and after conversion therapy could predict overall survival (OS). During postoperative recurrence assessment, the SUV and TBR of recurrent metastatic lesions could predict OS after CS. Additionally, the SUVmap and TBRAmaxp before conversion therapy, the MTV of the gastric lesion (MTVg), and the SUVmaxp after conversion therapy could predict the prognosis of patients who underwent CS (cutoff were 8.477, 3.477, 20.86, and 1.481 respectively, P were 0.016, 0.037, 0.037, and 0.047 respectively). ***Conclusion:*** Metabolic parameters of 18F-FDG PET/CT have excellent predictive value for the conversion therapy outcome and prognosis in GC patients with PM. ***References:*** 1. EPS-149
Value of ^{18}F-FAPI-04 PET-CT for prediction of pathologic response and survival in locally advanced pancreatic ductal adenocarcinoma after neoadjuvant chemotherapy
Y. Zhang[1], *M. Xu[1], Y. Wang[2], F. Yu[3], X. Chen[1], G. Wang[1], K. Zhao[1], X. Su[1];*
[1]Department of Nuclear Medicine, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, CHINA, [2]Department of Pharmacy, The Second Affiliated Hospital of Zhejiang Chinese Medical University, Hangzhou, CHINA, [3]Department of Pathology, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, CHINA.

Aim/Introduction: Accurate assessment of residual disease of tumor and lymph nodes after neoadjuvant chemotherapy (NCT) is crucial in the active surveillance for patients with pathological complete response (pCR) and the optimal extent of lymphadenectomy for patients with non-pCR. It has been reported that Fluorine-18 (18F)-labeled fibroblast activation protein inhibitor 18F-AlF-NOTA-FAPI-04 (18F-FAPI-04) PET/CT imaging outperformed 18F-FDG PET/CT in oncology for diagnosing and staging tumors. However, there are very few data on the use of 18F-FAPI-04 PET/CT for monitoring therapeutic

efficacy in oncology.This study aimed to evaluate the predictive value of 18F-AlF-NOTA-FAPI-04 (18F-FAPI-04) PET/CT for pathologic response to NCT in patients with locally advanced pancreatic ductal adenocarcinoma (LAPDAC). ***Materials and Methods:*** This retrospective study included 34 patients with histopathologically and radiologically confirmed LAPDAC who received 18F-FAPI-04 PET/CT scans before NCT. After 4-6 circles of NCT, these patients underwent radical resection. Pathological response to NCT was assessed by pathologic tumor regression grades (TRG) based on Evans system. PET/CT parameters, including the maximum standardized uptake value (SUVmax), FAPI-avid tumor volume (FTV), and total lesion FAP expression (TLF), were evaluated for their association with TRG after NCT using Spearman's rank test. Receiver operating characteristic (ROC) curve analysis was used to determine the optimal cut-off points for differentiating pathologic good response from pathologic poor response. Kaplan-Meier and Cox regression methods were used to analyses the relationship between recurrence-free survival (RFS) or overall survival (OS) and potential predictors. ***Results:*** Of 34 patients with LAPDAC, 12 patients were pathologic good response Evans III-IV), and 20 patients were pathologic poor response (Evans I-II). SUVmax, FTV and TLF in the groups of Evans III-IV were significantly lower than those in the groups of Evans I-II (15.22±6.61vs.20.23±7.07, 43.92±29.20 vs.76.80±47.40, 250.62±160.7 vs.532.42±388.26, all P <0.05). Furthermore, SUVmax and TLF were higher in poorly differentiated PDAC than those in well-to moderately differentiated neoplasms (15.33±5.87 vs.22.33±7.14, 303.63±219.40 vs.577.46±422.60, all P <0.05). On multivariate analysis, FTV >54.21 and TLF >290.21 had a poor RFS and OS, respectively (HR = 3.24, P = 0.014 and HR = 3.35, P = 0.019) and OS (HR = 7.35, P = 0.002 and HR = 7.09, P = 0.004) in PDCA after NCT. ***Conclusion:*** The parameters of 18F-FAPI-04 PET/CT showed a significant correlation with tumor aggressive pathological characteristics, and had the excellent performance for predicting pathologic tumor regression grades after NCT in LAPDAC. FTV and TLF were independent postoperative prognostic factors for RFS and OS for LAPDAC.

Comparison of ^{18}F-FAPI-74 PET/CT and Contrast-Enhanced CT in Gastric Cancer

J. Cai, *H. Chen, L. Sun, L. Yu, W. Xu, Y. Pang, L. Zhao; Department of Nuclear Medicine, First Affiliated Hospital of Xiamen University and School of Medicine, Xiamen University, Xiamen, CHINA.*

Aim/Introduction: Treatment decisions for gastric cancer rely on precise evaluation. This study aims to compare the efficacy of 18F-FAPI-74 PET and contrast-enhanced CT (CECT) in diagnosing and staging gastric cancer, as well as assessing their impact on clinical decision-making. ***Materials and Methods:*** This prospective study analyzed patients with confirmed gastric cancer who underwent concurrent 18F-FAPI-74 PET/CT and CECT between June 2022 and July 2023. PET/CT and CECT findings were confirmed by histopathology or radiographic follow-up. Two independent blinded experts read the scans, and their findings were combined for analysis. ***Results:*** Our cohort comprised 24 gastric cancer patients, 12 patients for initial staging and 12 for recurrence detection. Regarding lesion-based diagnostic accuracy, no significant advantage of 18F-FAPI-74 PET/CT over CECT was demonstrated. However, 18F-FAPI-74 exhibited higher sensitivity (55.95% vs. 32.14%) and accuracy (98.15% vs. 98.24%) than CE-CT in detecting lymph node metastasis. Moreover, 18F-FAPI-74 outperformed CECT in detecting abdominopelvic metastases in all regions (100%, 13/13), showing higher sensitivity (99.15% vs. 57.26%), specificity (76.92% vs. 51.28%), and accuracy (93.59% vs. 55.77%) than CECT. Compared with CECT, 18F-FAPI-74 PET/CT resulted in upstaging 6 patients' TNM staging among all patients (24.43%, [6/28]) and significantly altered the clinical management of 4 patients (14.29% [4/28]) in whom recurrence or metastases were detected. ***Conclusion:*** 18F-FAPI-74 PET/CT is more effective in assisting lymph node and peritoneal metastasis detection in gastric cancer patients compared to CECT. Integrated 18F-FAPI-74 is a potential method for staging in gastric cancer patients.

EPS-151

Metabolic activity via ^{18}F-FDG PET/CT is predictive of risk stratification and prognostic of hypermetabolic gastrointestinal stromal tumors

L. Zhang, *Y. Liu, Y. Deng, H. Chen, J. Wu, X. Lan, W. Cao; Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA.*

Aim/Introduction: Most gastrointestinal stromal tumors (GISTs) with positive uptake of $^{[18F]}$-FDG tend to have higher malignant potential. This study aimed to evaluate the value of various metabolic parameters of $^{[18F]}$-FDG PET/CT for predicting the risk stratification and prognosis for hypermetabolic GIST. ***Materials and Methods:*** We retrospectively analyzed 42 hypermetabolic GIST patients who underwent $^{[18F]}$-FDG PET/CT before curative resection as initial treatment. Intratumoral-metabolic heterogeneity (heterogeneity index, [HI] and heterogeneity factor, [HF]) and metabolic parameters (standardized uptake value [SUV], metabolic tumor volume [MTV], and total lesion glycolysis [TLG]) of the lesions were determined. MTV, TLG, HI and HF were calculated based on fixed threshold of SUVmax at 2.5, 3.0, 3.5. The area under the curve (AUC) was used to evaluate the predictive ability of factors for risk stratification. Overall survival (OS) was as endpoints. Based on the multivariate Cox regression analysis, independent risk factors were identified. ***Results:*** This study included 42 patients with GIST in hypermetabolism of the $^{[18F]}$-FDG PET/CT (SUVmax > 3.5), including 20 patients with non-high-risk and 22 patients with high-risk. Location, size, mitotic count, necrosis or hemorrhage, MTV (2.5, 3.0, 3.5), TLG (2.5, 3.0, 3.5), HI (2.5, 3.0, 3.5), and HF, in the high-risk group were significantly higher than those in the non-high-risk group (all P<0.05). Location, size, and metabolic parameters (MTV3.0, TLG2.5, HI3.0, HF) were chosen for logistic regression analyses. In multivariate logistic regression analyses, MTV3.0 (P=0.025, OR: 17.34), location (P=0.05, OR:7.09), and size (P=0.029, OR=9.07) were independently correlated with risk stratification. The AUC of the mathematical model of MTV3.0 + location+ size was 0.926 compare to the AUC of MTV3.0 was 0.805 (P<0.05). Gender, SUVmax, HI3.0 and HI3.5 were significant prognostic factors affecting OS (P<0.05). HI3.0 and HI3.5 were excluded from the multiple regression analysis, because of the VIF > 10 in multicollinearity. Therefore, SUVmax retained statistically significant prognostic value as independent determinants of OS. Patients with values of SUVmax>10.25 had a shorter OS (P=0.013). ***Conclusion:*** Various metabolic parameters derived from $^{[18F]}$-FDG PET/CT were higher in high-risk GIST. MTV3.0, location and size were independent risk factors for risk stratification, and the mathematical model could predict risk stratification more effectively for patients with hypermetabolic GIST preoperatively. In this group of hypermetabolic GIST patients, SUVmax were independent risk factors for OS.

EPS-152

Application of ^{18}F-FDG PET/MRI Guided Chemoradiotherapy in Esophageal Cancers: A Prospective Clinical Trial.

J. Dai, *H. Wang, R. Tian, B. Zou;*
Sichuan University, Chengdu, CHINA.

Aim/Introduction: Esophageal cancer (EC) is a highly fatal disease and causing approximately 500,000 deaths worldwide each year. Curative treatment for advanced EC typically includes chemoradiotherapy followed by surgery, nevertheless, EC patients still have a poor prognosis and with a five-year survival of less than 20%. It is the basis of patient management to evaluate response precisely. 18F-fluorodeoxyglucose positron emission tomography (18F-FDG PET) can reflect metabolism changes during treatment. Thus, we utilized multimodal images based on longitudinal 18F-FDG /magnetic resonance imaging (MRI), correlated imaging parameters with pathological tumor regression scores (TRS), aiming to assess intra-tumor heterogeneity through the dose-response matrix (DRM) and explore potential imaging biomarkers for TRS prediction. ***Materials and Methods:*** This study prospectively included patients with pathologically confirmed esophageal squamous cell carcinoma. All patients received two cycles of chemotherapy (albumin-paclitaxel and carboplatin) plus concurrent radiotherapy (40Gy/20f). Patients underwent 18F-FDG PET/MR scans pre- and post- neoadjuvant therapy. We delineated the region of interest by a cutoff of standard uptake value of 2.5, on which SUVmean and SUVmax were calculated. Following deformable image registration, a DRM model was constructed based on the change ratio of SUV in voxel level. The final response was assessed based on the pathological diagnosis of the surgical specimen. Patients were divided into positive TRS group (score 2 or 3) and negative TRS group (score 0 or 1). The primary outcome was the association of imaging parameters with TRS. ***Results:*** We prospectively recruited 14 EC patients with 13,667 voxels in total from October 2022 to July 2023 (ChiCTR2100051599). Of them, three patients had a positive TRS and ten patients achieved negative TRS. The DRM was 0.40±0.11 for the entire cohort. Only four patients had voxels with DRM>1.0. And the number of voxels with DRM>1 in each patient present significant difference between TRS+ and TRS- groups (p=0.008). However, mean, median, coefficient of variation, 25 and 75 percent values of DRM, SUVmean and SUVmax of pre- and post-therapy scans all did not show significant correlation with TRS. ***Conclusion:*** The voxel numbers with high DRM values in each patient, instead of SUV parameters at sole timepoint, has the potential to predict TRS. Voxel analysis based on longitudinal 18F-FDG PET/MRI might reflect spatial differences of tumor regression during neoadjuvant chemoradiotherapy. Further studies with larger sample size might yield more convincing results. ***References:*** [1] Yan D, Chen S, Krauss D J, et al. Int J Radiat Oncol Biol Phys, 2019, 104(1): 207-218.

EPS-153

Predictive Factors For Postembolization Syndrome After 166-Holmium Radioembolization

R. Silva, *J. A. Oliveira, M. Silva, L. Costa;*
Unidade Local de Saúde de Santo António, Porto, PORTUGAL.

Aim/Introduction: Transarterial catheter-directed therapies are used in primary and secondary hepatic malignancies that are unresectable and not amenable to other local treatments. Transarterial radioembolization(TARE), a subtype of these locoregional therapies, delivers microspheres containing 166Ho or 90Y into the tumor-supplying artery.[1] Post-embolization syndrome(PES) may occur 24-72h after and usually presents with fever, nausea and/or abdominal pain. This study aims to characterize the patients submitted to 166Ho-TARE and to identify predictors of PES. ***Materials and Methods:*** Prospective study including patients with BCLC stage 0, A and B hepatocellular carcinoma(HCC) or neuroendocrine tumor(NET)/colorectal cancer(CRC) metastasis with contraindications for other locoregional therapies submitted to 166Ho-TARE procedure during 2023 in a tertiary referral center. Patients were subdivided between two groups whether PES had occurred. Q-suite was used for dosimetry and SPSS v27 for statistical purposes. ***Results:*** Fourteen patients were deferred for 166Ho-microspheres therapy. The median age at the procedure was 64,0(13,3) years, 64% were female and the main type of cancer was HCC. Most lesions were solitary (1,1±0,4) with a median maximum diameter of 53mm. PES incidence was 29%(n=4), with nausea/vomiting being the most common symptoms. The majority of patients with PES were males(75%) with a median age of 66,5 years, although not statistically significant between groups.The number of vials used for liver malignancies was significantly higher in the PES group than the non-PES group, although the administered activity was similar between groups. Dosimetric and volumetric variables were similar between both groups. The area under curve (AUC) of the ROC curve using the number of vials as a predictive factor for the occurrence of PES was 0,700, which was considered acceptable. ***Conclusion:*** Data on PES occurrence rate after TARE is scarce, but broadly studied after transarterial chemoembolization(TACE). Our PES incidence(29%) was similar to few TARE studies[2], as its minimal embolic effect is associated with a lower incidence of PES (20-55%vs 15-90% in TACE). [3]Our studies suggest that the number of vials used for the treatment may be associated with higher PES occurrence rates(AUC0,700) rather than the administered activity and number of microspheres(AUC0,400). A higher number of vials may be associated with a more complex tumor vascular anatomy and burden. Also, the more vials are used, the greater the volume of saline solution perfused, which ultimately leads to stasis and reflux. These factors may play a role in PES[4], although it is pathophysiologically multifactorial and complex.[5]

EPS-154

The prognostic value of Choline PET/CT for the initial assessment of patients with hepatocarcinoma

I. Vierasu, *H. Levillain, M. Pezzullo, C. Marin, J. Dhont, M. Paesmans, P. Flamen;*
Hôpital Universitaire de Bruxelles, ULB, Bruxelles, BELGIUM.

Aim/Introduction: The aim of this study was to assess the added prognostic value of Choline PET/CT compared with MRI and FDG PET/CT as "standard of care" and the correlation with the overall survival (OS) in patients with hepatocarcinoma (HCC). Some articles showed that dual-tracer FDG/Choline PET/CT behavior of uptake shows high overlap between well and poorly differentiated HCC. Few data are available and the usefulness of Choline PET/CT in the clinical decision process in HCC is not established yet. ***Materials and Methods:*** This retrospective study included 78 treatment naïve patients with HCC who underwent Choline PET/CT for the initial assessment together with "standard of care" MRI and 18F-FDG PET/CT. To our knowledge this is the largest population of patients with HCC who underwent dual tracer PET/CT comparing to data already published. MRI and PET/CT exams were analyzed in a workflow created in order to make correlations with the MRI regarding the overlapping. The tumor volume (VOI) was defined on the MRI and this VOI was propagated

on the coregistered FDG and respectively Choline PET/CT in order to perform PET segmentation. MRI, Choline and FDG volumes were tested for association with overall survival (OS). The linear correlation between MRI and Choline volumes was evaluated and multivariate models were created on the basis of dichotomized variables using the median value of MRI, Choline and FDG volume as a threshold. ***Results:*** The results of univariate analyses showed that larger MRI and Choline volumes were associated with poor OS. MRI volume >17,81 was associated with poor OS in comparison with MRI <= 17,81 (p value 0,005; hazard ratio 0,35; 95% CI 0,16- 0,77). Choline volume > 8,4 was also associated with poor OS. The survival curves were significantly different for Choline volume median cutoff > 8,4 in comparison with Choline volume <=8,4 (p value 0,04; hazard ratio 0,4; 95% CI 0,21-1,01). A positive FDG PET/CT was associated with poor OS in comparison with a negative FDG PET/CT (p value 0,02). There was a significant statistical correlation between MRI volume and Choline volume (R squared 0,79; p value <0,0001). The multivariate analyses showed that neither Choline volume nor FDG volume had not statistically significant prognostic value (p value 0,8 and 0,2 respectively). ***Conclusion:*** In our study of a unique population of patients with HCC who underwent dual tracer PET/CT, Choline PET/CT did not have an added prognostic value compared with MRI.

EPS-155

Fibroblast activation protein alpha (FAPα) directed imaging in patients with peritoneal carcinomatosis (PC) of various tumor entities prior to laparoscopy for planned cytoreductive surgery (CRS)/hyperthermic intraperitoneal chemotherapy (HIPEC)

K. Pabst[1], *L. Kessler[2], T. Bartel[1], H. Lanzafame[1], J. T. Siveke[3], R. Hamacher[3], M. Nader[1], W. P. Fendler[1], K. Herrmann[1], A. D. Rink[4];*
[1]Department of Nuclear Medicine, University Hospital Essen, Essen, GERMANY, [2]Department of Diagnostic and Interventional Radiology and Neuroradiology, University Hospital Essen, Essen, GERMANY, [3]Department of Medical Oncology, West German Cancer Center, University Hospital Essen, Essen, GERMANY, [4]Department of General, Visceral and Transplant Surgery, West German Cancer Center, University Hospital Essen, Essen, GERMANY.

Aim/Introduction: Although the detection efficacy (DE) of PC on contrast-enhanced CT (ceCT) has improved, it still varies significantly depending on location, size and presence of ascites, resulting in an ongoing diagnostic challenge. The extent of PC and the involvement of the small intestine region are critical factors for the success of CRS/HIPEC. Here, we report the DE of FAPα directed imaging in PC of various tumor entities compared to 18F-FDG PET and ceCT. ***Materials and Methods:*** In a prospective observational study conducted between 01/2022 and 10/2023, 12 patients with expected PC underwent clinical 68Ga-FAPI-46, 18F-FDG PET, and ceCT. One blinded nuclear medicine physicist and radiologist independently performed a region-based analysis. Disagreement was resolved by joint consensus read. Evaluation included sensitivity, specificity, and positive/negative predictive values (PPV/NPV) on a regional basis and by lesion size score using a simplified PC index (PCI) grouping small intestine involvement in one region. Wilcoxon-test was performed to compare SUVmax and Tumor-to-Background Ratio (TBR; blood pool, liver, intestine, muscle). Standard of reference was the PCI obtained during subsequent laparoscopy. Impact on management was evaluated through a post-imaging questionnaire sent to the treating surgeon. ***Results:*** In 12 patients with n=6/3/3 colorectal cancer/gastric cancer/other, 72/120 regions (60%) were detected as tumor-positive during subsequent laparoscopy (mean PCI: 12 (range:0-30); time between 68Ga-FAPI-46/laparoscopy (mean (range): 17 days (1-71 days)). Region-based sensitivity/specificity/PPV/NPV were 53%/93%/90%/56% for 68Ga-FAPI-46 PET, 32%/96%/91%/51% for 18F-FDG PET and 47%/91%/89%/53% for ceCT, For all imaging modalities, DE decreases with decreasing lesion size score (Score 3 vs. 1: 68Ga-FAPI-46: 65% vs. 26%, 18F-FDG: 48% vs. 16%, ceCT: 57% vs. 23%). DE in small intestine involvement was 56% for 68Ga-FAPI-46/50% for 18F-FDG/56% for ceCT. Tumor uptake (SUVmax) for 68Ga-FAPI-46 PET vs. 18F-FDG PET was: 5.1 (2.5) vs. 3.8 (2.1) (average (SD)), p=0.16. Only TBRliver was significantly higher on 68Ga-FAPI-46 PET (5.4 (3.0) vs. 1.6 (1.0) (average (SD)), p=0.012) when compared to 18F-FDG PET. 3/12 patients were not treated with CRS/HIPEC. This decision was based on the finding of a high PCI during laparoscopy in n=2 and on the detection of extra-abdominal metastases on 68Ga-FAPI-46 PET in n=1. ***Conclusion:*** Detection of PC still remains challenging. DE of 68Ga-FAPI-46 PET was slightly superior to 18F-FDG PET/ceCT. It may be used additionally in equivocal cases, especially in the liver region due to better delineation, prior to planned CRS/HIPEC. In some cases, 68Ga-FAPI-46 PET might contribute to avoid unnecessary major surgery.

EPS-156

PET/CT imaging with [^{68}Ga]Ga-NOTA-anti-HER2-VHH1 in cancer patients with potential HER2 expression: first clinical results

L. De Mey[1,2], *O. Gondry[1,2], S. Bourgeois[2], A. Bracke[2], H. Everaert[2,1], L. Goethals[1,2], L. Raes[2,1], V. Caveliers[1,2], S. Van den Block[1,2], S. Joris[1,2], A. de Haar-Holleman[1,2], C. Fontaine[1,2], N. Devoogdt[1], H. Dierick[1,2], J. Cousaert[2], T. Lahoutte[1,2], M. Keyaerts[1,3];*
[1]VUB, Brussels, BELGIUM, [2]UZ Brussel, Brussels, BELGIUM, [3]Jessa Ziekenhuis, Hasselt, BELGIUM.

Aim/Introduction: Human epidermal growth factor receptor type 2 (HER2) can be highly expressed on the cell membrane of breast cancer (BC) and gastric cancer (GC). HER2-targeted therapies now also include antibody-drug conjugates that have also shown efficacy in cancers with a lower expression level (HER2-low). Information on the HER2-expression is important for therapy selection, and is currently assessed using tissue biopsies, but this does not allow assessment of spatial and temporal heterogeneity. This could be better assessed using PET/CT imaging. A phase I and-II clinical trial of [68Ga]Ga-NOTA-anti-HER2-VHH1 in 40 patients confirmed the excellent safety profile and repeatability of the tracer. We here report on cohort 2 of the current trial (NCT03924466). ***Materials and Methods:*** This single-centre, open-label, nonrandomized, phase II study evaluates the clinical potential of [68Ga]Ga-NOTA-anti-HER2-VHH1, a radiolabelled single domain antibody fragment for PET/CT imaging of HER2, in patients with different cancer types. Metastatic cancer patients with at least one lesion (minimum 10 mm; short axis for lymph nodes), were included. Per protocol, 37 - 185 MBq with up to 200 µg NOTA-Anti-HER2 VHH1 was administered and PET/CT was performed at 90±15min. Tracer uptake in metastases was measured using Standard Uptake Values (SUV) and compared with SUV-values on [18F]FDG PET/CT, both reported as ranges in different lesions. Liver and liver capsule metastases were analysed separately due to the increased HER2-signal in healthy liver. ***Results:*** Until April 2024, 6 patients were included and injected with 118.54+/-8.56 MBq. In patient 1, HER2-positive BC with skin and bone metastases, HER2-uptake was 0.71-1.61 while FDG-uptake was 3.35-7.03. In patient 2, HER2-positive oesophageal cancer with bone metastasis, HER2-uptake was 3.23 and FDG-uptake was 3.75. In patient 3,

HER2-positive GC with brain metastasis, HER2-uptake was 3.16. In patient 4 and 5, HER2-positive GC and HER2-low BC respectively, only liver metastases where present. In patient 6, HER2-low BC with bone metastasis, HER2-uptake was 2.66 and FDG-uptake was 6.24 on [18F]FDG PET/CT. For liver (capsule) metastasis, HER2-uptake was 6.21-11.28, irrelevant of HER2-status and likely due to nearby normal liver uptake. ***Conclusion:*** In conclusion, [68Ga]Ga-NOTA-anti-HER2-VHH1 is effective in targeting metastasis of HER2-positive and HER2-low metastatic cancer of different cancer types at the level of the brain and bone. Metastatic lesions in liver and gastro-intestinal are difficult to evaluate due to high physiological background activity.

EPS-157

^{68}Ga-FAPI-46 in patients with Gastrointestinal Stromal Tumors (GIST) - An Update of a Single-Center, Prospective, Observational Study (NCT04571086)

***T. Bartel*[1,2]**, *K. M. Pabst[1,2], R. Hamacher[3,2], H. Lanzafame[1,2], S. Bauer[3,2], J. Falkenhorst[3,2], J. T. Siveke[3,2,4], L. Kessler[5,2], M. Nader[1,2], K. Herrmann[1,2], W. P. Fendler[1,2];*
[1]Department of Nuclear Medicine, West German Cancer Center, University Hospital Essen, Essen, GERMANY, [2]German Cancer Consortium (DKTK), Partner site University Hospital Essen, Essen, GERMANY, [3]Department of Medical Oncology, West German Cancer Center, University Hospital Essen, Essen, GERMANY, [4]Bridge Institute of Experimental Tumor Therapy, West German Cancer Center, University Hospital Essen, Essen, GERMANY, [5]Department of Diagnostic and Interventional Radiology and Neuroradiology, University Hospital Essen, Essen, GERMANY.

Aim/Introduction: GISTs represent the most prevalent mesenchymal neoplasms of the gastrointestinal tract. Previous studies have demonstrated heterogeneous uptake on 68Ga-FAPI (fibroblast activation protein inhibitor)-46 PET in GISTs. Here, we compared detection efficacy, tumour uptake, and tumour-to-background ratio (TBR) of 68Ga-FAPI-46 PET with contrast-enhanced CT (ceCT) and 18F-FDG PET, and aimed to assess the impact on management in an extended cohort. ***Materials and Methods:*** All patients with GIST in our prospective observational study (NCT04571086) who underwent 68Ga-FAPI-46 PET/CT for initial staging/restaging between 06/2020 and 12/2023 were retrospectively reviewed. Clinical data and histopathology, including mutation status, were collected. A lesion-/region-based analysis was performed to evaluate the detection efficacy of 68Ga-FAPI-46 PET compared to 18F-FDG PET and ceCT, considering true/false positive/negative findings. Histopathology/follow-up were standard of reference. SUVmax/SUVpeak/TBRs were compared using Wilcoxon test. Subgroup analyses for age, sex, primary tumour location, current therapy, and number of prior therapies were performed for both PET modalities (Mann-Whitney U test). Impact on management was assessed using pre-/post-imaging physician questionnaires. ***Results:*** 23 patients with GIST (median age: 61 years; range: 24-84 years) were evaluated. C-KIT/other mutations were present in n=19 (83%)/n=4 (17%) patients. 144 lesions were detected across all imaging modalities (primary: n=34 (23.6%), lymph node: n=1 (0.7%), distant metastasis: n=109 (75.7%)). Detection rates for 68Ga-FAPI-46 PET/18F-FDG PET/ceCT were: n=11/32/34 (primary), n=1/1/1 (lymph node), n=66/50/80 (distant). False-positive findings on 18F-FDG PET/ceCT were n=23 lymph nodes in 3 patients (all true negative on 68Ga-FAPI-46 PET), and false-positive findings on 68Ga-FAPI-46 PET were n=3 distant metastases in 3 patients (all true negative on 18F-FDG PET/ceCT). SUVmax showed no significant difference between both tracers (68Ga-FAPI-46 vs. 18F-FDG: 7.6±5.1 vs. 9.0±8.8). Interpatient heterogeneity was confirmed with mean SUVpeak values ranging from 1.2 to 20.5 for 68Ga-FAPI-46 PET and from 1.6 to 31.2 for 18F-FDG PET. Subgroup analysis revealed a significant difference in SUVmax on 68Ga-FAPI-46 PET between patients with ≤1/>1 pretreatments (mean±standard deviation: 8.8±5.6 vs. 4.9±2.7, p=0.046) and patients on therapy vs. those with >1 month since last therapy (10.9±5.2 vs. 6.3±4.7, p=0.011). TBRliver/TBRbackground was significantly higher for 68Ga-FAPI-46 (p=0.005/p<0.001) and TBRbloodpool/TBRmuscle for 18F-FDG (p=0.011/p<0.001). Biopsy was avoided/additionally performed in n=3/n=2 patients. Based on 68Ga-FAPI-46 PET, treatment was changed from chemotherapy to active surveillance in one patient. ***Conclusion:*** 68Ga-FAPI-46 PET demonstrates a higher detection rate for distant metastases compared to 18F-FDG PET, with ceCT showing the highest overall detection efficacy. 68Ga-FAPI-46 PET uptake was highest in treatment-naïve patients.

EPS-158

Characteristics and Prognostic Relevance of ^{18}F-FDG PET/CT in Hepatoblastoma

***W. Hu*[1,2]**, *C. Qin[1,2], M. Li[1,2], X. Zhang[1,2], Y. Feng[1,2], X. Wang[1,2], X. Lan[1,2];*
[1]Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Scien, Wuhan, CHINA, [2]Hubei Key Laboratory of Molecular Imaging, Wuhan, CHINA.

Aim/Introduction: To evaluate the imaging features and prognostic relevance of metabolic parameters derived from pre-treatment 18F-FDG PET/CT scans in pediatric patients with hepatoblastoma (HB). ***Materials and Methods:*** A retrospective analysis was conducted on pediatric patients with extracranial solid tumors suspected of HB who underwent pretreatment 18F-FDG PET/CT scans. The study focused on patients who met specific inclusion criteria, including being under 18 years of age, having complete medical records, and receiving systemic therapy after the nuclide imaging. Patients who had undergone surgery or chemotherapy before the PET imaging or had concomitant tumors were excluded. Clinical data such as age, sex, and alpha fetoprotein (AFP) were collected. Metabolic parameters of the primary tumors, including maximum standardized uptake value (SUVmax), mean standardized uptake value (SUVmean), tumor metabolic volume (MTV), and total lesion glycolysis (TLG), were measured. The prognostic value of metabolic parameters and clinical data for overall survival (OS) and progression-free survival (PFS) was analyzed using the univariate Kaplan-Meier method. ***Results:*** Among the cohort of 47 patients diagnosed with extracranial solid tumors, a total of 12 patients (6 boys and 6 girls) were pathologically confirmed to have HB, and all of them showed positive results on PET imaging (sensitivity and specificity : 100%). The patients were initially diagnosed with HB at a median age of 19.0 months (6.0-73.0 months). The HB lesions exhibited high and heterogeneous accumulation of FDG and PET/CT imaging successfully visualized lymph node metastases in 7 cases. In the primary HB tumors, the median SUVmax was 7.48 (4.92-11.87), SUVmean was 4.02 (2.46-6.32), maximum diameter was 10.64±2.65 cm, MTV was 127.00 cm3 (25.82-696.00 cm3), and TLG was 400.65 g (112.44-1539.84 g). The median survival time was 458 days (3-1163 days). Factors such as age > 37.5 months (P=0.027 and P=0.009), SUVmax < 5.83 (both P=0.027), SUVmean < 3.07 (both P=0.027), and normal AFP (P=0.005) were identified as significant predictors for both progression-free survival and overall survival, with normal AFP predicting a shorter overall survival time. ***Conclusion:*** Our study demonstrated the clinical utility of 18F-FDG PET/CT in

diagnosing and assessing the prognosis of HB. The presence of higher levels of HB and normal AFP levels was associated with OS and PFS, aligning with established guidelines. Interestingly, our findings revealed that lower SUVmax and SUVmean values were also associated with worse OS and PFS outcomes, presenting a unique aspect of our research.

EPS-159

^{68}Ga-FAPI PET imaging assesses tumor immunity and guides TGF-β inhibition to sensitize metastatic colorectal cancer to immunotherapy

S. Tang, K. Li, W. Liu, ***S. Song;***
Fudan University Shanghai Cancer Center, Shanghai, CHINA.

Aim/Introduction: Improving and predicting tumor response to immunotherapy remains challenging. Combination therapy with a transforming growth factor-β receptor (TGF-βR) inhibitor that targets cancer associated fibroblasts (CAFs) is promising to enhance efficacy of immunotherapies. However, the effect of this approach in clinical trials is limited, requiring in vivo methods to better assess tumor responses to combination therapy. ***Materials and Methods:*** We measure CAFs in vivo using 68Ga-labeled fibroblast activation protein inhibitor (68Ga-FAPI)-04 for PET/CT imaging to guide combination of TGF-β inhibition and immunotherapy. 131 patients with metastatic colorectal cancer (CRC) underwent 68Ga-FAPI and 18F-fludeoxyglucose (18F-FDG) PET/CT imaging. Relationship between uptake of 68Ga-FAPI or 18F-FDG and tumor immunity was analyzed in patients. Mouse cohorts of metastatic CRC were treated with TGF-βR inhibitor combined with KN046 which blocks PD-L1 and CTLA4, followed with 68Ga-FAPI and 18F-FDG micro-PET/CT imaging to assess tumor responses. ***Results:*** (1) In our clinical trial, high uptakes of 68Ga-FAPI, but not 18F-FDG, demonstrated strong association with reduced tumor infiltrated T cells in patients with peritoneal or liver metastatic colorectal cancer.(2) In the preliminary trial, Patients who presented high uptakes of 68Ga-FAPI by PET/CT scan in their colorectal metastasis demonstrated poor prognosis upon PD-1/PD-L1 immunotherapy.(3) In preclinical mouse cohorts, TGF-β receptor inhibitor significantly sensitized metastatic colon cancer to KN046 (an ICB blocks PD-L1 and CTLA4), enhancing tumor infiltrated T cell number and function.(4) 68Ga-FAPI PET/CT imaging accurately monitored the dynamical changes of CAFs and tumor response to TGF-β receptor inhibitor combined with immunotherapy. 68Ga-FAPI PET/CT could guide scheduling of TGF-β inhibitor to optimize combination strategy with immune checkpoint blockade (ICB) in treating metastatic CRC. ***Conclusion:*** 68Ga-FAPI PET/CT imaging is powerful in assessing tumor immunity and response to immunotherapy in metastatic CRC. This study supports future clinical application of 68Ga-FAPI PET/CT to guide CRC patients for precise TGF-β inhibition plus immunotherapy, recommending 68Ga-FAPI and 18F-FDG dual PET/CT for CRC management.

EPS-160

FDG-PET/CT as a method of patient selection and response evaluation in patients with peritoneal metastasis treated with Pressurized IntraPeritoneal Aerosol Chemotherapy. The PIPAC-OPC7 study

S. Roensholdt[1], *M. G. Hildebrandt[2], S. Detlefsen[3], P. Pfeiffer[4], M. B. Mortensen[1];*
[1]Odense PIPAC Center, Department of Surgery, Odense University Hospital, Odense, DENMARK, [2]Odense PIPAC Center, Department of Nuclear Medicine, Odense University Hospital, Odense, DENMARK, [3]Odense PIPAC Center, Department of Pathology, Odense University Hospital, Odense, DENMARK, [4]Odense PIPAC Center, Department of Oncology, Odense University Hospital, Odense, DENMARK.

Aim/Introduction: Pressurized IntraPeritoneal Aerosol Chemotherapy (PIPAC) is increasingly used in the treatment of patients with peritoneal metastasis (PM). Most studies use RECIST, Peritoneal Cancer Index, or the histological Peritoneal Regression Grading Score (PRGS) to evaluate treatment response, but this assessment remains challenging and lacks consensus. Imaging with FDG-PET/CT is the cornerstone during response assessment in several cancer types, providing information on both morphological changes as well as qualitative and quantitative metabolic changes. This is the first study to evaluate the utility of FDG-PET/CT during PIPAC for patient selection and response evaluation in patients with PM. ***Materials and Methods:*** A prospective pilot study will be conducted on 16 patients suffering from peritoneal metastasis originating from four primary cancers: gastric, pancreatic, ovarian, and colorectal cancer. Patients are treated in a series of three PIPACs; peritoneal biopsies are taken during each treatment and evaluated according to PRGS. The FDG-PET/CT scans will be completed at baseline, and after PIPAC 1, and 3. Patients with FDG-negative PM at baseline are still included to investigate if PIPAC itself leads to FDG-positive changes after PIPAC 1. ***Results:*** The study started inclusion in March 2024. The primary objective is the number of patients with metabolic response according to FDG-PET/CT evaluated by PERCIST 1.0 after PIPAC 3. Secondary objectives include number of patients with metabolic response after PIPAC 1, number of patients with FDG-positive peritoneal surface after PIPAC 1 despite FDG-negative baseline PET/CT (false positive/feasibility), and the number of patients where FDG-PET/CT (evaluated by PERCIST one-lesion) agrees with histological response according to PRGS after PIPAC 1 and 3. ***Conclusion:*** We hypothesize that FDG-PET/CT and PERCIST 1.0 is feasible and can reflect metabolic response in patients with PM treated with PIPAC. This study may provide important data needed to plan future randomized controlled trials within the treatment of PM.

EPS-161

^{68}Ga-FAPI-46-PET/CT in Primary Sclerosing Cholangitis with Suspected Cholangiocarcinoma

D. Weiberg[1], *T. Felgenhauer[2], C. P. Czerner[1], J. Diekmann[1], H. Wedemeyer[3], F. M. Bengel[1], L. M. Martins Schlindwein[3], T. Wirth[3];*
[1]Department of Nuclear Medicine, Hannover Medical School, Hannover, GERMANY, [2]Department of Radiation Protection and Medical Physics, Hannover Medical School, Hannover, GERMANY, [3]Department of Gastroenterology, Hepatology and Endocrinology, Hannover Medical School, Hannover, GERMANY.

Aim/Introduction: Primary Sclerosing Cholangitis (PSC) is a rare inflammatory, fibrosing and stricturing biliary duct disease, that is associated with a high risk of cholangiocarcinoma (CCC). Recognition of CCC in PSC remains challenging due to a lack of sensitive and specific imaging markers. 68Ga-FAPI-PET/CT has recently been suggested as a suitable CCC imaging tool. We sought to evaluate its potential in the specific setting of PSC. ***Materials and Methods:*** 11 PSC patients (5w, 6m; mean duration of PSC 8.0±5.9y), 8 patients with histologically proven CCC (2w, 6m; mean duration of CCC 2.7±3.3y) and 5 controls without history of hepatic disease (1w, 4m) underwent 68Ga-FAPI-46 PET/CT. Results were compared to endoscopic retrograde cholangiopancreatography (ERCP), laboratory parameters and

clinical Fibrosis-4 (FIB-4) score. For PET analysis, physiological uptake was defined as mean SUVpeak of all controls, plus 2 SD. Non-physiologic liver uptake patterns were visually classified, and a FAP liver volume above physiologic uptake (FAP-livo) was calculated. ***Results:*** Physiological liver FAP signal in controls was homogeneous with a SUVbw of 1.5+0.3. FAP-livo was elevated in CCC as well as in PSC patients, and lesion SUVpeak did not differ between PSC and CCC (mean±SD, 9.9±3.9 vs. 13.7±5.6, p=0.10). Owing to the high level of diffuse FAP signal elevation in active PSC regions, additional detection of focal lesions typical for CCC was not feasible. However, PSC mainly showed diffuse regional uptake, while CCC showed mainly focal uptake. In PSC, FAP expression corresponded with ERCP results, being more intense along dominant strictures. FAP-livo correlated significantly with FIB-4 (r=0.67, p=0.03) and White-blood-cell-count (r=0.66, p=0.03) in PSC. ***Conclusion:*** Active PSC is associated with strongly elevated FAP overexpression, up to the level of CCC. While this complicates the detection of PSC-associated CCC, FAPI PET/CT may be used for the assessment of PSC activity as a measure of fibrotic disease progression risk or response to anti-inflammtory/anti-fibrotic therapy.

