Magnetic data storage systems are based on thin magnetic layers and heterostructures. For improving the functionality of existing devices and to develop new ones, a deep understanding of the properties of these layers and the coupling between them is essential. In this context not only the classic room temperature ferromagnets are of interest but also elements which can be polarised, like e.g. Pd, in which induced magnetism is observed when it is brought into contact with Fe. To monitor the structural and magnetic properties during the deposition process, *in-situ* polarised neutron reflectometry (PNR) is used as a novel analysis technique. These PNR experiments were carried out at the neutron reflectometer AMOR at PSI (Switzerland) using the Selene focusing optics to reduce measurement times.
In this contribution the evolution of the magnetism in polycrystalline Pd/Fe/Pd systems during its growth process will be presented. For only one monolayer of Fe deposited onto an initial Pd layer a high induced magnetic moment of approximately $1\mu_B$ was found in the Pd at the interface whereas the magnetic moment of the Fe is small compared to its bulk value. With more Pd deposited on top of the Fe layer, the magnetic moment of Fe increases while the induced magnetism in Pd decreases. An induced magnetisation of Pd was observed for a region of 7.5 Å on both sides of the Fe layer. The magnetic moment in Pd decreases with increasing distance from the Fe/Pd interface.

Mo.H-P101 - MAGNETIC PROPERTIES OF Fe-N THIN FILMS

Iron nitride films are good candidates for spintronic applications due to their high magnetization, expected large spin polarization and chemical stability, combined with the ability to form sharp interfaces with semiconducting nitrides. In this work, Fe-N thin films were deposited by reactive sputtering in Ar+N2 mixtures aiming at the production of cubic Fe4N. In a first study both cubic Fe4N and/or hexagonal Fe3+xN ferromagnetic nitride films were obtained depending on the nitrogen concentration during growth. Since the production of the cubic nitride was intended, the nitrogen fraction in the mixture was fixed at 10% and 15% and two series of films were produced. Substrates with different crystalline structures (TiO2, MgO and Al2O3) and specific orientations were selected to allow anisotropic induced strains. Ferromagnetic Fe4N cubic films were obtained with good crystallinity, saturation magnetization values above 1.6 Bohr magneton per Fe ion and magnetic anisotropy correlated with the strain induced by the substrate.

Mo.H-P102 - Tantalium-mediated Epitaxial Crystallization of Fe_3O_4 Films

T. Hee Kim[1], J. Hyun Gook[1], N. Jong Lee[1], Y. Jeong Bae[1], A. Michel[2]

1. Ewha Womans University, Seoul, South Korea
2. CNRS - Universite de Poitiers – ENSMA, Poitiers, France

The mixed valence of magnetite (Fe_3O_4) possesses several interesting and useful properties including ferrimagnetism with a high Curie temperature of 850°C and redox surface chemistry, while band structure calculations predict room-temperature half-metallicity[1].
In this work, Ta-mediated crystallization in Fe_3O_4 thin films was investigated for its successful implementation into spintronic devices. Beyond unetched Si wafers, room temperature (RT) deposition of 5nm Ta/5nm MgO/30nm Fe_3O_4 trilayers was performed by rf-sputtering and followed by post-annealing for 1 hour under vacuum at various tempaeratures from 300°C to 500°C. After post-annealing at 450 °C. stabilization of the thin epitaxial magnetite (001) phase was observed by using X-ray diffractometry and reflectometry measurements and vibrating sample magnetometer. Moreover, the temperature dependence of resistivity showed a hallark feature of magnetite, the Verway transition at around 120 K. We focussd on the comparative study of the underlayer effects on structural and magnetic properties of sputtered Fe_3O_4 films. The effect of a Ta underlayer on the crystalization of magnetite film grown directly on SiO_2 is considerably stong. For the Fe_3O_4 films deposited on both MgO(001) and SiO_2 surface without the Ta underlayer, the structural and magnetic properties of polycrystalline Fe_3O_4 films were seen, revealing only the diffraction peak of the (311) family of Fe_3O_4 planes. Our results indicate that the 5 nm thick Ta inserted between the adjacent MgO and SiO_2 layers is effective in improving the texture and the roughness of Fe_3O_4 through the crystallization process of MgO and Ta after annealing. The surface properties also play an important role in the process of Ta metal-induced crystallization of Fe_3O_4. Ta metal acts as a nucleating agent for the crystallization of Fe_3O_4.

