1. X-ray photoemission spectra

Pure ceria and Cu doped CeO₂ were characterized right after the deposition on MgO by in situ XPS using Al K α photons. In this work, the Ce³⁺ concentration has been estimated by fitting the Ce 3d XPS lines with Ce³⁺- and Ce⁴⁺-related components, following the procedure introduced by Skala et al.¹. From the results of the fitting procedure – shown together with the spectra in Figure S3 – 100% of Ce ions are in the Ce⁴⁺ state for all films.

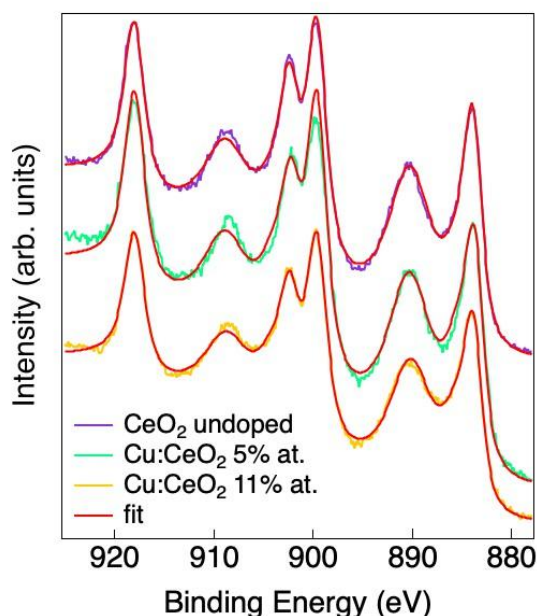

Figure S1 Ce 3d XPS spectra of the measured samples. The red curves in b) are the results of the fitting procedure

2. Reference NEXAFS spectra

The reference Ce M_{4,5} spectra on CeO₂ and Ce₂O₃ were obtained on commercial powders from Umicore and measured after controlled oxidation and reduction cycles in the reaction cell. The Cu L₃ reference spectra were measured in the same reaction cell at the APE-HE beamline from commercial CuO, Cu₂O, and Cu powders purchased by Sigma-Aldrich.

Figure S2 Reference spectra measured for a) CeO_2 and Ce_2O_3 and b) Cu , CuO , and Cu_2O

3. micro-GC signal from pure CeO_2

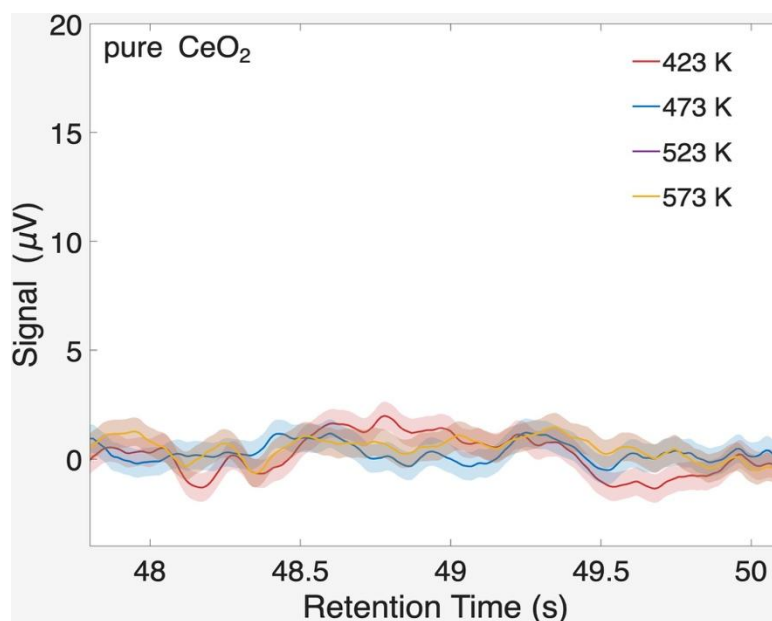

Figure S3 H_2 micro-GC signal as a function of time for the pure ceria film