EPS-162

The Role of 68Ga-FAPI-04 PET/CT in Predicting Pathological Response to Neoadjuvant Chemoradiotherapy in Rectal Cancer

Ö. Erol Fenercioglu[1], *E. Beyhan[2], R. Şahin[3], M. C. Baloğlu[3], G. Alçın[3], Ö. Mermut[4], B. Yalçın[4], E. Arslan[3], T. F. Çermik[3], N. Ergül[3];*
[1]Tekirdağ Dr. İsmail Fehmi Cumalıoğlu City Hospital, Department of Nuclear Medicine, Tekirdağ, TÜRKIYE, [2]Şırnak State Hospital, Department of Nuclear Medicine, Şırnak, TÜRKIYE, [3]University of Health Sciences Istanbul Training and Research Hospital, Department of Nuclear Medicine, Istanbul, TÜRKIYE, [4]University of Health Sciences Istanbul Training and Research Hospital, Department of Radiation Oncology, Istanbul, TÜRKIYE.

Aim/Introduction: Neoadjuvant chemoradiotherapy (nCRT) before surgery is the standard treatment approach in locally advanced rectal cancer.Patients with a complete response can be followed without surgery according to "wait and watch" protocol.Predicting the response to neoadjuvant treatment will reduce mortality and morbidity by personalizing treatment and increase the quality of life in this patient group with long life expectancy. Cancer-associated fibroblasts are responsible for tumor progression and resistance to treatment.Recent studies with 68Ga-FAPI PET/CT have reported its important role in determining treatment approaches as well as diagnosis.In our study, we aimed to determine the role of 68Ga-FAPI-04 PET/CT in predicting the pathological response to nCRT in rectal cancer, in comparison with 18F-FDG PET/CT. ***Materials and Methods:*** A total of 22 patients with newly diagnosed locally advanced rectal cancer were included in the study.68Ga-FAPI-04 PET/CT imaging was performed in the same week as ^{18}F-FDG PET/CT before neoadjuvant treatment.Both scans were acquired 60 minutes after the i.v. injection. SUVmax, SUVmean, SUVpeak of the primary tumor for both; GTV and TLF for 68Ga-FAPI; MTV and TLG values for ^{18}F-FDG were calculated.All patients received nCRT(capecitabine + radiotherapy).According to post-treatment MRI, colonoscopy and colonoscopic biopsy findings, 4 cases with complete response were included in the "watch and wait" protocol.Other patients undergone surgery and pathological response to treatment was evaluated and classified according to the Modified Ryan Tumor Regression Score.PET/CT findings of two main groups: complete responders and non-responders were compared and analyzed. ***Results:*** After nCRT, complete response (score 0) in 7 (32%), partial and poor response (score 2 and 3) in 15 (45% and 23%) patients were reported.While there was no difference between responders and non-responders SUVmax, SUVmean, SUVpeak in ^{18}F-FDG (p>0.05 for all); SUVmax, SUVmean and SUVpeak of the primary tumor in the complete responders were significantly lower than non-responders in 68Ga-FAPI-04 (p:0.003 for all).No significant difference was detected between ^{18}F-FDG and 68Ga-FAPI-04 SUVmax/mean/peak values in responders (p>0.05 for all).^{18}F-FDG SUVmax and SUVpeak were significantly higher than 68Ga-FAPI-04 in non-resporders (p:0.01, p:0.01).No significant difference was detected between SUVmean (p>0.05). MTV, TLG, GTV, and TLF values of responders were significantly lower than non-responders (p:0.001, p:0.012, p:0.004, p:0.005). ***Conclusion:*** Many retrospective studies have reported that stroma-rich colorectal tumors are associated with shorter disease-free and overall survival, and resistance to treatment.According to our study, treatments can be personalized, and treatment-related morbidities can be reduced with the predictive information provided by 68Ga-FAPI PET/CT in rectal cancer.

EPS-163

The Role of Ga68-NODAGA-Exendin-4 PET/CT Imaging in the Diagnosis of Endogenous Hyperinsulinemic Hypoglycemia

R. Sahin, *T. F. Çermik, M. C. Baloğlu, Z. Tosunoğlu, Ö. F. Şahin, A. E. Öztürk, G. Alçın, E. Arslan, N. Ergül;*
University of Health Sciences, Istanbul Training and Research Hospital, Department of Nuclear Medicine, Istanbul, TÜRKIYE.

Aim/Introduction: Endogenous hyperinsulinemic hypoglycemia (EHH) commonly involves the differential diagnosis of insulinoma and nesidioblastosis. Conventional methods are limited in localizing insulinoma. 68Ga-Exendin-4 PET/CT has gained attention recently. This study investigates the effectiveness of 68Ga-Exendin-4 PET/CT in detecting insulinomas in cases with suspected EHH and in differentiating nesidioblastosis. ***Materials and Methods:*** In this study, we included cases that were examined with the diagnosis of EHH and whose insulinoma could not be localized with conventional methods.Following the intravenous 68Ga-Exendin-4 injection in all patients, standard whole body images were taken at the 1st hour and abdomen at the 2nd hour. The patients were divided into two groups: cases with a focal focus suspicious for insulinoma on 68Ga-Exendin-4 PET/CT, and cases with no focus detected and suspected nesidioblastosis.Pancreatic volumes(PV), average pancreatic SUVmean(PS), average mediastinal SUVmean(MS) values as background activity and pancreatic burden (PB) = ((PSxPV) / MS)) values were calculated for 19 adult patients. Average PB (± SD) values for both groups were calculated. The level of difference in PB values between insulinoma and nesidioblastosis groups was evaluated by t-test. The findings were confirmed by pathology results. ***Results:*** PET/CT imaging with an average of 2.52 (±0.99) mCi 68Ga and 4.69 (±1.65) µg Exendin-4 was applied on 19 adults and 3 newborns. Focal 68G-Exendin-4 uptake, at least three times higher than physiological pancreatic uptake, was observed in 6 adults and 2 newborns, favoring insulinoma. In the insulinoma group, the average PB was calculated as 447.97±108.05, while in the nesidioblastosis group, it was 847.73± 666.6. Although 10 patients had PB values above the reference value set by the insulinoma group, suggesting nesidioblastosis, no significant difference was found in average PB values between the two groups (p:0.09). One case with PB: 2837.3, initially suspected of

nesidioblastosis, was confirmed to have diffuse cell hyperplasia on pathological analysis after distal pancreatectomy. All cases with focal uptake on 68Ga-Exendin-4 PET/CT were confirmed by pathology. ***Conclusion:*** In cases evaluated for EHH, 68Ga-Exendin-4 PET/CT enables tumor localization favoring insulinoma in those where conventional methods and 68Ga-DOTATATE PET/CT fail, facilitating the selection of limited surgical methods. The absence of focal uptake with 68Ga-Exendin-4 and high diffuse pancreatic uptake strengthens the preoperative diagnosis of nesidioblastosis, supporting total pancreatectomy as a primary method. Based on our results, we propose 68Ga-Exendin-4 PET/CT for diagnosing nesidioblastosis. 68Ga-Exendin-4 PET/CT stands out with its contribution to distinguishing insulinoma from nesidioblastosis, aiding in selecting the appropriate surgical approach.

EPS-164

Structured Reporting for the Diagnosis of Neuroendocrine Tumor (NET) in ^{18}F-SiFAlin-TATE PET/CT - Impact on Quality and Interdisciplinary Communication

A. Hinterberger*[1,2]*, *L. Trupka[3], S. Kortbein[4], J. Rübenthaler[4], F. Grawe[1,2];*
[1]DKFZ Hector Cancer Institute at the University Medical Center Mannheim, Heidelberg, GERMANY, [2]Department of Radiology and Nuclear Medicine, University Medical Center Mannheim, Mannheim, GERMANY, [3]Department of General, Visceral and Transplant Surgery, University Hospital, LMU Munich, Munich, GERMANY, [4]Department of Radiology, University Hospital, LMU Munich, Munich, GERMANY.

Aim/Introduction: Our retrospective single-center study aims to evaluate the impact of structured reporting (SR) using a self-developed template on report quality compared to conventional free-text reporting (FR) in ^{18}F-SiFAlin-TATE Positron Emission Tomography/Computer Tomography (PET/CT) for the primary staging and therapy monitoring of patients diagnosed with neuroendocrine tumors (NET). ***Materials and Methods:*** We included 50 patients who underwent ^{18}F-SiFAlin-TATE-PET/CTs for NET staging. FR reports were generated post-examination and compared to SR reports, which were composed retrospectively using a self-developed template within an established software tool (Smart Reporting). All findings were evaluated by a radiologist and a surgeon through a questionnaire to determine their contribution to facilitating clinical decision-making and to assess their completeness, linguistic quality, and overall quality. ***Results:*** In SR the rate of missing at least one key feature was significantly lower than in FR with missing information in 51% of FR vs. 11% of SR ($p < 0.001$). SR significantly increased the capacity of facilitating therapy decision-making from 32% in FR to 55% in SR ($p<0.001$). Trust in the report was significantly higher in SR with a mean of 5.0 (SD= 0.5) vs. 4.7 (SD= 0.5) for FR ($p < 0.001$). SR received significantly higher mean ratings regarding linguistic quality with 4.7 for SR vs. 4.4 for FR ($p =0.004$) and overall report quality with a mean of 4.9 for SR vs. 4.6 for FR ($p < 0.001$). ***Conclusion:*** Using SR over traditional FR enhances the overall quality of reports in ^{18}F-SiFAlin-TATE-PET/CTs for NET staging, serving as a tool to streamline clinical decision-making and enhance interdisciplinary communication in the future.

Severe radiation-induced lymphopenia during PRRT is associated with overall survival

G. G. de Harder, *C. H. A. M. Veerman, M. M. de Boer, T. T. P. Seijkens, M. E. T. Tesselaar, E. A. Aalbersberg;*
Antoni van Leeuwenhoek, Amsterdam, NETHERLANDS.

Aim/Introduction: The development of severe radiation-induced lymphopenia (RIL) has been shown to be associated with overall survival (OS) in patients undergoing external beam radiotherapy (EBRT). Since EBRT and peptide radionuclide therapy (PRRT) both utilize radiation, concerns have been raised regarding the potential negative impact of radiation exposure on lymphocytes during PRRT. The aim of this study was to investigate the effects of PRRT on RIL measured by absolute lymphocyte counts (ALC) and its relation with OS. ***Materials and Methods:*** In this retrospective study, all patients with a neuroendocrine tumor (NET) who received PRRT with [177Lu]Lu-HA-DOTATATE were included. ALC was determined in blood samples that were collected at baseline, 3- and 6-8 weeks post-therapy after each cycle, as well as at 3, 6, 9, and 12 months after conclusion of PRRT. The nadir value in this period was determined and used to determine RIL as per common terminology criteria for adverse events (CTCAE v5) criteria. OS was determined from start of PRRT until last follow-up or death of any cause. Additionally, the uptake of [177Lu]Lu-HA-DOTATATE in healthy organs (kidneys, liver, blood pool, and bone marrow) was quantified on SPECT/CT scans 24 hours after treatment. Statistical analysis included the Cox proportional hazard regression analysis to determine the hazard ratio (HR) for OS, and Spearman's rank correlation coefficient to assess correlations between the uptake of [177Lu]Lu-HA-DOTATATE and ALC. ***Results:*** 230 patients were included in this study cohort. Severe lymphopenia grade ≥3 was observed in 47.8 % of the study population. Median OS was 40 months (95% CI 32.3-47.7) in patients with grade ≥3 lymphopenia, in contrast to 53 months (95% CI 37.7-68.3) in patients with grade 0-2 lymphopenia. An association was found between OS and lymphopenia (grade ≥3 vs grade 0-2; HR 1.54; 95% CI 1.04-2.29; p=0.029). Furthermore, a significant negative correlation was found for the uptake of [177Lu]Lu-HA-DOTATATE in the spleen (r=-0.177, p=0.027) and blood pool (r=-0.175, p=0.029) and a percentage decrease from baseline ALC. ***Conclusion:*** In almost half of the patients severe RIL was observed after PRRT, which was associated with reduced OS. In addition, the uptake of [177Lu]Lu-HA-DOTATATE in the spleen and blood pool was found to negatively correlate with ALC. Further research is warranted to enhance knowledge on the etiology of lymphopenia during PRRT and potential beneficial lymphopenia-mitigating strategies.

Quality Of Life in Patients with Neuroendocrine Tumors Treated with Peptide Receptor Radionuclide Therapy

Q. Wang*[1,2]*, *D. Librizzi[1,3], S. Bagheri[1], A. Ebrahimifard[1], M. Luster[1], B. H. Yousefi[1,3];*
[1]Department of Nuclear Medicine, University Hospital Marburg, Philipps University Marburg, Marburg, GERMANY, [2]Shanxi Bethune Hospital, Shanxi Academy of Medical Sciences, Tongji Shanxi Hospital, Third Hospital of Shanxi Medical University, Tai Yuan, CHINA, [3]Core Facility Molecular Imaging, Center for Tumor Biology and Immunology, Philipps University Marburg, Marburg, GERMANY.

Aim/Introduction: Peptide Receptor Radionuclide Therapy (PRRT) is an effective treatment for patients with neuroendocrine tumors (NET), but there are few studies related to the impact of this treatment on the quality of life of patients with NET. We aimed to analyze and summarize the effect of PRRT on the quality of life in these patients by performing a Meta-Analysis. ***Materials and Methods:*** Relevant databases including PubMed, Web of

Science, Cochrane Library, and EMBASE databases were searched up to April 2024. A bibliometric analysis of articles highly relevant to the topic was conducted. Literature for meta-analysis was selected according to the PRISMA statement. Data were merged using STATA18 and fixed effects models were used to pool the data. ***Results:*** A total of 490 articles were collected, of which 15 full-text articles were highly relevant to the topic. EJNMMI and Clin Nucl Med. were the journals with the highest number of publications. Clin Nucl Med is the journal with the highest number of citations. A total of 4 articles were finally included in Meta-Analysis. The results showed that after 1-, 2-, 3-, and 4-cycles of PRRT, the quality of life of the patients improved significantly. The global quality of life score, role function score, and emotional function score improved significantly ($P < 0.05$) compared with pretherapy status. The patient's symptoms were also significantly improved compared to pretherapy status, and fatigue score and pain score were significantly decreased ($P < 0.05$). Moreover, by comparing the patients' quality of life after 4 cycles of PRRT with that after 2 cycles of PRRT, we found that the global quality of life score and role function score improved significantly ($P < 0.05$), fatigue score and pain score of patients decreased significantly ($P < 0.05$). ***Conclusion:*** [177Lu]Lu-DOTATATE and [177Lu]Lu-DOTATOC are currently key radiotherapeutics in the treatment of neuroendocrine tumors, and may significantly improve the quality of life of NET patients.

EPS-167

Prognostic value of inflammation biomarkers for survival in patients with neuroendocrine tumors treated with [^{177}Lu]Lu-DOTATATE

A. Piñeiro[1], *E. Triviño Ibáñez[1,2], J. Villa Palacios[1], M. Muros de Fuentes[1], R. Sánchez Sánchez[1];*
[1]Nuclear Medicine Department, Hospital Universitario Virgen de las Nieves, Granada, SPAIN, [2]Instituto de Investigación Biosanitaria ibs.GRANADA, Granada, España., Granada, SPAIN.

Aim/Introduction: Several analytical parameters and indexes related to inflammation and nutrition are currently used in various solid tumors in relation to patient prognosis and survival. Our aim was to assess the usefulness of different analytical parameters as predictors of survival in patients with neuroendocrine tumors (NETs) treated with [177Lu]Lu-DOTATATE. ***Materials and Methods:*** Retrospective study of 48 patients with NET treated with [177Lu]Lu-DOTATATE between 2020-2023, with a follow-up ≥6 months post-therapy. The following variables were included: origin, grade, Ki67, mitotic index and analytical parameters related to nutritional status (albumin, total protein), inflammation (C-reactive protein, NT-proBNP, systemic immune-inflammation index [SII]), hematological (hemoglobin, haematocrit, leukocytes, lymphocytes, neutrophils, neutrophil-to-lymphocyte ratio [NLR], platelet-to-lymphocyte ratio [PLR], platelets) before and after completion of therapy. Overall survival (OS) outcomes were recorded by Kaplan-Meier analysis and a multivariate Cox regression model was fitted to study factors associated with OS. ***Results:*** 48 patients with a mean age at diagnosis of 56.34±12.81 years, 52.1% male and a mean follow-up of 4.98±4.74 years. 74.5% of the NETs were gastroenteropancreatic and a Ki67 of 9.26±14.74%. Median overall survival (OS) was 96 months and 12 patients (25%) were deceased. Higher pre-treatment (HR:0.21, p=0.005) and post-therapy (HR:0.12, p=0.031) lymphocyte counts are associated with longer OS. Likewise, higher hemoglobin (HR: 0.65, p=0.04) and hematocrit (HR:0.862, p=0.041) values are associated with longer OS. Analytical parameters related to nutritional status were not associated with changes in OS. NT-proBNP values >300 pg/ml (HR: 10.5, p<0.001) in patients with grades 2-3 as well as SII values >400 (HR: 4,337; p=0,037) were significantly associated with lower OS. NLR>2 (HR:3.87, p=0.049) and PLR>300 (HR:11.88, p=0.01) values are associated with lower OS. ***Conclusion:*** Higher pre and post-therapy lymphocyte counts as well as higher hemoglobin and hematocrit values are related to increased OS. NT-proBNP values >300 pg/ml are associated with decreased OS in patients with grades 2-3 NETs. Moreover, higher SII, NLR and PLR values are associated with decreased OS.

EPS-168

Lutadose Trial: the impact on treatment outcomes of dosimetry after the first administration of [177Lu]Lu-DOTATATE in gastro-entero-pancreatic neuroendocrine neoplasms (GEP NENs) patients

M. Cuomo[1,2], *M. Bauckneht[3], M. Bagnalasta[2], S. Mazzaglia[2], F. Scalorbi[2], G. Argiroffi[2], M. Kirienko[2], A. Lorenzoni[2], S. Pusceddu[2], G. Calaresu[2], E. Garanzini[2], J. Coppa[2], C. Chiesa[2], M. Maccauro[2];*
[1]University of the study of Milan, Milan, ITALY, [2]Fondazione IRCCS Istituto Nazionale Tumori, Milan, ITALY, [3]IRCCS Ospedale Policlinico San Martino, Genova, ITALY.

Aim/Introduction: In radioligand therapy (RLT) with [177Lu]Lu-DOTATATE of gastro-enteropancreatic neuroendocrine neoplasms (GEP NENs), questions remain about the potential benefits of personalized dosimetry.This prospective observational study examines the impact of individualized dosimetry on treatment outcomes in patients with GEP NENs G1-G2 following the standard treatment regimen with [177Lu]Lu-DOTATATE (7.4 GBq x 4 cycles). ***Materials and Methods:*** The analysis was conducted on 42 GEP NEN patients treated following the registered [177Lu] Lu-DOTATATE schedule.Dosimetry was performed after the first and the last cycle, with two SPECT/CT scans 1 and 7 days after administration.Global mean tumour absorbed dose (GTD) was calculated as the sum of lesion doses weighted by lesion mass. Cumulative GTD was calculated as the mean between cycle 1 and 4 multiplied by 4. Patients were followed-up for at least one year, up to a maximum of three years, through blood tests and contrast-enhanced CT (ceCT). The study assessed the correlation between global tumour dose (GTD) and median progression-free survival (PFS) through the Log rank test of PFS Kaplan Meyer curves. ***Results:*** Using dosimetry after the first cycle, GTD was statistically associated with PFS. The stratification of patients on GTD with the cut-off at 21 Gy provided significantly different PFS of 27.4 months versus non reached (p=0.03), with a hazard ratio of 3.3. At 20 months, PFS was 100% versus 75%. Using the cumulative GTD_TOT with cut-off at about 77 Gy, the same PFS interval were obtained. Low cumulative GTD correlated with a higher risk of progression (hazard ratio: 4.593, p=0.03). GTD_4 after the fourth administration was not associated with PFS. ***Conclusion:*** Our results support the predictive power of dosimetry after the first cycle predicting PFS. This might enter in the decision-making process, especially in scenarios where therapy might be optimized.

^{177}Lu-PSMA-617 Therapy in a Patient on Haemodialysis with End Stage Renal Failure

L. MacFarlane, *M. Eifer, J. Saghebi;*
Peter MacCallum Cancer Centre, Melbourne, AUSTRALIA.

Aim/Introduction: We present a prospective case-study of a patient, who presented with metastatic castration-resistant prostate cancer (mCRPC) for consideration of [177Lu] Lutetium-PSMA-617 (LuPSMA) radioligand therapy (RLT), following progression through several lines of localised and systemic therapy. A significant co-morbidity was his end-stage renal failure (ESRF), requiring haemodialysis three times a week. ***Materials and Methods:*** At presentation, the patient's eGFR was 13mL/min/1.73m2, serum creatinine was 360µmol/L and PSA was 42.8µg/L. ECOG status 3. Total tumour volume on 68Ga-GaPSMA PET scan was 325mL, with SUVmean of 12.7 and SUVmax of 114, and no discordant sites on 18F-FDG PET scan. The main discussion was around determining safe and effective administered activity. The Vision trial1 used 7.4GBq (200mCi) dosing for each of 6 cycles, delivered 6-weekly. We concluded that halving this dose and giving 3.7GBq (100mCi) should provide a therapeutic benefit without compromising patient safety. We also chose to treat at 8-week intervals due to patient's ECOG status and transport logistics. ***Results:*** The patient received 4 cycles of LuPSMA RLT, with a median dose of 3.7GBq. 24-hour SPECT imaging and dosimetry was acquired after each cycle, with additional imaging and dosimetry performed 4 hours after cycle 1. Salivary glands received an estimated dose of 3-4Gy, comparable to published literature. No appreciable liver/kidney/spleen uptake seen on 4hr or 24hr imaging. Patient maintained his thrice-weekly haemodialysis sessions throughout the process. The patient's PSA dropped from 42.8 pre-treatment to 0.14 after cycle 4 (>99% PSA response). eGFR remained low but did not worsen over the course of 4 cycles (13 pre-treatment to 28 after cycle 4). The patient reported a noticeable decrease in pain with associated decrease in opiate use. The tumour volume on post-therapy imaging dropped from 1367mLs after cycle 1 to 40mLs after cycle 4. Unfortunately a GaPSMA-avid lesion in his lungs did not respond to the LuPSMA RLT and over the course of 4 cycles, the lung lesion increased in size. Due to the decrease in PSMA-avid disease, corresponding drop in PSA, and subsequent increase in size of lung lesion, it was agreed to cease LuPSMA RLT. This is the first such published case-study in Australia. ***Conclusion:*** With careful planning, a patient with ESRF on haemodialysis, with baseline eGFR <30 can be successfully and safely treated with LuPSMA RLT. ***References:*** 1. OP-509

Treatment of metastatic castrate-resistant prostate cancer patient with two cycles of ^{67}Cu-SAR-bisPSMA (8 GBq) leads to complete response (RECIST) and undetectable PSA level: A case report

O. Gervasio[1], L. Nordquist[2];
[1]Clarity Pharmaceuticals, Eveleigh, AUSTRALIA, [2]XCancer, Omaha, NE, UNITED STATES OF AMERICA.

Aim/Introduction: Patients with metastatic prostate cancer (PC) have poor outcomes, despite recent advances in treatment options. Prostate-specific membrane antigen (PSMA) is overexpressed in PC cells and its target is used to image/treat PC patients. The bivalent structure of SAR-bisPSMA (64Cu-SAR-bisPSMA, imaging and 67Cu-SAR-bisPSMA, therapy) may offer advantages (including higher uptake/retention in lesions) compared to current PSMA agents. We report the administration of two cycles of 67Cu-SAR-bisPSMA in a 74-year-old male patient with metastatic castrate-resistant PC (mCRPC) resulting in an undetectable prostate specific antigen (PSA) and complete resolution of his disease. ***Materials and Methods:*** The patient was diagnosed with localized Gleason 9 (PSA 20.5 ng/ml) PC in 2017 and underwent neoadjuvant chemotherapy and definitive radiation with androgen deprivation therapy (ADT) for two years. ADT was resumed in 2020 due to PSA recurrence. The patient had evidence of metastatic disease in 2022 and underwent several lines of systemic therapies including abiraterone, enzalutamide and a clinical trial (PARP inhibitor). Upon progression (May 2023), the patient was enrolled in the phase I/IIa SECuRE clinical trial (NCT04868604) and received one cycle of 67Cu-SAR-bisPSMA, followed by an additional cycle under the FDA Expanded Access Program (EAP) (8 GBq each dose). ***Results:*** Within three months of the first dose of 67Cu-SAR-bisPSMA, the patient's PSA declined from 47.2 to 0.3 ng/ml (99.4% reduction), with a significant decrease in the size of his tumours on imaging and in PSMA uptake (utilizing 64Cu-SAR-bisPSMA). The patient received a second dose of 67Cu-SAR-bisPSMA (September 2023) under the EAP. In October 2023, his PSA further declined to undetectable levels (<0.05 ng/ml, confirmed by two consecutive tests), with all lesions but one achieving complete response (CR) by RECIST v1.1 (one lesion missed CR cut-off by 2 mm, reduction from 27 mm to 12 mm). A CR has been confirmed in all target and non-target lesions at the last follow-up (April 2024), with the PSA remaining at undetectable levels. Adverse events related to 67Cu-SAR-bisPSMA: dry mouth, altered taste and thrombocytopenia (all Grade 1, improved), fatigue (Grade 2, resolved), anaemia (Grade 3, improved to Grade 2). Additional doses are being withheld unless there is disease progression. ***Conclusion:*** This case shows for the first time the anti-tumour effect of two doses of 67Cu-SAR-bisPSMA

in a patient with mCRPC leading to a CR and undetectable PSA level. 67Cu-SAR-bisPSMA had a manageable safety profile and may represent an effective option for the treatment of patients with mCRPC.

OP-510

Alpha-particle therapy in mCRPC: Case Studies utilizing ctDNA as a therapeutic biomarker for early clinical outcome prediction

***M. Amghar*[1],** *T. Rausch[2], T. Hielscher[1], H. Ozgur[2], M. Roscher[1], U. Bauder-Wüst[1], Y. Remde[1], G. Bakos[3], M. Schäfer[1], F. Bruchertseifer[4], A. Morgenstern[4], V. Beneš[2], C. Kratochwil[5], M. Benešová-Schäfer[1]; [1]DKFZ, Heidelberg, GERMANY, [2]EMBL, Heidelberg, GERMANY, [3]GSI, Darmstad, GERMANY, [4]European Commission, Joint Research Centre (JRC), Karlsruhe, GERMANY, [5]Department of Nuclear Medicine, University Hospital, Heidelberg, GERMANY.*

Aim/Introduction: First clinical experiences employing prostate-specific membrane antigen (PSMA)-addressing radiopharmaceuticals with the alpha-particle-emitting radionuclide actinium-225 (225Ac) showed astonishing treatment responses in metastasized castration-resistant prostate cancer (mCRPC) patients. In light of the scarcity of 225Ac alongside with eventual treatment resistance, it is crucial to identify patients who will benefit from targeted alpha-therapy (TαT) early in their treatment course. Detecting early clinical outcomes through non-invasive liquid biopsies represents an unmet clinical need in stratifying patient responsiveness. Circulating tumor DNA (ctDNA) is a promising biomarker of disease burden and therapeutic response, since — unlike conventional markers — this metric is agnostic to cancer type. The recent focus has been on stratifying patients based on liquid biopsies. Our case study reports the clinical courses of four distinct patient responses. By comparing clinical data and whole genome sequencing coupled with ichorCNA analysis, we aim to uncover potential mechanisms for treatment resistance and relapse encoded in the patient's ctDNA. ***Materials and Methods:*** Within the framework of ethical approval (S-882/2020), this study involved collecting blood samples from mCRPC patients scheduled for bimonthly [225Ac]Ac-/[177Lu]Lu-PSMA-617 cycles. CtDNA was extracted and prepared for ultra-low-pass whole genome sequencing (ULP-WGS). The study employed ichorCNA algorithm via R (version 3.3.1) for analyzing the sequencing data, which estimates genome-wide copy number alterations (CNA) and tumor fraction (TFx) from the sparse sequencing data. Baseline-adjusted values for TFx and prostate-specific antigen (PSA) percentages are used for comparison. ***Results:*** Patient 10 exhibited a progressive decline in PSA levels across four cycles, -89.0%, with concurrent reduction in tumor fraction to below detection limits, showcasing complete therapeutic response. Patient 5 achieved undetectable PSA levels with a corresponding reduction in initial TFx, demonstrating the treatment's potential effectiveness. Patient 38 experienced a notable initial response with a 74.7% reduction in PSA levels over four treatment cycles, followed by a 22.1% increase indicating progressive disease. Concurrently, TFx decreased by 99.94% along only two cycles followed by relapse to baseline levels, suggesting early relapse detection. Lastly, Patient 34 displayed a partial response with 37.3% reduction in PSA levels after the first cycle, followed by a dramatic 681.1% increase after the second cycle, alongside TFx fluctuations, reflecting large genomic instability. ***Conclusion:*** The reported cases highlight ctDNA`s potential to provide real-time tumor dynamics, offering a nuanced understanding of therapeutic responses over traditional biomarkers like PSA, revealing its capacity to detect both PSMA-positive and -negative metastases, thus offering a complete assessment of tumor burden.

OP-511

Feasibility of ^{99m}Tc-MIP-1404 PSMA Radioguided Surgery in a Patient with Lymph Node Metastases in Recurrent Prostate CancerFeasibility of ^{99m}Tc-MIP-1404 PSMA Radioguided Surgery in a Patient with Lymph Node Metastases in Recurrent Prostate Cancer

F. Forrer, *H. Geiger, C. Babst, D. Engeler, O. C. Maas; Kantonsspital St. Gallen, St. Gallen, SWITZERLAND.*

Aim/Introduction: After histological confirmation of prostate cancer (PCa) in a 61-year-old patient, radical prostatectomy with lymphadenectomy was performed in October 2019. With rising PSA levels, a salvage radiotherapy of the prostate region was performed 2020. As PSA levels continued to rise, imaging without evidence of local recurrence was performed in October 2021 (PSMA-PET/CT), in July 2022 (Choline-PET/CT) and in January 2023 (Choline-PET/CT). Only in April 2023, a PET/CT detected two pelvic PSMA-positive lymphnode metastases. Curatively intended radiotherapy could not be realized due to previous radiotherapy. The indication for surgical salvage lymphadenectomy was set. To enable less invasive and successful laparoscopic dissection of the two lymph nodes radiolabeling of the target was requested. ***Materials and Methods:*** We used 99mTc-MIP-1404, a 99mTc-labelled PSMA-radioligand for preoperative labelling of the metastatic lymph nodes. 740 MBq 99mTc-MIP-1404 was administered preoperatively. 18 hours p.i. a preoperative SPECT/CT was acquired. Intraoperatively a laparoscopic gamma probe was used to localize the suspicious lymphnodes. ***Results:*** SPECT/CT acquired 18 hours p.i. a demonstrated activity only in one (of two) PET/CT-positive lesions. Intraoperatively both lymphnodes could be reliably detected. Histopathological work-up of the resected specimens confirmed metastases of the known adenocarcinoma of the prostate. Six weeks after PSMA-RGS, serum PSA decreased from 4.22 ng/ml to 0.02 ng/ml (complete biochemical response). ***Conclusion:*** This is the first implementation of RGS in metastatic PCa in Switzerland. 99mTc-MIP-1404 represents a promising radiotracer for RGS and further use in selected cases is encouraged. In our case one lymphnode was detected intraopoeratively even though it was not visualized in pre-operative SPECT.

Multimodal treatment Strategies for Advanced Hepatocellular Carcinoma: a 12-Year Follow-up Case Report

***B. Criscuoli*[1],** *F. Corica[1], G. Follacchio[1], C. Manni[1], L. Montani[2], S. Fattori[2], L. Faloppi[3], R. Scibè[4], A. Iozzelli[5], S. Alborino[6], F. Capoccetti[1];*
[1]Nuclear Medicine Unit, Macerata Hospital, AST Macerata, Italy, Macerata, ITALY, [2]Physics Unit, Macerata Hospital, AST Macerata, Italy, Macerata, ITALY, [3]Oncology Unit, San Severino Hospital , AST Macerata Italy, San Severino Marche, ITALY, [4]Surgery Unit, Macerata Hospital, AST Macerata, Italy, Macerata, ITALY, [5]Radiology Unit, Macerata Hospital, AST Macerata, Italy, Macerata, ITALY, [6]Interventional Radiology Unit, Macerata Hospital, AST Macerata, Italy, Macerata, ITALY.

Aim/Introduction: Multidisciplinary treatment approach is recommended for the management of patients with hepatocellular carcinoma (HCC). ***Materials and Methods:*** A 71-year-old male was diagnosed in 2010 with hepatitis C virus-related hepatocellular carcinoma (HCC). Baseline CT scan showed a single hepatic lesion of 11 cm (VII-VI S). The patient

was initially treated with sorafenib, which was interrupted due to relevant toxicity. Therefore, after evaluation of liver function and discussion in the multidisciplinary board, the target lesion was treated with superselective transarterial radioembolization (TARE) in 2010 (1050 MBq of 90Y-Glass MicroSphere, 120 Gy to target lesion), subsequently with transarterial chemoembolization (TACE) in 2011 (DC-BEADS 100-300 and 300-500 doxorubicin100 mg-loaded particles) and morfological complete response. The patient was followed up with CT scans and liver functional assessment from 2011 to 2017, showing stable disease and liver function. However, in 2017, a CT scan showed a relapse in IVS (2.8 cm), which was subsequently treated with TACE in 2017 and 2018 (respectively, with DC-BEADS 100-300 doxorubicin 75 mg -loaded particles and Lifepearl 200 mu doxorubicin 75 mg-loaded particles), resulting in a partial response. A new dosimetry with 99mTc-MAA was performed in 2018 to predict retreatment with TARE, but the distribution of the macroaggregates was too extensive compared to the margins of the lesion. Therefore, the patient underwent particle-transarterial chemoembolization (p-TACE) in 2019 (100 microns microspheres doxorubicin 75 mg-loaded particles). Nevertheless, a subsequent CT scan in 2020 showed progressive disease due to the presence of new lesions in segments III (11 mm) and IV (4 and 13 mm) of the liver. As a result of disease progression after several loco-regional treatments, systemic therapy was initiated with standard regimen of lenvatinib as a first-line approach, followed by a metronomic capecitabine regimen and, finally, standard regimen of capozantinib. ***Results:*** Unfortunately, the patient died in 2022 at the age of 8,3 due to liver failure, 12 years after the initial diagnosis of HCC ***Conclusion:*** In conclusion, this report highlights the benefits of a multimodal therapy approach, which are reflected in both treatment choice and timing, to achieve a personalized approach and so obtain finally , in an unfavorable prognostic scenario, as the advanced HCC, a survival exceeding 10 years.

OP-513

Exploring [177Lu] PSMA-I&T Therapy in Refractory Multiple Myeloma

C. Ramos, *F. Ribeiro, F. Pericole, K. Amaral, A. Santos, S. Brunetto, M. Takahashi, V. Castro, C. Souza;*
University of Campinas, Campinas, BRAZIL.

Aim/Introduction: Triple-refractory multiple myeloma (MM) presents a daunting prognosis. It is a neoplasm characterized by notable genomic heterogeneity. Recent investigations within our group have unveiled significant uptake of [68Ga]Ga-PSMA-11 in select MM patients, hinting at the potential theranostic utility of PSMA in specific cases (1). This study reports the initial administration of [177Lu]PSMA in a patient with refractory MM. ***Materials and Methods:*** A 76-year-old male with IgA/Kappa MM, resistant to six therapeutic regimens including daratumumab, lenalidomide, and bortezomib, underwent PET/CT scans with $^{[18F]}$PSMA-1007, exhibiting pronounced tracer uptake in numerous osteolytic lesions, many with extensive soft tissue involvement. Subsequent PET/CT with $^{[18F]}$FDG revealed similar findings. After signing appropriate consent forms, the patient was selected for compassionate treatment with [177Lu]PSMA. ***Results:*** The patient received an initial dose of 7,400 MBq (200 mCi) of [177Lu]PSMA-I&T, which was well tolerated, manifesting slight clinical amelioration in the following week. Visual analysis of whole-body scans at 21h, 30h, and 7 days post-treatment displayed moderate tracer uptake in the lesions, with modest washout observed between the 21h and 30h scans, escalating after 7 days. Following 4 weeks, repeat PET/CTs demonstrated siimilar findings to the initial scans, with a slight reduction in tracer uptake in select lesions and an enlargement in the volume of certain soft tissue lesions, attributed to post-treatment inflammation. A second dose of 7,400 MBq (200 mCi) of [177Lu]PSMA-I&T was administered after 6 weeks, with subsequent whole-body scans showing consistent tracer uptake compared to prior post-therapy images. However, an intercurrent femoral fracture impeded mobility and precluded further imaging evaluations and treatment continuation, culminating in the patient's demise after a brief period. ***Conclusion:*** This preliminary report suggests the feasibility and tolerability of treating MM with [177Lu]PSMA-I&T. While a subtle clinical and imaging response was noted after the first dose, the occurrence of a fracture complication and the severity of the case precluded further assessment and treatment continuation. Nonetheless, [177Lu]PSMA therapy in MM appears safe, with promising initial responses. Comprehensive studies encompassing full treatment cycles (4 doses) and involving less clinically severe patients are warranted to ascertain the efficacy of this therapeutic modality. ***References:*** (1) Souza SPM et al. First-In-Human Experience of Peptide Receptor Radionuclide Therapy with ^{177}Lu-DOTATATE in Patients with Advanced Multiple Myeloma

W. Delbart, *I. Karfis, M. Vercruyssen, S. Vercauteren, Z. Wimana, N. Meuleman, P. Flamen, E. Woff;*
BE0257981101, Anderlecht, BELGIUM.

Aim/Introduction: We conducted an academic prospective phase II trial (SCARLET, NCT04379817) to assess the level of somatostatin receptor 2 (SSTR2) expression in symptomatic relapsing and refractory multiple myeloma (rrMM) patients. Half of the included patients demonstrated favorable imaging criteria (high SSTR2 expression, absence of 18F-FDG positive/SSTR2 negative lesions) and were eligible for peptide receptor radionuclide therapy (PRRT). Two patients included in the SCARLET trial received 177Lu-DOTATATE on an off-label basis. ***Materials and Methods:*** Both patients (1 female 47 y.o, 1 male 67 y.o) were diagnosed with stage III MM according to the Salmon and Durie criteria and had received four previous lines of treatment. Both patients underwent 68Ga-DOTATATE and 18F-FDG PET/CT as part of the SCARLET trial and were subsequently offered treatment with 177Lu-DOTATATE. At baseline, DOTATATE PET/CT demonstrated high SSTR expression at multiple disease sites (patient 1: 6 lesions, patient 2: 17 lesions, no extramedullary lesions) and no 18F-FDG-avid/68Ga-DOTATATE-negative lesions were detected. Both patients had adequate hematological and kidney functions. The treatment was approved by the multidisciplinary tumour board and by the local ethics committee of Jules Bordet Institute. Written informed consent was obtained from both patients. ***Results:*** Patient 1 received 2 cycles of 177Lu-DOTATATE (7.4 GBq) 9 weeks apart. After 2 cycles, a complete metabolic response was observed on 18F-FDG PET/CT, while 68Ga-DOTATATE PET/CT demonstrated the disappearance of target lesions, the stabilization of the remaining lesions and a new discreet uptake in a single preexisting cranial parietal lesion (which was eventually treated with radiotherapy). Light chains remained stable after 2 cycles. Treatment was well tolerated, with grade I nausea, bone pain and alopecia, grade II fatigue and asymptomatic grade III lymphocyte and platelet count decreased. Patient 2 recently received the first cycle of 177Lu-DOTATATE (7.4 GBq) and the treatment was well tolerated

with only a grade II fatigue as an adverse event. ***Conclusion:*** We report the world premiere administration of 177Lu-DOTATATE in two heavily pretreated rrMM patients. The first patient achieved a complete metabolic response after 2 cycles. Disease assessment for the second patient is awaited. Treatment was well tolerated, with minor adverse effects consistent with the known toxicity profile of 177Lu-DOTATATE. A SSTR-based radiotheranostic trial in rrMM patients will soon commence in our Institution.