Multilayer Giant Magnetoresistance (GMR) films are a core constituent of magnetoresistive sensor devices. In order to achieve optimal performance the film structure and properties the film must be carefully tailored and often unresolved performance issues remain. One of the more challenging issues to resolve through conventional transport and magnetometry measurements is the optimization of the RKKY coupling throughout the multilayer. We demonstrate the use of Polarized Neutron Reflectometry (PNR), while not an unfamiliar tool to understanding GMR and RKKY coupling in multilayers, to observe and understand the magnetic coupling in GMR multilayers and optimize the material properties. The film under study is a Ta/Py/[Cu/Py/Cu/CoFe]4/Cu/Ta multilayer grown by DC magnetron sputtering deposition. PNR results show significant rotation of the magnetization of the magnetic layers near the Ta/Py seed layer while the layers near have a good antiferromagnetic coupling consistent with strong 2nd order RKKY coupling. The rotation can be attributed to the Py portion of the seed layer being magnetically relaxed resulting in a tilting of the active layers' magnetization from a biquadratic-like coupling. Two approaches were then used in an attempt to improve the coupling. First, the copper layer separating the seed and active layers was thickened. This notably improved the GMR, but at the expense of a disproportionately reduced sheet resistance. Second, we substituted the Py seed for a compatible non-magnetic 5 nm Ruthenium also augments the GMR, indicating improved coupling and has the advantage of maintaining the proper resistivity. Thickening of the Ru layer to 10 nm reduces the multilayer performance and is likely due to the formation of (111) texturing.

Mo.H-P105 - The effect of Ta buffer layer on the microstructure, roughness and dead layer of CoFeB/MgO systems

J. Kanak[1], J. Wrona[1,3], M. Banasik[1], A. Zywczak[2], W. Powroznik[1], M. Czapkiewicz[1], T. Stobiecki[1]

3. Singulus Technologies AG, Kahl am Main, Germany

In this work we discuss structural and magnetic properties of samples with different thickness of Ta seed-buffer layer. Samples with structure: Ta (5, 10, 15) nm / wedge $Co_{40}Fe_{40}B_{20}$ 0.8-2.9 nm / MgO 5 nm/ Ta 3 nm were deposited on thermally oxidized Si(001) substrates and then annealed at 330°C for 20 min using Singulus Timaris PVD Cluster Tool system. The microstructure of the layers was characterized by x-ray diffraction (XRD) θ-2θ, rocking curve and x-ray reflectivity measurements. Topography of the samples was investigated using an atomic force microscopy. The magnetic moment and effective anisotropy were determined from vibrating sample magnetometer (VSM) measurements.
XRD analysis shows that Ta in buffers has grown in amorphous phase or disoriented β structure and MgO has grown with highly (001)-oriented texture. Rocking curves measured at position MgO (200) exhibit changes depending on Ta buffer layer thickness. By comparing the full widths at half maximum (FWHM) obtained from rocking curve profiles fits, it was found that the strongest MgO texture was for buffer Ta 5 nm and it decreased successively with increasing of Ta thickness. The smallest buffer roughness was for Ta 5 nm thick and then increased with the thickness of Ta.
From the magnetic moment per unit area as a function of CoFeB layer the magnetic dead layer thickness was determined. It was found that the thickest dead layer was for the smoothest buffer Ta 5 nm while for the roughest buffer Ta 15 nm the dead layer was the thinnest.

Project was financed by the Polish National Science Center Grant DEC-2012/05/E/ST7/00240. T.S. acknowledges Swiss Contribution by NANOSPIN PSPB-045/2010 grant.