When Lutetium-177 DOTATATE Is Not Available: Insights Into Use of Terbium-161 in the Treatment of Metastatic Paraganglioma

N. Jacobs[1], *O. Kolade[1,2], K. Hlongwa[1,3], S. More[1];*
[1]University of Cape Town, Cape Town, SOUTH AFRICA, [2]University College Hospital, Ibadan, NIGERIA, [3]Red Cross War Memorial Children's Hospital, Cape Town, SOUTH AFRICA.

Aim/Introduction: Multiple publications advocate for the use of radioligand therapy in the treatment of advanced neuroendocrine tumours including metastatic paraganglioma. Lutetium-177 DOTATATE has shown impressive clinical results. Terbium-161 has grown in traction as a potential radionuclide therapy. Minimal published research exists on its clinical outcomes in the management of neuroendocrine tumours1,2. We present its use in the case of a 30-year-old male with previous metastatic grade 2 extra-adrenal paraganglioma and left nephrectomy with disease recurrence. ***Materials and Methods:*** CT imaging showed extensive, inoperable tumour burden with liver metastases. Gallium-68 DOTANOC staging PET-CT demonstrated extensive nodal and liver disease. No discordant lesions were demonstrated on F^{18} FDG PET-CT. His baseline chromogranin A (CGA) was elevated. He had a baseline Eastern Cooperative Oncology Group (ECOG) performance status of 0, with normal haematological and liver biochemistry. His renogram and GFR parameters were acceptable for radionuclide treatment. ***Results:*** After one cycle of Lutetium-177 DOTATATE, post therapy scintigraphy showed uptake concordant with known disease. His CGA also decreased. Owing to logistical issues related to the procurement and delivery of Lutetium-177, he was treated with Terbium-161 DOTATATE. There was post therapy uptake in known disease sites. No additional therapies were administered, and the patient has since demonstrated stable disease. He continued to improve, with a further two-and-a-half fold decrease in CGA ten months post treatment and normal liver function. His serum creatinine, used as a marker of renal function, and bone marrow reserve have shown improvement. His ECOG remains at 0, and his progression-free survival is 14 months. He has also acquired employment, further demonstrating excellent functional status. ***Conclusion:*** Terbium-161 DOTATATE is a potential radioligand alternative to the well-established Lutetium-177 DOTATATE . These results form a foundation for further research into alternative radionuclide therapies in the management of advanced neuroendocrine tumours. ***References:***

Prolonged disease-free survival and bladder preservation in a patient with chemotherapy-resistant Muscle Invasive Bladder Cancer (MIBC) after first-in-human ^{177}Lu-FAP radioligand treatment - the RadioMolecularIncubator Experience within the Bladder BRIDGister.

R. Wirtz[1], *L. Kastner[2], E. Storz[2], M. von Brandenstein[2], F. Friedersdorff[3], D. Barski[4], T. Otto[5], M. Waldner[6], J. Graff[6], E. Veltrup[1], F. Linden[1], M. Fuss[1], R. Hake[7], S. Eidt[7], J. Roggisch[8], C. Rieger[2], S. Koch[9], T. Ecke[10], A. Heidenreich[2], L. Greifenstein[11], R. Baum[11];*
[1]STRATIFYER Molcular Pathology GmbH, Köln, GERMANY, [2]Dpt of Urology, University of Cologne, Köln, GERMANY, [3]Dpt. of Urology, Evangelisches Krankenhaus Königin Elisabeth Herzberge, Berlin, GERMANY, [4]Dpt. of Urology, Rheinlandklinikum, Neuss, GERMANY, [5]Dpt. of Urology, Rheinlandklinikum, Köln, GERMANY, [6]Dpt. of Urology St. Elisabeth Hospital, Köln, GERMANY, [7]Institute of Pathology at the St. Elisabeth Hospital, Köln, GERMANY, [8]Institute of Pathology, HELIOS Hospital, Bad Saarow, GERMANY, [9]Institute of Pathology, HELIOS Hospital, Köln, GERMANY, [10]Dpt of Urology, HELIOS Hospital, Bad Saarow, GERMANY, [11]CURANOSTICUM Wiesbaden-Frankfurt, Wiesbaden, GERMANY.

Aim/Introduction: Patients with MIBC achieving pathological complete response (pCR) upon neoadjuvant chemotherapy (NACT) have improved prognosis. Luminal tumours respond better to NACT. Expression of the radioligand targets FAP and CXCR4 is also found in chemotherapy-resistant tumours. The objective of this study was to validate the predictive value of tissue-based molecular stratification of bladder cancer in vitro for PET/CT imaging and 177Lu-FAP treatment in vivo. ***Materials and Methods:*** FFPE tissues from the first 100 TURB samples from the BladderBRIDGister were collected, RNA extracted, and relative gene expression subtyping markers (KRT5, KRT20, PPARG), ADC targets (TROP2, NECTIN4), CPI targets (PD-L1, PD-1, CTLA4) and radioligand targets (CXCR4, FAP) were analysed by RT-qPCR as well as hierarchical clustering. For exploring the therapeutic potential of FAP expression, a 67-y-o male (initially pT1 high grade bladder cancer in 08/2022) with high FAP in non-luminal MIBC was selected. Re-TURB in 10/22 revealed a high-grade MIBC (pT2a G3) and molecular analysis showed a non-luminal MIBC with high FAP expression. Restaging in 12/2022 (CT) exhibited locally advanced tumour expansion into the perivesical tissue without metastatic lesions. Three cycles Gemcitabin/Cisplatin chemotherapy were applied; however, the patient denied planned cystectomy. ***Results:*** Hierarchical clustering revealed three different clusters by combining target gene quantitation of ADC and theranostic drugs and subtyping markers with luminal characteristics as defined by high intermediate or low mRNA expression of KRT20 and PPARG. Instillation of 177Lu-FAP (3.7 GBq) into the bladder in in 03/23 resulted in high uptake into the non-luminal MIBC invading the perivesical soft tissue and the acetabulum. The second PTRT in 05/23 included intravesical application via transurethral catheter of 2.9 GB 177Lu-3BP-3940 followed by i.v. application of 3.9 GBq 177Lu-3BP-3940 plus 200 mg Pembrolizumab infusion as radiosensitizer 3h after radioligand therapy. Comparison of SPECT/CT at first and second cycle revealed complete elimination of one tumour site in the bladder and significant reduction of the second larger lesion. First endoscopic re-evaluation and resection in 07/23 showed pT2 G3 carcinoma with significant reduction of tumour cell content and markedly increased immune invasion (8fold). Subsequent urethrocystoscopies in 10/23& 01/24 revealed

no malignancy (pCR). ***Conclusion:*** To the best of our knowledge this is the first molecularly stratified, theranostic application of FAP radioligand therapy (RLT) by transurethral intravesical instillation plus systemic administration in combination with immune checkpoint inhibitor therapy after initial immune-sensitizing RLT. Remarkably, complete response of chemotherapy-resistant MIBC was achieved. A phase I/II study is currently initiated.

Optimized ^{211}At production: a study to unravel the impact of the ^{210}At-contaminant

M. Sevenois[1], *H. J. Jensen[2], F. Haddad[3], T. Bäck[4], M. D'Huyvetter[1], P. Covens[1], L. Navarro[5];*
[1]VUB (Vrije Universiteit Brussel), Brussel, BELGIUM, [2]Copenhagen University Hospital (Rigshospitalet), Copenhagen, DENMARK, [3]Nantes Université, Nantes, FRANCE, [4]University of Gothenburg, Gothenburg, SWEDEN, [5]Precirix, Brussel, BELGIUM.

Aim/Introduction: A limitation to the availability of 211At via 209Bi(α,2n) is the restriction of the incident α-beam energy during production to avoid the co-production of 210At which decays predominantly to 210Po. However, recent data measured a significant increase in 211At activity at increased beam energy, highlighting the need for an optimised approach and stressing the importance of studying the radiochemical separation and the biodistribution of 210Po after radioligand therapy with 211At/210At-labelled radiopharmaceuticals. For this reason, we acquired targets irradiated at high α-beam energies and performed: (i) the determination of the activity balance of 211At, 210At and 210Po after radiochemical separation of astatine by extraction chromatography [1] and (ii) a preclinical feasibility study to assess the biodistribution of 211At, 210At and 210Po. ***Materials and Methods:*** Targets irradiated by Arronax, Nantes were used to establish activity balances during radiochemical separation. After dissolution of the target and radiochemical separation by extraction chromatography, astatine was measured by gamma spectrometry, whereas 210Po was determined by liquid scintillation counting. Dissolution yields, extraction yields, and separation capabilities were assessed. For the preclinical study, irradiated targets were acquired from Rigshospitalet, Copenhagen. After target dissolution and radiochemical separation, anti-HER2 sdAb 2Rs15d [2] was labelled with 210At/211At, after which 1 MBq 211At was injected in healthy mice. The biodistribution of 211At, 210At and 210Po was assessed 1h post tracer injection. ***Results:*** Activity balances during target processing and radiochemical separation show mean decay-corrected dissolution yields of >84% and extraction yields of 210At/211At >80%. At the same time,>95% of the 210Po formed before extraction was removed. The biodistributions of 211At, 210At and 210Po in healthy mice show the highest uptake in the kidneys (60-70% ID/g) while stomach, small intestine and thyroid range between 2-4% ID/g, the latter ones showing a potentially limited dehalogenation. The time between the end of conjugation and time of sacrifice allowed a total of 0.03% of the 210At activity to be decayed to 210Po (1-2 Bq). Kidney measurements after complete decay resulted in a total 210Po activity (0.5 Bq) which is slightly higher than the expected 0.3 Bq due to the measured 210At at time of sacrifice and subsequent ingrowth. ***Conclusion:*** Our results show that extraction yields are >84% when using extraction chromatography while safely isolating the previously formed 210Po. The biodistributions of 211At, 210At and 210Po in healthy mice indicate a limited impact of 210Po, paving the way towards increased 211At production yield. ***References:*** [1]Burns,SeparationandPurificationTechnology 256(2021):117794 [2]Vaneycken,TheFASEBJournal25.7(2011):2433-2446.

OP-528

Production of the true theranostic matched pair ^{61}Cu and^{67}Cu at the compact cyclotron TR-Flex

S. Brühlmann[1,2], *M. Walther[1], K. Kopka[1,2], M. Kreller[1];*
[1]Helmholtz-Zentrum Dresden-Rossendorf, Institute of Radiopharmaceutical Cancer Research, Dresden, GERMANY, [2]Technische Universität Dresden, School of Science, Faculty of Chemistry and Food Chemistry, Dresden, GERMANY.

Aim/Introduction: The radionuclide theranostic approach gained prominence in the radiopharmaceutical sciences and nowadays theranostic matched pairs of radionuclides are of utmost clinical interest. Furthermore, out of the handful of true theranostic matched radionuclides, copper radioisotopes stand out as an attractive alternative[1]. With already an FDA-approved 64Cu-radiolabeled somatostatin receptor ligand, DetecnetTM[2], full potential of copper-based radiopharmaceuticals could be further exploited with a shorter-lived PET radionuclide, i.e., 61Cu (3.34 h, Emean=500 keV, 61%) and a therapeutic (β--emitter) counterpart, i.e., 67Cu (61.8 h, Emean=141 keV, 100%). Having our [64Cu]CuCl2 production established at HZDR, we present here our alternative routes for 61Cu and 67Cu production at our compact cyclotron. ***Materials and Methods:*** Targetry for 61Cu production consists of enriched 62Ni electrodeposition onto gold coins, followed by proton irradiation with the HZDR TR-Flex (ACSI) cyclotron, using optimized parameters from simulations and test irradiations for the 62Ni(p,2n)61Cu nuclear reaction (20 MeV and 70 µA for 1-2 h). Radiochemical separation is performed with a single column, containing either anion-exchange AG-1x8 or TK201 resin. Furthermore, 67Cu is produced from enriched 70Zn electroplated targets onto rectangular silver plates via the 70Zn(p,α)67Cu nuclear reaction (17 MeV, 60 µA for up to 20 h). Radiochemical purification is carried out with an AG-1x8 column combined with chromatographic resins TK221 and TK201. Radionuclidic purity, RNP, of [61/67Cu]CuCl2 is analyzed with calibrated HPGe gamma-spectroscopy, while the apparent molar activity, AMA, is tested by titration with the macrocyclic chelator TETA (1,4,8,11-Tetraazacyclotetradecane-1,4,8,11-tetraacetic acid)[3,4]. ***Results:*** Up to 8 GBq and 0.8 GBq of 61Cu and 67Cu, respectively, have been obtained at end of purification. Production scalability could easily be performed by extending the irradiation time; e.g. 200-minute irradiation would result in up to 20 GBq of [61Cu]CuCl2. RNP of over 99.5% for both [61Cu]CuCl2 and [67Cu]CuCl2 solutions and AMA of over 250 GBq/µmol and 150 GBq/µmol, respectively, have been quantified, thus proving quality sufficient for clinical transfer. ***Conclusion:*** Production of 61Cu and 67Cu at HZDR has been established to enable the development of radiocopper-based radiopharmaceuticals. Currently, the produced radiocopper is being used for in vitro and in vivo experiments, although our alternative 61Cu production could easily be upscaled to meet up clinical demands. We believe that radiocopper availability will boost radiopharmaceutical development and enable its safe translation into the clinics. ***References:*** [1]Wadas et al. Curr Pharm Des 2007,13,1,3-16. OP-529

Mixed-LET ^{161}Tb-ART-101 radiopharmaceutical enhances therapeutic responses in advanced prostate cancer

M. Bio Idrissou[1], *J. Tromp[1], H. Comas Rojas[1], L. Lambert[1], A. Pinchuk[2], Y. Medina[1], A. Carston[1], R. Hernandez[1];*
[1]Department of Medical Physics, University of Wisconsin-Madison, Madison, WI, UNITED STATES OF AMERICA,
[2]Departments of Radiology, University of Wisconsin-MadisonDepartments of Medical Physics, University of Wisconsin-Madison, Madison, WI, UNITED STATES OF AMERICA.

Aim/Introduction: 177Lu-PSMA-617 is an effective radiopharmaceutical to treat men with metastatic castration-resistant prostate cancer (mCRPC); however, disease progression remains certain. To improve the clinical activity of RPT in mCRPC, we developed ART-101, a PSMA-targeting small molecule displaying enhanced tumor uptake and retention characteristics to deliver Terbium-161 (t1/2= 6.9 days), a novel therapeutic radionuclide with emissions optimally suited to treat disseminated and occult disease. ***Materials and Methods:*** We radiolabeled ART-101 or PSMA-617 with 161Tb and 177Lu under similar conditions. The radio-stability of the compounds was assessed in saline and human serum by HPLC. In vitro, competitive homologous radioligand binding assay evaluated the PSMA-binding properties of PSMA-617 vs. ART-101 in PSMA-expressing cell PC3-PIP. For cytotoxicity studies, PC3-PIP, LNCaP, and 22RV1 cell lines were incubated with increasing activities of free 177Lu or 161Tb (0-4 MBq/mL), and viability was measured. Therapy studies employed groups of 8-week-old nude male mice (n=5-10) bearing PC3-PIP xenografts injected (IV) with 161Tb-ART-101, 161Tb-PSMA-617, 177Lu-PSMA-617 or vehicle. Tumor growth, animal survival, and well-being were recorded thrice a week. 161Tb-ART-101 and 161Tb-PSMA-617 treated mice underwent serial SPECT/CT scans from 2 to 168h p.i. (post-injection) to evaluate the radioligands' biodistribution and estimate dosimetry. Maximum tolerated dose studies in wild-type ICR mice are undergoing to determine 161Tb-ART-101 safety profile. ***Results:*** 161Tb-ART-101 achieved radiolabeling yield and radiochemical purity surpassing 95%, and remaining stable in human serum over 72h. The competitive binding assays showed comparable IC50s for PSMA-617 (11.0 nM) and ART-101 (3.5 nM). In vitro, free 161Tb and 177Lu showed comparable cytotoxicity, corroborating that the dosimetric advantages of 161Tb's low energy Auger electrons manifest upon radioligand internalization. SPECT/CT imaging revealed elevated and sustained tumor uptake of 161Tb-ART-101 vs. 161Tb-PSMA-617: 11 ± 1 vs. 6 ± 2 %IA/g (p = 0.02) at 24h, and 7 ± 2 vs. 2 ± 1 %IA/g (p= 0.005) at 120h, while largely clearing from critical tissues/organs within 72 hours. This translated into significantly enhanced tumor-absorbed doses delivered by 161Tb-ART-101 compared to 161Tb-PSMA-617. In therapeutic studies, mice administered 161Tb-ART-101/PSMA-617 show significant tumor regression and extended survival compared to 177Lu-labeled agents. No overt radiotoxicity was observed for any of the agents. ***Conclusion:*** Our findings demonstrate enhanced pharmacology of ART-101, leading to superior therapeutic efficacy of 161Tb-ART-101 compared to 161Tb-PSMA-617 or their 177Lu counterparts. These results reiterate our excitement around 161Tb as promising radionuclide for RPT and warrants its clinical implementation, especially in the context of residual or micrometastatic disease.

OP-530

The Rise of Alpha Star: Challenges and Innovations in ^{212}Pb Production for Targeted Therapy

Y. Buchatskaya[1], *K. Al Ayed[1], K. van der Schilden[1], M. Arntzenius[1], D. van der Born[2], J. Hill[2], P. Nieuwland[2];*
[1]NRG | PALLAS, Petten, NETHERLANDS,
[2]FutureChemistry, Wageningen, NETHERLANDS.

Aim/Introduction: Over the past decade, Lead-212 (212Pb) has attracted significant interest in the field of targeted alpha therapy (TAT). Its unique properties including a half-life of 10.6 hours, 1 alpha-emission within the decay chain, and imaging capabilities, position it as a promising candidate with considerable clinical potential for TAT. To facilitate ongoing (pre)clinical research and explore its potential in clinical applications, the establishment of an efficient and scalable production route for the 212Pb isotope is necessary. ***Materials and Methods:*** Lead-212 (212Pb) is produced within the decay chain of thorium-228 (228Th). The latter is generated through neutron irradiation of radium-226 (226Ra) targets within a high-flux reactor (HFR) located in Petten, the Netherlands. The source material for the targets, 226Ra, is a highly radiotoxic α-emitter. As it undergoes decay, it releases radioactive radon gas (222Rn). Consequently, handling this material necessitates a shielded environment equipped with dedicated infrastructure (including α-tight containment and radon gas monitoring). This infrastructure is specifically designed to handle the targets before and after irradiation. After 228Th is extracted and purified from the irradiated material, it serves as a longer-lived radioactive source that continuously generates 212Pb through radioactive decay. Two distinct production routes were developed to isolate 212Pb from 228Th based on column chromatography and gas-phase separation. The column method involves a stepwise separation of 228Th decay products, firstly the purification of 224Ra from 228Th, then 212Pb from 224Ra. The gas generator represents an innovative production method for 212Pb based on the emanation and isolation of the gaseous 220Rn, a decay product 228Th. ***Results:*** High-quality 212Pb product was prepared using both column and gas generator methods. The chemical and radionuclide purity of the resulting 212Pb samples was evaluated through gamma-spectrometry and inductively coupled plasma mass spectrometry (ICP-MS). Both production methods were tested at various scales and 212Pb samples were delivered for preclinical research experiments, demonstrating their suitability for further investigation. The feasibility of implementing both production methods within a Good Manufacturing Practice (GMP) facility was carefully evaluated. This assessment considered factors such as scalability, safety, and regulatory compliance. ***Conclusion:*** The successful development of these two efficient and scalable production routes of 212Pb allows this isotope to take a lead in clinical implementation of targeted alpha therapy.

OP-531

Novel ^{212}Pb-PSMA Targeted Alpha Therapy for the Treatment of Metastatic Castration-Resistant Prostate Cancer

T. Kryza[1], *F. Liu[1], K. C. Li[1], P. Francis[1], K. Kuan[2], W. Tieu[2], D. Akhter[3], N. Fletcher[3], S. Taylor[2], A. Karmann[2], S. Rose[1], S. Puttick[1];*
[1]Advancell, Brisbane, AUSTRALIA, [2]Advancell, Sydney, AUSTRALIA, [3]Centre for Advanced Imaging - UQ, Brisbane, AUSTRALIA.

Aim/Introduction: Recent clinical data demonstrated the utility of PSMA-targeted radiopharmaceuticals with Lu-177 and Ac-225 but also revealed toxicities being potentially prohibitive to moving into broader patient populations and earlier treatment

lines. Pb-212, is a promising radioisotope with a short half-life allowing delivery of high energy alpha radiation to target cells while simultaneously being cleared quickly from non-target tissues. 212Pb- ADVC001 is a novel and proprietary 212Pb-based TAT (212Pb-PSMA) which is currently being evaluated in a Phase Ib/IIa clinical trial (NCT05720130) for patients with metastatic Castration-Resistant Prostate Cancer (mCRPC). Here, we present the preclinical data for this novel 212Pb-PSMA targeting radioligand. ***Materials and Methods:*** The affinity of 212Pb-ADVC001 to PSMA was determined by radioligand-binding assays in prostate cancer (PC) cell line overexpressing PSMA. Cytotoxic activity of 212Pb-ADVC001 against PC cell lines was measured by cell viability and clonogenic assays. The molecular mechanisms associated to 212Pb-ADVC001 mediated cell-death were assessed in PC cells. In vivo biodistribution and anti-tumor efficacy studies were performed in human PC-bearing mice. ***Results:*** 212Pb-ADVC001 has strong affinity for PSMA and induces internalization in PC cells. In vitro, 212Pb-ADVC001 exerted specific cytotoxic activity against human PC cell lines expressing PSMA, with no cytotoxic activity against PSMA negative cells. Transcriptomics analysis of PC cells after 212Pb-ADVC001 treatment revealed the activation of signalling pathways related to DNA damage, cell cycle arrest and senescence, and immune response modulation - revealing the multiple mechanisms of action of 212Pb-TAT. In vivo biodistribution of 212Pb-ADVC001 showed favourable biodistribution with rapid tumor uptake, tumor retention, and favorable tumor:kidney ratios. Minimal uptake was observed in other normal tissues. Single dose preclinical efficacy studies of 212Pb-ADVC001 (0.43 MBq) demonstrated improved survival compared to 177Lu-PSMA I&T (20 MBq), at 84 versus 48 days, respectively. Multidose efficacy studies have shown superior tumour response with two cycles of 212Pb-ADVC001 (0.46 MBq) compared to two cycles of 177Lu-PSMA I&T (15 MBq). Follow-up administration of 212Pb-ADVC001 (0.43 MBq) after initial relapse from 177Lu-PSMA I&T therapy (15 MBq) also resulted in improved survival benefit. ***Conclusion:*** Preclinical pharmacokinetic, biodistribution and efficacy data demonstrate the potential of 212Pb-PSMA for the treatment of mCRPC. In vivo, improved efficacy with more durable responses is observed with 212Pb-ADVC001 compared to 177Lu-PSMA I&T suggesting that 212Pb-ADVC001 has the potential to not only limit toxicities associated with conventional PSMA-targeted radiopharmaceuticals, but also to improve treatment of mCRPC.

OP-532

Development of [^{161}Tb]Tb-DOTA-HYNIC-panPSMA for targeted radionuclide therapy of prostate cancer

C. Morgat*[1,2]*, *D. Vimont*[2]*, K. Attia*[3]*;*
[1]*Nuclear Medicine Department - University Hospital of Bordeaux, Bordeaux, FRANCE,* [2]*University of Bordeaux, UMR CNRS 5287, INCIA, Talence, FRANCE,* [3]*Telix Pharmaceuticals, Herstal, BELGIUM.*

Aim/Introduction: Prostate-specific membrane antigen (PSMA) is over-expressed in metastatic castration-resistant prostate cancer (mCRPC). [177Lu]Lu-PSMA-617 is approved for targeted radionuclide therapy of these patients. DOTA-HYNIC-panPSMA (formerly DOTA-HYNIC-iPSMA) is a compound with high affinity for PSMA targeting, and [177Lu]Lu-DOTA-HYNIC-iPSMA ([177Lu]Lu-panPSMA) has been studied in patients with mCRPC and showed overall survival of 21.7 months and decreased prostate specific antigen levels in 73% of patients.1 Terbium-161 (161Tb) is a radiolanthanide that can deliver a high radiation dose to tumour cells due to the abundance of Auger and conversion electrons in its decay spectrum.2 The aim of this work was to develop DOTA-HYNIC-panPSMA radiolabelled with 161Tb. ***Materials and Methods:*** DOTA-HYNIC-panPSMA (600 ± 60 µg) was available in prefilled vials. Radiolabelling with 161TbCl3 (in HCl 0.05M, produced up to 15 days before radiolabeling) was tested using increasing activities (100, 200, 300 and 400MBq) in ammonium acetate buffer. Uncomplexed 161Tb, radiolysis products, and [161Tb]Tb-DOTA-HYNIC-panPSMA ([161Tb]Tb-panPSMA) were monitored using radio-HPLC over 4 days. Affinity, internalized fraction, membrane-bound fraction efflux, and therapy studies (from 0.01 to 20MBq/mL) were carried out on PC3-pip cells over-expressing PSMA. ***Results:*** Quantitative radiolabelling and radiochemical purities >95% were achieved for all tested activities without the need of purification. Radiolysis products remained <1.5% for 100 and 200MBq activities but increased up to 7.5% for 400MBq at day 4. Addition of 10µL ascorbic acid at 150g/L prevents the formation of radiolysis products. Uncomplexed 161Tb rapidly increases up to 14% at day 4 for the 400MBq activity, justifying the addition of a chelating agent such as EDTA. [161Tb]Tb-panPSMA displayed high affinity towards PSMA (6.1nM) similar to that of [177Lu]Lu-panPSMA's affinity (6.3nM), high PSMA specific membrane-bound fraction of 10% of applied dose at 4h, a specific internalised fraction of 5% of applied dose at 4h overpassing the value of 0.5% for [177Lu]Lu-panPSMA1, and moderate efflux of 35% of total binding being externalised at 4h. Therapy study showed a log(dose) dependent decrease in cell viability. ***Conclusion:*** [161Tb]Tb-panPSMA stands as a promising radiopharmaceutical for clinical translation for the treatment of mCRPC. ***References:*** 1. ^{225}Ac-SSO110 induces long-lasting anti-tumour responses in contrast to ^{225}Ac-DOTA-TATE and ^{161}Tb-DOTA-TATE in the treatment of SSTR2-positive tumour xenografts

P. Desai, *M. Sturzbecher-Hoehne, D. Mewis, M. Ruediger, A. Jaekel;*
Ariceum Therapeutics GmbH, Berlin, GERMANY.

Aim/Introduction: SSO110 (DOTA-JR11) is a somatostatin receptor 2 (SSTR2) antagonist currently under clinical development as 177Lu-SSO110 in small cell lung cancer (SCLC). We have previously demonstrated better efficacy of 177Lu-SSO110 over 177Lu-DOTA-TATE in different xenograft models owing to the ability of SSO110 to target a higher number of SSTR2 binding sites and showing longer tumour retention. Our aim here was to compare differently radiolabelled SSO110 (225Ac, 161Tb, 177Lu) to the respective DOTA-TATE compounds. ***Materials and Methods:*** Balb/c or Swiss nude mice were engrafted with the SSTR2-positive xenografts NCI-H69 (SCLC model) or AR42J (pancreatic cancer model), respectively, and randomized based on tumour volume one day before treatment start. The therapeutic efficacy of 225Ac , 161Tb-, and 177Lu-labelled SSO110 was compared to 225Ac- and 161Tb-labelled DOTA-TATE using clinically relevant mouse-equivalent dose ranges. ***Results:*** In NCI-H69 SCLC model, single doses of 20 MBq 177Lu-SSO110 and 21 kBq 225Ac-SSO110 demonstrated significantly better efficacy with regards to tumour volume reduction and growth delay than a single dose of 42 kBq 225Ac-DOTA-TATE or 20 MBq 161Tb-DOTA-TATE. Most remarkably, a single dose of 30 kBq 225Ac-SSO110

reproducibly induced 100% complete tumour remission. In the same NCI-H69 model, administration of 20 MBq 161Tb-SSO110 was similarly effective as 42 kBq 225Ac-DOTA-TATE and less potent than 20 MBq 177Lu-SSO110 or a lower dose of 21 kBq 225Ac-SSO110. In the AR42J model, injection of 37 kBq 225Ac-SSO110 induced tumour growth control with tumour volume being stable immediately after treatment, while the vehicle group progressed rapidly, reaching a median survival of 11 days. The median survival of mice treated with 20 MBq 161Tb-SSO110 and 37 kBq 225Ac-DOTA-TATE was similar (36 vs 33 days). In contrast to the NCI-H69 model, 20 MBq 161Tb-SSO110 induced a stronger tumour growth delay than 20 MBq 177Lu-SSO110 (median survival 36 vs 30.5 days). All treatments were well-tolerated. ***Conclusion:*** Our results highlight that 225Ac-SSO110 shows the strongest anti-tumoral effect in vivo even at low, single doses when evaluating SSO110 and DOTA-TATE radiolabelled with different isotopes. The comparison of 161Tb-SSO110 to 177Lu-SSO110 in two models was inconclusive indicating that additional Auger emissions of 161Tb are not generally increasing the anti-tumour efficacy of 161Tb-SSO110 and further model-intrinsic mechanisms could be involved. Irrespective of the isotopes used, the superior pharmacokinetic profile of SSO110 translates into higher pre-clinical anti-tumour efficacy compared to DOTA-TATE. The assessment of radiolabelled SSO110 and DOTA-TATE will help guide clinical development of SSO110 across SSTR2-expressing indications.

OP-534

Development of an Innovative^{61}Cu/^{67}Cu Platform forTheranostic Solutions in Oncology: from Discovery to Clinical Trials

F. De Rose[1], *A. Bolognani[2], M. Baier[1], S. Schleser[1], N. Schubert[1], J. Millul[3], R. Mansi[3], A. Johayem[4], C. D'Alessandria[2], M. Fani[3], W. Weber[2], L. Jaafar[1];*
[1]Nuclidium (DE) GmbH, Erlangen, GERMANY, [2]Technical University Munich, Munich, GERMANY, [3]University Hospital Basel, Basel, SWITZERLAND, [4]University Hospital Zurich, Zurich, SWITZERLAND.

Aim/Introduction: Although new radioisotopes have been introduced in nuclear medicine, the search for an ideal theranostic radionuclide pair continues. Factors such as demand, cost, and availability must be considered. The isotopes 61Cu (t1/2 = 3.3h, 61% β+-fraction, Eβ+mean = 800keV) for PET imaging and 67Cu (t1/2 = 61.8h, 100% β--fraction) for SPECT and PRRT represent a superior theranostic match compared to 68Ga/177Lu, as 61/67Cu-radiopharmaceuticals share the same chemical structure. 61Cu's physical properties offer advantages over current PET standards (18F, 68Ga, 64Cu), enabling broader distribution from production sites and delayed PET scans with enhanced resolution and sensitivity. 67Cu is a viable alternative to 177Lu, with its production potential by linear accelerator and a half-life that aligns with the pharmacokinetics of peptide ligands for effective treatment. This study aims to introduce our promising 61Cu/67Cu platform to overcome the limitations of standard treatments. ***Materials and Methods:*** 61Cu was produced via the cyclotron from 61Ni(p,n)61Cu reaction, with automated purification optimized using GE FASTlab2. In vitro and in vivo preclinical screenings were conducted to characterize combinations of oncological vectors and chelators, radiolabelling with 61Cu and 68Ga. Lead compounds, chosen for favorable biodistribution, were radiolabelled with 67Cu to assess safety and efficacy in vivo compared to 177Lu-radiopharmaceuticals. Translational steps included optimizing module-automated and kit-based radiolabelling, assessing radiopharmaceutical formulations for stability, and establishing QC methods and specifications. 61/67Cu-NODAGA-PSMA I&T was administered to patients for imaging in accordance with German regulations. ***Results:*** 61Cu production can be scaled up to 70 GBq per batch, with >90% recovery post-purification, radionuclidic purity ≥99.99%, and specific activity >1.3 GBq/μg. The screening process selected NODAGA-conjugated lead compounds as a theranostic for prostate cancer (NODAGA-PSMA-I&T), NETs (NODAGA-LM3) and TME (NODAGA-Kalios-02). The radiolabelling by module-automated or kit was quantitative within 5 minutes at room temperature and physiological pH, with stability ≥24h. The comparison with established radiopharmaceuticals showed enhanced biodistribution, with > 1.5 times tumor uptake and significantly improved tumor-to-background ratio at delayed time points. Preclinical tests with 67Cu-radiopharmaceuticals indicated no adverse effects, and survival rates similar to 177Lu-labelled competitors. First-in-human imaging with NODAGA-PSMA-I&T effectively identified multifocal metastatic prostate cancer. ***Conclusion:*** Our project explored the effectiveness of a 61Cu/67Cu platform in enhancing diagnostic accuracy and therapeutic outcomes, considering production efficiency, economic viability, and patient safety. Our approach addresses current radionuclides logistical and supply challenges. It eventually enables advanced dosimetry estimation for oncology patients, paving the way for personalized medicine. ***References:*** JNuclMed.2023Dec;64(12):1855-1857

Preclinical Assessment of Lead-212 (212Pb) Radio-DARPin Therapeutic (RDT) Targeting Delta-like ligand 3 (DLL3) in Small Cell Lung Cancer (SCLC)

A. Croset[1], *A. Saidi[2], F. Malvezzi[1], T. Stallons[2], M. Mettier[1], A. Wong[2], J. Rantanen[1], F. Rojas Quijano[2], S. Wullschleger[1], Y. Kaufmann[1], T. Lekishvili[1], S. Riesenberg[1], J. Blunschi[1], L. Abduli[1], C. Reichen[1], C. Lizak[1], A. Schatzmann[2], A. Goubier[1], J. Torgue[2], D. Steiner[1];*
[1]Molecular Partners, Zürich-Schlieren, SWITZERLAND, [2]Orano Med LLC, Plano, TX, UNITED STATES OF AMERICA.

Aim/Introduction: Radioligand therapy has shown strong clinical potential for treatment of certain neuroendocrine and prostate tumors. However, successful approaches in other cancer types are currently limited by the absence of suitable targeting agents for relevant tumor-associated antigens. DLL3 is one of these promising targets highly upregulated in SCLC and other high-grade neuroendocrine tumors. We present the first high-affinity DLL3-targeting RDT combining the advantages of a small protein-based delivery vector and the short-lived alpha particle-emitting radioisotope 212Pb. DARPins (Designed Ankyrin Repeat Proteins) are a versatile class of highly affine and specific binding proteins that can be generated against a broad range of tumor targets. Their intrinsic properties, including small size and robust architecture, make DARPins attractive vector candidates for radiopharmaceuticals to achieve efficient tumor uptake and penetration, while limiting exposure of healthy tissue. We previously showed that their accumulation in the kidneys, a key limitation observed for all small-size polypeptide vectors, can be overcome by engineering the DARPin scaffold surface in combination with half-life extension (HLE). 212Pb is a radioisotope with a short half-life of 11h and a favourable decay chain, allowing high energy deposition on tumor in a short time frame. By combining 212Pb with a HLE anti-DLL3 DARPin candidate, we aimed to generate a targeted RDT with high efficacy and safety. ***Materials and Methods:*** Potential clinical candidates for anti-DLL3 212Pb-RDT were identified by screening

combinations of HLE (using serum albumin binding moieties) and anti-DLL3-binding DARPins. 212Pb-labelled DARPin molecules were analysed for their in vivo biodistribution properties, and their antitumor activity/safety in different mouse xenograft tumor models. ***Results:*** In vivo biodistribution studies showed that 212Pb-DLL3-HLE DARPin constructs reached a tumor to kidney ratio >1 at 4h and 24h post injection in the MC38-hDLL3 tumor model (high DLL3 expression) and ≥1 at 24h in the NCI-H82 tumor model (low DLL3 expression). A range of different 212Pb-DLL3 DARPin constructs showed low kidney accumulation (<20% at 4h post injection) and high tumor uptake was observed in both models up to 24h. The best DARPins constructs were selected for further characterization. Strong tumor reduction was confirmed in a mouse efficacy study, while no major toxicity was observed in a dose-finding study up to 40µCi of injected 212Pb-RDT compound. ***Conclusion:*** These initial preclinical results support 212Pb based RDT against DLL3 as a promising treatment option for SCLC, with encouraging in vivo antitumor activity and a good safety profile for our first DLL3-targeting 212Pb-RDT candidate.

Imaging Alpha's or: How I Learned to Stop Worrying and Love At-211

L. Raes[1,2], *M. Sevenois[2], L. De Mey[1], A. Bracke[1], S. Bourgeois[1];*
[1]Universitair Ziekenhuis Brussel, Brussels, BELGIUM,
[2]Vrije Universiteit Brussel, Brussels, BELGIUM.

Aim/Introduction: Alpha-emitting radionuclides have gained significant attention in targeted alpha therapy due to their high linear energy transfer and short range, offering promising therapeutic potential with minimal damage to surrounding healthy tissues. Among these, At-211 has emerged as a candidate with favourable properties. This study aims to evaluate the imaging capabilities of At-211 using a clinical SPECT/CT system. ***Materials and Methods:*** A point source and a flask containing a known concentration of 41.83kBq/mL of At-211 were imaged using a Siemens Symbia Intevo Bold SPECT/CT system to characterize the emission spectrum with and without collimators (LEHR) mounted on the detector heads. Subsequently, the spheres of a NEMA phantom were filled with 39.73kBq/mL of At-211 to simulate lesion uptake. ***Results:*** Based on Monte Carlo simulations[1] and confirmed by the measured spectrum, the energy windows were based on the characteristic X-ray production due to the At-211 EC Decay and were defined as 79±12keV for the main emission and 59±8keV for lower scatter. A supplemental window was placed at 245±24.5keV to evaluate the presence of co-produced contaminant At-210. Imaging was performed using a 128x128 matrix, LEHR collimator in non-circular step-and-shoot mode with 60 frames of 40s. The imaging experiments yielded excellent visualisations of the activity in all phantoms, even showing activity in the smallest sphere (10mm diameter) of the NEMA phantom, affirming its potential for targeted alpha therapy. Quantification was possible, as a calibration factor of 34.38±0.51cps/MBq was calculated using the large volume of the bottle. Quantification uncertainty for NEMA spheres is larger [3-6cps/MBq] for the three largest spheres. ***Conclusion:*** Our study demonstrates the successful imaging and quantification of At-211 using a clinical SPECT/CT system. Further optimisations using Monte Carlo simulations[2] are being performed to determine the contamination of the acquired At-211 spectrum as a consequence of photon interactions with the equipment (collimator,...) and its influence on image optimization and quantification. These findings support further research and development of At-211-based targeted alpha therapy for clinical applications and further imaging optimisations, paving the way for personalized and effective cancer treatment strategies. ***References:*** 1. An investigation of the accuracy of ^{177}Lu SPECT/CT bone marrow activity quantification using a 3D-printed ICRP phantom

A. Theisen, *J. Leube, L. Pieper, M. Salas-Ramirez, M. Laßmann, J. Tran-Gia;*
Department of Nuclear Medicine, University Hospital Würzburg, Würzburg, GERMANY.

Aim/Introduction: Red marrow (RM) is a dose-limiting organ in many radiopharmaceutical therapies. Due to low bone marrow uptake of most radiopharmaceuticals, SPECT imaging reaches its limits with respect to quantification. In this work, the uncertainty in RM activity quantification was systematically investigated based on 177Lu SPECT/CT Monte-Carlo simulations and phantom measurements of a lumbar spine phantom with removable kidneys. ***Materials and Methods:*** The study was based on a 3D model of a lumbar spine (L1 to L5) and two removable kidneys as defined in ICRP145 [1]. To replicate attenuation in cortical bone, a high-density resin (HU: 813.2[2]) was selected for 3D printing a fillable lumbar spine phantom. To mimic attenuation in spongiosa (1.11g/cm3[1]), the vertebrae were filled with K2HPO4 dissolved in pentetic acid with 33kBq/ml of [177Lu]LuCl3. Kidney phantoms, produced using a lower-density resin (HU: 121.0[2]), were filled with 310kBq/ml [177Lu]LuCl3 dissolved in HCl. SPECT/CT imaging (MELP collimator, 20s-per-projection, 128x128 matrix, 4.8cm3 voxel size) was performed on a NEMA IEC phantom: Three repetitions with mounted lumbar vertebrae and kidneys; three repetitions without kidneys. SPECT simulations of lumbar spine with/without kidneys were performed using SIMIND[3]. 1,000 SPECT datasets with varying representations of Poisson noise were generated. Reconstructions were performed using PyTomography [4] (OSEM with resolution modelling, AC, TEW-SC, 20i4s). Activity quantification accuracy was evaluated by comparing SPECT-based (ICRP145 mask enlarged by 4-mm) and true activity. ***Results:*** Without kidneys, activity ratios between SPECT-based and true activity were similar across all vertebrae with mean(STD) of 1.11(0.01) [simulation] and 1.18(0.05) [measurement] across L1-L5. The positive bias might be explained by the low-count statistics (with a maximum of 7 counts per projection for all measurements), potentially resulting in activity overestimation for OSEM reconstructions[5]. The activity ratios changed considerably with kidney inserts, where vertebrae overlaid by the kidneys

showed significantly decreased activities (1.7/1.8-fold decrease in L1 compared with a 1.1/1.1-fold decrease in L5 [simulation/measurement]). ***Conclusion:*** A general overestimation of 177Lu SPECT/CT-based activities in the lumbar spine for realistic activity concentrations was found. In addition, our analysis revealed a strong dependence of the accuracy of activity quantification on the axial positioning of the lumbar spine. An overlap of the axial position of the kidneys with individual vertebrae leads to an underestimation of the activity in these vertebrae. ***References:*** [1] Kim et al., ICRP 49(3):2020:13-201 [2]Kalidindi et al., Micromachines 14(10):2023:1928 [3]Ljungberg et al., Comput Meth Prog Bio 29(4):1989:257-272 [4]Polson et al., arXiv:2309.01977, 2023 [5]Reilhac et al., NeuroImage 39(1);2008:359-368

OP-538

Evaluation of Medium and High Energy Collimators for ^{212}Pb SPECT/CT imaging using NEMA NU 1-23

M. Griffiths[1], *E. Pienaar[2], K. Kuan[3], S. Taylor[3], D. A. Pattison[1];*
[1]Department of Nuclear Medicine & Specialist PET Services, Royal Brisbane and Women's Hospital, Brisbane, AUSTRALIA, [2]Queensland University of Technology, Brisbane, AUSTRALIA, [3]AdvanCell, Sydney, AUSTRALIA.

Aim/Introduction: Recent publications of 212Pb SPECT/CT imaging for isotope localisation and dosimetry estimates have used High Energy collimators (HEC). Publications of phantom data using Medium Energy Collimators (MEC) and HEC provide mixed recommendations. We investigate HEC and MEC SPECT performance using NEMA NU 1-23. ***Materials and Methods:*** System Planar Sensitivity (SPS) and Collimator Penetration, SPECT Reconstructed Spatial Resolution with Scatter and System Volume Sensitivity were assessed. Imaging used two simultaneous triple-energy windows 78 keV ± 20% (20% scatter) and 239 keV ± 10% (10% scatter). Planar assessment used scatter corrected images. SPECT scatter and attenuation corrected images for 78keV + 238 keV were combined to provided summed images (SI). ***Results:*** The MEC SI provided the highest Planar System Sensitivity and System Volume Sensitivity. 238 keV has the highest SPECT resolution and the HEC performs better. The SI resolution is marginally better than 78 keV. SI dual photo peak imaging improves sensitivity with a small reduction in resolution compared to 238 keV. 238 keV reconstructions provides higher resolution if required. Specifically. HEC SPS was 189, 100 and 273 c/s/MBq for 78, 238 keV and SI, respectively. MEC SPS was 377, 100 and 478 c/s/MBq for 78, 238 keV and SI. HEC Penetration factor was 0.22, -0.18 and 0.12 for 78, 238 keV and SI. MEC Penetration factor was 0.26, 0.04 and 0.19 for 78, 238 keV and SI. SPECT Reconstructed Spatial Resolution with Scatter. MEC FWHM 11.2, 8.4, 17 mm tangential, radial and central 78 keV. MEC FWHM 10.2, 7.8, 14.9 mm tangential, radial and central 238 keV. MEC FWHM 10.9, 8.4, 16.5 mm tangential, radial and central SI. HEC FWHM 10.0, 8.0, 15.9 mm for tangential, radial and central 78 keV. HEC FWHM 9.3, 7.6, 13.5 mm for tangential, radial and central 238 keV. HEC FWHM 9.5, 8.1, 15.8 mm for tangential, radial and central SI. System Volume Sensitivity. HEC 936, 743, 1679 (kcts/sec) / (MBq/cm^3) for 78, 238 keV and SI. MEC 1589, 1151, 2741 (kcts/sec) / (MBq/cm^3) for 78, 238 keV and SI. ***Conclusion:*** The MEC should be suitable, especially for larger lesions, with only a small reduction of resolution while achieving 1.22x increased sensitivity. MEC use could reduce acquisition time, enabling whole body imaging, or improve contrast through increased count studies. The HEC's better resolution is superior for imaging and quantitative dose assessment of smaller lesions.

OP-539

The potential of Ho-166 on a 3D CZT SPECT/CT

V. Nuttens[1], *P. De Bondt[1], M. Koole[2];*
[1]OLVZ, Aalst, BELGIUM, [2]KU Leuven, Leuven, BELGIUM.

Aim/Introduction: Transarterial radioembolization (TARE) is a minimally invasive procedure used to treat primary and secondary malignancies in the liver that are not amenable to curative resection. Next-generation SPECT/CT systems with swiveling CdZnTe (CZT) digital detectors in a ring-like setup are emerging in clinical routine. This study aims to investigate the potential of Ho-166 imaging on a 3D CZT SPECT/CT and a conventional SPECT/CT for post-therapy SPECT/CT imaging the day after treatment. ***Materials and Methods:*** The NEMA IQ phantom was adapted so that the smallest sphere of the standard NEMA phantom setup was replaced by a larger one, more suitable for SPECT image quality assessment and more corresponding to clinical lesion volumes. This resulted in inner sphere diameters of 13 mm, 17 mm, 22 mm, 28 mm, 37 mm and 60 mm. The NEMA IQ phantom was filled with an activity concentration of 1301 kBq/mL for the spheres and 270 kBq/mL for the background, resulting in a 4.8:1 contrast ratio. As such, a high-count scan was emulated, followed by scans with decreasing activity concentrations due to physical decay. The scans were performed on a conventional dual-head and a 3D CZT SPECT/CT system for comparison. ***Results:*** The average counts in the background of the reconstructed image are analyzed in relation to the activity concentration in the background. The dead time, measured as the deviation to a linear fit, was 20% for 90 kBq/mL for the conventional system (comparable with [1]) and 300 kBq/mL for the 3D CZT system. Noise (coefficient of variation in the background) was lower for the 3D CZT system (2.4 fold lower for the highest count scan but gradually leveling up for for the lower count scans). Recovery coefficients were generally higher for the conventional system while not all of the four largest spheres could be detected for all scans with the 3D CZT SPECT/CT. ***Conclusion:*** There is a large potential for Ho-166 imaging on a 3D CZT system with an improved sensitivity and reduced deadtime. However, further work must be done to optimize the reconstruction and scatter correction as this has a major impact on the sphere-to-backgroun ratio with respect to the noise for the CZT SPECT images. ***References:*** [1] Stella, M., Braat, A.J.A.T., Lam, M.G.E.H. et al. Gamma camera characterization at high holmium-166 activity in liver radioembolization. EJNMMI Phys 8, 22 (2021). https://doi.org/10.1186/s40658-021-00372-9

OP-540

Quantification Accuracy of SPECT Imaging with Low ^{212}Pb Activity Concentrations; Assessments by 3D-Printed Anthropomorphic Phantoms

J. Høiness[1,2], *E. E. H. H. Hernes[3], L. G. Mikalsen[2,4], C. Stokke[1,2], M. Kvassheim[2,5];*
[1]Department of Physics, University of Oslo, Oslo, NORWAY, [2]Department of Physics and Computational Radiology, Division of Radiology and Nuclear Medicine, Oslo University Hospital, Oslo, NORWAY, [3]Division of Radiology and Nuclear Medicine, Oslo University Hospital, Oslo, NORWAY, [4]Department of Life Sciences and Health, Oslo Metropolitan University, Oslo, NORWAY, [5]Faculty of Medicine, University of Oslo, Oslo, NORWAY.

Aim/Introduction: 212Pb presents a promising alternative to beta emitters in targeted radiotherapy, but it can pose a challenge for imaging. To investigate the accuracy of SPECT imaging of 212Pb for patient geometries, we imaged anthropomorphic phantoms with 212Pb, and studied the deviations of activity

concentrations measured from SPECT images from gamma counter measurements. ***Materials and Methods:*** Phantom shells were generated for kidneys, liver, and five vertebrae (T11-L3) based on a patient's CT-image. The phantoms were 3D-printed using a modified Creality Ender-3 Pro and an UltiMaker S5. The vertebrae were printed with inner compartments in the vertebral body and vertebral arch, with a filament of enhanced attenuation. The posterior compartments were filled with a solution of water and 30% of dipotassium hydrogen phosphate by weight, and the vertebral body compartments were filled with radioactive water. The phantoms were imaged three times with a Siemens Symbia Intevo Bold SPECT/CT with a total of 4.4-4.9 MBq 212Pb (711-793 Bq/mL, 1110-1239 Bq/mL, 1095-1222 Bq/mL, 61-68 Bq/mL, and 59-65 Bq/mL in the left and right kidney, liver, vertebral bodies, and background respectively). The distribution was based on measurements from the modelled patient's 18F-PSMA PET. A 40% energy window centred at 79 keV, with scatter windows of 20%, was used. Images were acquired with 30 seconds per view, 60 views, 256x256 matrix, and high energy collimators. The images were reconstructed with 30 iterations and 1 subset, a 12 mm Gaussian filter, triple energy window scatter correction, and attenuation correction based on CT. Activity concentrations were estimated by placing spherical volumes of interest within the boundaries of the phantom compartments and using a calibration factor determined from imaging a uniform phantom with the same acquisition and reconstruction parameters. Well counter measurements of 1 mL samples from each phantom compartment were used as true activity concentrations. ***Results:*** Image derived activity concentrations deviated from well counter measurements by 12%±7%, 23%±13%, and -27%±9% for the liver, right kidney, and left kidney respectively. The image derived activity concentrations for the vertebra and background compartments deviated by 700%-1000%. ***Conclusion:*** Quantification of 212Pb SPECT images is promising for larger volumes like liver and kidneys with activity concentrations higher than 0.8 kBq/mL. Neither small vertebra volumes nor the large background volume with activity concentrations lower than 70 Bq/mL could be accurately quantified from the SPECT images.

OP-541

Evaluating the accuracy of planar scintigraphy LSF and SPECT/CT LSF estimations using Monte Carlo simulations with virtual 4D anthropomorphic phantoms.

S. Cournane[1,2], *N. McArdle[1,2], J. McCavana[1,2], D. McCague[1], L. Leon Vintro[3,2];*
[1]St Vincent's University Hospital, Dublin 4, IRELAND, [2]UCD Centre for Physics in Health and Medicine, Dublin, IRELAND, [3]UCD School of Physics, Dublin 4, IRELAND.

Aim/Introduction: Prior to 90Y selective internal radiation therapy (SIRT), planar 99mTc-MAA scintigraphy imaging is used to estimate the lung shunt fraction (LSF). The recommended method for LSF estimation, as per 90Y SIRT manufacturers, is through analysis of planar imaging, neglecting scatter radiation and respiratory motion. The method leads to significant LSF overestimations and, hence, affects dosimetric accuracy. LSFs calculated using SPECT/CT images are considered to be the most accurate. However, SPECT/CT and planar LSF comparisons and accuracy evaluations have been conducted with basic phantoms and in patient cohorts where the true LSF has been unavailable. An easily implementable scatter window based correction using planar images has previously been reported to significantly improve LSF estimation accuracy. The technique has been demonstrated for an average-sized anthropomorphic phantom and has yet to be established for relevant patient ranges. The objective of this study was to evaluate the accuracy of the scatter-corrected planar LSF estimation technique and that of SPECT/CT, for known LSFs, for a set of 4D virtual anthropomorphic phantoms, with a range of BMIs representative of a typical SIRT patient population. ***Materials and Methods:*** A GE 870 DR SPECT/CT system was used to acquire planar and SPECT/CT imaging datasets of an anthropomorphic Radiological Support Devices (RSD) Heart and Thorax phantom with LSFs of 2.8, 6.3 and 10.9%. SIMIND Monte Carlo (MC) simulations were validated for this experimental data. Further, planar and SPECT/CT imaging datasets of a range of 6 Extended Cardiac-Torso (XCAT) 4D digital anatomical phantoms were MC simulated for LSF quantification. These phantoms represented a BMI range of 21-38 kg.m-2 and included respiratory and cardiac motion. The accuracy of each LSF quantification approach was evaluated for a range of planar and SPECT/CT estimates, with and without scatter correction, and compared for significance ($p < 0.05$) using repeated measures ANOVA. ***Results:*** The planar LSF overestimated the true LSF by 69 ±25% while the scatter corrected planar LSF estimation led to a significantly improved accuracy ($p<0.05$) of within 24 ±14%. For SPECT/CT, with and without scatter correction, differences from the true values were found to be 25 ±8% and 22 ±20%, respectively. ***Conclusion:*** The use of MC simulations and voxel-based phantoms allowed for comparison between true and estimated LSFs for a range of virtual phantom sizes representative of the patient population. The study quantified the SPECT/CT and scatter-corrected planar LSF estimation techniques to be comparable to the true LSF values.

Innovative renal phantom ready for 3D-Ring CZT dynamic imaging and first results.

G. Metrard, *G. Le Rouzic, B. Chapelle, M. Bailly;*
CHU - Medecine nucleaire, Orléans La Source, FRANCE.

Aim/Introduction: Isotopic renography is pivotal for assessing upper urinary tract obstruction and provides renal functional parameters. New 3D-Ring CZT cameras offer innovative 3D protocols that need to be validated on phantoms. Current renal phantoms were often complex and suitable for 2D imaging. We propose a novel renal phantom design, adapted to 3D imaging which also offers a quarter split renal function. ***Materials and Methods:*** A 3D-printed renal phantom mimicking pediatric/adult kidneys with separation for upper/lower halves was designed. Each kidney subunit, connected to a bladder-bag, was programmably infused with 7.5 MBq of 99mTc to simulate reproductible normal nephrograms. An asymmetry of renal activity was also simulated using different activity ratios. The phantom underwent testing using a NaI conventional gamma camera and a 3D-Ring CZT gamma camera. ***Results:*** Normal kidney simulations displayed characteristic time-activity curves with mean Tmax at 3.14 +/- 0.31, T1/2 of 4.9 +/- 0.63 min, and 20-min/max count ratio of 17.0 +/- 3.27%. These results were all within the normal range for clinical practice. Ratios between subunits were consistent at 54.6/45.4%. Pathology simulations showed a good linear correlation ($r=0.951$, $p<0.001$) between activity and AUC, used for the split renal function evaluation. Results were similar on 3D-Ring CZT camera with dynamic protocol. ***Conclusion:*** The proposed 3D phantom offered a simple yet effective tool for the evaluation of renal scan protocols. Its use with dynamic protocol of new 3D-Ring CZT cameras holds promise for improved imaging protocols.

Correlation of tracer uptake in sentinel lymph nodes as measured on SPECT/CT and during intra-operative gamma tracing with a drop in gamma probe: the UZ Leuven experience

***M. Manley*[1]**, *S. Jentjens*[1], *L. De Wever*[2], *C. M. Deroose*[1], *W. Everaerts*[3], *K. Goffin*[1];
[1]*Nuclear Medicine, University Hospitals Leuven, Leuven, BELGIUM,* [2]*Radiology, University Hospitals Leuven, Leuven, BELGIUM,* [3]*Urology, University Hospitals Leuven, Leuven, BELGIUM.*

Aim/Introduction: This retrospective analysis aims to study the relationship between tracer uptake in sentinel lymph nodes (SLNs) as measured on SPECT/CT and during intra-operative gamma tracing with a drop-in gamma probe in patients who participated in the UZ Leuven cohort of a prospective multicentre clinical trial evaluating a drop-in gamma probe for minimally-invasive SLN biopsy (SLNB) in prostate cancer [1] Correlation of pre- and intraoperative imaging can allow for improved surgical planning, providing important information to guide intraoperative findings. ***Materials and Methods:*** Nine patients with histologically proven prostate cancer scheduled for radical prostatectomy (RP) with extended pelvic lymph node dissection (ePLND) were prospectively selected for preoperative lymphoscintigraphy with SPECT/CT the day before surgery after intra-prostatic injection of 240 MBq of 99mTc-nanocolloid under ultrasound guidance. SLNB was performed with the drop-in gamma probe during standard of care RP with ePLND. SLN detection and counts on SPECT/CT and in vivo and ex vivo probe measurements were compared. ***Results:*** Patient-based detection rate of at least one SLN was 100% on SPECT/CT and 100% intraoperatively with the drop-in gamma probe. In total, 29 SLNs were detected with the probe and 32 SLNs on SPECT/CT (table 1). In three patients, SLNs were identified on preoperative SPECT/CT imaging (4 SLNs in total) that were not resected due to localisation outside the ePLND template and related operative surgical risk. In one patient, two adjacent resection specimens could be matched to one preoperative imaging result. Seven of 29 SLNs identified by the drop-in gamma probe were located outside of the ePLND template. The correlation between SPECT/CT counts and in vivo and ex vivo probe measurements was significant but moderate (r=0.57, p=0.002 and r=0.64, p=0.0003, respectively). ***Conclusion:*** SPECT/CT and drop-in gamma probe had a detection rate of 100% for SLNs in prostate cancer. The counts measured in SLNs on SPECT/CT had a moderate concordance with uptake measured in vivo using the drop-in gamma probe for minimally invasive SLN dissection. The drop-in gamma probe thus constitutes a valuable tool in the intraoperative detection of SLNs, providing important information about the lymphatic drainage pattern of prostate cancer. SPECT/CT uptake values can be used as an estimate for in vivo detection of SLNs with the probe. ***References:*** 1. Everaerts W, Walz J, Abascal Junquera JM, et al. A Multicentre Clinical Trial Evaluating a Drop-in Gamma Probe for Minimally Invasive Sentinel Lymph Node Dissection in Prostate Cancer. Eur Urol Focus. 2023;24:S2405-4569(23)00174-8.

SPECT/CT Calibration and Quantification with ^{161}Tb for Kidney Dosimetry

***F. Westerbergh*[1]**, *N. P. van der Meulen*[2], *C. Müller*[3], *A. Grings*[4], *P. Ritt*[4], *P. Bernhardt*[1,5];
[1]*Department of Medical Radiation Sciences, Institute of Clinical Sciences, Sahlgrenska Academy at University of Gothenburg, Gothenburg, SWEDEN,* [2]*Laboratory of Radiochemistry, Paul Scherrer Institute, Villigen-PSI, SWITZERLAND,* [3]*Center for Radiopharmaceutical Sciences, Paul Scherrer Institute, Villigen-PSI, SWITZERLAND,* [4]*Clinic of Nuclear Medicine, University Hospital Erlangen, Erlangen, GERMANY,* [5]*Department of Medical Physics and Biomedical Engineering (MFT), Sahlgrenska University Hospital, Gothenburg, SWEDEN.*

Aim/Introduction: 161Tb has gained recognition as a promising candidate for targeted radionuclide therapy. However, its decay features yield a complex photon emission profile, potentially complicating image-based quantification. The aim of this study was to investigate the effects of employing different collimators, calibration factors, and quantification methods in 161Tb SPECT/CT-based kidney dosimetry. ***Materials and Methods:*** A GE Discovery NM/CT 670 Pro system (5/8") and one 75 keV±10% photopeak window were employed, using three collimators: low-energy high-resolution (LEHR), extended low-energy general-purpose (ELEGP), and medium-energy general-purpose (MEGP). Calibration measurements were performed using both a homogeneous cylinder phantom (V = 6.9 L) and a large hot sphere (V = 113 mL) in water. For the cylinder, three different volume-of-interest (VOI) geometries were employed to derive the calibration factor: a small cylinder (V = 940 mL), a large cylinder (V = 3.8 L), and a VOI matching the physical size of the phantom. For the sphere, the same two cylinder VOIs were employed, as well as one spherical VOI with a 1-cm margin (V = 268 mL). Imaging was performed using a realistic 3D-printed kidney insert (V = 158 mL). Quantification was carried out using the small VOI method with differently sized VOIs (0.6, 2, and 4 mL x 5 VOIs). A central 30-mL VOI was used as a reference for true activity. Reconstructions were performed with a clinical OSEM algorithm (Xeleris 4.0), including compensations of attenuation, scatter, and collimator-detector response with 20-200 updates. ***Results:*** The calibration factor was approximately two-fold higher with ELEGP compared to LEHR and MEGP (40.8, 20.2, and 19.1 cps/MBq, respectively). Source and VOI geometry significantly impacted the derived calibration factor. The highest calibration factor was obtained using the large cylinder VOI over the sphere (+20%, +17%, and +16% for ELEGP, LEHR, and MEGP). In kidney quantifications, the small VOI method generally underestimated the activity, with the underestimation increasing with updates. For MEGP and ELEGP, larger VOIs induced greater underestimations, whereas results were similar regardless of VOI size for LEHR. Generally, the best results were obtained at 40 updates with the 0.6-mL VOIs. ***Conclusion:*** Accurate SPECT-based kidney activity quantification appears feasible with 161Tb. Good results were obtained regardless of collimator; however, the low-energy collimators are associated with increased amounts of scatter. Consideration should be given to the source and VOI geometry used for determining the calibration factor, as these factors significantly impact the results, warranting further investigation.

Identifying Intra-abdominal Desmoid Tumors Mimicking GISTs: The Potential Role of [18F]FAPI-42 PET/CT

C. Wu[1,2], *X. Wang[2], X. Lin[2], A. W. J. M. Glaudemans[1], B. Cornelissen[1], W. Noordzij[1], F. Wen[2], X. Hu[2], Y. Zeng[2], K. Sun[2], S. Cai[2], S. Huang[2], X. Zhang[2], X. Zhang[2];*
[1]University of Groningen, University Medical Center Groningen, Groningen, NETHERLANDS, [2]The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, CHINA.

Aim/Introduction: Intra-abdominal desmoid tumors (IADT) can mimic gastrointestinal stromal tumors (GISTs), particularly recurrence and metastases [1,2]. However, it is difficult to radiologically differentiate these two diseases [2,3]. This study aimed to investigate the clinical utility of fluorine 18 (18F)-labeled fibroblast activation protein inhibitor ([18F]FAPI-42) PET/CT for differentiating between IADT and GISTs by comparing to [18F] FDG PET/CT. ***Materials and Methods:*** This study retrospectively included a total of 24 patients (12 patients with IADT and 12 patients with recurrent/metastatic GISTs) who underwent both [18F]FAPI-42 and [18F]FDG PET/CT. The differences in the ratio of tumor SUVmax to liver SUVmean on [18F]FAPI-42 PET/CT (TLRFAPI) and [18F]FDG PET/CT (TLRFDG) and the ratio of TLRFAPI to TLRFDG (TLRFAPI/ TLRFDG) were compared between IADT and GISTs. AUC analysis was used to compare the discriminative performance of both tracers PET/CT for distinguishing IADT and GISTs. Immunohistochemistry was used to verify FAP expression of all IADT lesions and GISTs lesions. ***Results:*** TLRFAPI of IADT was significantly higher than that of GISTs [10.3 (3.3, 18.2) vs 5.0 (2.1, 19.6), P=0.024], while TLRFDG of IADT was significantly lower than that GISTs [1.2 (0.5, 3.0) vs 3.3 (0.7, 9.7), P=0.007]. TLRFAPI/ TLRFDG of IADT was significantly higher than that of GISTs [9.4 (2.8, 22.8) vs 1.9 (0.7, 23.2), P<0.001]. The discriminative performance of TLRFAPI/TLRFDG for distinguishing IADT and GISTs was best (AUC = 0.889), with 91.7% sensitivity, 83.8% specificity, and 87.5% accuracy. The expression of FAP in IADT was markedly higher compared to GISTs, with ten IADT lesions and one GISTs lesion showing a high level of expression, respectively [83.3% (10/12) vs 8.3% (1/12), P<0.001]. ***Conclusion:*** [18F]FAPI-42 PET/CT is a promising method for identifying IADT mimicking GISTs due to IADT showing higher FAP uptake and FAP expression than GISTs. Furthermore, combining [18F]FAPI-42 PET/CT and [18F]FDG PET/CT can help further differentiate IADT from GISTs. ***References:*** [1] Lee JC, Curtis D, Williamson JB, Ligato S. OP-546

Comparison of potential false-positive findings rate on 68Ga FAPI PET/CT in initial staging and post-surgery restaging of patients with gastric cancer.

P. Bochev[1], *G. Mateva[1], N. Novoselska[1], A. Konsulova[2], I. Takorov[3];*
[1]Acibadem Cityclinic Oncology hospital, Sofia, BULGARIA,
[2]USHATO Ivan Chernozemski, Sofia, BULGARIA,
[3]Military Medical Academy, Sofia, BULGARIA.

Aim/Introduction: To compare the rate of potential false-positive findings on 68Ga FAPI PET/CT in patients with surgery naïve gastric cancer (staging) and those that had prior surgery (restaging) ***Materials and Methods:*** A total of 38 patients with gastric cancer, referred for staging (endoscopic biopsy only, 13 patients/16 scans) or restaging after abdominal surgery (25 patients, 33 scans) were included. Only intraabdominal findings were analyzed, categorized as: Tumor related: Primary tumor, locoregional lymph nodes, obvious metastases. Tumor-related findings served as lesion-based exclusion criteria. Non-tumor related: FAPI positive lesions with a clear benign explanation (uterine fibroids etc.) Equivocal/ Surgery related: All sites that can be either benign or malignant: anastomoses, metal clips uptake, mesentery, peritoneum (FAPI uptake with no CT findings). Equivocal sites were followed up by imaging or histologically confirmed. Secondary primaries: Lesions with characteristics of another primary (histology confirmation) ***Results:*** Staging cohort: 13 patients (3 patients were rescanned after NACT and were also considered staging). Of those 7 patients (10 scans) showed no false positive findings (63%), 2 patients had uterine fibroids, 2 - pancreatic uptake, 1 - diffuse esophageal uptake, 1 patient - lung tumor (proven to be second primary). All findings were categorized as non-tumor related, one as secondary primary. None was categorized as equivocal. Restaging cohort: Of 25patients (32 scans) two were excluded because of extensive intraabdominal disease (dominant tumor-related lesions) Only two patients had no false positive findings (8%). 9 patients had diffuse pancreatic uptake, 2 - anastomosis uptake, 3- esophageal uptake, 2 - diffuse liver uptake/fibrosis, 1 - segmental liver uptake, 1 - portal vein thrombosis, 1 subphrenic abscess, 1 mesenteric uptake, 2 - surgery site/metal clips uptake, 3 - fibroids, 1 - diverticles, 1 - bowel wall uptake (ileus), 3 - laparotomy /abdominal wall. In one patient rectal cancer as secondary primary was detected (biopsy confirmed) Seven patients were categorized as equivocal. One patient with abdominal wall implant progressed locally, two patients progressed to an extend that the equivocal lesions were no more assessable, in 3 patients equivocal findings resolved, in one (subphrenic abscess) no change was noted on follow up. ***Conclusion:*** 68Ga FAPI PET CT shows high uptake in various benign conditions and especially surgery-related changes and should be used with caution in restaging patients with gastric cancer who underwent surgery. Contrary- in surgery-naïve patients it performs unequivocally and seems to be a reliable tool for staging gastric cancer.

OP-547

Diagnostic accuracy of ^{68}Ga-FAPI-46 PET/CT vs.^{18}F-FDG PET/CT vs. conventional CT imaging in patients with cancer of the upper gastrointestinal tract

M. Desaulniers[1], *H. Lanzafame[1], C. Berliner[1], F. Barbato[1], R. Hamacher[1], S. Kasper[1], J. T. Siveke[1], L. Umultu[1], M. Trajkovic-Arsic[1], M. Eckstein[2], K. M. Pabst[1], I. A. Mavroeidi[1], M. Nader[1], T. Telli[1], K. Herrmann[1], W. P. Fendler[1];*
[1]Universitätsklinikum Essen, Essen, GERMANY,
[2]Uniklinikum Erlangen, Erlangen, GERMANY.

Aim/Introduction: Due to intestinal physiological activity of 18F-FDG and pitfalls of inflammation, cancers of the upper gastrointestinal tract are difficult to assess. The 68Ga-FAPI-46 PET/CT (FAPI-PET) has demonstrated a higher lesion detection rate and tumor-to-background ratio (TBR) than 18F-FDG PET/CT (FDG-PET) in many cancers. The aim of this study is to assess the accuracy of FAPI-PET compared with FDG-PET or CT for the detection of cancers of the upper gastrointestinal tract. ***Materials and Methods:*** Fifteen patients with cancer of the

esophagus, stomach or duodenum who underwent FAPI-PET were enrolled in a prospective observational trial (NCT04571086). They all additionally underwent FDG-PET and CT. The primary endpoint was the accuracy of FAPI-PET compared with FDG-PET or CT on a per-patient and per-region basis for tumor location (primary tumour, lymph node, distant metastasis) confirmed by histopathology, follow-up CT or clinical data. Secondary endpoints were detection rate, comparison on a per-region basis of SUVmax and TBR between FAPI-PET and FDG-PET (Wilcoxon), association between FAPI-PET uptake intensity and histopathological FAP expression (Spearman r), inter-reader reproducibility (Fleiss k) and change in management. The data set were interpreted by two masked readers. ***Results:*** The 15 patients had cancer of the esophagus (n=7, 46.7%), stomach (n=6, 40.0%) or duodenum (n=2, 13.3%). Patients had no disease (n=1, 6.7%), locoregional disease (n=3, 20.0%) or distant disease (n=11, 73.3%). FAPI-PET was equivalent in accuracy to FDG-PET or CT for primary tumours (86.7%, 86.7%, 93.3% respectively) and lymph nodes (93.3%, 86.7%, 86.7%). FAPI-PET was more accurate than FDG-PET or CT for distant metastases (86.7%, 66.7%, 66.7%). The detection rate was higher with FAPI-PET than FDG-PET or CT for primary tumours (73.3%, 73.3%, 66.7% respectively), lymph nodes (60.0%, 53.3%, 53.3%) and distant metastases (53.3%, 33.3%, 20.0%). There was no significant difference between FAPI-PET and FDG-PET uptakes for primary tumours (p=0.5), lymph nodes (p=0.3) and distant metastases (p=0.9). However, TBR (liver) was significantly higher for FAPI-PET than FDG-PET for primary tumours and lymph nodes (p<0.05). There was no positive correlation between uptake on FAPI-PET and FAP immunohistochemistry score (r=-0.03, p=0.94). After FAPI-PET, only 3 (20.0%) patients had a major change in management. ***Conclusion:*** In patients with cancer of the upper gastrointestinal tract, FAPI-PET showed equal accuracy for locoregional disease and greater accuracy for distant disease vs. FDG-PET, while providing better contrast for the detection of primary tumours and lymph nodes.

Fibroblast activation protein α (FAPα) directed Imaging in Patients with Biliary Tract Cancer (BTC) - an Update of a Single-Center, Prospective, Observational Study (NCT04571086)

K. Pabst[1,2], *T. Bartel[1,2], H. Lanzafame[1,2], R. Hamacher[3,2], J. T. Siveke[3,2,4], M. Trajkovic-Arsic[5,2], I. A. Mavroeidi[3,2], H. Schürmann[3,2], L. Kessler[6,2], K. Kostbade[3,2], S. Kasper[3,2], K. Herrmann[1,2], M. Nader[1,2], W. P. Fendler[1,2];*
[1]Department of Nuclear Medicine, West German Cancer Center, University Hospital Essen, Essen, GERMANY, [2]German Cancer Consortium (DKTK), Partner site University Hospital Essen, Essen, GERMANY, [3]Department of Medical Oncology, West German Cancer Center, University Hospital Essen, Essen, GERMANY, [4]Bridge Institute of Experimental Tumor Therapy, West German Cancer Center, University Hospital Essen, Essen, GERMANY, [5]Division of Solid Tumor Translational Oncology, German Cancer Research Center, Heidelberg, Germany, Essen, GERMANY, [6]Department of Radiology and Neuroradiology, University Hospital Essen, Essen, GERMANY.

Aim/Introduction: BTC has an unfavourable prognosis, and therapeutic options are limited. Therefore, accurate staging and development of new therapies is critically important. In previous studies, 68Ga-FAPI-46 PET/CT demonstrated promising results in BTC. Here, we aimed to investigate the detection efficacy (DE) of 68Ga-FAPI-46 PET in BTC patients and its impact on treatment management in an extended cohort, and to identify potential candidates for FAP-directed radioligand therapy (RLT). ***Materials and Methods:*** A retrospective review was performed on all BTC patients who had undergone 68Ga-FAPI-46 PET/CT for initial staging/restaging between 08/2020 and 03/2024 as part of our prospective observational study, and clinical 18F-FDG PET/CT. Clinical data and histopathological results were collected. To evaluate the DE, a region-based analysis of 68Ga-FAPI-46 PET, 18F-FDG PET and contrast-enhanced CT (ceCT) was performed by two independent nuclear medicine physicians. Follow-up and histopathology were used as reference standard. Interobserver reliability was assessed using Cohen's kappa. Region-based SUVmax and tumour-to-background ratios (TBR) of both ligands were compared using Wilcoxon test. Change in treatment management was assessed by pre- and post-imaging physician's questionnaires. Imaging criterion for potential FAP-RLT candidates was defined as SUVmax ≥10 in >50% of tumor manifestations on 68Ga-FAPI-46 PET. ***Results:*** N=37 BTC patients (median age: 57 years; range: 29-81 years) were analysed (n=27 intrahepatic/n=4 perihilar/n=5 distant cholangiocarcinoma/n=1 gallbladder cancer). Highest DE was observed for all regions on 68Ga-FAPI-46 PET, followed by 18F-FDG PET and ceCT (primary tumour: 100%/79%/76%, regional lymph node metastases (rLN): 86%/71%/50%, distant lymph nodes metastases (dLN): 86%/69%/69%, distant metastases: 96%/75%/75%, osseous metastases: 100%/78%/89%). The highest interobserver reliability was seen on 68Ga-FAPI-46 PET (68Ga-FAPI-46/18F-FDG/ceCT: primary (1/0.63/0.83), dLN (1/1/0.34), distant (0.65/0.64/0.57) and osseous metastases (1/0.18/-0.2). Region-based mean SUVmax values were significantly higher on 68Ga-FAPI-46 PET compared to 18F-FDG PET in primary tumours (mean±SD: 16.5±8.3 vs. 10.5±8.0; p<0.001) and distant metastases (12.6±12,6 vs. 10.6±8.2 p=0.042). In all investigated regions, TBRLiver was significantly higher on 68Ga-FAPI-46 PET vs. 18F-FDG PET (primary tumour: 13.3±7.0 vs. 4.9±3.9, p<0.001; rLN: 9.1±6.7 vs. 4.3±3.2; dLN: 12.1±11.8 vs. 4.5±2.8; distant metastases: 10.2±6.9 vs. 5.1±3.6; osseous metastases: 10.4±6.0 vs. 4.3±2.9; all p-values <0,05). Based on 68Ga-FAPI-46 PET, additional procedures, i.e. laparoscopy/biopsy, were performed/avoided in n=3/1 patients. Change in treatment was observed in one patient. 13 patients (35%) met the criterion for FAP-RLT. ***Conclusion:*** 68Ga-FAPI-46 PET demonstrates an improved detection rate and higher uptake in BTC patients compared to 18F-FDG PET and ceCT. One third of patients are potential candidates for RLT.

OP-549

Comparative Evaluation of 68Ga-FAPI PET/CT versus ^{18}F-FDG PET/CT in Gallbladder Carcinomas: A Prospective Head-to-Head Analysis

D. Manda, *M. M V, V. Shukla, A. Suresh, S. Patel, M. Tripathi; MPMMCC & HBCH, Tata Memorial Centre, Varanasi, INDIA.*

Aim/Introduction: Recently developed radiolabelled FAPI (FAP inhibitors) have attracted researcher's attention in diagnosing various tumours due to its high specificity and better tumour to background ratio. The aim of this study is to evaluate the effectiveness of 18Ga-FAPI-PET/CT imaging for the evaluation of newly diagnosed and recurrent gall bladder carcinoma as well as its comparison with 18F-FDG PET/CT. ***Materials and Methods:*** This prospective analysis included 35 patients with pathologically confirmed gall bladder carcinoma who underwent simultaneous 68Ga-FAPI and 18F-FDG PET/CT scan on two different days (within a week) either for initial staging assessment or recurrence detection (re-staging). Images of both the scans were analysed based upon visual assessment, and semi-quantitative parameters (target-to-background ratio [TBR], maximum standard uptake

value [SUVmax]) for both primary tumours and metastases. ***Results:*** 35 patients (15 male, 20 female; mean age: 58.5 ± 12.3 SD; range: 41-84 years) with primary or recurrent gall bladder carcinoma were evaluated. The sensitivity rates were comparable in patients for both the modalities for primary and recurrent tumours (92.3% each), hepatic (100% each) and lung (100% each) metastases. However, sensitivity rates with 68Ga-FAPI PET/CT is more as compared to ^{18}F-FDG PET/CT in evaluation of positive lymph nodes (95.5% vs 77.3%), peritoneal metastases (100% vs 78.6%) and bone metastases (100% vs 66.6%). The mean SUVmax of 68Ga-FAPI PET/CT vs ^{18}F-FDG PET/CT for primary tumour (11.9 vs 10.4), recurrent tumours (12.6 vs 9.9), lymph nodal metastases (9.7 vs 8.4) and distant metastases (liver: 10.6 vs 8.7; peritoneal: 9.0 vs 7.4; bone: 6.6 vs 3.2) were higher. The mean TBRs on 68Ga-FAPI PET/CT vs ^{18}F-FDG PET/CT for primary tumour (9.4 vs 8.1), recurrent tumours (10.1 vs 7.7), lymph nodal metastases (7.9 vs 6.1) and distant metastases (liver: 7.7 vs 6.3; peritoneal: 6.9 vs 4.6; bone: 5.3 vs 1.6) were also higher. Statistically significant differences for both mean SUVmax (p value 0.004) and TBR (p value < 0.001) was seen in bone metastases. Lung metastases detected in only one patient with SUVmax (11.7 vs 4.8) and TBR (10.2 vs 3.2) values significantly higher with 68Ga-FAPI PET CT. ***Conclusion:*** 68Ga-FAPI PET/CT with its enhanced TBRs and sensitivity detection rates suggest complimentary role to ^{18}F-FDG PET/CT in assessment of gall bladder carcinoma, prompting further exploration with expanded cohorts.