Mo.H-P106 - Growth and characterisation studies of the metamagnet Eu3O4 Thin Films Grown on Si and Graphene

R. Aboljadayel[1], G. Cheglakov[1], A. Ionescu[1], J. Rackham[1], C. Cimorra[1], P. Monteiro[1], D. Love[1], C. Barnes[1]

1. TFM Group, Cavendish Laboratory, University of Cambridge, Cambridge, United Kingdom

Trieuropium tetroxide (Eu3O4) is a mixed-valence compound of Eu2+ and Eu3+ ions. Eu3O4 has an antiferromagnetic arrangement below 5 K and shows a metamagnetic behaviour in low magnetic fields, below the Néel temperature (TN) [1]. The magnetic properties of this compound are determined mainly by the Eu3+, which has a high magnetic moment in comparison to Eu2+. This characteristic behaviour may be attributed to the interaction of 4f electrons with the conduction band which results in unique magnetic, structural and thermal properties [2]. Graphene is a promising material for spintronics applications due to its desirable properties such as its long spin-diffusion length and high electron mobility. So far no study on the Eu3O4/graphene system has been reported and this may well be due to the difficulty of growing Eu3O4, which is the unstable high temperature phase of Eu-oxides. Therefore, growing a single crystalline Eu3O4 and investigating the interface of this system would provide a fundamental understanding on the exchange coupling between a metamagnet and graphene. In this study, 25 nm Eu3O4 thick films were grown on Si/SiO2 substrates and on graphene sheets by molecular beam epitaxy and capped with 5 nm of Au. Eu was deposited at high temperatures (300-600 °C) in an oxygen flux. The growth parameters such as the oxygen partial pressure, temperature and deposition rate were optimised to achieve a single crystalline Eu3O4 phase. The effect of the deposition conditions on the crystallinity of the films was studied by X-ray diffraction and reflection, where SQUID magnetometry was used to study their magnetic properties. The results show a successful growth of a crystalline, highly textured Eu3O4 (100) films with a Curie temperature of 5 K, which is in agreement with the value reported in [3]. This represents the first successful step towards integrating a metamagnetic “switch” in two widely used electronic substrates.

Nowadays, an interest in the study of MCE in materials with reduced dimensions has grown in order to produce miniaturized devices. For refrigeration systems based on magnetocaloric thin films it becomes necessary to study the influence of thermal cycles in order to simulate their behavior in a real device. In this work we investigated the influence of the thermal cycling of a $Gd_5Si_{1.3}Ge_{2.7}$ thin film on its microstructure, magnetic phase transition and magnetic entropy value. This thin film was deposited on a SiO_2-covered Si substrate by a femtosecond pulsed laser. This study was performed by immersing the thin film in liquid nitrogen up to 450 cycles. In each cycle, the film was immersed in a bath for 30-60 seconds in order to ensure thermal equilibrium with the bath and then removed to rest in air, for 60 seconds. The magnetization curves show two magnetic transitions, one of first and other of second order. It is observed that the thermal cycling does not affect the high temperature (249 K) magnetic transition, whereas the lower temperature (197 K), which corresponds to a magnetostructural transition (MST), shows major differences. In fact, there is a clear decrease (16%) on the thermal hysteresis after the 450 cycles, showing a change on the phase transition dynamics. This decrease in the hysteresis occurs because of the reduction of the amount of phase undergoing the MST. Consequently this decrease of the MST affects the magnetocaloric effect. Hence, the thermal cycling causes a 19% decrease of the MCE peak value ($-DSm_{max}$ occurs at 193 K) because of the O(II) phase arresting. This phase is arrested due to the strong strain fields that are created after consecutive MST. Nonetheless, the MCE value shows a tendency to stabilize and reach an equilibrium state, which is crucial for future applications.

Mo.H-P108 - Magnetic percolation in Co/Ag multilayers grown by molecular beam epitaxy

We have fabricated, by molecular beam epitaxy, multi-layered (Cox/Auy)z/MgO samples (x and y give the number of nominal Co and Ag monolayers per period,respectively, and z gives the number of period repetitions). The total number of Comonolayers was kept constant at x * z = 32, whereas y varied from 4 up to 16 which resulted in a variation of the Co nominal volume concentration, given by XCo = x/(x + y), from 0.06 up to 0.72. The structure and periods pile up of the samples were examined by using x-rays (reflectometry, rocking curves and wide angle diffraction), whereas their morphology was investigated by means of transmission electron microscopy.From the x-rays data we concluded about the coherence of the structure along the direction perpendicular to the plane of the deposits. The results obtained from the transmission microscopy evidenced the presence of close-to-monodisperse Co clusters (having an average diameter of ca. 1.5 nm) in the samples having XCo values below 0.14, progressively percolating into continuous Co layers with the increase of the nominal Co volume concentration. The hysteretic properties of the samples were measured in the temperature range from 5 up to 290 K by using a vibrating sample magnetometer under in-plane fields of up to 6 T. The corresponding data allowed us to evaluate the Co concentration dependence of the temperatures below which hysteresis was measurable in the different samples (e.g.: the samples with XCo > 0.3 magnetically percolate at room temperature). Correlation of the low concentration hysteretic behaviour with the morphology data suggests that the global samples behaviour cannot be simply ascribed to a canonical superparamagnetic behaviour.

Mo.I-P01 - Influence of the seed layer on the exchange spring coupling of the NiFe/IrMn/Co trilayer

I. Castro Merino[1], V. Pedruzzi Nascimento[2], E. Passamani Caetano[3], E. Baggio Saitovitch[4]

1. Centro Brasileiro de Pesquisas Físicas-CBPF, Rio de Janeiro, Brazil
2. Universidade Federal do Espírito Santo-UFES, Vitória, Espírito Santo, Brazil
3. Universidade Federal do Espírito Santo-UFES, Vitória, Espírito Santo, Brazil
4. Centro Brasileiro de Pesquisas Físicas-CBPF, Rio de Janeiro, Brazil

A systematic investigation, through structural and magnetic characterizations, is discussed regarding the influence of the crystallographic texture on the Exchange Spring observed in the NiFe/IrMn/Co trilayer grown on different seed layers (Cu or Ta) deposited at room temperature with Magnetron Sputtering technique. Using X-ray diffraction, it was shown that Ta and Cu seed layers provoke different degrees of (111) fcc-texture that directly affect the exchange bias and indirectly modify the exchange spring coupling behavior. Combining results from the combination of DC magnetization and ferromagnetic resonance techniques, performed at room temperature, it is provided a planar magnetic anisotropy and an understanding of the Exchange Bias and the Exchange Spring effects in NiFe/IrMn/Co heterostructures. DC magnetization data suggest that the Exchange Spring exists before the field cooling protocol. The Exchange Spring phenomenon was shown to be strongly dependent on the degree of [111] texture in the IrMn layer, which is, in turn, dependent on the seed layer deposited on Si(100) substrate. It has also been demonstrated, a posteriori, that a field cooling of 10 Oe is sufficient to set the Exchange Bias effect on both interfaces (NiFe/IrMn and IrMn/Co). In addition, it was observed that the highest Exchange Bias field occurs when an unstressed L12 IrMn structure is stabilized at 6-8 nm IrMn thickness intervals. Increasing the IrMn thickness, it was observed that the coupling angle between the Co and NiFe ferromagnetic layers increases for the Cu seed system, but it reduces for the Ta case. The results were explained considering: (i) different anisotropies of the Co and IrMn layers induced by the [111] texture and (ii) distinct Exchange Bias field in NiFe/IrMn and IrMn/Co interfaces in both systems. It was shown that the coupling angle is strongly correlated by both Exchange Bias and Exchange Spring effects.