OP-550

Relationship between Al^{18}F-NOTA-FAPI-04 SUVmax and clinicopathological features of primary lesions in gastric cancer

F. Chao, *R. Wang, X. Han;*
Department of Nuclear Medicine,the First Affiliated Hospital of Zhengzhou University, Zhengzhou, CHINA.

Aim/Introduction: To investigate the relationship between Al18F-NOTA-FAPI-04 SUVmax of primary lesions and clinicopathological factors in patients with gastric cancer. ***Materials and Methods:*** Twenty-nine patients with histologically proven gastric cancer were prospectively recruited. Each patient underwent Al18F-NOTA-FAPI-04 PET/CT before surgery. Three patients with negative PET/CT imaging were excluded, resulting in a final inclusion of twenty-six patients (17 males, 9 females, age range 37-78 years). Mann-Whitney U test or Kruskal-Wallis rank sum test was employed to compare the differences in SUVmax of primary lesions among various clinicopathological factors. Additionally, Spearman rank correlation analysis was conducted to assess the correlation between different clinicopathological features and SUVmax of primary lesions. Factors with statistical significance in the univariate analysis were included in a multivariate linear regression analysis model for further multifactorial analysis. For parameters with statistical significance in the multifactorial analysis, receiver operating characteristic curves (ROC) were generated to determine the optimal parameters and diagnostic performance for discriminating between the two groups. ***Results:*** The sensitivity of Al18F-NOTA-FAPI-04 PET/CT in detecting primary lesions of gastric cancer was 89.7% (26/29). The sensitivity for T1 stage gastric cancer was 57.1% (4/7), with 50% sensitivity for T1a stage (2/4) and 66.7% for T1b stage (2/3). The sensitivity for T2-4 stage was 100% (22/22). The SUVmax of primary lesions in all gastric cancer patients was 8.7, where T1 stage SUVmax was significantly lower than T2-4 stage (3.3 vs. 9.2, P=0.004). Univariate analysis revealed that vascular and/or neural invasion (rs value: 0.502, P=0.009), pT stage (rs value: 0.575, P=0.002), pN stage (rs value: 0.582, P=0.002), and pTNM stage (rs value: 0.545, P=0.004) were positively correlated with SUVmax of primary lesions, while age, tumor location, pathological type, histological grade, and Lauren classification showed no correlation with SUVmax. Multivariate analysis indicated that only pT stage (β=2.284, t=3.649, P=0.001) was a significant independent predictor of SUVmax in primary lesions of gastric cancer. The optimized threshold of the Al18F-NOTA-FAPI-04 SUVmax for pT1 stage from pT2-4 stage was 5.0. The corresponding sensitivity, specificity, and area under the curve (AUC) of the ROC analysis were 86.4%, 100%, and 0.955, respectively. ***Conclusion:*** Vascular and/or neural invasion, pT stage, pN stage, and pTNM stage are associated with Al18F-NOTA-FAPI-04 SUVmax in primary lesions of gastric cancer, with pT stage being an independent factor influencing SUVmax.

OP-551

Diagnostic potential of static and dynamic ^{68}Ga-FAPI PET/CT for the differentiation of mass forming pancreatitis and pancreatic ductal adenocarcinomas

M. Röhrich[1,2], *M. Preussig[2], M. Lang[2], C. Schroeter[2], E. Gutjahr[2], M. Schreckenberger[1], U. Haberkorn[2];*
[1]University hospital Mainz, Mainz, GERMANY, [2]University hospital Heidelberg, Heidelberg, GERMANY.

Aim/Introduction: The differentiation of mass forming pancreatitis (MFP) and pancreatic ductal adenocarcinomas (PDAC) based on conventional imaging methods like ultrasound, CT and MRI is frequently not possible. Here, we applied static (60 minutes post injection) and dynamic PET/CT with 68Gallium-labelled Fibroblast Activated Protein Inhibitors (68Ga-FAPI-PET/CT) in 32 preoperative, treatment-naive patients with unclear pancreatic masses to evaluate the potential diagnostic value of this new imaging method for the differentiation of MFP and PDAC. ***Materials and Methods:*** 32 Patients with unclear pancreatic masses underwent static and dynamic 68 Ga-FAPI-PET/CT before surgical resection or biopsy of the pancreas and subsequent histological diagnoses. Static parameters (SUVmax and SUVmean) were generated from VOIs of pancreatic masses. Time activity curves and dynamic parameters including kinetic modeling were extracted from dynamic PET data using PMOD software. ***Results:*** Histology revealed PDAC in 13 patients and MFP in 19 patients. We observed a markedly higher 68Ga-FAPI-uptake in PDACs than in MFP (SUVmax: 17,43+/-4,79 versus 12,20+/-3,77 SUVmean: 10,41+/-2,82 versus 7,23+/-2,13). In dynamic PET-imaging, PDAC and MFP showed distinctive and characteristic time activity curves: While PDAC increased for 15+/-5 minutes followed by a plateau phase after the perfusion peak, MFP showed a steady decrease after a perfusion peak. The average time to peak was markedly longer for PDAC (19 minutes) than for MFP (4 minutes). PDAC showed higher K1and K2 values than MFP (K1:0,64+/-0,25 versus 0,33 +/-0,1, K2:0,77+/-0,63 versus 0,26+/-0,13). ***Conclusion:*** 68Ga-FAPI-PET/CT should be considered for patients where other imaging methods are not able to distinguish between malignant and inflammatory pancreatic masses. Overall, PDAC show higher 68Ga-FAPI-uptake than MFP. However, an overlap of PDAC and MFP-related uptake is possible. Dynamic time activity curves are distinctive for both PDAC and MFP, which underlines the additional value of dynamic 68Ga-FAPI-PET acquisition for the differentiation between malignancy-associated and inflammatory FAPI-uptake.

[^{68}Ga]FAPI-46PET/CT for preoperative assessment of peritoneal carcinomatosis- Preliminary analysis of FAPeCa trial

A. Arçay Öztürk[1], *G. Liberale[2], A. Hendlisz[3], L. Polastro[3], A. Veron Sanchez[4], A. Deleu[1], P. Kristanto[5], Z. Wimana[6], S. Vercauteren[6], P. Flamen[1];*
[1]Institut Jules Bordet, Hôpital Universitaire de Bruxelles (H.U.B), Université Libre de Bruxelles (ULB), Department of Nuclear Medicine, Brussels, BELGIUM, [2]Institut Jules Bordet, Hôpital Universitaire de Bruxelles (H.U.B), Université Libre de Bruxelles (ULB),Department of Surgery, Brussels, BELGIUM, [3]Institut Jules Bordet, Hôpital Universitaire de Bruxelles (H.U.B), Université Libre de Bruxelles (ULB),Department of Medical Oncology, Brussels, BELGIUM, [4]Institut Jules Bordet, Hôpital Universitaire de Bruxelles (H.U.B), Université Libre de Bruxelles (ULB),Department of Radiology, Brussels, BELGIUM, [5]Institut Jules Bordet, Hôpital Universitaire de Bruxelles (H.U.B), Université Libre de Bruxelles (ULB), Data Center, Brussels, BELGIUM, [6]Institut Jules Bordet, Hôpital Universitaire de Bruxelles (H.U.B), Université Libre de Bruxelles (ULB), Department of Radiopharmacy, Brussels, BELGIUM.

Aim/Introduction: Standard imaging modalities; CT, MRI, and FDG PET/CT face challenges in accurate preoperative staging of peritoneal metastases (PM) and often underestimate PM extent, leading to unexpected non-resectable disease during surgery. Preliminary reports suggest [68Ga]FAPI PET/CT, targeting fibroblast activation protein, may offer superior sensitivity for PM detection. This study aims to assess the potential of [68Ga]FAPI-46 PET/CT as a preoperative imaging tool for peritoneal carcinomatosis by correlating [68Ga]FAPI-46 PET findings with surgical outcomes and standard imaging modalities in colorectal and ovarian cancer patients. ***Materials and Methods:*** In this prospective study (NCT06061874), eligible patients with confirmed/suspected PM undergo [68Ga]FAPI-46PET/CT, [18F]FDG PET/CT, and abdominopelvic MRI within four weeks before scheduled cytoreductive surgery (CRS) and/or diagnostic laparoscopy (DL). Patients receiving neoadjuvant chemotherapy (NAC) undergo scans before and after NAC. The study targets the enrollment of eighty patients.The extent of PM was determined by the peritoneal cancer index (PCI) scoring system. Intraclass correlation coefficient (ICC) was used to assess the concordance between the PCI determined based on [68Ga]FAPI-46 PET/CT (FAPI-PCI), [18F]FDG PET/CT (FDG-PCI), MRI (MRI-PCI) and the PCI found during surgery (S-PCI). ***Results:*** Twenty-nine patients (six male, twenty-three female, mean age 63.8) were analyzed, including twenty-two ovarian and seven colorectal cancer patients. The mean PCI score at surgery (n=31; 22 based on CRS, 9 based on DL) was 15.7±8.9. The mean FAPI-PCI score (n=31, 13.7±8.9) was significantly higher than the mean MRI-PCI (n=18, 8.7±7.9, p=0.006) and FDG-PCI (n=31, 6.5±7.8, p<0.001). FAPI-PCI correlated very well with surgical PCI (ICC 0.80, 95% CI: 0.63-0.90). The ICC between S-PCI and FAPI-PCI was substantially higher than that between S-PCI and MRI-PCI (0.66, 95% CI: 0.28-0.86) and S-PCI and FDG-PCI (ICC 0.39, 95% CI: 0.05-0.65).The quantitative parameters; SUVmax (maximum standardized uptake value), TBR (target-to-background ratio) and PTV (total peritoneal tumour volumes) of [68Ga]FAPI-46 PET/CT for the PM lesions were significantly higher than those of [18F]FDG PET/CT (mean SUVmax: 12±6.8 vs. 7.5±7.9,p<0.001, mean TBR: 9.2±5.8 vs. 3.9±3.9,p<0.001, mean PTV: 151.3±296.4 ml vs. 90.4±271.8 ml,p=0.001, Wilcoxon signed-rank test). A case-by-case review of six patients receiving NAC revealed the accuracy of [68Ga]FAPI-46 PET in demonstrating the chemotherapy response of PM, correlating well with surgical findings. ***Conclusion:*** [68Ga]FAPI-46 PET-based PCI score evaluation demonstrated a very good correlation with PCI scores assessed during surgery in colorectal and ovarian cancer patients. [68Ga]FAPI-46 PET outperforms the current standard imaging modalities, MRI and [18F]FDG PET, making it a significant advancement for preoperative peritoneal disease assessment.

OP-553

First-in-Humans PET Imaging of ^{68}Ga-FT-FAPI and side-by-side comparison with ^{68}Ga-FAPI-04

S. Yang, *J. Ye, Z. Quan, F. Kang, J. Wang;*
Xijing Hospital, Xi'an City, CHINA.

Aim/Introduction: Fibroblast activation protein (FAP) is a potential target for tumor theranostics. FT-FAPI, a novel FAP inhibitor with an organotrifluoroborate, was reported by Liu's team at Peking University and has been verified for the biological effect and stability preclinically. This study reported the dosimetry of 68Ga-FT-FAPI in healthy volunteers, and assessed diagnostic accuracy for gastrointestinal (GI) solid tumors comparing with 68Ga-FAPI-04 PET/CT side-by-side. ***Materials and Methods:*** Six healthy volunteers were included and divided into two groups to the 1 h dynamic and 2 and 3 h static PET imaging with 68Ga-FT-FAPI and 68Ga-FAPI-04, respectively. Blood samples were collected to perform the pharmacokinetic using the PKSlover program. The dosimetry was calculated based on the mean standardized uptake value (SUVmean) using OLINDA/EXM. Six patients with different GI cancers were included, underwent 68Ga-FAPI-04 PET/CT and 68Ga-FT-FAPI scans at 2 time points (1 h and 3 h), respectively. Based on the 68Ga-FAPI-04 and 68Ga-FT-FAPI images, SUVs and tumor-to-background ratio (TBR) were generated. ***Results:*** 68Ga-FT-FAPI was tolerated well, and no adverse events were found. The pharmacokinetic characteristics of FT-FAPI in humans best fit the two-compartment model. The clearance half-life (T1/2β) of 68Ga-FT-FAPI and 68Ga-FAPI-04 was similar (75.0 min vs. 77.2 min). The results indicated that its pharmacokinetic properties in vivo were ideal. 68Ga-FT-FAPI showed low radiation dose, the effective dose (ED) of 68Ga-FT-FAPI was 12.4 ± 1.51 μSv·MBq-1, slightly higher than 68Ga-FAPI-04 (9.99 ± 1.85 μSv·MBq-1). For GI cancers, the radiotracer uptake and TBR of primary for 68Ga-FT-FAPI were higher than those of 68Ga-FAPI-04 (primary tumors: SUVmax 27.04 ± 14.62 vs. 24.23 ± 15.44 [p = 0.777], and TBR, 20.80 ± 12.22 vs. 16.23 ± 7.58 [p = 0.234]). And the radiotracer uptake and TBR of metastatic lesions for 68Ga-FT-FAPI were significantly higher than those of 68Ga-FAPI-04 (metastases: SUVmax, 17.57±11.64 vs. 12.81±6.611 [p < 0.001], and TBR, 24.35±18.8 vs. 15.26±9.477 [p < 0.001]), revealed an improved lesion detection rate and tumor delineation. ***Conclusion:*** This study has shown that it was safe and feasible for diagnosis using 68Ga-FT-FAPI as a FAP-targeted probe for GI cancer. It will be valuable in providing more experimental evidence for advancing the clinical translation of FT-FAPI.

LATE like pattern in FDG-PET of MCI subjects: clinical characteristics, amyloid burden and conversion to AD-dementia.

***F. Minguez*[1],** *E. Prieto*[1], *E. F. Guillen*[2], *M. Romera*[1], *V. Betech-Antar*[1], *K. Hirschmüller*[1], *B. Echeveste*[1], *M. Riverol*[1], *J. Arbizu*[1];
[1]*Clínica Universidad de Navarra, Pamplona, SPAIN,*
[2]*Clínica Universidad de Navarra, Madrid, SPAIN.*

Aim/Introduction: Describe the incidence of medial temporal hypometabolism as a pattern of possible Limbic-Predominant Age-Related TDP-43 encephalopathy (LATE), as well as its clinical characteristics, amyloid load and conversion to Alzheimer Disease (AD) dementia in a cohort of patients with mild cognitive impairment (MCI). ***Materials and Methods:*** We studied 207 MCI patients (mean age 72±6.1; MMSE 27±2.6; 50.8% males) who underwent FDG and Amyloid PET scans at diagnosis, with a clinical follow-up (24±17.5 months). FDG-PET patterns of hypometabolism were visually evaluated using a voxel-based analysis against an age-adjusted normality database and classified as LATE-like (medial temporal), AD and Mixed (AD-LATE) (1). Differences between these three patterns were evaluated by statistical parametric analysis (SPM12) using our healthy subject population as a control group. Amyloid-PET using approved radiotracers were visually classified as positive/negative and processed using a commercially available solution to calculate composite standard uptake value ratios (SUVR) using tracer-specific 'target/reference' regions, and converted to the Centiloid scale using appropriate SUVR-to-Centiloid conversion equations. Differences in clinical characteristics, amyloid load and conversion to AD-dementia were explored using SPSS (CHI-squared test, one-way ANOVA and Cox-regression). ***Results:*** LATE-like pattern was present in 22 patients (10.6%), AD pattern in 57 patients (27.5%), and Mixed in 21 patients (10.1%). The remaining 107 patients (51.7%) presented non-AD defined patterns (FTLD, Dementia with Lewy bodies, among others) and were excluded from the analysis. SPM analysis confirmed significant higher medial-temporal hypometabolism in LATE-like group, while the hypometabolism of posterior cingulate and parieto-temporal cortex were more significant in the AD followed by Mixed group. LATE-like group exhibited higher MMSE scores, lower percentage of amyloid positivity and Centiloid values than in AD and Mixed groups ($p<0.01$; Table 1). However, LATE-like group was non-significantly older than AD and Mixed groups. Conversion to AD-dementia was slower in LATE-like group than AD (p=0.005; Hazard Ratio=0.26 [0.1-0.67]) and Mixed groups (p=0.02; HR=0.29 [0.11-0.83]). Although, non-significant statistical differences were observed between AD and Mixed groups (p=0.7; HR=0.88 [0.47-1.65]). ***Conclusion:*** LATE-like pattern in FDG brain PET is not uncommon and occur in cognitively less affected MCI subjects with a lower brain amyloid load. Interestingly, MCI patients with LATE-like pattern exhibit a longer time to conversion to AD-dementia than those with an typical AD or a Mixed (AD and LATE-like) patterns. ***References:*** 1. Grothe. M, Moscoso A, Silva-Rodríguez J, et al. Differential diagnosis of amnestic dementia patients based on an FDG-PET signature of autopsy-confirmed LATE-NC. Alzheimer´s Dement. 2023;19:1234-44.

Aim/Introduction: Alzheimer's disease (AD) is the most common neurodegenerative disease and is characterized by the accumulation of amyloid-β (Aβ) plaques and neurofibrillary tangles in the brain. P-glycoprotein (P-gp), an essential efflux transporter at the blood-brain barrier (BBB) and plays a critical role in Aβ transport out of the brain, making it a potential therapeutic target [1]. Positron emission tomography (PET) imaging offers a unique quantitative approach to investigate the role of P-gp function at the BBB in vivo. In the past few years, several radiotracers have been developed and validated for PET imaging of the P-gp function. These radioligands are typically derivatives of avid P-gp substrates and therefore only suitable to measure decreases in P-gp function. [18F]MC225 is a novel weak P-gp substrate tracer that was developed to measure both increases and decreases in P-gp function. It has already been administered in both preclinical and clinical studies in healthy subjects [2,3]. The aim of this study is to assess BBB P-gp function in AD patients by quantitatively comparing [18F]MC225 kinetics with those in healthy volunteers. ***Materials and Methods:*** Thus far, fourteen healthy volunteers (HV; age 67±5y) and three AD patients (68±6y) were included. Subjects underwent a 60 minutes [18F]MC225 (200 MBq) dynamic PET scan with continuous arterial blood sampling and a cerebral T1weighted MRI scan as anatomical reference. Tissue time-activity curves, extracted using the Hammers maximum-probability atlas, were fitted to a reversible two-tissue compartment model to obtain the volume of distribution (VT), using the metabolite corrected plasma and uncorrected whole blood curves as input functions. ***Results:*** No significant differences were found in plasma curves, plasma/whole blood ratios and parent fractions between AD and HV groups. However, almost every brain region showed a significant difference in VT between AD and HV groups, except for thalamus and corpus callosum. The largest differences were found for globus pallidus and basal ganglia, with increases of 88 and 77%, respectively. For the whole brain grey matter region, VT increased by 52% (HV: VT=6.5±1.2 vs AD: VT=11.1±10.6; p= 0.021). ***Conclusion:*** This proof of concept study showed significant differences in P-gp function at the BBB between AD patients and HV. These findings support the further use [18F]MC225 PET in larger AD cohorts. It addition, it will be a potential in vivo tool to monitor response to disease modifying drugs. ***References:*** 1. Gil-Martins (2023) 2. Garcia-Varela (2021) 3. Mossel (2022).

Multi-modal Multi-probe PET/MR Imaging in evaluation of the effect of CSUL surgery in AD patients

***P. Yuan*[1],** *M. Xin*[1], *X. Li*[2], *C. Zhang*[1], *J. Liu*[1];
[1]*Department of Nuclear Medicine, Renji Hospital, School of Medicine, Shanghai Jiaotong University, Shanghai, CHINA,* [2]*Department of Geriatric Psychiatry, Shanghai Mental Health Center, School of Medicine, Shanghai Jiaotong University, Shanghai, CHINA.*

Aim/Introduction: Recent studies have found that the glymphatic system plays an important role in clearing metabolic waste from the brain. Impairment of glymphatic system may underlie the pathological accumulation of proteins such as amyloid-β (Aβ) in Alzheimer's disease (AD) patients. Therefore, cervical shunting to unclog cerebral lymphatic systems (CSUL) surgery may promote the drainage of the glymphatic system and accelerate the clearance of harmful proteins. In this study, multi-modal multi-probe PET/MR Imaging, including 18F-AV45 and 18F-FDG, was used to analyze the changes of Aβ, glucose metabolism and diffusion tensor imaging (DTI) in the brain of AD patients before and after CSUL surgery. ***Materials and Methods:*** Three AD patients who underwent CSUL surgery were enrolled in this study. All participants underwent psychological testing, 18F-FDG PET, 18F-AV45 PET imaging, and 3.0 T brain multimodal MRI scans before and after surgery. With the cerebellar cortex as the reference area, SUVR of FDG and AV45 in each brain regions was analyzed. Whole-brain glymphatic activity was measured by diffusion tensor image analysis along the perivascular space (DTI-ALPS). ***Results:*** The index of DTI-ALPS increased in all three patients ($p<0.05$), indicating that surgery did improve the glymphatic drainage. Clinical evaluation after surgery showed a 2-3 point improvement in mini-mental status examination (MMSE) scores, indicating an improvement in cognitive function. Activity of daily living (ADL) scores decreased by 2-5 points, indicating increased mobility. AV45 PET showed an overall reduction of Aβ in the brain, demonstrating that surgery can promote the clearance of pathological proteins in the brain. FDG PET also showed improved overall glucose metabolism in the brain. However, unlike the decrease of AV45 uptake in almost all brain regions, FDG uptake in some brain regions such as superior parietal cortex, posterior medial temporal cortex, posterior cingulate cortex and primary visual cortex did not improve significantly, indicating that pathological protein clearance in some brain regions could not completely improve brain metabolism. ***Conclusion:*** Multi-modal multi-probe PET/MR preliminarily revealed the therapeutic effect and shortcomings of the newly developed CSUL surgery for AD patients, and provided a theoretical basis for improving the treatment regimen and subsequent surgical treatment for more AD patients.

OP-557

Sources of reading errors in the clinical assessment of Vizamyl™PET images and the potential benefits of quantification to support clinical reads

C. Buckley[1], *P. Sherwin[2], G. Farrar[1], M. Battle[1];*
[1]GE Healthcare Pharmaceutical Diagnostics R&D, Chalfont St. Giles, UNITED KINGDOM, [2]GE Healthcare Pharmaceutical Diagnostics R&D, Marlborough, MA, UNITED STATES OF AMERICA.

Aim/Introduction: [18F]flutemetamol (trade name VizamylTM) was approved for amyloid brain PET based on the ability of amyloid-naive readers who completed a reader training program to identify significant levels of Aβ pathology (vs. autopsy as the truth standard). Post-approval, GE HealthCare conducted a European study involving 6 countries, 12 sites and 18 readers. The study aimed to assess real-world effectiveness of the VIZAMYL™ reader training programmes (in-person or electronic1) by estimating diagnostic accuracy, sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV), of the visual interpretation of VIZAMYL™ images obtained in clinical practice, and to identify likely reasons for false-positive and false-negative results. ***Materials and Methods:*** Routine clinical classifications of 209 VizamylTM PET images were independently assessed blindly by 5 expert readers, whose majority opinion was the gold standard classification. Agreement (Cohen's kappa)2 between each clinical classification and the majority opinion was calculated. A root-cause analysis examined the reasons for any disagreements. In a further post-hoc analysis, images were quantified on the centiloid (CL) scale and classified positive if uptake was ≥ 30 CL. Agreement between the clinical and expert readers' classifications and the quantitative classifications were compared. ***Results:*** The expert-majority and clinical-reader classifications agreement was 87% (kappa 0.66). The ratio of false positives to false negatives was 2.75 : 1. Sources of clinical reader errors were: incorrect alignments, wrong order of regional assessments, non-scrolled review, infrequent reviews (< 1/week), misplaced scrolling-plane, and time since reader training > 2 years. The expert-majority and quantitative classifications agreed with a kappa of 0.82 (near perfect agreement), while the clinical-reader and quantitative classifications agreed with a kappa of 0.62 (fair-to-good agreement). ***Conclusion:*** Insights from the study results and post-study interviews with clinical readers were captured in EMA-approved updated/refresher training materials with region-specific pitfall avoidance strategies. The post-hoc quantitative analysis showed near perfect agreement between expert majority and 30CL quantitative threshold. This strongly suggests that local clinical readers could use quantitation to assist their interpretation VizamylTM PET images (i.e. as a proxy for an expert read) and their reading accuracy would likely benefit from this adjunct. ***References:*** 1. OP-558

Clinical characterization of a three-level Centiloid-based classification of amyloid distribution

G. Mathoux[1], *C. Boccalini[2], D. E. Peretti[2], G. B. Frisoni[3], V. Garibotto[1];*
[1]Hôpitaux Universitaires de Genève, Genève, SWITZERLAND, [2]Laboratory of Neuroimaging and Innovative Molecular Tracers (NIMTlab), Geneva University Neurocenter and Faculty of Medicine, University of Geneva, Genève, SWITZERLAND, [3]Memory Clinic, Hôpitaux Universitaires de Genève, Genève, SWITZERLAND.

Aim/Introduction: β-amyloid (A) deposition is an Alzheimer's disease feature that can be studied in vivo with amyloid-PET. The images can be defined as positive or negative using visual assessment or semi-quantification, namely using the "Centiloid" unit, a tracer-independent scoring. The dichotomous nature of this classification is however limited by the presence of visually discordant cases and the use of different thresholds for the semi-quantitative index across studies. Our study aims to evaluate a three-level classification based on the Centiloid scale in a memory clinic population. ***Materials and Methods:*** We enrolled 580 subjects (70.4±7.8 years) ranging from cognitively unimpaired to mild cognitive impairment and dementia, who were evaluated at the Geneva Memory Center and underwent amyloid-PET scans using either [18F]florbetapir or [18F]flutemetamol. A subset of participants underwent [18F]Flortaucipir-PET (n=185) and CSF biomarkers (n=190) within a year. Amyloid status was visually assessed and Centiloid was calculated from amyloid-PET. Based on centiloid values, subjects were categorized into three categories: i) NEGATIVE: centiloid<12, ii) GRAY-ZONE: 12≤ centiloid ≤37, iii) POSITIVE: centiloid >37. Tau (T) status was evaluated both visually

and semi-quantitatively from tau-PET. Associations between amyloid categories and demographics, clinical diagnosis, tau status, cognitive function, and CSF biomarkers were assessed using Chi-squared and Kruskal-Wallis tests. Linear mixed-effects models were applied to test the prognostic values of amyloid categories. ***Results:*** NEGATIVE individuals were younger and had higher baseline MMSE scores compared to GRAY-ZONE and POSITIVE individuals (p<0.001). 99% of POSITIVE individuals were consistently visually identified as A+ and 97% of NEGATIVE individuals were visually classified as A-, while only 44% of GRAY-ZONE individuals were reported as A+. We found a systematic decrease of CSF-Aβ42 across the amyloid categories, significantly differing between the three levels (p<0.01). This decrease was most pronounced in POSITIVE individuals, followed by GRAY-ZONE subjects. Global tau also increased significantly across all three amyloid categories with POSITIVE individuals exhibiting the highest tau load (p<0.05). Linear mixed-effect models showed that both POSITIVE and GRAY-ZONE individuals exhibited a significantly faster cognitive decline compared to the NEGATIVE group (p<0.01) with GRAY-ZONE category showing intermediate cognitive decline (p<0.01). ***Conclusion:*** Our study shows distinct biomarker profiles in the proposed three-level Centiloid-based classification. Individuals classified as GRAY-ZONE exhibit different characteristics compared to both NEGATIVE and POSITIVE subjects, highlighting the need of identifying this population when establishing clinical management strategies. This is of the utmost importance considering that amyloid positivity is a requirement for the anti-amyloid monoclonal antibodies.

OP-559

Amyloid PET in individuals with subjective cognitive decline: differences in baseline signal on amyloid accumulators.

G. Domingues Kolinger[1], *M. Marquié[2,3], O. Sotolongo-Grau[2], N. Roé-Vellvé[1], E. Pérez-Martínez[1], N. Koglin[1], A. Stephens[1], J. Tartari[2], Á. Sanabria[2,3], L. Tárraga[2,3], A. Ruiz[2,3], S. Bullich[1], M. Boada[2,3];*
[1]Life Molecular Imaging GmbH, Berlin, GERMANY, [2]Ace Alzheimer Center Barcelona – Universitat Internacional de Catalunya, Barcelona, SPAIN, [3]Centro de Investigación Biomédica en Red de Enfermedades Neurodegenerativas (CIBERNED), Instituto de Salud Carlos III, Madrid, SPAIN.

Aim/Introduction: Positron emission tomography (PET) with [18F] florbetaben is an established tool for detection of brain amyloid-beta (Aβ) load. Changes of the Aβ load over time can be assessed using quantitative PET measurements such as standardised uptake value ratio (SUVR) for regional assessment or the Centiloid (CL) method for the global quantification of Aβ load. This study compared quantification of baseline Aβ negative (Aβ-) PET scans from individuals with subjective cognitive decline (SCD) that showed Aβ accumulation over time with those that presented stable levels of amyloid over several years. ***Materials and Methods:*** The Fundació ACE Healthy Brain Initiative (FACEHBI) study recruited 197 SCD individuals and performed at least two [18F]florbetaben PET scans (4.2±1.5 years apart) on them. A CL cutoff of 13.5 was used to identify the Aβ- scans at baseline [1]. Aβ annualised rate of change (ARC; CL/year) was assessed with a linear mixed effects model (LMM) and a cutoff point to identify individuals that accumulate Aβ was obtained using a 2-curve gaussian mixed model (GMM) applied to the ARC distribution from the LMM. A voxel-wise analysis using statistical parametric mapping (SPM) compared SUVR images (whole cerebellum as reference region) of Aβ- individuals that accumulated Aβ with those that did not. A minimum cluster size of 125 voxels (1mL) was considered significant at p<0.001. Finally, a post-hoc analysis was performed using the volume of interest defined by the SPM analysis. ***Results:*** 160 individuals were Aβ- on the baseline quantification. The distribution of ARC gave a cutoff to define accumulators at 1.5 CL/year based on 3 standard deviations above the mean of the lowest curve of the GMM. Given that, 129 ED individuals did not show accumulation (baseline CL=-2.8±5.6; ARC=0.2±0.5 CL/year) while 31 were Aβ accumulators (baseline CL=1.1±6.9; ARC=2.8±1.1 CL/year). SPM analysis identified a region within the precuneus (near the border with the cingulum and roughly symmetrical around the longitudinal fissure) with significantly higher baseline SUVR for accumulators. The ROI defined from this analysis showed an average SUVR of 1.00±0.10 for accumulators and 0.87±0.07 for non-accumulators (p=10-7). ***Conclusion:*** Baseline SUVR voxel-wise analysis was able to identify a region within the precuneus that showed higher signal in Aβ- SCD individuals that accumulated Aβ from those with stable amyloid load. This shows a promising method to identify pre-clinical AD in an SCD population. ***References:*** [1] Bullich, et al. Alzheimer's research & therapy 13 (2021)

OP-560

Quantification of demyelination in cerebral lesions in patients with multiple sclerosis: an [11C]MeDAS PET study

C. Van Der Weijden, *A. van der Hoorn, R. A. J. O. Dierckx, J. F. Meilof, E. F. J. de Vries;*
UMCG, Groningen, NETHERLANDS.

Aim/Introduction: Multiple sclerosis (MS) is an demyelinating neurodegenerative disease, characterized by inflammatory lesions. Current treatments are aimed at inhibiting the inflammatory response, limiting the damage to myelin and neurons. However, damage that has already occurred is not repaired. Myelin repair treatments are in development but so far failed in clinical trials, probably due to the use of subjective clinical scores to determine their efficacy. Hence, there is a need for an objective biomarker that can quantify myelin density in MS lesions reliably. [11C]MeDAS PET appears promising for quantifying myelin density in MS lesions. However, to determine the efficacy of new myelin repair treatments, myelin imaging should be able to capture changes in myelin density in MS lesions. Since there is ongoing demyelination in MS lesions, this study aims to determine the sensitivity of [11C] MeDAS PET to detect changes in myelin density in MS lesions over time. ***Materials and Methods:*** Seven MS patients underwent two dynamic brain [11C]MeDAS PET scans with arterial blood sampling with a 1.4±0.5 year follow-up interval. A T1w MRI was acquired for anatomical reference and lesion detection. The [11C]MeDAS PET uptake in MS lesions were quantified using the 2T3k model. ***Results:*** In total 219 lesions with a diameter >3 mm were detected on MRI. In 54 of the 219 lesions, the Ki was estimated with a standard error >25% either at baseline or follow-up and hence omitted from further evaluation. Within the 165 lesions, an overall decrease in tracer uptake (T=3.71, p<0.001) was observed at follow-up (0.073±0.023) compared to baseline (0.083±0.023). No significant differences in [11C]MeDAS uptake over time were found for black holes (T=0.72, p=0.474, N=58) and remyelinated lesions (T=2.95, p=0.208, N=2). Significant decreases in [11C]MeDAS uptake at follow-up were found for demyelinated (T=2.93, p=0.005, N=58) and partial remyelinated lesions (T=2.19, p=0.033, N=47). ***Conclusion:*** [11C]MeDAS uptake was reduced in MS lesions over time, in particular in demyelinated lesions and partial demyelinated lesions. These findings correspond with the

demyelinating nature of MS pathology. Hence, [11C]MeDAS PET seems to be a sensitive myelin imaging tool to detect changes in myelin density in lesions over time, which is of particular interest for the development of myelin repair treatments.

OP-561

FDG PET as a systemic biomarker of Amyotrophic lateral sclerosis: brain-body connection, staging and subtyping

J. Hong[1], *L. Lopes[1], A. Rominger[1], K. Shi[1], S. Hu[2], Y. Tang[2];*
[1]University of Bern/Inselspital, Bern, SWITZERLAND, [2]Xiangya Hospital, Central South University, Hunan, CHINA.

Aim/Introduction: Amyotrophic lateral sclerosis (ALS) is a clinically diverse disease with underexplored metabolic changes and clinical manifestations. This study uses unsupervised learning to model ALS heterogeneity through metabolic changes on FDG-PET, alongside whole-body PET to explore the brain-body connection. ***Materials and Methods:*** We collected a total of 253 FDG-PET scans, consisting of 128 from clinically diagnosed healthy controls (HC) and 125 from ALS patients. All scans were spatially normalized (SPM8), and 15 groups of regions of interest (ROIs) were identified (AAL atlas) based on prior findings. These included the Frontal (FL), Parietal (PL), Occipital (OL), and Temporal (TL) lobes; Primary Motor(PM), Supplementary Motor(SPM), Sensory Motor(SM), Supplementary Sensory Motor (SSM), and Visual areas(VA); Basal Ganglia(BG), Thalamus (TH), Brainstem (BS); Limbic system(LB), Cingulum(CG); and the Cerebellum(CB). The standardized uptake value ratio (SUVr) was calculated for each ROI, normalized by the average value of the whole brain. Z-scores were derived after correcting for age and sex. An unsupervised machine-learning technique was utilized which identifies subtypes and stages simultaneously by combining clustering and data-driven disease progression modeling with a mixture of linear z-score models. Clinical manifestation presented by King's score and four key domains on the ALS Functional Rating Scale (ALSFRS) were compared between each subtype and stages. Survival analyses were conducted. Amongst ALS patients, 70 Whole-body (WB) scans were acquired, and the standard uptake value (SUV) was calculated within the organs and muscles (MOOSE V2). ***Results:*** Regions such as the TL, PM, SM, BG, TH, LB, AND CB exhibited hypometabolism concurrent with ALS progression. Two subtypes were identified: one with alterations in the motor cortex (subtype 1, 76%) and another associated with the brainstem (subtype2, 24%). ANOVA showed significant function disparities, such as swallowing and walking, between subtypes ($p < 0.05$). Subtype 1 showed greater difficulties with walking, while subtype 2 had more pronounced challenges with swallowing and salivation. Subtype 2 exhibited more hypometabolism in the kidney, stomach, and heart, and hypermetabolism in veins compared to subtype 1. It also indicated more severe clinical progression and shorter survival time. ***Conclusion:*** This study elucidates the metabolic patterns tied to ALS, presenting a novel stratification of disease progression that aligns with distinct clinical manifestations through FDG PET.

OP-562

Exploring Synaptic Density Patterns in Cerebral Small Vessel Disease: Insights from [18F]SynVesT-1 PET Imaging

Y. Yang[1], *T. Zhao[2], L. Xiao[1], J. Xia[2], S. Hu[1];*
[1]Department of Nuclear Medicine, Xiangya Hospital, Central South University, Changsha, CHINA, [2]Department of Neurology, Xiangya Hospital, Central South University, Changsha, CHINA.

Aim/Introduction: Cognitive dysfunction caused by cerebral small vessel disease (CSVD) is the most common cause of VaD. [18F]SynVesT-1 is a promising PET tracer binding Synaptic vesicle glycoprotein 2A (SV2A) which is an potential biomarker for CSVD diagnosis. This study aimed to discern distinct synaptic density patterns associated with CSVD using [18F]SynVesT-1 PET and to elucidate the correlation between synaptic density and cognitive performance. ***Materials and Methods:*** Sixteen CSVD patients and ten age- and sex-matched healthy controls (HCs) underwent [18F] SynVesT-1 PET imaging to quantify synaptic density. Comparative analyses were conducted between CSVD and HCs and within different CSVD subgroups based on burden scores and cognitive status. Moreover, associations between regional synaptic density and neuropsychological assessment outcomes in CSVD patients were explored. ***Results:*** CSVD patients exhibited decreased [18F] SynVesT-1 uptake in the bilateral hippocampus-insula region and the left postcentral gyrus compared to HCs ($P<0.001$, cluster size>50). Neuropsychological performance correlated with regional standardized uptake values ($P<0.05$). Specifically, CSVD patients with burden scores of 0-1 demonstrated reduced synaptic density in the left insula and lingual gyrus compared to HCs. Conversely, patients with burden scores of 2-4 manifested diminished uptake in the bilateral insula, left parahippocampal gyrus, and right anterior cingulate and paracingulate gyri ($P<0.001$, cluster size>50). Moreover, CSVD patients without cognitive impairment exhibited decreased uptake in the left hippocampus-insula region relative to HCs, while those with cognitive impairment displayed synaptic loss in the bilateral insula, left hippocampus, and anterior cingulate and paracingulate gyri ($P<0.001$, cluster size>50). ***Conclusion:*** This study represents the first investigation of synaptic density in vivo in CSVD utilizing [18F]SynVesT-1 PET imaging. Our findings suggest the potential of synaptic density as a biomarker for diagnosing CSVD and assessing cognitive impairment and disease progression.

Ventilation-perfusion mismatch correlates with hemodynamics in patients with Chronic Thromboembolic Pulmonary Hypertension: A quantitative analysis of Ventilation/Perfusion SPECT

H. Weis[1], *T. Kramer[2], M. Hellmich[3], S. Rosenkranz[2], A. Drzezga[1], M. Schmidt[1];*
[1]Department of Nuclear Medicine, Faculty of Medicine and University Hospital of Cologne, University of Cologne, Cologne,

GERMANY, [2]Klinik III für Innere Medizin, Cologne Cardiovascular Research Center (CCRC), Heart Center, University of Cologne, Cologne, GERMANY, [3]Institute of Medical Statistics and Computational Biology, Faculty of Medicine and University Hospital of Cologne, University of Cologne, Cologne, GERMANY.