Mo.I-P02 - Exchange bias induced at a Co2FeAl0.5Si0.5 /Cr interface

N. T. Chris Yu[1], A. Vick[1], N. Inami[2], K. Ono[2], A. Hirohata[3]

2. Institute of Materials Structure Science
3. Department of Electronics, University of York, Heslington, England, United Kingdom

Four sets of epitaxial thin films were grown on MgO(110) substrates by an UHV molecular beam epitaxy (MBE) system. All samples have the structure of Cr (3nm)/Ag (30nm)/[CFAS (1nm-4nm)/Cr (0.9nm)]3/MgO (3nm). An antiferromagnetic exchange coupling at the Cr/Co2FeAl0.5Si0.5 interface was achieved when the structure was even in the as deposited state. Owing to lattice mismatch, Cr lattices were stretched on the Heusler layer and induce an exchange coupling to the interfacial moments in the Heusler alloy layer [1]. Virbrating sample magnetometry was used for the magnetic measurement at room temperature. CFAS has been reported to be cubic to exhibit fourfold magnetic anisotropy [2]. However, it only shows uniaxial anisotropy in the thinner region which is not consistent with the theory but similar to ultrathin Fe film by lattice mismatch [3]. For 2 nm thick Heusler alloy sample, the magnetic anisotropy is found to be the maximum and it is tilted to 30° from the MgO[110] axis. This minor tilt agrees with the X-ray diffraction (XRD) result. The largest value of squareness (Mr/Ms) is 0.98 and the smallest Mr/Ms is 0.34 in 2 nm of Heusler alloy layers sample. By varying the thickness of both Cr and CFAS, Ms and Hc vary from 690 to 1060 emu/cm3 and 6 to 10 Oe, respectively. As the thickness of the Heusler alloy layer increases above 3 nm, Hc is found to decrease, which is the result of emerging bulk-like properties of the Heusler-alloy layers. These results indicate that the magnetic properties of the Heusler alloy films can be controlled by tuning the lattice matching.

Exchange bias of a magnitude of up to 65 KOe has been observed in members of a family of doped orthoferrites $La_{1-x}Sr_xFe_{1-y}My_{O3.0-\delta}$ (where M = transition metal and $\delta \approx 0$) which is ascribed to the kinetic arrest of ferromagnetic clusters embedded in the antiferromagnetic matrix. The origin of these clusters is partly due to the disproportionation of the Fe(IV) sites in the lattice.

Mo.I-P04 - Independently tuning the interfacial and bulk contributions to exchange bias for ferromagnetic / (antiferromagnetic) thin films with (IrMn/Pt/FeMn) based composite antiferromagnets

L. Frangou[1,2,3], K. Akmaldinov[1,2,3,4], Cl. Ducruet[4], I. Joumard[1,2,3], B. Dieny[1,2,3], V. Baltz[1,2,3]

Spintronics devices require a wide range of ferromagnetic/antiferromagnetic (F/AF) exchange bias properties and subsequently of AF materials. For example, the reference layer of thermally assisted magnetic random access memories (TA-MRAM) requires high blocking (TB) and Néel temperatures (TN). In contrast, for the storage layer, mostly moderate TB,N are needed [1]. Tunability of TB,N by adjusting the thermal stability of the AF bulk is thus desirable to minimize the write power consumption (related to TN) while insuring proper data retention (related to TB) on the device temperature operating range [2]. In addition to that, low-freezing spins behave like spin-glasses at the F/AF interface. Their random spread over the sheet film contributes to the bit-cell dispersion of exchange bias properties once the sheet film is processed into a functional MRAM chip. Mastering the quality of the F/AF interface is another issue to deal with in parallel. Here, the interfacial and bulk exchange bias properties were studied for (IrMn/Pt/FeMn) and (FeMn/Pt/IrMn) AFs, where the thicknesses of the IrMn and FeMn layers were varied. The F/AF magnetic interfacial qualities and the AF grains' thermal stability were probed via measurements of the low- and high-temperature contributions to the blocking-temperature distributions, respectively. For such F/AF bilayers with composite AFs, we observed that it was possible to tune independently the interfacial and bulk contributions to exchange bias.