Aim/Introduction: Accurate diagnosis of chronic thromboembolic pulmonary hypertension (CTEPH) is crucial for individualizing treatment strategies, including pulmonary endarterectomy, balloon pulmonary angioplasty, medical therapy, or their combinations. Ventilation/perfusion (V/Q) single-photon emission computed tomography (SPECT) serves as the primary diagnostic imaging modality. While V/Q mismatch indicates thromboembolic disease, its precise quantification remains challenging due to high interobserver disagreement with semiquantitative methods. Here, we present a quantitative, observer-independent method to measure the extent of ventilation/perfusion mismatches. ***Materials and Methods:*** We retrospectively analyzed 23 patients clinically diagnosed with CTEPH according to the 2015 ESC/ERS guidelines on PH. Each patient underwent V/Q SPECT with 99mTc-Argongas inhalation for ventilation and injection of 99mTc albumin-aggregated for perfusion scan. Right heart catheterization was performed prior to treatment, within three months of the V/Q scan. Quantitative analysis of the V/Q scans involved the following: Ventilation scans were corrected for decay and for differences in acquisition time between V and Q (V(corr)). Remaining activity from V(corr) was subtracted from Q (Q(corr)). Lung boundaries were determined using a 10% threshold to the sum of V and Q(corr). Total counts within the lung were calculated for V and Q(corr) (CV and CQ). V was normalized to CQ (V(norm)=VxCQ/CV). The ratio of ventilation to perfusion was calculated as V/Q=V(norm)/Q(corr). The extent of a V/Q mismatch was determined as the fraction of lung volume with a V/Q above 2.5, 5 (V/QVol>5), and 10. V/Q heterogeneity was calculated using the log standard deviation of the V/Q distribution curve (logSD(V/Q)). Finally, statistical evaluation included a Pearson test for the relationship between V/Q mismatch and hemodynamic parameters as well as clinical scores. ***Results:*** Ventilation/perfusion mismatch (V/QVol>5) and its heterogeneity (logSD(V/Q) significantly correlated with pulmonary vascular resistance (r=0.55,p<0.01 and r=0.55,p<0.01 resp.), transpulmonary pressure gradient (r=0.52,p<0.05 and r=0.53,p<0.01 resp.), mean pulmonary arterial pressure (r=0.43,p<0.05 and r=0.48,p<0.05 resp.), and pulmonary arterial compliance (r=-0.51,p<0.05 and r=-0.64,p<0.01 resp.). Furthermore, right ventricular enddiastolic diameter, determined by echocardiography, significantly correlated with V/Q mismatches and heterogeneity (r=0.44,p<0.05 and r=0.68,p<0.01 resp.). ***Conclusion:*** For the first time in a cohort of patients with initial CTEPH diagnosis, we established an objective method to quantify V/Q mismatches in V/Q SPECT. The extent of V/Q mismatches significantly correlated with crucial hemodynamic parameters characterizing the severity of pulmonary hypertension. Objective V/Q analysis may therefore not only enhance diagnostic accuracy during the initial evaluation but may also be utilized in therapy assessment.

EPS-170

Quantitative analysis of SPECT/CT pulmonary perfusion imaging in the evaluation of postoperative effects of BPA in CTEPH patients

R. Ma, *S. Yang, P. Han, H. Li, L. Fu;*
China-Japan Friendship Hospital, Beijing, CHINA.

Aim/Introduction: To investigate the value of SPECT/CT pulmonary perfusion imaging (Q-LDCT) quantitative analysis in the evaluation of balloon pulmonary angioplasty(BPA) after chronic thromboembolic pulmonary hypertension (CTEPH). ***Materials and Methods:*** A total of 262 lung segments were prospectively treated in 50 patients diagnosed with CTEPH and treated with BPA in China-Japan Hospital from January 2020 to February 2023. Q-LDCT imaging was performed again within one week before and after reexamination.The SUVmax and SUVmean values of 262 lung segments before and after operation were calculated by manually extracting ROI in the Siemens back office(Symbia Intevo 16 VB21A).By visual analysis (Q-LDCT) to determine whether pulmonary perfusion was improved in each lung segment after surgery, pulmonary angiography was used as the gold standard to compare the diagnostic efficacy of Q-LDCT, SUVmax and SUVmean at lung segment level. P<0.05 was considered statistically significant. ***Results:*** The AUC of Q-LDCT, SUVmax and SUVmean for diagnosing pulmonary perfusion improvement were 0.61, 0.73 and 0.69, respectively.There were statistical differences in sensitivity, accuracy and AUC between Q-LDCT visual analysis and SUVmax (P<0.01), but no statistical differences in specificity (P>0.05).There were statistical differences in sensitivity and AUC between Q-LDCT visual analysis and SUVmean (P<0.05), but no statistical differences in specificity and accuracy between Q-LDCT visual analysis and SUVmean visual analysis (P>0.05).The diagnostic results of these three methods were in high consistency with pulmonary angiography, and the kappa values were (0.671, 0.792, 0.721), respectively. ***Conclusion:*** Compared with visual analysis, quantitative indicators SUVmax and SUVmean at lung segment level were more effective in diagnosing the recovery of pulmonary perfusion after BPA surgery in CTEPH patients. Quantitative analysis of Q-LDCT imaging can be used to evaluate the postoperative efficacy of BPA in CTEPH patients.

EPS-171

Combination of CZT SPECT coronary flow reserve, stress myocardial blood flow and coronary artery calcium scoring in prediction of coronary artery disease

M. Havel[1,2], *M. Kaminek[2,3], V. Kincl[3], L. Henzlova[2], M. Dolezilek[2], L. Hudson[2], L. Quinn[2];*
[1]University of Ostrava and University Hospital Ostrava, Department of Nuclear Medicine, Ostrava, CZECH REPUBLIC, [2]Department of Nuclear Medicine, University Hospital, Palacky University, Olomouc, CZECH REPUBLIC, [3]International Clinical Research Center and Department of Internal Medicine/Cardiology, St. Anne´s University Hospital, Faculty of Medicine, Masaryk University, Brno, CZECH REPUBLIC.

Aim/Introduction: Coronary flow reserve (CFR) obtained during the dynamic SPECT examination is usable prognostic and diagnostic marker for coronary artery disease (CAD). However, the complexity of stress and rest study for CFR calculation (CFR = stress myocardial blood flow (stressMBF) / rest myocardial blood flow (restMBF)) is time consuming in clinical praxis and combination of two examination is related with higher radiation dose. Aim of this study is to assess the prognostic significance of stressMBF, CFR, and coronary artery calcium score (CACS). ***Materials and Methods:*** We analysed retrospectively 77 patients (29 men, 66±9 years) examined with rest-stress dynamic myocardial SPECT and CACS. The adverse cardiac event (CE) defined as sudden cardiac death, myocardial infarction, situationsrequiring coronary revascularization, and hospitalization for heart failure with reduced ejection fraction, were recorded. ***Results:*** During a mean follow-up of 12 months there were 15 (19.5%) CE recorded.

Patients with CE had significantly higher CACS (median 680 vs 31.5, P=0.0001), significantly lower stress MBF (1.89±1.03 vs 2.86±0.99 ml/min/g, P=0.0012) and a lower CFR (1.56±0.61 vs 2.48±0.87, P=0.0002). A cut-off value for the prediction of CE were: CACS 230,2 (sensitivity of 92 % and a specificity of 80 %, AUC = 0.84, HR 29.5), stressMBF 2.29 ml/min/g (sensitivity of 87 % and a specificity of 71 %, AUC = 0.80, HR 10.5), and CFR 1.94 (sensitivity of 73 % and a specificity of 77 %, AUC = 0.8, HR 7.0). CFR and stressMBF did not show different performance in the identification of CE (AUC = 0.80 vs. AUC = 0.80, P=0.679). No CE occurred in patients with the combination of stress MBF > 2.29 ml/min/g and CACS < 230.2. ***Conclusion:*** CE can be predicted by low stressMBF, low CFR and high CACS, whereas there is not superiority of CFR over stressMBF. Such resulting possible simplification of dynamic SPECT protocol (stress-first/stress-only) enables expansion of the MBF quantification for a larger number of patients. Supported by MH CZ - DRO (FNOl, 00098892). ***References:*** Kaminek M, Havel M, Kincl V, Henzlova L, Hudson L. EPS-172

Higher Precision and Processing Repeatability of Myocardial Blood Flow and Flow Reserve Calculated Using Net Retention Model Compared to One Compartment Model in ^{99m}Tc-MIBI CZT SPECT studies

P. Cichocki[1], *A. Plachcinska[2], M. Blaszczyk[1], Z. Adamczewski[1];*
[1]Department of Nuclear Medicine, Medical University of Lodz, Lodz, POLAND, [2]Department of Quality Control and Radiological Protection, Medical University of Lodz, Lodz, POLAND.

Aim/Introduction: The aim of this study is to assess the processing repeatability of myocardial blood flow (MBF) and myocardial flow reserve (MFR) values in dynamic SPECT studies calculated using two models - net retention (RET) and one compartment (1CM), in the latest version of Corridor 4DM software (v2024). ***Materials and Methods:*** Data of 107 patients with coronary artery disease referred for dynamic SPECT were analyzed retrospectively. 57 of these patients were previously assessed in older version of 4DM (v2015) [1], 50 were new. SPECT study was carried out using a two-day rest-stress (dipyridamole) protocol with 592 MBq of 99mTc-MIBI administered each day. Data was processed in 4DM v2024 twice by one operator and once by another operator. Repeatability of MBF and MFR values was compared between 4DM v2015 and v2024 in 1CM model (57 patients) and between 1CM and RET models (107 patients) in 4DM v2024. ***Results:*** Automatic heart image positioning during post-processing in 4DM v2024 was significantly improved compared to v2015, reducing the number of studies requiring significant manual corrections from 41% to 12%. This significantly improved interobserver processing repeatability of MFR values in RCA territory from r=0.67 to 0.85 (p = 0.0034) in 1CM model. Interobserver processing repeatability of MBF and MFR was significantly better in RET model compared to 1CM model. Also, in 4DM v2024, a measure of precision in form of standard deviation of percentage differences of MBF and MFR in both models is almost two times lower compared to results published in recent literature [2,3]. ***Conclusion:*** Repeatability of MBF and MFR values based on dynamic SPECT data calculated using RET model are better compared to 1CM model. Improved automatic positioning of heart images in 4DM v2024 significantly improved their processing repeatability. There is still a need for better standardization of dynamic SPECT MFR study processing methodology. ***References:*** [1] Cichocki P, Błaszczyk M, Cygulska K, et al. EPS-173

Application exploration in prognosis evaluation of resynchronization therapy by dynamic change of mechanical contraction synchronization parameters in CZT-SPECT

Q. Sun[1], *S. Li[2], S. Fu[1], C. Wu[1];*
[1]Shanxi Cardiovascular Hospital, Taiyuan, CHINA, [2]Department of Nuclear Medicine, First Hospital of Shanxi Medical University, Taiyuan, CHINA.

Aim/Introduction: Left ventricular mechanical systolic synchrony parameters was evaluated by GMPI phase analysis technique, and we analyze the predictive value of dynamic changes of mechanical systolic synchrony parameters for the prognosis of patients with chronic heart failure treated with resynchronization. ***Materials and Methods:*** A total of 15 patients with chronic heart failure prospectively enrolled, including 10 males and 5 females, with an average age (65.31±9.46) years old. Mechanical systolic synchronization parameters included PSD and PHB were evaluated by CZT-SPECT GMPI phase analysis technique before implantation, 1 week in the short term after implantation, and 6-12 months after implantation. The outcome was assessed according to the improvement of clinical symptoms and cardiac function parameters by CZT-SPECT. The relationship between mechanical synchrony parameters and cardiac function parameters was analyzed by using dynamic change curves. ***Results:*** During the follow-up of 15 patients. Finally, 12 patients were enrolled in the study for resynchronization therapy, 10 patients underwent CRT-D and 2 patients underwent CRT-P, including 7 patients with traditional CRT, 2 patients with left bundle branch region pacing, and 3 patients with LBBP-optimized CRT (LOT-CRT). According to the outcome criteria, all of the 12 patients were response, and 3 (25%) were sup-response. Preoperative relevant parameters of 12 patients are as follows: cardiac function parameters EDV and ESV respectively were (204.4±62.95) ml and (155.3±65.75) ml, and EF were (26.1±9.05)%. Synchronization parameters PSD and PHB respectively were (51.14±25.38) ° and (167.5±83.74) °. One week after resynchronization follow-up parameters: EDV and ESV respectively were (166.6±77.14) ml and (120.6±69.12) ml, and EF were (30.7±9.13)%. PSD and PHB were (33.87±13.98) ° and (104.2±46.02) °. Long-term follow-up (6-12 months) parameters: EDV and ESV were (137.2±77.33) ml and (86.9±67.30) ml, EF was (42.1±13.22)%. PSD and PHB were (32.69±17.60) ° and (101±57.92) °, respectively. The changes tend of synchronization parameters and left ventricular size and cardiac function were consistent according to the dynamic change trend curve of the short and long term the follow-up, it suggested that left ventricular size are reduced and left ventricular systolic function are improved with the improvement of left ventricular mechanical contraction

synchronization. ***Conclusion:*** The change trend of mechanical contraction synchronization may become a new way to predict the efficacy of resynchronization therapy in patients with heart failure.

EPS-174

Lung-to-Heart Ratio (LHR) on Myocardial Perfusion Imaging (MPI): A Potential Tool for Heart Failure Management?

M. Abdi[1], *D. Djermane[2], Q. Naili[1], Y. Bououdina[3], M. Habbache[1], B. Said[1];*
[1]Centre d'imagerie scintigraphique Blida, Blida, ALGERIA, [2]Cardio A2, CHU Mustapha Bacha, Algiers, ALGERIA, [3]Service de Cardiologie, CHU de Frantz Fanon, Blida, ALGERIA.

Aim/Introduction: Heart failure (HF) management remains challenging. Prior research suggests that SPECT Myocardial Perfusion Imaging (MPI) with AI-based algorithms improves HF hospitalization prediction [1]. Lung ultrasound, a non-invasive tool, diagnoses HF and predicts hospitalization based on comet tails, an indicator of lung fluid [2]. This study investigates the potential of the Lung-to-Heart Ratio (LHR) derived from MPI scans as a marker for lung fluid accumulation, aiming to improve HF management. ***Materials and Methods:*** We prospectively enrolled 21 patients (average age 62) undergoing both MPI (Rest 99mTc-sestamibi) and lung ultrasound on the same day. Patients with varying degrees of lung uptake were included. We quantified the number of comet tails per field of view on lung ultrasound images. LHR was measured on perfusion scans using a simplified method: the ratio of counts in a lung Region Of Interest (ROI) adjacent to the heart to the counts in the heart ROI (anterolateral wall). Both ROIs were rectangular and equal in size. ***Results:*** Eleven patients (nine with coronary disease) had high comet tail counts (≥3 per field) and high LHR (mean LHR value 0.67 ± 0.07, all ≥0.57). Ten patients (seven with coronary disease) had low comet tail counts (<3 per field) and low LHR (mean LHR value 0.42 ± 0.07, all <0.57). The Pearson correlation coefficient R=0.8026, p=.000012 (p<.01), indicating a positive correlation between lung fluid and LHR. ***Conclusion:*** Our initial findings suggest a link between lung fluid accumulation, as measured by lung ultrasound, and factors influencing LHR derived from MPI. LHR from MPI might offer a valuable, non-invasive assessment of lung congestion, potentially guiding HF management. However, further validation with a larger and more diverse patient population is needed. This study adds to the understanding of MPI's role in HF, potentially complementing the work by Feher, Attila et al. (2024) on MPI and HF hospitalization risk prediction [1]. Future research will determine if including LHR in MPI reports improves HF treatment strategies. ***References:*** 1: Feher, Attila, et al. EPS-175

Transient ischemic dilation ratio thresholds in patients undergoing vasodilator stress [^{13}N]-ammonia positron emission tomography myocardial perfusion imaging

S. Ersözlü[1,2], *A. Giannopoulos[1], R. Büchel[1], D. Benz[1,2], P. Kaufmann[1], A. Pazhenkottil[1];*
[1]University Hospital Zurich, Department of Nuclear Medicine, Zurich, SWITZERLAND, [2]University Hospital Zurich, Department of Cardiology, Zurich, SWITZERLAND.

Aim/Introduction: Transient ischemic dilatation (TID) i.e. dilatation of the left ventricular cavity during vasodilator stress myocardial perfusion imaging (MPI) is a marker of extensive coronary artery disease (CAD) and adverse outcomes. TID has also been described in hypertrophic cardiomyopathy (HCM). While cut-off values are available for [82Rb]-PET MPI and single photon emission computed tomography, normal values have not been reported for [13N]-ammonia-PET. In the present study, we aim to describe TID cut-off values for [13N]-ammonia-PET in a patient cohort without CAD using two different commercially available software packages. ***Materials and Methods:*** We retrospectively included patients undergoing clinically indicated, adenosine or regadenoson [13N]-ammonia-PET MPI (08.2014-02.2023) without perfusion defects, normal hyperemic myocardial blood flow, normal myocardial blood flow reserve, and coronary artery calcium score (CACS) = 0. Patients with HCM and patients with severely depressed left ventricle ejection fraction (LVEF) were excluded. TID ratios were automatically generated using two different commercially available software tools with manual correction when indicated. Upper limits of normal TIDs were calculated using the mean +2 standard deviations. LV volumes and LVEF were derived from gated images. Patient demographics and cardiovascular risk factors were obtained from electronic medical records. ***Results:*** A total of 151 patients, 75 males (49.7%) and 76 females (50.3%) with a mean age of 54.9 ± 12.9 years and a median BMI of 24.8 kg/m2 (IQR 21.9 - 29.2) were included. Stress testing was performed using adenosine in 68 patients (45.0%) and regadenoson in 83 patients (55.0%). The mean TID for software 1 was 1.08±0.09 with the following upper normal limits: 1.23 in males and 1.25 in females using regadenoson and 1.26 in males and 1.31 in females using adenosine. The mean TID for software 2 was 1.01±0.08 with the following upper normal limits: 1.15 in males and 1.15 in females using regadenoson and 1.19 in males and 1.17 in females using adenosine. Cardiovascular risk factors included arterial hypertension (31.8%), dyslipidemia (27.2%), obesity (20.5%), smoking (13.9%), diabetes mellitus (12.6%) and a positive family history (11.9%). ***Conclusion:*** We report for the first time, TID cut-off values for [13N]-ammonia PET in a patient population without evidence of CAD. TID cut-off values vary based on the software, type of vasodilator, and gender. The TID cut-offs were found to be slightly higher than those established for [82Rb]-PET MPI using software 2 (1.13) in a healthy population defined by a low likelihood of CAD and normal MPI.

EPS-176

Simulation of a weight-based dose protocol for rubidium-82 cardiac PET: impact on clinical metrics and image quality

I. Armstrong[1], *V. Flanagan[2], P. Arumugam[1];*
[1]Manchester University NHS Foundation Trust, Manchester, UNITED KINGDOM, [2]The Christie NHS Foundation Trust, Manchester, UNITED KINGDOM.

Aim/Introduction: Rubidium-82 is the most widely used PET tracer for Myocardial Perfusion Imaging Positron Emission Tomography (MPI PET). Updated generator cart delivery systems facilitate individual patient weight-based dosing protocols as opposed to our existing standard 740 MBq for all comers. Currently all images are acquired on a SiPM PET-CT with 214 ps timing resolution and are deemed acceptable quality in our entire patient population. Our previous retrospective analysis of image quality in consecutive patients of varying weights led us to

look at a weight-based protocol in patients below 100 kg which forms nearly 80% of our referrals. This work simulates this protocol and assesses the impact of this protocol on clinical metrics and the visual interpretation of images. ***Materials and Methods:*** Event-by-event listmode resampling was performed to simulate a reduction in activity from fixed 740 MBq to 7.4 MBq/kg in 50 consecutive patients below 100 kg, which we have proposed from prior work to be appropriate for our patient population. Static relative perfusion and dynamic images were reconstructed with OSEM+TOF for original and resampled data. Total Perfusion Deficit (TPD) was derived from the static images and myocardial blood flow (MBF) and reserve (MBFR) were calculated from the dynamic data. A blinded visual assessment was performed by a nuclear medicine physician, on pairs of original and resampled patient images, viewed with both rest and stress in each case, with images ranked in terms of quality on a 5-point Likert scale. ***Results:*** No significant differences were observed in clinical metrics when comparing original and resampled data. TPD varied between -1 to +1 in 45 stress images and 40 rest images, with remaining changes of up to 4, that were not clinically significant. Mean and standard deviation in percentage difference for stress MBF, rest MBF and MBFR was +1.0%±4.1, -0.8%±4.4 and 1.9%±4.7, respectively, with all differences falling within the reported test-retest variability. For the visual assessment, all but three image pairs were scored equally on the Likert scale, with the remaining placed 1 rank apart. ***Conclusion:*** This work has confirmed that a weight-based protocol can be implemented in patients with weight less than 100kg undergoing MPI PET and achieve acceptable image quality and quantification. This would result in a dose reduction in the vast majority of our patients, achieving an effective dose for the test of between 1 and 2 mSv, for a rest-stress exam with a single CT for attenuation correction.

EPS-177

Effect of acute beta-blocker administration on myocardial blood flow as derived from quantitative 13N-ammonia PET myocardial perfusion imaging

R. Buechel, *M. Gajic, D. C. Benz, A. P. Pazhenkottil, A. A. Giannopoulos, P. A. Kaufmann;*
Department of Nuclear Medicine, Cardiac Imaging, Zurich, SWITZERLAND.

Aim/Introduction: The study aimed to evaluate the impact of acute intravenous beta-blocker administration on myocardial blood flow (MBF) during same-day hybrid coronary computed tomography angiography (CCTA) and positron emission tomography (PET) myocardial perfusion imaging (MPI) with 13N-ammonia. This investigation explores how beta-blockers, commonly used during CCTA for heart-rate control, might alter quantitative MBF measurements. Previous studies on the effects of discontinuing oral beta-blockers before MPI have yielded inconsistent and sometimes contradictory results. No studies have yet addressed this issue in the context of same-day hybrid imaging with intravenous beta-blocker administration. ***Materials and Methods:*** This retrospective, single-center study included patients who underwent same-day hybrid CCTA/13N-ammonia PET MPI for suspected chronic coronary syndromes. Patients received intravenous beta-blocker (metoprolol, up to 30 mg) as needed for heart-rate control prior to CCTA. We excluded all patients with coronary artery stenosis ≥50% on CCTA and/or regional perfusion abnormalities (i.e. ischemia and/or scar) on 13N-ammonia PET. Patients already on established oral beta-blocker therapy were also excluded. MBF was measured at rest (rMBF), during vasodilator-induced stress (sMBF), and the myocardial flow reserve (MFR) was calculated. ***Results:*** After excluding 281 patients who met the exclusion criteria, 154 remaining patients were used for propensity-score matching, resulting in a final cohort of 108 patients divided into two equal groups: those who had received beta-blockers prior to CCTA and those who had not. These groups did not differ in baseline characteristics. Among those who received beta-blockers, the median dose was 0.11 mg·kg-1 (IQR 0.07-0.20). The average time-interval between beta-blocker infusion and stress PET was 2.2±1.0 hours. The main finding was a significant reduction in sMBF (2.21 [IQR 1.72-2.78] versus 2.46 [2.08-2.99] ml·min-1·g-1, p=0.027) and consequently, as rMBF was highly comparable (0.65 [0.54-0.78] versus 0.64 [0.55-0.76] ml·min-1·g-1, p=0.931), a reduction of MFR (3.46 [2.70-4.05] versus 3.79 [3.22-4.46], p=0.030) in patients who received beta-blockers compared to those who did not. On average, sMBF and MFR were 10.2% and 8.7% lower, respectively. ***Conclusion:*** Acute administration of beta-blockers significantly influences MBF as measured by 13N-ammonia PET, leading to a significant reduction in sMBF and MFR. In contrast, rMBF appears unaffected, suggesting that beta-blockers primarily impact the coronary capacity to respond to vasodilators.

EPS-178

Routine clinical reproducibility of myocardial blood flow measurements with ^{15}O-water PET

M. Lubberink, *J. Nordström, J. Sigfridsson, P. Svanström, K. Eggers, J. Sörensen, T. Kero;*
Uppsala University, Uppsala, SWEDEN.

Aim/Introduction: Hyperemic myocardial blood flow (MBF) has been shown to provide the most accurate non-invasive diagnosis of hemodynamically significant CAD. A high reproducibility of hyperemic MBF measurements is important for accurate stratification of patients. Previous studies have shown that whole-myocardium hyperemic MBF measurement with 82Rb has a repeatability coefficient (RC) of 50% (1.3 mL/g/min) for a two-day test-retest using adenosine in healthy controls1 and 21% (0.51 mL/g/min) and 38% (0.90 mL/g/min) for a single-session and two-day test-retest using dipyridamole, respectively, in patients in clinical routine2. For 15O-water and adenosine, an RC of 25% (0.90 mL/g/min) has been reported in 1999 for healthy controls, whereas RC at the regional level was >50%3. The aim of the current work is to assess the reproducibility of hyperemic MBF measurements with 15O-water using state of the art technology. ***Materials and Methods:*** Sixteen patients referred for assessment of ischemia underwent a same day test-retest protocol consisting of 4-min dynamic rest and stress scans starting simultaneously with controlled bolus injection of 400 MBq 15O-water on a digital PET-CT scanner. Patients left the scanner between test and retest sessions and time between test and retest scan sessions was circa 1 h. Adenosine infusion at 140 µg/kg/min was started 2 min prior to each stress scan and continued during the entire scan. Images were analysed using fully automated software. RC (1.96 x SD of test-retest differences), mean relative test-retest difference and within-subject coefficient of variation (wCV) were calculated at the whole myocardium, regional and segmental levels. ***Results:*** Whole myocardium hyperemic MBF ranged from 1.3 to 4.6 mL/g/min. RC was 14% (0.38 mL/g/min), 21% (0.59) and 24% (0.71) at whole myocardium, regional and segmental levels, respectively. Mean test-retest difference was 6%, 9% and 10%, and wCV was 5.3%, 7.6% and 9.0%, respectively. Data from two subjects was excluded because of excessive motion and technical problems. ***Conclusion:*** Automated data analysis and use of modern PET scanners results in a large improvement of reproducibility of

hyperemic MBF measurements with 15O-water. Reproducibility of hyperemic MBF with 15O-water is superior to previously published values for 82Rb. ***References:*** 1 Byrne et al, J Nucl Cardiol 2020; 2 Kitkungvan et al, JACC cardiovasc imag 2017; 3 Kaufmann et al, J Nucl Med 1999.

EPS-179

Feasibility of right ventricular imaging with F^{18} Flurpiridaz positron emission tomography

C. Czerner[1], *J. Diekmann[1], D. Weiberg[1], C. Napp[2], J. Bauersachs[2], F. M. Bengel[1];*
[1]Department of Nuclear Medicine, Hannover Medical School, Hannover, GERMANY, [2]Department of Cardiology and Angiology, Hannover Medical School, Hannover, GERMANY.

Aim/Introduction: F^{18} Flurpiridaz is a novel PET perfusion tracer with nearly linear myocardial extraction, providing superior image quality for the assessment of left ventricular (LV) perfusion, flow and function. Here, we sought to evaluate the feasibility for right ventricular (RV) imaging. ***Materials and Methods:*** Thirteen patients (4w, 9m) underwent routine one-day rest and regadenoson stress F^{18} Flurpiridaz PET for the workup of suspected or known coronary artery disease (injected dose: 121 MBq (IQR: 108-130) for rest, 227 MBq (IQR: 201-260) for stress). Disease involving the right coronary artery (RCA) was present in 5/13. None had evidence of congenital heart defects, shunts or right ventricular hypertrophy. Static, gated and dynamic images were generated for visual, semi-quantitative and quantitative analysis using commercially available software. ***Results:*** LV analysis revealed static perfusion defects in 5/13 subjects (2 rest and 5 stress exams; 4 involving RCA territory). Gated analysis showed a median LVEF of 64% (IQR: 61-71) at rest and 65% (IQR: 60-70) at stress, while median LV stroke volume was 89 ml (IQR: 78-100) at rest and 89 (IQR: 80-94) ml at stress. Global myocardial flow reserve was 3.1 (IQR: 2.2-4.3). RV analysis revealed good contrast for visualization of the myocardium. Median RV myocardium-to-cavity ratio was 6.5 at stress (IQR: 4.5-7.4) and 3.2 at rest (IQR: 3.0-3.5), which was lower than for LV (stress: 9.1, IQR: 7.8-12.8 / rest: 7.8, IQR: 5.7-10.7). RV was not visually discernible in two rest studies. In the remaining 24 studies (including 4 of 4 patients with RCA disease), regional RV perfusion was generally heterogeneous and clearcut perfusion defects were not readily discernible. For gated RV analysis, automated contouring was limited. We included 7 stress and matching 3 rest exams that had segmentations with only minor issues for a further analysis. Here, median RVEF was 72% (IQR: 64-75) at rest and 78% (IQR: 68-79) at stress. RV stroke volume was 76 ml (IQR: 70-89) at rest and 90 ml (IQR: 78-91) at rest. Pairwise comparison of LV and RV SV showed no significant difference in these subjects, providing internal validation (rest: p=0.25; stress: p=0.29). ***Conclusion:*** RV analysis seems feasible with F^{18} Flurpidaz PET perfusion imaging, but should be tested in larger patient cohorts using independent validation and optimized acquisition and analysis techniques.

EPS-180

Assessment of Cardiac FDG PET/MRI in Predicting Functional Recovery After AMI PCI: A Retrospective Study

E. Kong, *S. Kim;*
Yeunanam university hospital, Daegu, KOREA, REPUBLIC OF.

Aim/Introduction: Late gadolinium enhancement (LGE) in cardiac magnetic resonance imaging (MRI) has been identified as an accurate diagnostic tool for detecting non-viable myocardium. However, the role of F^{18} fluorodeoxyglucose (FDG) positron emission tomography (PET)/MRI in detecting viable myocardium has not been fully investigated. The aim of this study is to evaluate the diagnostic efficacy of cardiac FDG PET/MRI in detecting functional recovery of non-viable myocardium, which is identified by cardiac MRI following successful percutaneous coronary intervention (PCI) for patients with acute myocardial infarction (AMI). ***Materials and Methods:*** We retrospectively reviewed a total of 42 patients with AMI who underwent PET/MRI within 7 days after AMI PCI. Among the study population, 28 patients (66.67%) were identified as having non-viable myocardium, defined as ≥50% transmurality of LGE. We categorized these patients based on FDG uptake: group A (perserved FDG uptake, n=14) and group B (decreased FDG uptake, n=14). We analyzed infarct-related regional wall motion recovery at 9 months after PCI. ***Results:*** Clinical and angiographic findings were similar between the two groups. Peak troponin-I levels were also not significantly different between the two groups (34.29±31.76 ng/mL vs. 49.06±37.38 ng/mL, p=0.100). Baseline echocardiographic findings also showed similar results, including left ventricular ejection fraction (49.0±10.34% vs. 42.07±9.25%, p=0.268) and regional wall motion index (1.46±0.40 vs. 1.55±0.30, p=0.473). At 9 months after PCI, infarct-related regional wall motion index recovery was significantly more pronounced in group A (Initial: 1.98±0.57, follow up: 1.70±0.68, p=0.008) compared to group B (Initial: 2.23±0.50, follow up: 2.06±0.69, p=0.108). ***Conclusion:*** Although MRI findings indicated non-viable myocardium, FDG uptake could serve as a predictor for functional recovery after AMI PCI.

EPS-181

Development and validation of a novel prognostic model for predicting MACE based on ^{18}F-FDG PET myocardial ischemic memory imaging in patients with suspected UA: results from an observational cohort study in China

F. Zhang[1], *X. Shao[2], J. Wang[2], Y. Wang[2];*
[1]Medical College of Yangzhou University, Yangzhou, CHINA, [2]the Third Affiliated Hospital of Soochow University, Changzhou, CHINA.

Aim/Introduction: ^{18}F-FDG PET myocardial ischemic memory imaging can be used to diagnose myocardial ischemia. Our previously unpublished study found that ^{18}F-FDG PET myocardial ischemic memory imaging can serve as a novel prognostic marker for predicting major adverse cardiovascular events (MACE) in suspected unstable angina (UA) patients presenting with chest pain, exhibiting significantly incremental prognostic value. This study aims to develop and validate a nomogram model for predicting the risk of MACE in suspected UA patients. ***Materials and Methods:*** Conducted as a post-hoc analysis of prospective research, the study enrolled 240 patients who presented with chest pain, normal initial electrocardiogram (ECG), and initial negative cardiac biomarkers but still had clinical suspicion for UA. All patients underwent rest ^{18}F-FDG PET myocardial ischemic memory imaging, and coronary angiography was performed within one week. "Focal" or "focal on diffuse" myocardial ^{18}F-FDG uptake was defined as ^{18}F-FDG positive (myocardial ischemia). The primary endpoint was MACE, defined as the composite of cardiovascular death, rehospitalization for UA, acute myocardial infarction, heart failure, unplanned coronary revascularization, or stroke. With a median follow-up duration of 26 months, 50 cases (20.8%) of MACE were recorded. Patients were randomly divided into training (n = 168) and internal validation (n = 72) group at a

7:3 ratio. The influencing factors of MACE were selected using least absolute shrinkage and selection operator (Lasso) regression and multivariate COX regression, and a nomogram prediction model was established. Discrimination, calibration, and clinical validity of the nomogram model were evaluated using area under the receiver operating characteristic curve (AUC), calibration curves, and decision curve analysis (DCA), respectively. ***Results:*** The final nomogram model included six predictive factors: male, previous myocardial infarction, hypertension, abdominal circumference, GRACE score, and ^{18}F-FDG positive. At a median follow-up of 26 months, the AUC demonstrated excellent discriminative ability, with values of 0.876 (95% CI 0.811-0.943) for the training group and 0.769 (95% CI 0.708-0.860) for the validation group. Calibration curves for both groups exhibited strong agreement with the ideal model. DCA and clinical impact of Kaplan-Meier survival analysis underscored the favorable clinical utility of the nomogram prediction model. ***Conclusion:*** The nomogram model developed in this study effectively identifies high-risk populations among suspected UA patients presenting with chest pain, offering specific predictive value for MACE occurrence. Larger-scale, multicenter prospective studies are warranted to validate and refine these findings.

EPS-182

Immune-checkpoint inhibition does not affect arterial [18F]FDG uptake in cancer sequential PET/CTs

N. Hempfling[1,2], *S. Weber[3,2], A. Buellesbach[1,2], A. Maier[1,2], I. Bojti[1,2], M. C. Gißler[1,2], D. Westermann[1,2], P. T. Meyer[4,2], D. Wolf[1,2], L. Bacmeister[1,2], C. Goetz[4,2];*
[1]Cardiology and Angiology, University Heart Center, University Medical Center, Freiburg, GERMANY, [2]Faculty of Medicine, University of Freiburg, Freiburg, GERMANY, [3]Institute of Medical Biometry and Statistics (IMBI), University Medical Center, Freiburg, GERMANY, [4]Department of Nuclear Medicine, Medical Center University of Freiburg, Faculty of Medicine, University of Freiburg, Freiburg, GERMANY.

Aim/Introduction: There is increasing evidence that immune checkpoint inhibition (ICI) may accelerate atherosclerosis, leading to increased incidence of cardiovascular events. However, evidence is conflicting as to whether ICI increases short-term arterial inflammation, which may be measured by [18F]FDG uptake. Furthermore, long-term trajectories have not been evaluated. Aim of the present study was to analyse arterial uptake over time in cancer patients. ***Materials and Methods:*** Inclusion criteria were presence of a tumor eligible for ICI treatment, age >65 years, initial PET/CT upfront ICI use, and follow-up with at least 3 PET/CTs over 36 months. We quantified the vascular target-to-background ratio (vTBR) of six vascular regions: both carotid bifurcations, aortic arch and abdomen, aortic bifurcation, left renal and femoral artery. Mixed-effects linear and logistic regression models were used for baseline and follow-up analyses for continuous and dichotomized outcomes, including regional measurements. All models were adjusted for a number of potential confounders, and the time-dependent model was adjusted for the time since the first PET/CT. ***Results:*** Inclusion criteria were met in 156 patients (81 melanoma, 23 non-small cell lung cancer, 18 small cell lung cancer, 12 lymphoma and 22 with other cancers). 51 patients were treated with ICI. Statin use (25.0%), hypertension (67.3%), pre-existing coronary heart disease (17.3%), stroke (12.2%), current or former smoking (18.6%), chronic kidney disease (17.9%) and diabetes (23.1%) were similar between ICI and control groups. Baseline vTBR did not differ significantly between groups. Predictors of higher vTBR at baseline were male sex (odds ratio [OR] 3.30, 95% confidence interval [CI] 1.77, 6.16, p<0.001) and BMI (OR 2.30, CI 1.26, 4.20, p=0.007). Statin use (OR 0.64, CI 0.31, 1.32, p=0.226), smoking (OR 1.36, CI 0.61, 3.02, p=0.452) and age (OR 1.31, CI 0.72, 2.38, p=0.374) were not significantly associated with higher vTBR at baseline. Follow-up vTBR values were analysed over a median of 725 days (IQR 658, 770). Statin use correlated negatively (p=0.003) and BMI correlated positively (p=0.014) with vTBR over time. No association (regression coefficient [RC] -0.006 [CI -0.015, 0.004], p=0.229) was found between ICI therapy and vTBR. ***Conclusion:*** In cancer patients with cardiovascular comorbidities, ICI was not associated with long-term arterial uptake trajectories assessed by routine [18F]FDG PET/CTs. The sensitivity to inflammatory modifiers is supported by the inverse associations with BMI and statin use found in our study. Conversely, the lack of association with ICI suggests that [18F]FDG may not adequately reflect ICI-induced low-grade arterial inflammation.

EPS-183

Evaluation of ^{11}C-PIB PET/CT and ^{99m}Tc-DPD scintigraphy in the subtype diagnosis and survival prediction of cardiac amyloidosis

Z. Hong, *Z. Jiang, C. P Spielvogel, J. Yu, K. Kluge, M. Hacker, X. Li;*
Vienna General Hospital, Vienna, AUSTRIA.

Aim/Introduction: This study sought to evaluate the application of combined 11C-Pittsburgh compound B (PiB) positron emission tomography (PET) /computed tomography (CT) and 99mTc-diphosphono-1,2-propanodicarboxylic acid (99mTc-DPD) scintigraphy in diagnosing subtypes of cardiac amyloidosis (CA) i.e. immunoglobulin light-chain (AL), transthyretin (ATTR) amyloidosis and predicting patient survival time. ***Materials and Methods:*** The cohort consisted of 50 patients, including 12 with AL-type CA,15 with ATTR-type CA, and 23 with non-CA. All patients underwent 11C-PIB PET/CT and 99mTc-DPD scintigraphy, and clinical features, pathological results, serological indicators (proBNP, Tn, kappa, lambda), cardiac MRI, echocardiography and follow-up data were collected. Quantitative assessment of 11C-PIB activity was performed using the SUVmax and SUVmean of the left ventricular myocardium and paraspinal muscle and calculation of target-to-background SUV ratio. CAM of 99mTc-DPD scintigraphy was performed using deep-leaning. Furthermore, this study developed 1-year, 3-year, and 5-year survival prediction models, using survival analysis techniques for model evaluation. ***Results:*** Preliminary results indicate that the combined 11C-PIB PET/CT and 99mTc-DPD imaging demonstrates high sensitivity and specificity in differentiating between AL and ATTR types of cardiac amyloidosis. Additionally, the survival prediction models integrating clinical features and imaging parameters showed good accuracy in predicting both short-term and long-term patient survival rates. ***Conclusion:*** These findings suggest that 11C-PIB PET/CT and 99mTc-DPD scintigraphy not only serve as accurate diagnostic tools for the subtypes of cardiac amyloidosis but also provide valuable prognostic assessment capabilities.