Self-assembly of colloidal microspheres or nanospheres has been proven an effective strategy for bottom-up fabrication of ordered nanostructures. It is therefore suitable for the fabrication of model exchange biasing systems where precise control of microstructure is desirable [1-3]. In this work we present a study of exchange biasing phenomena in sputtered cobalt oxide/cobalt bilayers that have been nanostructured by using polystyrene spheres (970nm and 170nm) both as a template for the deposition of nanocaps and as a mask for the formation of triangular-like islands (330nm and 60nm respectively). Cobalt layers 30nm thick have been magnetron sputtered deposited and subsequently oxidized by prolonged heat treatment at 8000C in O2 atmosphere to form a 15nm thick CoO layer. Upon field cooling under 30kOe, the nanocaps show coercivity HC =1kOe and exchange biasing Hex=0.4 to 0.6 kOe that does not depend sensitively on the size compared to HC =0.1 kOe and Hex=0.27 kOe of a continuous film prepared under the same conditions. The nano-islands show Hc =1kOe and Hex=0.37 kOe only for the smaller size. The HC and Hex values correlate well with blocking temperatures estimated by magnetization vs temperature measurements. Mn_3Ir is an antiferromagnetic material widely used in spin valve structure. Mn_3Ir has attractive properties of large exchange bias field and high blocking temperature. However, the high price and the scarcity of Ir are crucial problems. Antiferromagnetic Hesuler alloys are promising materials for the replacement of Mn_3Ir. There have been only a few reports to date about the exchange bias properties of antiferromagnetic Heusler alloys[1]. In this study, we have focused on Ni_2MnAl with a comparatively high Néel temperature, and structural, transport and magnetic properties of epitaxially grown Ni_2MnAl/*X* bilayers (*X*: Fe, Co, Co_2MnSi) have been investigated systematically.

Ni_2MnAl films with a thickness of 100 nm were prepared on MgO (100) single crystal substrates with different growth temperatures from RT to 600 ˚C by magnetron sputtering. A ferromagnetic *X* layer of 3 nm was deposited on the Ni_2MnAl film. The structural, transport and magnetic properties were measured by using a x-ray diffractometer, van der Pauw technique and a superconducting quantum interference device, respectively.

*B*2-ordered Ni_2MnAl (100) films were successfully grown on MgO (100) substrates. The temperature dependence of the electrical resistivity showed an anomaly at a temperature, which was varied from 220 to 300 K depending on the growth temperature of the film. The anomaly is considered to correspond to the Néel temperature. Loop shifts by exchange bias were observed in the magnetization curves at 10 K for Ni_2MnAl/*X* bilayers. Interfacial exchange coupling energy density for *X* = Co_2MnSi, Fe was deduced to be 0.03 erg/cm^2 that was higher than those for *X* = Co (0.015 erg/cm^2), which implies better lattice matching causes higher J_k.

This work was supported by HARFIR (SICORP-EU) from the JST, and is a cooperative program (No. 14G0412) of the CRDAM-IMR, Tohoku University.

The exchange bias effect has drawn significant research interest due to its potential in enabling current applications such as read/write heads, and future electric-field-control-based devices [1,2]. Previously, we have shown the in- and out-of-plane (applied magnetic field relative to substrate) exchange bias effects in NiFe/Cr-oxide bilayers [3]. To further study the implications of the upper limit of oxygen incorporation into Cr-oxide layers during deposition, as well as the effects that annealing the Cr-oxide layers can have on the magnetic properties, NiFe (~ 10 nm)/Cr-oxide (~ 15 nm) bilayers with oxygen content up to 41%O2/Ar in the Cr-oxide layer were fabricated. While these films exhibited soft magnetic properties at room temperature, an enhanced coercive (Hc) and exchange bias field (Hex) were observed at 10 K after a 10 kOe field-cooling (FC) process from 400 K. In addition, Hex values were found to increase for films with increasing deposited oxygen content, from Hex ~ -50 Oe for 30%O2/Ar, to Hex ~ -75 Oe for 41%O2/Ar. In contrast, with annealing, a decreased Hex (~ -25 Oe) for the NiFe/annealed Cr-oxide bilayers are attributed to a structural phase transition from AF Cr2O3 to Cr3O4, as determined by electron diffraction patterns and x-ray photoelectron spectroscopy. The temperature dependent low-field magnetization (M(T)) of the NiFe/Cr-oxide bilayers under FC and ZFC processes was characterized also. The different oxygen contents of the Cr-oxide layers played an important role in affecting the magnetization of ferromagnetic NiFe crystallites, as revealed by an alteration of the irreversibility temperatures (Tirr) and differences in M(T). Furthermore, the Tirr as well as alterations of Hex in NiFe/Cr-oxide bilayer deposited on Al2O3(0001) substrates imply changes in spin structures by using single crystalline substrates.