EPS-184

Multigene panel analysis had limited additional value compared to transthyretin gene analysis only for patients with suspected cardiac amyloidosis with Perugini grade 2-3 on bone scintigraphy

M. Berends[1], *H. S. A. Tingen[1], A. Tubben[1], J. Bijzet[1], H. H. Lemmink[1], F. L. H. Muntighe[1], E. J. Houwerzijl[1], P. van der Meer[1], R. O. B. Gans[1], B. P. C. Hazenberg[1], H. L. A. Nienhuis[1], P. A. van der Zwaag[1], R. H. J. A. Slart[1,2];*
[1]University Medical Center Groningen, Groningen,

NETHERLANDS, [2]University of Twente, Enschede, NETHERLANDS.

Aim/Introduction: Gillmore et al., introduced a diagnostic algorithm for cardiac amyloidosis where bone scintigraphy is pivotal. For Perugini grade 2-3 cardiac bone tracer uptake, only transthyretin (TTR) genotyping is recommended to distinguish between wildtype transthyretin (ATTRwt) amyloidosis and hereditary transthyretin (ATTRv) amyloidosis after excluding immunoglobulin light chain amyloidosis. For Perugini grade 0-1 cardiac bone tracer uptake and persistent suspicion of cardiac amyloidosis, the amyloid type should be identified through histologic tests. Several cases of rare hereditary forms of cardiac amyloidosis have been reported with cardiac bone tracer uptake, that would have been diagnosed with ATTRwt amyloidosis by following the Gillmore algorithm. While typically considered rare, they can be more common than thought and therefore misdiagnosed as ATTRwt cardiomyopathy. Therefore, addition of multigene panel analysis to bone scintigraphy may enhance the accuracy of identifying patients with cardiac amyloidosis and establishing the correct type of amyloidosis (ATTRv amyloidosis, ATTRwt amyloidosis or a rare hereditary type of amyloidosis). Distinguishing between hereditary and non-hereditary types of cardiac amyloidosis based on genetic analysis has treatment implications and is relevant for family members. This study aims to evaluate the diagnostic yield of multigene panel analysis in patients with suspected cardiac amyloidosis based on bone scintigraphy. ***Materials and Methods:*** All consecutive patients with suspected cardiac amyloidosis without a known family history of hereditary amyloidosis referred to the University Medical Center Groningen between 2017-2023 were enrolled. Patients underwent genetic analysis using the multigene panel Amyloidosis (twelve genes). The results of genetic analysis were related to findings on bone scintigraphy. Perugini grade 2-3 indicates cardiac transthyretin amyloidosis (ATTR-CM). ***Results:*** In total, 246 unrelated patients were included, of whom fourteen (5.7%) had a pathogenic gene variant. Ten patients with a TTR-gene variant had Perugini grade 2-3, indicating ATTR-CM. One patient with Perugini grade 1 had an APOAI-gene variant consistent with AApoAI-amyloid in fat tissuse biopsy. One patient with an OSMR-gene variant had Perugini grade 0 but this variant was not associated with the cardiomyopathy. Two other patients with Perugini grade 3 had pathogenic variants unrelated to the cardiomyopathy. ***Conclusion:*** The yield of multigene panel analysis was 4.5%. In patients with Perugini grade 0-1, multigene panel analysis might provide additional value to identify rare hereditary types of amyloidosis beyond what TTR-genotyping only and bone scintigraphy can reveal. However, in those with Perugini grade 2-3, multigene panel analysis does not provide additional value compared to bone scintigraphy and TTR-genotyping only.

EPS-185

Census of Cardiac Uptake on Routine Bone Scintigraphy, a Methodology to Assess the Prevalence of the TTr Cardiac Amyloidosis

F. Chehade[1], *A. El Khoury[2], S. Nasr[2];*
[1]Nuclear Medicine, Medical Sciences Faculty, Lebanese University, Hadath, LEBANON, [2]Cardiology Department, Mount Lebanon Hospital, Hazmieh, LEBANON.

Aim/Introduction: Transthyretin cardiac amyloidosis (TTrCA) is a rapidly progressive restrictive cardiomyopathy remaining underdiagnosed. Diagnosis is challenging and cannot be based on ultrasound and MRI findings alone because they lack sufficient accuracy. It requires invasive test of myocardial or fat pad biopsies. The non-invasive scintigraphic technique using bone-seeking radiopharmaceuticals has become a cornerstone in the workup revealing a myocardial uptake. Our work consists of a single institution retrospective study aiming to look of myocardial uptake on bone scintigraphies, and to estimate the prevalence of TTrCA. ***Materials and Methods:*** A total of 2211 consecutive cases of bone scintigraphy realized mostly for oncologic purposes between 2009 and 2020 in patients ranging between 31- and 95-y-old (mean age = 61.40 ± 15.42) were included in this study, 1261 are females (57%) and 950 are males (43%). The visual analysis of scintigraphic images classifies the cardiac uptake into 4 Perugini grades and evokes the diagnosis of TTrCA in high grades 2 and 3. The medical records of high grades patients were reviewed to exclude other pathologies that could be a cause of myocardial uptake. Patients with positive uptake underwent echocardiography to demonstrate restrictive cardiomyopathy. ***Results:*** Grades 1, 2 and 3 myocardial uptakes, were observed in 1.72% of all patients. Prevalence of uptakes, was 0.37% in the 50th, increased dramatically at the 60th, (2.49%), and reached 4% above the age of 80. Low grade 1 cases are the majority of positive cases, constituting 86.4%. Cases of high grades 2 and 3 were identified in 0.23% of overall patients (5 cases) ranging between 56- and 91-y-old. ***Conclusion:*** Our results agree with the trend of disease increases with age, and the low percentage of true positive cases is in concordance with the rarity of disease, as shown in other published series. The careful analysis of the bone scintigraphy of all incoming adult patients should allow to make the diagnosis of the TTRrCA at a preclinical stage and establish the effective treatments. Special cardiac care must be given to patients aged over 60 with cardiac uptake, even those of grade 1, due to the high prevalence of TTrCA in this age group. Our results provide an estimate of the number of patients that could be diagnosed and improve the awareness of the prevalence of disease. In this way, multicentric studies should be implemented by enrolling large cohorts of bone scintigraphy cases.

Clinical management of patients with Perugini grade 1 on [^{99}mTc]-HDP cardiac scintigraphy

M. Calls Calahorro, *P. Stefaneli, V. Camacho, M. Velasco, J. Duch, A. Fernández, C. Soldevila, G. Guzmán, S. Castejón, A. Maestro, S. Mirabet, A. Flotats;*
Hospital de la Santa Creu i Sant Pau, Barcelona, SPAIN.

Aim/Introduction: Perugini grades 2 or 3 on cardiac scintigraphy with [99mTc]-HDP (CS) offer a non-invasive diagnostic criterion of cardiac transthyretin amyloidosis (ATTR) in the setting of typical echocardiographic/cardiac magnetic resonance (CMR) findings when clonal dyscrasia is excluded. However, confirmatory endomyocardial biopsy is needed for CS with Perugini grade 1. Our objective was to assess the proportion of patients with Perugini grade 1 on CS who finally undergo endomyocardial biopsy in the clinical practice in our centre. ***Materials and Methods:*** This is a single-centre retrospective observational study. From 2015 to 2024, 292 patients underwent CS. There were 32 patients with Perugini grade 1 whose clinical records were assessed in search of histological confirmation or any additional testing supporting the diagnosis of cardiac ATTR. The pre-CS clinical suspicion of cardiac ATTR was assessed according to the presence of red flags, considering high suspicion >1 red flag and low suspicion ≤1 red flag. ***Results:*** Twelve patients (37.5%) underwent additional examinations after CS (mainly cardiac MR) but only 4 patients (12.5%) underwent endomyocardial biopsy, having 3 of them

high suspicion of cardiac ATTR and one of them low suspicion. Of the remaining 8 patients, only 2 patients had high suspicion of cardiac ATTR but no histological confirmation due to high-risk comorbidities; the other 6 patients had CMR not suggestive of infiltrative cardiomyopathy (n=4) or died during the diagnostic process (n=2). Twenty patients (62.5%) did not undergo additional diagnostic testing. Only 3 (15%) of these patients had high suspicion of cardiac ATTR but also had high-risk comorbidities that precluded endomyocardial biopsy. In the remaining 17 patients, 12 patients had alternative cardiological diagnosis, 3 patients had very low suspicion of cardiac ATTR (0 red flags), one patient rejected additional testing and another patient lacked follow-up. ***Conclusion:*** In our routine clinical practice, many patients with Perugini grade 1 on CS do not undergo additional diagnostic testing and only a minority have endomyocardial biopsy, mainly due to associated comorbidities and low clinical suspicion of cardiac ATTR.

EPS-187

Multimodal Imaging in Cardiac Amyloidosis: Correlation between ^{99m}Tc-PYP SPECT/CT, Echocardiography, and Cardiac Magnetic Resonance: A Case Series

E. Silvera, *C. Ferreira, J. Hermida, O. Alonso, G. Dos Santos; UDELAR, Montevideo, URUGUAY.*

Aim/Introduction: Cardiac amyloidosis (CA) is an infiltrative cardiomyopathy marked by deposition of amyloid in the myocardial tissue. 99mTc-pyrophosphate (99mTc-PYP) is a non-invasive imaging technique that allows the diagnosis of transthyretin type (ATTR) of CA. The study aims to compare the scintigraphic findings with echocardiography (ECHO) and cardiac magnetic resonance (CMR) in patients with clinical suspicion of CA. ***Materials and Methods:*** Our study involved 21 patients (mean age: 63, range: 42-75 years) with suspected cardiac amyloidosis (CA), who underwent 99mTc-PYP scintigraphy and SPECT-CT. Two experienced nuclear physicians analyzed planar and SPECT-CT images obtained 1-3 hours post-injection. We employed visual and quantitative analysis, calculating the C/CL ratio (counts of a region of interest over the heart vs. contralateral hemithorax). A ratio >1.5 with myocardial 99mTc-PYP uptake on tomographic images indicated ATTR positivity. Data from previous echocardiography (ECHO) and cardiac magnetic resonance (CMR) studies, including ventricular wall thickening, ejection fraction (EF), and late gadolinium enhancement, were also collected. ***Results:*** Myocardial 99mTc-PYP uptake was identified in the left ventricle in 10 patients and in the right ventricle in 6 patients. In these cases, the C/CL ratio was > 1.5. In the remaining 11 patients, myocardial uptake was ruled out with SPECT/CT images, and the C/CL ratio was <1.5, except in one patient. Vascular pool activity was identified in the tomographic images of 8 patients. All patients showed on ECHO an increase in the thickness of the left ventricular wall (>12mm), right ventricular wall thickening (>5mm) (n=6), interatrial septum thickening (>5 mm) (n=5), biauricular enlargement (n=10), preserved EF (n=12) and 9 patients showed reduced EF with globally reduced longitudinal strain (absolute value less than -15%). On the other hand, the finding evaluated with CMR were thickening of the left ventricle (n=14), right ventricular wall thickening (n=6), interatrial septum thickening (n=5), biauricular enlargement (n=12), preserved EF (n=9), reduced EF (n=5) were observed. In the late gadolinium enhancement (LGE) images the pattern was diffuse (n=11) and subendocardial (n=2). In only one case was it not possible to null the myocardial signal with different inversion times. Also LGE was evident in the left ventricle (n=13), right ventricle (n=6), and interatrial septum (n=5). ***Conclusion:*** This study highlights the significance of 99mTc-PYP scintigraphy and SPECT-CT in diagnosing cardiac amyloidosis (CA), especially in determining the subtype (ATTR). Our findings were consistent with abnormalities detected in echocardiography (ECHO) and cardiac magnetic resonance (CMR).

EPS-188

The Value of Na$^{[18F]}$F Imaging in the Early Assessment of Aortic Valve Degeneration Following Transcatheter Aortic Valve Implantation (TAVI)

M. Opalinska[1], *D. Sorysz[2], A. Sowa-Staszczak[1], A. Grochowska[3], A. Dziewierz[2], N. Maruszak[4], M. Bagieński[5], K. Gawlik[6], D. Dudek[7]; [1]Department of Endocrinology, Jagiellonian University Medical College, Krakow, Poland, Krakow, POLAND, [2]2nd Department of Cardiology, Institute of Cardiology, Jagiellonian University Medical College, Krakow, Poland, Krakow, POLAND, [3]Department of Radiology, University Hospital, Krakow, Poland, Krakow, POLAND, [4]Clinical Department of Cardiology and Cardiovascular Interventions University Hospital, Krakow, Poland, Krakow, POLAND, [5]Intensive Cardiac Care Unit, University Hospital, Krakow, Poland, Krakow, POLAND, [6]Department of Clinical Biochemistry, Jagiellonian University Medical College, Krakow, Poland., Krakow, POLAND, [7]Center for Digital Medicine and Robotics, Jagiellonian University Medical College, Krakow, Poland, Krakow, POLAND.*

Aim/Introduction: Transcatheter aortic valve implantation (TAVI) is a standard, minimally invasive treatment of severe symptomatic aortic stenosis associated with aging. Patomechanism of the degenerative process on the biological valve leaflets in elderly is rather known, but the process of TAVI degeneration, limiting their durability, is not fully elucidated. We aimed to investigate the utility of Na$^{[18F]}$ PET/CT in assessment of an TAVI microcalcification and its influence to potential TAVI degeneration. ***Materials and Methods:*** Seventy-one TAVI patients underwent transthoracic echocardiography (TTE), transesophageal echocardiography (TEE), biochemical assessment of calcification and inflammation parameters and PET/CT with Na$^{[18F]}$F. According to the protocol TTE, TEE and PET/CT were planded at baseline and after 6 month follow up. Biochemical assays were performed as baseline and at 3, 6, 12 and 24 months. Of these, 30 patients had follow-up examinations, while the rest were lost to mortality and the COVID pandemic. In all patients included to the analysis TAVI valve morphology and function were assessed using TTE and TEE. SUVmax, SUVmean and tissue-to-background (TBR) of Na$^{[18F]}$F in the projection of the aortic valve were measured. Na$^{[18F]}$F uptakes were compared between baseline and follow-up PET/CT scans, performed 18.2 (±11.3) and 19.8 (±12.7) months after baseline. ***Results:*** Na$^{[18F]}$F PET/CT, as well as echocardiographic and biochemical data, were analyzed in 30 patients after TAVI (M11, F19), all of whom underwent follow-up PET/CT. The median age of the patients was 84.0 (IQR 80.0-87.0) years. After TAVI implantation, significant improvement in valve function was observed in all patients. The mean SUVmax of Na$^{[18F]}$F uptake on TAVI was 2.07 (IQR 1.67; 2.46). A positive correlation was found between changes in SUVmax values and selected echocardiographic parameters such as changes in maximal and mean transvalvular gradient, R=0,68, p=0,034 and R=0,3362, P=0,045, respectively. Among all biochemical assessments, a significant correlation was found between PET/CT results and baseline ox-LDL (R=0.3067, p=0.051) and osteoprotegerin (R=-0, 3024, p=0.0249), as well as control concentrations of osteopontin (R= -0.3903, p=0.0363), Lp(a) (R= 0.4026, p=0.0568) and matrix metalloproteinase-3 (R= -0.4844, p=0.009). ***Conclusion:*** Na$^{[18F]}$F

PET/CT appears to be an interesting new imaging modality for the evaluation of TAVI valve microcalcifications, which correlates with selected echographic parameters and biochemical markers. However, the possible use of PET/CT imaging for prediction of degenerative process on TAVI, as well as understanding of the pathomechanism of their destruction requires further research.

Genetic biomarkers for response prediction to PSMA RLT treatment in mCRPC Patients
A. Antic Nikolic[1], *A. Gaeble[1], C. Pfob[1], M. Kircher[1], A. Dierks[1], S. Dintner[2], B. Maerkl[2], C. Lapa[1], R. A. Bundschuh[1];*
[1]Nuclear Medicine, Faculty of Medicine, University of Ausgburg, Augsburg, GERMANY, [2]Pathology, Faculty of Medicine, University of Ausgburg, Augsburg, GERMANY.

Aim/Introduction: Radioligand treatment (RLT) with Lutetium-177(177Lu)-labeled ligands to the prostate-specific membrane antigen (PSMA) is becoming increasingly important in the treatment of progressive metastatic castration-resistant prostate cancer (mCRPC). However, there is still a substantial number of patients without treatment response and progression under RLT, likely due to the complex genetic portrait of prostate cancer and commonly altered DNA damage response genes that confer resistance to radiation. The aim of this study was to investigate the association between response to 177Lu-PSMA-based RLT and tumor mutations in genes involved in DNA repair pathways. ***Materials and Methods:*** We analysed a total of 32 patients who received RLT between January 2021 and March 2024 and in whom prior genetical testing for at least the following genes was available: ATM, BARD1, BRCA1, BRCA2, BRIP1, CDK12, CHEK1, CHEK2, FANCA, FANCL, NBN, PALB2, RAD51B, RAD51C, RAD51D, RAD54L, TP53, FANCC, FANCG, FANCD2, MSH2, MSH6, MLH1, PMS2, and EPCAM. For response assessment, we used radiologic assessment including [68Ga]Ga-PSMA PET/CT and $^{[18F]}$F-FDG PET/CT as well as prostate-specific antigen (PSA) levels before and after two administered therapy cycles according to the Prostate Cancer Working Group 3 (PCWG3) criteria. ***Results:*** In this cohort of patients, we identified 21/32 patients (66 %) harbouring pathogenic mutations in the following genes: T53 (n= 14, 67%), ATM (n=2, 10%), BRCA2 (n=2, 10%) NBN (n=2, 10%) and CHEK2 (n=1, 5%). The group of mutation carriers had a median baseline PSA of 160 ng/ml, whereas in patients without mutations in predefined genes, the median baseline PSA level was 15 ng/ml (p=0.21). Interestingly, the cohort of mutation carriers had also a shorter median time from the initial diagnosis to PSMA-RLT (4 years) as compared to the control group with an interval of 6 years (p<0.05). Regarding the number of administered RLT cycles, the group with DNA repair pathway mutations received a median of 4 cycles (range, 1-6) compared to the group without mutations with a median of 5 cycles (range, 2-8; p<0.05). In the 24 patients in whom treatment response assessment was available, 90% (9/10) of subjects without DNA repair pathway mutations achieved a partial response/stable disease while 10 % (1/10) showed disease progression. In contrast, 50% (7/14) of patients carrying mutations suffered from disease progression. Interestingly, no statistical difference (p=0.67) was found between the two groups regarding biochemical response. ***Conclusion:*** Genetic testing prior to PSMA-RLT could predict treatment response and thereby improve patient selection and treatment tailoring.

OP-571
Dynamic change in tumour PSMA expression between baseline and day 15 after commencing enzalutamide in poor-risk, metastatic, castration-resistant prostate cancer (mCRPC): Findings from the randomised, phase 2, ENZA-p trial (ANZUP 1901)

Hospital; and, School of Medicine, University of Queensland, Brisbane, AUSTRALIA, [12]Department of Medical Oncology, Peter MacCallum Cancer Centre, Melbourne, AUSTRALIA, [13]Molecular imaging and Therapeutic Nuclear Medicine, Peter MacCallum Cancer Centre, Melbourne, AUSTRALIA, [14]Cancer Imaging Department, Victorian Comprehensive Cancer Centre, Melbourne, AUSTRALIA, [15]Medical Oncology Dept., Calvary Mater Hospital Newcastle, Newcastle, AUSTRALIA, [16]Nuclear Medicine, Hunter New England Health Imaging Service, New Lambton, AUSTRALIA, [17]Eastern Health Clinical School, Monash University and Eastern Health, Melbourne, AUSTRALIA.

Aim/Introduction: Prostate-specific membrane antigen (PSMA) receptor expression changes with androgen receptor blockade in prostate cancer. The combination of enzalutamide (ENZA) and lutetium-177-PSMA-617 (LuPSMA) improved PSA progression-free survival (PFS) over ENZA alone in mCRPC in the ENZA-p trial. It is unknown whether this is due to complementary effects on heterogenous cell populations or synergistic effect with PSMA upregulation due to ENZA in clonal subpopulations. In this ENZA-p substudy, we evaluate the frequency, magnitude, and significance of change in PSMA PET/CT quantitative parameters between baseline and day 15 after commencing ENZA. ***Materials and Methods:*** Participants (pts) had mCRPC not previously treated with chemotherapy or AR antagonist (abiraterone permitted), 68Ga-PSMA-avid disease, and at least two risk factors associated with early progression on ENZA. Pts were randomised (1:1) to either ENZA 160 mg daily (ENZA-alone), or ENZA 160 mg daily plus adaptive- dosed LuPSMA 7.5 GBq (2 or 4 doses) dependent on persistent PSMA-avid disease on interim 68Ga-PSMA PET. All patients underwent a 68Ga-PSMA PET/CT at baseline and day 15 after commencing ENZA, with LuPSMA administered on day 16 in the experimental arm. All 68Ga-PSMA PET/CT were quantified (MIM Encore) to derive total tumour volume (TTV), SUVmean, and SUVmax. Change in TTV, SUVmax, and SUVmean were calculated using the baseline and day 15 PSMA PET/CT. PSA-PFS outcomes associated with these parameters were assessed using Kaplan Meier analysis. ***Results:*** We randomised 162 pts from Aug 2020 to Jul 2022: median age 71 (range 45-96), prior docetaxel in 54%, and prior abiraterone in 13%. All patients underwent baseline imaging and 149 had day 15 PSMA PET/CT available for quantification. A rise in SUVmax of any magnitude was recorded in 105/149 pts (70%), with the median SUVmax rise in these pts being 29.7% (IQR 10.9-48.3). 103 (69%) had a rise in SUVmean and 102 (69%) a rise in TTV. In those with increased SUVmax, 16/105 (15%) had a discordant fall in SUVmean. Associations between change in baseline and day 15 imaging parameters and PSA-PFS will be calculated for both the ENZA and ENZA+LuPSMA arms (results will be available at presentation). ***Conclusion:*** A majority of pts in the ENZA-p trial demonstrated increased PSMA SUVmax between baseline and day 15 PSMA PET/CT after commencing ENZA for mCRPC. This [was/was not] associated with PSA PFS in patients on ENZA and combination treatment.

OP-572

Investigation of Variations in DNA Repair Genes on [177Lu]Lu PSMA Treatment Response in Patients with Prostate Cancer

N. Alan-Selcuk[1], *G. Beydagi[1], T. Isbir[2];*
[1]Yeditepe University, Department of Nuclear Medicine, Istanbul, TÜRKIYE, [2]Yeditepe University, Department of Molecular Medicine, Istanbul, TÜRKIYE.

Aim/Introduction: The aim of this study was to investigate the relationship between ERCC2 gene variants, [177Lu]Lu PSMA treatment, and miRNA-182 and miRNA-187 expression levels. ***Materials and Methods:*** Seven prostate cancer patients participated in this study, receiving varying doses of [177Lu]Lu PSMA: 150 mCi, 200 mCi, and 250 mCi. The study employed high-performance liquid chromatography (HPLC) to verify radiochemical purity before administration, and Sanger sequencing was used to assess the relationship between ERCC2 gene variants and miRNA expression levels. ***Results:*** Post-treatment observations showed a significant increase in miRNA-182 and miRNA-187 levels, particularly in patients receiving higher doses (200 mCi and 250 mCi). The ERCC2 gene variations exhibited a discernible correlation with the altered miRNA expressions, indicating genetic modulation of treatment responsiveness. Patients who received treatment, including [177Lu]Lu PSMA, had significantly higher levels of miRNA-182 ($p<0.001$) and miRNA-187 ($p=0.000$) than patients who received no treatment. A significant relationship was found between the post-treatment expression level of miRNA-182 and the change in post-treatment DNA concentration ($p=0.028$). The ERCC2 gene variants of prostate cancer patients who received and did not receive [177Lu]Lu PSMA treatment were investigated. The rs13181 variant was found in heterozygous mutant and wild-type genotypes in both patients who received treatment and those who did not. For the rs1799793 variant, patients who received treatment had wild-type and homozygous mutant genotypes, while patients who did not receive treatment had homozygous mutant and heterozygous mutant genotypes. A post-treatment analysis revealed that 50% of patients who responded to PSA treatment had the heterozygous mutant variant of the ERCC2 rs13181 gene, while 66.66% of patients who did not respond to treatment had the wild-type genotype. For ERCC2 rs1799793, 100% of patients who had a PSA response had the heterozygous mutant genotype, while 50% of patients who did not have a PSA response had the wild type genotype and 50% had the homozygous mutant genotype. Additionally, it was found that patients who had high levels of miRNA-182 after treatment were more likely to have the ERCC2 rs13181 heterozygous mutant genotype ($p=0.028$). ***Conclusion:*** The results emphasize the importance of genetic and molecular diagnostics in optimizing treatment strategies for prostate cancer. By evaluating miRNA levels and DNA repair gene variations, the effectiveness of Lu-177 PSMA therapy can be enhanced, facilitating more personalized and effective treatment approaches. This study contributes to the growing field of precision medicine in oncology, advocating for targeted treatment strategies based on genetic profiles.

Hospital Würzburg, Wurzburg, GERMANY, [11]CDE Dosimetry Services, Knoxville, TN, UNITED STATES OF AMERICA, [12]Novartis Institutes for BioMedical Research, Basel, SWITZERLAND, [13]Novartis Institutes for BioMedical Research, East Hanover, NJ, UNITED STATES OF AMERICA, [14]Novartis Pharma AG, Basel, SWITZERLAND, [15]University Hospital Münster, Munster, GERMANY.

Aim/Introduction: In VISION, [177Lu]Lu-PSMA-617 (177Lu-PSMA-617) plus protocol-permitted standard of care (SoC) significantly improved overall survival and radiographic progression-free survival in patients with PSMA-positive metastatic castration-resistant prostate cancer. In the VISION dosimetry sub-study, 177Lu-PSMA-617 had a good safety profile with low radiotoxicity in at-risk organs. Here, we present the tumour dosimetry for 177Lu-PSMA-617 across cycles 1-6. ***Materials and Methods:*** Dosimetry was assessed in a separate cohort of 29 non-randomized patients. Participants received 177Lu-PSMA-617 (7.4 GBq/6 weeks, ≤6 cycles) plus SoC. Participants underwent SPECT/CT scans during cycle 1 at approximately 2, 26, 48 and 168 hours after 177Lu-PSMA-617 injection, and in subsequent cycles at 36-48 hours post-injection. Region of interest/volume of interest construction was performed on PET/CT images (cycle 1) and SPECT/CT images (cycles 2-6) to determine tumour volumes and morphology, with kinetic data derived from SPECT images. The present analysis included patients with at least one evaluable tumour in cycles 2-6 following selection of up to 5 tumours per patient in cycle 1. The normalized number of disintegrations were calculated assuming consistent uptake and retention half-times across cycles, with variations occurring solely in the magnitude of activity uptake. The ratio of individual tumour activities in each cycle to cycle 1 was utilized to scale the normalized disintegrations from cycle 1 to subsequent cycles. Tumour dosimetry parameters were estimated using the standard Medical Internal Radiation Dose/Radiation Dose Assessment Resource method. ***Results:*** In total, 60 unique, delineated prostate cancer tumours were analysed across cycles 1-6, in 18 patients who had evaluable tumours in cycles 2-6. The mean radiation-absorbed dose for all tumours declined from 7.9 Gy/GBq (SD 10; range 0.17-55) in cycle 1 (60 tumours) to 1.6 Gy/GBq (SD 1.7; range 0.11-7.5) in cycle 6 (20 tumours). For tumours in bone, the mean absorbed dose was 6.4 Gy/GBq (SD 7.3; range 0.17-45) in cycle 1 (46 tumours) and 1.3 Gy/GBq (SD 0.95; range 0.11-3.9) in cycle 6 (17 tumours). For tumours in lymphatic tissue, the mean absorbed dose was 11 Gy/GBq (SD 15; range 0.99-55) in cycle 1 (12 tumours) and 3.2 Gy/GBq (SD 3.8; range 0.14-7.5) in cycle 6 (3 tumours). Based on these data, patients received a median 6-cycle cumulative absorbed dose of approximately 100 Gy. ***Conclusion:*** Declining radiation-absorbed doses across cycles 1-6 in this dosimetry sub-study were consistent with the anti-tumour efficacy of 177Lu-PSMA-617 observed in VISION.

OP-574

Real-life data on [177Lu]Lu-PSMA-617 : Descriptive analysis on the largest RLT metastatic castration-resistant prostate cancer (mCRPC) cohort treated in France.

A. Giraudet[1], *C. Bailly[2], P. Barthelemy[3], F. Somme[3], P. Olivier[4], V. Massard[5], Y. Godbert[6], G. Roubaud[6], S. Girault[7], S. Abadie[7], C. Viala[2], A. Flechon[1];*
[1]Centre Léon Bérard, Lyon, FRANCE, [2]Centre Hospitalier Universitaire, Nantes, FRANCE, [3]Institut de cancérologie Strasbourg Europe, Strasbourg, FRANCE, [4]Centre hospitalier régional et universitaire de Nancy, Vandoeuvre-lès-Nancy, FRANCE, [5]Institut de Cancérologie de Lorraine, Vandoeuvre-lès-Nancy, FRANCE, [6]Institut Bergonié, Bordeaux, FRANCE, [7]Institut de cancérologie de l'Ouest Paul Papin, Angers, FRANCE.

Aim/Introduction: VISION study showed that [177Lu]Lu-PSMA-617 added to BSoC prolonged imaging-based progression-free survival and overall survival in patients with PSMA-positive mCRPC. French Health Authorities has granted a "cohort" early access for [177Lu]Lu-PSMA-617 in this indication. ***Materials and Methods:*** PSMA positive mCRPC patients pretreated with at least 1 taxane-based chemotherapy regimen and ≥1 androgen receptor pathway inhibitor (ARPI) were included. [177Lu]Lu-PSMA-617 (7.4 GBq) was administered up to 6 cycles every 6 weeks. Patients' characteristics and safety data are described for the entire population, it's evolving and reflects the care of mCRPC and eligibility for these treatments in real life in France. Efficacy was analyzed within a sub population with 6 months follow-up min after 1st [177Lu]Lu-PSMA-617 injection. Adverse events (AE) grading was not evaluated. ***Results:*** From 12/1/2021 to 1/31/2024, 1626 patients were included, and 790 patients were analyzed for efficacy from 12/1/2021 to 4/30/2023. At data cut-off, 728 were still under treatment, and 909 stopped treatment due to disease progression (48.0%), AE (8.6%) or death (6.3%). 284 patients (31.2%) completed all 6 injections. Patients baseline characteristics: median age 73.3 (37-92) years; ECOG 0-1: 87.2%; median PSA level 58.0 (0-6972) ng/ml; metastatic sites: bone 93.5%, lymph node 60.0%, liver 9.2%; previous taxane regimen: 97.8% of which 53.8% have received 2; prior ARPI treatment: 100% and 60.8% received 2 or more (median: 2). Concomitant treatment with ARPI was observed in 25.3%. In terms of efficacy results, the imaging PFS is 7.3 months. Median time to clinical symptoms progression was 7.9 months. 69.4% patients had a decrease in PSA level at any time point. Median time to PSA decrease was 1.18 (0.0-8.6) months. 12.3% (n= 201) of patients experienced >1 treatment-related (TR) AE, including 161 patients with ≥1 serious AE. 5 fatal cases related to treatment have been reported. The most reported TRAEs were thrombocytopenia (4.4% of patients) and anemia (4.2% of patients). ***Conclusion:*** In this large real-life cohort of mCRPC treated with [177Lu] Lu-PSMA-617 patients profile is evolving from heavily pretreated to standardized patient profile. In the global cohort they received less concomitant ARPI treatment and higher incidence of 2 prior taxane regimens compared to VISION study. Safety profile of [177Lu]Lu-PSMA-617 remains favorable. Since the cohort is still ongoing, updated results will be presented at EANM congress, including longer follow-up period and higher number of patients who completed treatment.

OP-575

GRPr antagonist [^{177}Lu]Lu-AMTG for treatment of in prostate cancer patients: first in-human biodistribution, in vivo stability, and dosimetry

J. Kurth[1], *M. Heuschkel[1], V. Felber[2], M. Joksch[1], T. Suhrbier[1], N. Holzleitner[2], H. J. Wester[2], S. M. Schwarzenböck[1], T. Günther[3], B. J. Krause[1];*
[1]Rostock University Medical Center, Rostock, GERMANY, [2]Technical University of Munich, Garching, GERMANY, [3]Stanford University, Stanford, CA, UNITED STATES OF AMERICA.

Aim/Introduction: Gastrin-releasing peptide receptor (GRPr) could be an alternative molecular target for theranostic approach in prostate cancer patients with insufficient PSMA expression. Recently, a new GRPr ligand AMTG has been introduced and clinically used as a 68Ga-labelled PET/CT-diagnostic. This ligand is expected to show higher in vivo stability, suggesting higher tumor doses when labeled with a therapeutic radio-metal.

Therefore, this study focused on evaluating biodistribution, in vivo stability, and absorbed doses (AD) to organs at risk (OAR) and tumor lesions for [177Lu]Lu-AMTG in mCRPC patients with insufficient PSMA expression. ***Materials and Methods:*** 4 patients without treatment options for approved therapies who showed sufficient uptake in GRPr-PET/CT were recruited for [177Lu]Lu-AMTG-therapy. Mean activity administered was 7.5 ± 0.2 GBq. 2 patients received 2 or 3 treatment cycles. Therapies were carried out as individual treatments under the German Medicines Act (AMG, §13[2b]). AD in kidneys, pancreas, liver, spleen, bone marrow, and 34 tumor lesions were calculated according to the MIRD dosimetry scheme and EANM dosimetry guidelines. For this purpose, quantitative SPECT/CT scans were performed at approx. 1, 24, 48, and 72 h p.i. and blood samples were taken. To assess in vivo stability, blood samples were centrifuged, the supernatant collected, and the plasma proteins precipitated by treatment with MeCN and subsequent centrifugation. Serum samples were analyzed using radio-RP-HPLC. ***Results:*** [177Lu]Lu-AMTG-therapy was well tolerated and no treatment-related side effects were observed. Rapid uptake was observed in the tumor lesions and the pancreas within the first hour after injection. In contrast to rapid washout from the OAR, binding in tumor tissue was more stable. This was reflected by effective half-lives of 45.5 and 62.8 hours in soft tissue and bone metastases, respectively. Table 1 summarises AD and dose rates in OAR and tumor lesions. [177Lu]Lu-AMTG also showed high stability in vivo in human serum (see Table 2). In blood samples taken later than 6 hours p.i., no significant activity could be detected. ***Conclusion:*** [177Lu]Lu-AMTG has advantageous properties in terms of biodistribution, in vivo stability, and dosimetry, which predestine it for therapeutic use. Its rapid washout from the pancreas, which is considered the main OAR, and the resulting low dose exposure distinguish it from its parent peptide RM2. It binds significantly longer in tumor tissue and therapeutically relevant doses can be achieved. This advantageous profile also allows the application of higher activities or more biologically effective radionuclides to increase tumor control probability.

OP-576

SatisfACtion: a phase 1/2 study of [^{225}Ac]Ac-PSMA-R2 in patients with PSMA-positive metastatic castration-resistant prostate cancer with or without previous [^{177}Lu]Lu-PSMA radioligand therapy

F. Kraeber-Bodéré[1], *H. Mahammedi[2], A. Giraudet[3], J. Wehbe[4], C. Wilke[4], P. Olivier[5];*
[1]Nantes Université, Univ Angers, CHU Nantes, INSERM, CNRS, CRCI2NA, Nantes, FRANCE, [2]Medical Oncology Department, Centre Jean Perrin, and UMR INSERM 1240 Imost, Clermont-Ferrand, FRANCE, [3]Lumen Nuclear Medicine Department, Centre Léon Bérard, Lyon, FRANCE, [4]Novartis Pharma AG, Basel, SWITZERLAND, [5]Centre Hospitalier Régional Universitaire de Nancy, Département de Médecine Nucléaire, Nancy, FRANCE.

Aim/Introduction: The PSMA-targeted radioligand therapy (RLT) [177Lu]Lu-PSMA-617 prolonged overall survival (OS) and radiographic progression-free survival (rPFS) when added to standard of care (SoC) in patients with metastatic castration-resistant prostate cancer (mCRPC) in the VISION study. The α-emitter 225Ac mainly causes double-strand DNA breaks, whereas the β-emitter 177Lu mainly causes single-strand breaks. Radiolabelled PSMA-R2, a PSMA-targeting ligand, has been associated with low radiation-absorbed doses in at-risk organs. SatisfACtion is an ongoing study of [225Ac]Ac-PSMA-R2 (225Ac-PSMA-R2) in patients with PSMA-positive mCRPC. ***Materials and Methods:*** SatisfACtion (NCT05983198) is an open-label, multicentre, phase 1/2 study of 225Ac-PSMA-R2. Participants with and without previous exposure to 177Lu-PSMA RLT are assigned to separate parallel groups. Eligible patients are adults with progressive PSMA-positive mCRPC confirmed by [68Ga]Ga-PSMA-targeted PET/CT, who have adequate organ function, and have previously received androgen-receptor pathway inhibitor and taxane therapy. Patients who have received systemic anti-cancer therapy ≤28 days before Cycle 1 are ineligible. The study has two phases: dose escalation (phase 1; ongoing) and dose expansion (phase 2). In both phases, participants in each group receive intravenous 225Ac-PSMA-R2 plus SoC once every 6 (±1) weeks for a ≤6 cycles. Patients attend a safety follow-up visit approximately 41 days after the final dose then enter long-term follow-up (assessments every ~12 weeks). The ongoing dose-escalation phase aims to evaluate the safety and tolerability of 225Ac-PSMA-R2 and determine the recommended dose for expansion (RDE). Dose escalation will proceed in each group using independent Bayesian logistic regression models following the escalation with overdose control (EWOC) principle. A starting dose of 7 MBq may be increased to 10, 12 or 14 MBq providing the EWOC criteria are met, and safety and tolerability are acceptable. Approximately 18-22 participants per group are being enrolled (3-6 per dose cohort; ≥6 receiving the RDE). The primary endpoints are the incidence and severity of dose-limiting toxicities, adverse events (AEs) and serious AEs, and dose intensity and treatment modifications. The dose-expansion phase will enrol approximately 80 participants per group to evaluate further the anti-tumour activity of 225Ac-PSMA-R2 at the RDE. The primary endpoints are objective response rate and PSA50 response rate. Secondary endpoints in both phases include response rates, rPFS, PFS, OS, time to symptomatic skeletal event, PSA response, change in alkaline phosphatase and lactate dehydrogenase levels, pharmacokinetics and health-related quality of life. Exploratory endpoints include analysis of PSMA PET parameters and associations between molecular biomarkers and clinical efficacy.

Aim/Introduction: Prostate-specific membrane antigen (PSMA) therapy and imaging have advanced the management of prostate cancer, particularly metastatic castrate-resistant prostate cancer (mCRPC). Despite advancements, mCRPC remains incurable.

Identifying biomarkers to better personalise PSMA-targeted radionuclide therapy is crucial. 177Lu-PSMA SPECT/CT imaging may be valuable in assessing dynamic changes in tumour volume and PSMA avidity. Achieving consistency in qualitative and quantitative parameters across different centres necessitates harmonisation efforts. This study aimed to standardise series of 177Lu-PSMA SPECT/CT images acquired from various centres. ***Materials and Methods:*** Serial 177Lu-PSMA SPECT/CT images obtained from 15 centres participating in the phase II clinical trials ENZAp (NCT004419402), were included. Each centre received three phantoms to allow for derivation of CT-based attenuation correction, SPECT sensitivity, and confirmation of quantitative accuracy (IEC body phantom). Data were centrally analysed in MIM software using the SPECTRA licence and a consistent approach to reconstruction (3D OSEM with 6i21s, double energy window scatter correction, CT based attenuation correction, and geometry-based resolution recovery). Raw clinical SPECT projection and CT data were transferred to a cloud-based server for quantitative reconstruction using derived sensitivity factors and consistent analysis. The SPECT/CT series were harmonised by applying camera-specific sensitivity factors and centrally reconstructed. ***Results:*** A total of 81 patients from the experimental arm of ENZAp receiving 2 to 4 doses of 177Lu-PSMA therapy were included in this study. Sensitivity factors were achieved in 12 out of 15 centres, ranging from 5.02 to 10.29 cps/MBq. Harmonisation was unsuccessful in one centre due to non-compliance with acquisition guidelines, while two centres failed initial phantom site assessment. Serial SPECT/CT images from 80 patients were successfully harmonised and centrally reconstructed to provide comparable clinical data. ***Conclusion:*** Harmonisation of 177Lu-PSMA SPECT/CT images is key for standardising both visual and quantitative parameters, enabling multisite trial evaluation of disease progression on 177Lu-PSMA therapy.

Aim/Introduction: Whole-body tumour dosimetry was previously correlated with prostate-specific antigen (PSA) response in patients with metastatic castration-resistant prostate cancer (mCRPC) treated with Lutetium-177 [177Lu]Lu-PSMA-617 [1]. We aim to validate post-cycle 1 (C1) single time point whole-body tumour dosimetry (WBTD) as an independent prognostic biomarker. ***Materials and Methods:*** This prospective, single-centre analysis included patients with progressive mCRPC who were treated with at least one cycle of [177Lu]Lu-PSMA-617 in the ProsTIC Registry (NCT04769817). Eligible patients completed post-C1 quantitative SPECT/CT and weren't treated on prior trials with [177Lu]Lu-PSMA-617. WBTD was performed using single time point, voxel-level analysis, with automated tumour segmentation using open-source AI models and reviewed by experienced nuclear medicine physicians. Association between WBTD and 12-week PSA response was analysed. Logistic regression, adjusted for conventional prognostic factors and imaging parameters, evaluated the association between WBTD and PSA reduction of ≥50% or ≥90% from baseline (PSA-50/90). Overall survival (OS) was analysed using Kaplan-Meier methods with the previously identified 10Gy threshold [1]. ***Results:*** Between May 1st 2021 and March 30th 2023, 181 of 195 patients were eligible, with a median (IQR) age of 74 (68-78) years and PSA of 73 (18-220) ng/mL. Previous treatments included docetaxel in 148 (82%), cabazitaxel in 63 (35%), enzalutamide in 116 (64%) and abiraterone in 77 (43%). Median (IQR) radiation absorbed dose was 8.9 (7.0-13.7) Gy. Of the 181 patients, 111 (61%) and 49 (27%) achieved PSA-50 and PSA-90 by 180 days post-C1, respectively. WBTD was significantly prognostic of PSA-50 (odds ratio [OR] per 1Gy: 1.16 [95%CI 1.06-1.26]; p=0.001) and PSA-90 (OR: 1.18 [1.08-1.27]; p<0.001), independent of ECOG (0 vs ≥1), alkaline phosphatase, haemoglobin, bone and/or liver metastasis. After adjusting for [18F] FDG PET metabolic tumour volume (MTV) and PSMA PET mean standardised uptake value (SUVmean), the PSA-90 association with WBTD remained independently prognostic (OR: 1.22 [95%CI 1.08-1.38]; p=0.001). Patients with ≥10Gy radiation absorbed dose had a significantly longer median OS of 15.2 (12.1-21.1) months vs 11.4 (9.9-14.9) months for <10Gy (p=0.009). ***Conclusion:*** Single-time point whole-body tumour dosimetry at cycle 1 of [177Lu] Lu-PSMA-617 is an independent biomarker for PSA response. Higher radiation absorbed dose is prognostic for favourable PSA responses and overall survival. ***References:*** Violet J, Jackson P, Ferdinandus J, Sandhu S, Akhurst T, Iravani A, et al. Open label, single arm, adaptive study assessing Safety and Accuracy of ^{18}F-SYN2 - a novel PET myocardial perfusion tracER in patients with suspected functionally significant coronary stenoses - SAFER phase 2 clinical trial
M. Dziuk[1], *M. Kobylecka[2], B. Chrapko[3], J. Knuuti[4], M. Kostkiewicz[5], E. Witkowska Patena[1], S. Krajewski[6], L. Steczek[6], K. Gotowicz[6], J. Wlostowska[6], J. Towpik[6], P. B. Kozanecki[6];*
[1]Military Institute of Medicine and Affidea, PET-CT, Warsaw, POLAND, [2]Warsaw Medical University, Warsaw, POLAND, [3]Lublin Medical University, Lublin, POLAND, [4]University of Turku, Turku PET Centre, Turku, FINLAND, [5]John Paul II Hospital, Jagiellonian University, Cracow, POLAND, [6]Synektik SA, Warsaw, POLAND.

Aim/Introduction: [18F]SYN2 (18F labeled acridinium derivative) is a novel radiotracer for PET myocardial perfusion imaging. The primary objective was to assess safety and tolerability of [18F]SYN2 in patients with suspected CAD and referral to invasive coronary angiography (ICA). The secondary objective was to assess the diagnostic ability of [18F]SYN2 in the detection of coronary stenosis using ICA with FFR as the reference standard. ***Materials and Methods:*** Out 57 patients screened - 40 pts were enrolled. 21 (52%) were female and 19 (48%) were male. The mean age was 63.2 ± 10.5. The mean BMI was 30.69 ± 4.83 kg/m2. Six subjects (15%) had a history of angina, and none had a history of acute coronary event. Other comorbidities : arterial hypertension (n = 29, 72.5%), diabetes (n = 12, 30%), dyslipidemia (n = 24, 60%), atrial fibrillation (n = 6, 15%). Patients were screened within 28 days prior to first dosing day. First dosing and PET scan (resting

baseline - 250 MBq ±10%). The second dosing and stress PET scan (during regadenosone vasodilation) was performed 1 day - 7 days after - 250 MBq ±10%. Safety visit was 5 ± 2 days after the last dosing. During the follow-up period the ICA was performed for all patients. All subjects also received follow-up call 30 ± 7 days after the last PET examination. ***Results:*** 4 adverse events (AE) (12%) were possibly related (diarrhea, musculoskeletal pain, palpitations) to the study drug administration. AEs of the highest incidence were general disorders and administration site conditions (5 cases in 5 (12.5%) patients), cardiac disorders (6 cases in 4 (10.0%) patients), and nervous system disorders (6 cases in 4 (10.0%) patients). The most common AE was headache (n = 4, 12%).In the intention to treat (ITT) population, sensitivity, specificity, accuracy, positive predictive value and negative predictive value of [18F]SYN2 PET-CT MPI (results provided by independent panel) in comparison to ICA with FFR in diagnosis of CAD were 80.0%, 75.0%, 76.7%, 61.5% and 88.2%, respectively. In the per protocol (PP) population these values were as follows: 80.0%, 73.7%, 75.9%, 61.5% and 87.5%. ***Conclusion:*** [18F]SYN2 tracer administration for PET/CT imaging in subjects with coronary artery disease suspicion was feasible and safe. The good diagnostic ability in the phase 2 study entitle to conduct the assessment of the SYN2 tracer in phase 3 trial.

OP-591

Dual PET/MRI arterial input function determination in an extracorporeal shunt setup for mouse scans with accurate dispersion correction

F. Büther[1], *F. Gierse[2], J. Cufe[2], S. Hermann[2], K. P. Schäfers[2], C. Faber[1], M. Schäfers[1], P. Backhaus[1];*
[1]University Hospital Münster, Münster, GERMANY,
[2]University of Münster, Münster, GERMANY.

Aim/Introduction: Accurate determination of individual arterial input functions (AIF) for pharmacokinetic modelling of dynamic PET and MRI data is exceedingly difficult in mice. We here present an approach for dual PET/MRI AIF measurements using an extracorporeal shunt setup and a novel catheter dispersion correction. ***Materials and Methods:*** Our setup includes an extracorporeal shunt design based on our proposed MRI AIF determination design comprising two reservoirs (1 mm inner diameter) within the shunt, placed inside the MRI field-of-view [1]. We additionally incorporated a flow-through radioactivity detector into the setup (time resolution: 1 s). Shunt flow was maintained by mouse blood pressure alone. Catheter dispersion effects were modelled as a convolution of unknown gamma variate dispersion kernels with the true AIF, both for the MR image-derived reservoir AIF and the radiotracer AIF [2]. As deconvolution with an unknown kernel is an ill-posed problem, we incorporated population-averaged AIF peak information derived from intra-aortal positron-sensitive microprobe measurements into the iterative semi-blind deconvolution process [2], resulting in deconvolved AIF solutions for the reservoir and radioactivity detector curves. We tested this approach in six mice co-injected with 10 - 80 MBq [18F]PSMA-1007 and 35 mM gadobutrol in 0.1 mL at 1 mL/min in a 9.4 T small animal MRI system. MRI involved T1 mapping and a 3D-flash sequence for dynamic imaging (time resolution: 4 s). We compared the resulting MRI AIF to those calculated from deconvolutions with a fixed kernel derived from reservoir-to-reservoir comparisons as in [1] and an image-derived MRI AIF from a small region in the venous sinus sagittalis. ***Results:*** Incorporation of microprobe-derived average AIF peak information numerically stabilized the iterative deconvolution process for both MRI as well as PET AIF, as evidenced by convergence to identical solutions from different initial trial input functions. All three MRI AIF exhibited highly similar curve shapes. However, the sinus-based AIF clearly demonstrated underestimation of absolute contrast agent concentrations, as evidenced by AIF peak heights (2.3±0.5 mM, 2.0±0.7 mM, 1.1±0.5 mM for semi-blind deconvolution, fixed kernel deconvolution, and the sinus AIF, respectively). This might be due to partial volume effects or uncertainties in calculating in vivo Gd concentrations in contrast-enhanced MRI. ***Conclusion:*** Our proposed shunt setup, in combination with the novel dispersion correction approach, was successfully able to record dual PET/MRI AIF in mice. ***References:*** [1] Backhaus P et al. Magn Reson Med. 2020;84:1404-1415. [2] Cufe J et al. EJNMMI Res. 2023;13:86.

OP-592

Monitoring of Pulmonary Hypertension Progression and Therapy Response by Using a novel serotonin transporter targeted agent - [18F]FPBM2 and PET/CT

Z. Ruiyue[1], *Y. Deng[1], Y. Luo[2], L. Zhu[2], H. Kung[3], X. Wang[1];*
[1]The First Affiliated Hospital of Guangzhou Medical University, Guangzhou, Guangzhou, CHINA, [2]Beijing Normal University, Beijing, CHINA, [3]University of Pennsylvania, Philadelphia, PA, UNITED STATES OF AMERICA.

Aim/Introduction: Pulmonary hypertension (PH) is characterized by progressive pulmonary vascular remodeling leading to right heart failure and mortality. The serotonin hypothesis proposes that serotonin contributes to PH pathogenesis by inducing vasoconstriction and stimulating proliferation and hypertrophy of pulmonary arterial smooth muscle cells, thereby promoting arterial remodeling and increased pulmonary arterial pressure. Here, we utilized a novel 18F-labeled serotonin transporter (SERT) targeting agent ([18F]FPBM2) in conjunction with PET imaging to dynamically monitor PH and its response to anrisentan therapy. ***Materials and Methods:*** [18F]FPBM2 was synthesized by an automated radiosynthesis module (BIBD-F) with solid-phase extraction (SPE) purification for producing desired high purity doses. Monocrotaline (MCT)-induced pulmonary hypertension (PH) was established in rats, followed by three weeks of oral anrisentan therapy (10mg/kg/daily). Weekly [18F]FPBM2 PET/CT imaging was conducted in MCT rats, and 3 weeks post-MCT induction, right heart (RV) catheterization, histological staining, and SERT immunofluorescence were evaluated. ***Results:*** [18F]FPBM2 synthesis was completed in 45 minutes with high radiochemical purity (>95%) and yields of 10-15% (n = 10, decay corrected), with chemical impurities lower than 100 μg per batch. Ex vivo stability testing showed 74% activity retention in rat lungs were [18F]FPBM2 compared to 25% in blood at 60 minutes post-injection. [18F]FPBM2 showed specific SERT binding to pulmonary arterial smooth muscle cells. In MCT rats standardized uptake value ratio (SUVR) of whole lungs was significantly increased from baseline (1.5) to week-3 (4.0) ($P < 0.01$). Anrisentan-treated rats exhibited minimal SUVR changes compared to baseline. RV pressure was significantly elevated in MCT rats versus anrisentan-treated and healthy controls (48 vs 40 vs 31 mmHg). Histological analysis revealed lung vessel thickening in MCT rats, with a measurable higher SERT expression (IHC score: 76% vs 67% vs 54%, $P < 0.01$) as compared to anrisentan-treated and healthy controls. While RV pressure serves as the gold standard for PH evaluation, it lacks insight into small blood vessel changes in the lung. By noninvasively mapping SERT levels in pulmonary artery smooth muscle cells and directly measuring vascular remodeling, this study offers a promising approach for PH assessment. ***Conclusion:*** This study demonstrated the potential of [18F]FPBM2 PET/CT imaging for assessing and monitoring progression of pulmonary hypertension and response to anrisentan therapy. It is reasonable

to conclude that results of this study provide physiological basis in testing the serotonin hypothesis and highlighting its potential utility as a promising imaging biomarker in clinical settings.

OP-593

Granzyme B PET imaging for non-invasive early diagnosis of acute heart allograft rejection

Z. Wei;
Fuwai Hospital, National Center for Cardiovascular Diseases, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, CHINA.

Aim/Introduction: Cardiac transplantation remains the single most effective treatment for end-stage heart failure. Despite the routine use of anti-rejection drugs in clinical practice, approximately 40% of cardiac transplant patients still experience unavoidable rejection. Timely diagnosis of early acute rejection (AR) is essential to prevent further tissue damage through effective immunosuppressive therapy. Transplant rejection and graft damage is primarily mediated by recipient cytotoxic CD8+ T cells, which attack allografts by releasing perforin and granzyme B (GzmB). This study aimed to evaluate whether GzmB-targeted positron emission tomography (PET) imaging agent (68Ga-grazytracer) can characterize T lymphocyte infiltration in acute cellular rejection. ***Materials and Methods:*** The mouse cervical heterotopic heart transplantation model was established. Mice were subjected to GzmB-targeted PET/CT on post-operative days 3, 5, and 7. Autoradiography, Masson staining, immunohistochemistry, and flow cytometry were performed to verify the inflammatory infiltration and graft damage after AR in vitro. Allograft-bearing mice were intraperitoneally administered with tacrolimus (2 mg kg−1) daily from operative day to post-operative day (POD) 7. The immune status assessment of treatment group was measured using the above method. ***Results:*** The uptake of 68Ga-grazytracer was observed increased with the extension of rejection time compared with syngeneic mouse heart transplantation (SUVmax:0.54 ± 0.07 vs. 0.19 ± 0.05 at POD 7 days, P<0.001). To assess 68Ga-grazytracer sensitivity and specificity between isograft and allograft groups, POD 7 PET/CT imaging were analyzed for their catalytic activities by receiver-operating-characteristic (ROC) analysis (AUC=0.93, 95% CI = 0.8143-1). Hematoxylin and eosin staining of the myocardium indicated massive inflammatory cell infiltration and disruption of the myocardial integrity in the allograft myocardium. Immunohistochemistry and flow cytometry showed significantly high expression of GzmB and CD8, in line with the PET/CT imaging results. Autoradiography revealed 68Ga-grazytracer accumulation in the transplanted heart. The 68Ga-grazytracer uptake of treated mice was significantly reduced compared with that in the allograft group (SUVmax: 0.262±0.05% vs. 0.54 ± 0.07 at POD 7 days; P<0.001). Daily treatment with tacrolimus improved heart allograft outcome and graft survival curves revealed complete rejections of the allograft within POD 15 ± 3 days. ***Conclusion:*** This study demonstrated the potential of 68Ga-grazytracer imaging to delineate early non-invasive diagnosis of heart allograft rejection. This study provides an entirely imaging-based method for monitoring allograft status. In the future, the development of imaging of GzmB may be more readily translated into clinical applications.

OP-594

Targeting of Liver Fibrosis with ^{89}Zr-labeled SP02SP26-ABD, a Pan-Fibrosis Theranostic Vector Directed Against PDGFRb on Activated Myofibroblasts

J. A. Muns[1], *E. Schooten[1], R. van Dasselaar[1], Y. E. Noordman[1], K. Adamzek[1], A. C. Eibergen[1], S. Pronk[2], S. Cali[1], N. J. Sijbrandi[1], E. Merkul[1], S. Oliveira[2,3], P. M. P. van Bergen en Henegouwen[2], R. B. Takkenberg[4], J. Verheij[5], S. F. J. van de Graaf[6,7], B. Nijmeijer[1], G. A. M. S. van Dongen[1,8];*
[1]LinXis Pharmaceuticals, Amsterdam, NETHERLANDS, [2]Utrecht University - Department of Biology, Cell Biology, Neurology and Biophysics, Utrecht, NETHERLANDS, [3]Utrecht University - Department of Pharmaceutical Sciences, Utrecht, NETHERLANDS, [4]Amsterdam UMC - Department of Gastroenterology and Hepatology, Amsterdam, NETHERLANDS, [5]Amsterdam UMC - Department of Pathology, Amsterdam, NETHERLANDS, [6]Tytgat Institute for Liver and Intestinal Research, Amsterdam, NETHERLANDS, [7]Amsterdam UMC - Department of Gastroenterology, Endocrinology and Metabolism, Amsterdam, NETHERLANDS, [8]Amsterdam UMC - Department of Radiology and Nuclear Medicine, Amsterdam, NETHERLANDS.

Aim/Introduction: As the prevalences of obesity and type 2 diabetes mellitus are rapidly rising, so is the prevalence of liver fibrosis. Unfortunately, reliable options to detect and treat active fibrosis are lacking. Hepatic fibrosis develops as a response to chronic liver injury, resulting in the formation of fibrous scars and liver failure. This process is fueled by collagen-producing activated myofibroblasts, the common driver cells across different fibrotic diseases in different organs, which reportedly express high levels of platelet derived growth factor receptor-β (PDGFRβ). We developed SP02SP26-ABD, a PDGFRβ-specific biparatopic VHH-construct, as a pan-fibrotic theranostic targeting vector. SP02SP26-ABD is equipped with an albumin binding domain (ABD), increasing bio-availability by decreasing renal excretion, and a cysteine in the C-terminal region allowing site-specific conjugation of diagnostic or therapeutic payloads. Here, we assessed SP02SP26-ABD for its fibrosis-targeting potential in the specific setting of liver fibrosis. ***Materials and Methods:*** Binding characteristics and cellular uptake of SP02SP26-ABD were assessed in vitro using human-, mouse-, and rat PDGFRβ ectodomains and PDGFRβ-expressing cells. Intracellular payload delivery was evaluated in vitro using SP02SP26-ABD conjugated to the cytotoxic payload auristatinF. Validity of PDGFRβ as a marker of active (liver-) fibrosis was assessed by immunohistochemistry and RT-PCR in human liver samples and 3 different mouse models of liver fibrosis (DDC, CCl4, CDA-HFD). After synthesis of SP02SP26-ABD-DFO*-Zr[89Zr], it's targeting ability was assessed in healthy mice and mice with liver fibrosis by PET-CT imaging, ex vivo biodistribution and autoradiography. ***Results:*** SP02SP26-ABD displayed similar nanomolar affinity for human-, mouse-, and rat PDGFRβ, facilitating clinical translation. Specific intracellular payload delivery was evident as AuristatinF-conjugated SP02SP26-ABD exerted subnanomolar cytotoxicity only in PDGFRβ-expressing cells. Immunohistochemistry of human- and mouse fibrotic livers confirmed co-localization of PDGFRβ with markers of active fibrosis. In all three mouse models, PET-CT imaging and radionuclide counting revealed increased uptake of SP02SP26-ABD-DFO*-Zr[89Zr] in fibrotic livers. Uptake in DDC-, CCl4-, and CDA-HFD-induced fibrotic livers, upon injection of 15 nmol/kg, was 20.93±4.35, 13.27±1.70, and 12.29±1.29%ID/g, respectively, compared to 7.56±0.85 %ID/g in healthy livers. Autoradiography revealed preferential uptake in PDGFRβ-expressing fibrotic areas. ***Conclusion:*** SP02SP26-ABD selectively and efficiently targets PDGFRβ-expressing activated myofibroblasts in liver fibrosis.

Based on these results, and preliminary results obtained in kidney- and lung fibrosis models, it qualifies as a theranostic vector. Clinical PET-CT studies with SP02SP26-ABD-DFO*-Zr[89Zr] will be initiated in different fibrotic indications.

OP-595

Preclinical and First-in-human Study of a Novel SPECT Myocardial Perfusion Imaging Agent with Rapid and Stable Heart Uptake: ^{99m}Tc-4BOH

Y. Gu[1], *L. Wang[1], S. Liu[2], W. Fang[1];*
[1]Fuwai Hospital, National Centre for Cardiovascular Diseases, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, CHINA, [2]Purdue University, West Lafayette, IN, UNITED STATES OF AMERICA.

Aim/Introduction: An ideal myocardial perfusion radiotracer with high first-pass extraction fraction (EF) and stable heart retention is necessary for accurate myocardial blood flow (MBF) quantitation. Popular 99mTc-Sestamibi suffers from low K1 value (K1=MBF*EF). Meanwhile, the fast myocardial washout of 99mTc-Teboroxime makes it hard to acquire high quality images. This study evaluated a novel SPECT perfusion agent in swine, 99mTc-4BOH, and compared it with 99mTc-Sestamibi and 99mTc-Teboroxime. Furthermore, patient volunteers were enrolled to compare 99mTc-4BOH and 99mTc-Sestamibi head-to-head. ***Materials and Methods:*** Fifteen swine were divided into three groups and injected with 99mTc-4BOH, 99mTc-Sestamibi or 99mTc-Teboroxime separately. Fifteen patients were eligible for myocardial perfusion imaging with 99mTc-4BOH and 99mTc-Sestamibi. Dynamic scans were obtained on GE 530c CZT camera. K1 and k2 were estimated by fitting one-compartment model in an inhouse software. The heart uptake, liver uptake and heart/liver ratio were assessed using ImageJ. ***Results:*** Firstly, the comparison of kinetic parameters from swine demonstrated that both rest and stress K1 values of 99mTc-4BOH were prominently higher than those of 99mTc-Sestamibi (rest: 0.81±0.03 vs 0.43±0.09 mL·min-1·g-1, P<0.05; stress: 1.19±0.26 vs. 0.50±0.10 mL·min-1·g-1, P<0.05), indicating higher first-pass extraction fraction. k2 values were significantly lower than those of 99mTc-Teboroxime (rest: 0.18±0.03 vs. 0.26±0.01 min-1, P<0.05; stress: 0.26±0.04 vs. 0.38±0.08 min-1, P<0.05), suggesting more stable heart retention of 99mTc-4BOH. High K1 and low k2 values derived 99mTc-4BOH superior kinetic properties for MBF quantification and an excellent candidate for further clinical translation. Thirteen volunteers finished the head-to-head comparison between 99mTc-4BOH and 99mTc-Sestamibi. K1 values of 99mTc-4BOH were prominently greater than those of 99mTc-Sestamibi (rest: 0.71±0.14 vs 0.38±0.06 mL·min-1·g-1, P<0.05; stress: 1.47±0.24 vs. 0.59±0.08 mL·min-1·g-1, P<0.05). K1 values of 99mTc-4BOH demonstrated a near-linear uptake, whereas 99mTc-Sestamibi plateaued especially during stress. Higher K1 values equipped 99mTc-4BOH better clinical potential for MBF quantification than 99mTc-Sestamibi. Consistently, heart uptake of 99mTc-4BOH in patients was much higher than that of 99mTc-Sestamibi. Moreover, heart/liver ratios of 99mTc-4BOH were higher than that of 99mTc-Sestamibi during the first 8 minutes post injection, which may contribute to excellent quality SPECT images of 99mTc-4BOH. ***Conclusion:*** 99mTc-4BOH exhibited not only faster heart uptake and higher K1 values than 99mTc-Sestamibi, but also more stable myocardial retention than 99mTc-Teboroxime. The primary clinical trial further demonstrated that 99mTc-4BOH is a promising radiotracer for MBF quantification for future clinical translation.

Unlocking the potential of imaging the low-density lipoprotein receptors in glioblastoma

I. Tworowska[1], *L. Flores[1], X. Qu[1], C. Malicet[2], P. Lecorche[2], R. Zielinski[3], E. Delpassand[1], J. Temsamani[2];*
[1]RadioMedix Inc., Houston, TX, UNITED STATES OF AMERICA, [2]Vect-Horus, Marseille Cedex 15, FRANCE, [3]MDAnderson, Houston, TX, UNITED STATES OF AMERICA.

Aim/Introduction: Overexpression of the low-density lipoprotein receptors (LDLR) in solid tumors has been linked to the poor prognosis of cancer. LDLRs mediate the transport of the endogenous ligands across the blood-brain barrier (BBB). We selected a library of radiolabeled peptide-conjugates, RMX-VH, with affinity to LDLR. These conjugates can serve as isotope delivery vectors capable of crossing the BBB in GBM. To improve the PK properties of RMX-VH, we have incorporated an albumin binder PIBA (4-p-iodophenyl) butyryl acid) to the conjugate. This study aimed to assess the potential of optimized 203Pb-DOTAM-peptide, RMX-VH-PIB, as a novel SPECT imaging agent of glioblastoma. ***Materials and Methods:*** The 203Pb-RMX-VH-PIB was labeled manually in 0.4M NH4OAC buffer pH=6.0. Ascorbate was used as a scavenger at 40mg/ml concentration. 203Pb was produced by UAB Cyclotron Facility, UA, in Birmingham. The radiochemical/ purity was analyzed using iTLC and radio/UV HPLC. SPECT images were captured using a gamma-eye camera (Bioemtech, Greece) at different times (1h, 2h, 3h, 24h, and 48h post-injection), followed by biodistribution studies. ***Results:*** Radiolabeling was carried out with RCY>98%. 203Pb-RMX-VH-PIB showed high radiolytic stability as monitored up to 24hours post-synthesis. SPECT studies indicated selective accumulation of the agent in U87MG xenografts as early as 1 h post-injection. 203Pb-RMX-VH-PIB demonstrated longer blood exposition. The optimal time for tumor accumulation was 24hours post-injection. The addition of the albumin-binding motif, PIBA, significantly increased blood circulation time and tumor accumulation compared to RMX-VH. The bioD studies demonstrated 6.2±1.8%ID/g tumor retention of the agent at 1h, which remained almost the same (5.8±0.3%ID/g) at the 3h and was reduced to 3.3±0.2%ID/g at the 24h. Liver accumulation remained at a similar level at all time points (6.6±0.7%ID/g at 1 hour, 8.2±1.3%ID/g, 2h, and almost unchanged at the 24h. The initial high blood pool of activity at 1h (8.7±0.7%ID/g) was reduced to 1.1±0.1%ID/g at the 24h. The bone marrow uptake was 1.2±0.7%ID/g at the early time point and reduced three-fold at 24hours, suggesting stable coordination of 203Pb. The renal retention of the agent was lower than that observed for RMX-VH without the albumin-binding motif. The tumor retention of radiolabeled RMX-VH-PIB was higher than RMX_VH conjugates with shorter blood circulation time, showing the advantages of structural modification with an albumin binding linker. ***Conclusion:*** Structural modification by incorporating PIBA (203Pb-RMX-VH-PIB) improved the LDLR-targeting properties of the conjugate. eIND study will include 68Ga/203Pb-RMX-VH with albumin binding linker for selecting LDLR(+) solid tumors (GBM and PDAC).

OP-597

Effects of remote ischemic conditioning on pigs with myocardial ischemic reperfusion injury evaluated by serially multi-target PET/CT molecular imaging and the underlying mechanisms

Y. Lu, *X. Zhang;*
Department of Nuclear Medicine, Beijing Anzhen Hospital, Capital Medical University, Beijing, CHINA.

Aim/Introduction: This study aims to dynamically to assess the effects and mechanisms of remote ischemic conditioning (RIC) on the myocardial ischemic reperfusion (MIR) porcine model through multi-target molecular imaging (myocardial perfusion, metabolism, inflammation, and fibroblast activation). ***Materials and Methods:*** MIR was established in 14 pigs (7 males; age: 6-8 months) and they were randomly divided into RIC group (n=7) and non-RIC group. RIC was performed in pigs by blood pressure inflation on the upper and lower limbs for 5 min period and 4 cycles immediately after MIR. A series of 99mTc-MIBI D-SPECT myocardial perfusion imaging, fasting 18F-FDG myocardial inflammatory imaging, and 18F-AlF-NOTA-FAPI imaging were performed longitudinally at the 3rd, 14th, 28th, 56th day after MIR. At the same time, biomarkers were serially tested.P value<0.05 was considered statistically significant. The correlation between imaging parameters and cardiac outcomes was analyzed. ***Results:*** Compared with the non-RIC group, RIC group exhibited significantly reduced infarct size (P<0.05). The RIC group also showed a significant increase in ΔLVEF and a significant decrease in ΔESV (P<0.05). At the acute phase, RIC group had significantly lower FAPI uptake intensity in the peri-infarct region [SUVmax: (5.39±1.55) vs. (8.26±2.26), P=0.014]; at the subacute phase, RIC group had significantly lower FDG uptake extent and intensity in the FDG+ area, infarct region, and peri-infarct compared with the non-RIC group (P<0.05). At both acute and subacute phases, bone marrow uptake in the RIC group was lower(P<0.05). Moreover, ΔIL-1β2w-3d in the RIC group was lower , while ΔIL-102w-3d was higher than that in the non-RIC group (P<0.05). Additionally,The extent and intensity of FAPI and FDG uptake at the acute phase were negatively correlated with cardiac function in the chronic phase and positively correlated with LV remodeling (P<0.05). Furthermore, we found that the changes of FAPI uptake intensity from 3 day to 2 week was positively correlated with ΔLVEF and negatively correlated with ΔESV at subacute and chronic phases, whereas the changes of FDG uptake intensity from 3 day to 2 week was negatively correlated with ΔLVEF and positively correlated with ΔESV at subacute and chronic phases (all P<0.05). ***Conclusion:*** RIC could reduce systemic inflammation at acute and subacute phase, attenuate fibrosis in the peri-infarct region at the acute phase, and cardiac inflammation in both infarct and peri-infarct region, ultimately resulting in a reduction in infarct size, improvement in cardiac function and reverse remodeling, which may provide a new therapeutic approach for MIRI.

OP-598

Molecular imaging of fibroblast activation protein in response to cardiac injury using [^{68}Ga]GaDATA^{5m}.SA.FAPi

V. Weissenböck[1], *X. Li[1], M. Schlederer[1], L. Weber[1], E. Acar[1], S. Baydar[1], A. Antunes Goncalves[1], J. Stanek[1], L. Breyer[1], F. Rösch[2], B. Podesser[1], L. Kenner[1], M. Hacker[1], A. Kiss[1], C. Philippe[1];*
[1]Medical University of Vienna, Vienna, AUSTRIA, [2]AIT Austrian Institute of Technology GmbH, Tulln, AUSTRIA.

Aim/Introduction: The fibroblast activation protein (FAP) has gained tremendous traction as a target for tumor imaging and cancer treatment, but is also involved in fibrosis. Increased FAP expression has been demonstrated in myofibroblasts during fibrogenesis, which predicts the quality of cardiac remodeling after myocardial infarction or other entities of heart failure. The aim of this study was to evaluate [68Ga]GaDATA5m.SA.FAPi for PET imaging in regards to replacement or interstitial fibrosis due to myocardial infarction (MI) and pressure overload-induced hypertrophy in mice (TAC), respectively. ***Materials and Methods:*** [68Ga]GaDATA5m.SA.FAPi was manually produced. Myocardial infarction was induced by a permanent ligation of the left anterior descending coronary artery in male adult C57BL/6 mice (MI group). For pressure overload-induced cardiac remodeling, mice underwent a surgery for constriction of the transverse aorta (TAC group). Sham-operated animals served as controls. One, two, six and 12 weeks after surgery, [68Ga]GaDATA5m.SA.FAPi was injected i.v. into the anesthetized mice and after 45 min of tracer distribution (under isoflurane anesthesia) a static PET/CT scan (10 min PET+5 min CT) was conducted. Subsequently, mice were sacrificed and hearts were harvested for assessment of total radioactivity followed by ex vivo autoradiography and immunohistochemistry (IHC). Hypertrophy simulating cell uptake was assessed in isolated human ventricular cardiac fibroblasts cell culture experiments (high-stretched 18-20%/low-stretched 2-3%). ***Results:*** Cardiac uptake was highly significantly (p=0.002) increased two weeks after MI induction (MI: 2.1±0.2%ID/g (n=7) vs. SHAM: 1.1±0.2%ID/g (n=5)), also confirmed by ex vivo autoradiography. This confirms the replacement fibrosis within the infarcted area in the sub-acute phase of adverse post MI remodeling. No significant difference in [68Ga]GaDATA5m.SA.FAPi uptake was found at six weeks after surgery (MI: 1.1±0.1%ID/g (n=4) vs. SHAM: 0.8±0.0%ID/g (n=3)), indicating the completion of infarct healing. In contrast, cardiac uptake increased significantly (p=0.0110) in the TAC vs. SHAM mice after 6 weeks (TAC: 1.8±0.2%ID/g (n=6)) due to progressive hypertrophy and fibrosis. In line with that, high-stretched cardiac fibroblasts showed a higher uptake compared to low-stretched conditioned ones. IHC confirmed the expression of FAP in cardiac tissue in both models. ***Conclusion:*** This study for the first time demonstrated the efficacy of [68Ga]GaDATA5m.SA.FAPi for longitudinal imaging of cardiac fibrosis in response to different injury in mice. In vivo imaging of FAP during cardiac remodeling might be a promising target for diagnosis and prognosis of disease progression and could aid clinical management of patients.

Image guided robotics: Hybrid sensory enrichment as means to extend surgical workflows with robotic-SPECT and - Fluorescence Molecular Tomography

L. J. Slof[1], *M. N. van Oosterom[1], S. I. van Leeuwen[1], S. Azargoshasb[1], A. Berrens[2], K. H. M. Houwing[1], H. G. van der Poel[2], F. W. B. van Leeuwen[1];*
[1]LUMC (Leiden University Medical Center), Leiden, NETHERLANDS, [2]AVL (Antoni van Leeuwenhoek), Amsterdam, NETHERLANDS.

Aim/Introduction: Accurate assessment of the surgical environment and the targets therein sets the stage for precision surgery. Target visualization can be facilitated via intraoperative molecular imaging e.g. making use of surgery dedicated hybrid tracers that combine radioactive and fluorescent emissions. The emergence of such tracers during minimally invasive robotic surgery has created a need for matching sensory hardware, so-called 'smart' instruments. By converting the steerable surgical

instruments to sensory devices themselves, it becomes possible to employ the robots dexterity for the enhancement of the environmental perception. Here, we present a hybrid detector, that put both radioactive- (99mTc) and fluorescent- (ICG) sensing at the surgeons 'fingertips'. ***Materials and Methods:*** To transfer hybrid sensory experiences to the ProGrasp robotic forceps, a hybrid Click-On detector was designed. The prototype, which includes markers for video-tracking, was build using 3D printing and precision multi-axis machining (3-axis turning methodologies). Using custom computer-vision algorithms the two sensory read-outs were coupled to the probe positions. When combined with a look-up table and Maximum-Likelihood Expectation-Maximization (MLEM) reconstruction methods this allowed for the creation of 3D SPECT and fluorescence molecular tomography (FMT) scans. Following initial sensitivity evaluations in the lab, the prototype was used to evaluate 17 tissue specimens (lymph nodes and prostate) from 7 prostate cancer patients undergoing ICG-99mTc-nanoscan guided prostatectomy and lymph node dissections. Handheld gamma probe tracing and laparoscopic fluorescence imaging were used as reference. ***Results:*** The Click-On functionalized ProGrasp instrument preserves the instruments grasping function while complementing it with autonomous, 6-degree-of-freedom, bi-modal molecular sensing at the robotic instrument tip. Sensitivity of the newly developed hybrid modality allowed for detection of 99mTc- (>10^-4 MBq) and ICG-emissions (>10^-6 mg/mL). Analysis of surgical specimens confirmed both readouts were compatible with real-life ICG-99mTc-nanoscan signal intensities. Robotic-SPECT and -FMT scans helped convert the sensory readouts to a visible image. These images and could in turn be used to augment the laparoscopic view. The findings of the new 'robotic imaging' techniques aligned well with the reference measurements of handheld obtained using the gamma probe and fluorescence endoscope. ***Conclusion:*** With the new Click-On modality, a first step towards 'fingertip' radio- and fluorescence-sensing by surgical instruments has been realized. Hereby the sensory read-out sets the stage for unique new robotic tomographic molecular imaging solutions, that help enhance the surgical experience.

First Measurements with On-Chip PET Detectors

C. Clement[1], *F. Pagano[2,3], M. Pizzichemi[2,3], G. Terragni[2,4], M. Kruithof-De Julio[1], S. Ziegler[5], A. Rominger[1], E. Auffray[2], K. Shi[1]; [1]Inselspital, Universitätsspital Bern, Bern, SWITZERLAND, [2]CERN, Geneva, SWITZERLAND, [3]University of Milano-Bicocca, Milan, ITALY, [4]Technical University of Vienna, Vienna, AUSTRIA, [5]LMU Klinikum, University Hospital Munich, Munich, GERMANY.*

Aim/Introduction: We previously introduced a dedicated On-Chip PET scanner designed for functional imaging of Organs-on-Chips (OOCs). OOCs aim to provide an alternative to conventional in vitro and animal models for drug development, disease modeling, and toxicity testing. Up to now, we have enhanced the system design using Monte-Carlo simulations and implemented a deep learning-based positron range correction algorithm. This study presents the initial real-world measurements using the On-Chip PET scanner. ***Materials and Methods:*** The first version of the On-Chip PET system comprises two detectors, each consisting of a monolithic LYSO crystal measuring 50 mm x 50 mm x 15 mm. The back surface of each crystal is optically coupled to four Hamamatsu S14161 3 mm 8 x 8 SiPM arrays. The readout electronics utilize PETsys Electronics' SiPM readout system, which includes four front-end modules each connected to two SiPM arrays, and one FEB/D board that processes a total of 512 channels. The assembly of the two detectors and the front-end modules is secured within custom 3D-printed housings, positioned on top of each other with an adjustable gap of currently 10 mm between them. A Na-22 370 kBq point source was placed between the two detectors during data acquisition. Additionally, we developed a 3D-printable phantom, modeled on a commercially available OOC device with multiple compartments connected by microfluidic channels. This OOC phantom allows for comparison of Monte Carlo simulation results with actual measurements. ***Results:*** After completing the ASIC calibration, which included adjusting discriminators, time-to-digital converters, and charge integrators, we conducted several data acquisitions with the point source positioned in the middle and at the four corners of the field of view of the detector for 60 seconds each. Each data acquisition recorded approximately 25 million single events. Analysis of constructed flood maps and energy spectra from these single events revealed distributions consistent with expected variations based on the source's positioning. ***Conclusion:*** These preliminary measurements using the dedicated On-Chip PET scanner confirm the functionality of the design and mark the first step towards enabling functional imaging for OOCs. Next steps will focus on measurements using the OOC phantom, prior to imaging actual OOC devices.