Mo.I-P08 - Dependence of the interfacial coupling in FeMn/NiFe/Cu/Co spin valves on the thickness of the Cu spacer

M. Sousa[1], P. Barreto[1], F. Pelegrini[2], E. Baggio-Saitovitch[1]

1. Centro Brasileiro de Pesquisas Físicas, Rio de Janeiro, Brazil

The Ferromagnetic Resonance (FMR) technique was used to study the magnetic properties of Si(100)/Cu(20nm)/FeMn(40nm)/NiFe(5nm)/Cu(t)/Co(5nm)/Ta(10nm) spin valves with thickness of the Cu layer varying in the range 1-10 nm. The samples studied were produced using the magnetron sputtering technique, under constant Ar working pressure of 3 x 10-3 Torr and in the presence of an applied field of 400 Oe in order to set the unidirectional anisotropy. The FMR experiments were done at room temperature using a high sensitivity Bruker ESP-300 spectrometer operating at the X-band microwave frequency, with swept static magnetic field and the usual modulation and phase sensitive detection techniques. The in-plane angular variations of the absorption fields reveal the presence of uniaxial and unidirectional anisotropies in the samples. For the NiFe resonance mode, the effect of the interfacial coupling (exchange bias) at the FeMn/NiFe interface, is much higher than that due to the uniaxial anisotropy; for the Co resonance mode, only the effect of the uniaxial anisotropy is present. The anisotropy parameters were deduced from the experiments by assuming the formation of planar domains in the antiferromagnetic layer and a coherent rotation of the ferromagnetic magnetization. The exchange coupling field increases approximately linearly with the Cu thickness. Since the samples differ only by the thickness of the Cu spacer, this may be associated with the magnetic coupling between the NiFe and Co magnetizations mediated by the Cu layer, implying that the magnetostatic orange peel coupling is dominant in the system.

Mo.I-P09 - Photo-control of exchange bias in BiFeO3/La2/3Sr1/3MnO3 thin films

J. Jung[1], K. Sung[1], T. Lee[1]

1. Inha University, Incheon, South Korea

To date, electric fields have been widely used to control the magnetic properties of BiFeO3-based antiferromagnet/ferromagnet heterostructures through application of an exchange bias. To extend the applicability of exchange bias, however, an alternative mechanism to electric fields is required. Here, we report the photo-control of exchange bias in BiFeO3/La2/3Sr1/3MnO3 thin films on an SrTiO3 substrate. Through an ex-situ pulsed laser deposition technique, we successfully synthesized epitaxial BiFeO3/La2/3Sr1/3MnO3 thin films on SrTiO3 substrates. By measuring magnetoresistance under light illumination, we investigated the effect of light illumination on resistance, exchange bias, and coercive field in BiFeO3/La2/3Sr1/3MnO3 thin films. After illumination of red and blue lights, the exchange bias was sharply reduced compared to that measured in the dark. With increasing light intensity, the exchange bias under red and blue lights initially decreased to zero and then appeared again. It is possible to reasonably explain these behaviors by considering photo-injection from SrTiO3 and the photo-conductivity of La2/3Sr1/3MnO3. This study may provide a fundamental understanding of the mechanism underlying photo-controlled exchange bias, which is significant for the development of new functional spintronic devices.

Mo.I-P10 - Angular dependent FORC studies on FeMn/Co exchange bias systems utilizing the magneto-optical Kerr effect

M. Schmidt[1], J. Gräfe[1], G. Schütz[1], E. Goering[1]

1. Max Planck Institute For Intelligent Systems, Stuttgart, Germany

First order reversal curves (FORC) are a powerful method for magnetic sample characterization, separating all magnetic states of an investigated system according to their coercivity and internal interactions. A so called FORC distribution is calculated from a set of minor loops with appropriate reversal fields and displayed as a contour plot [1]. In our contribution, we will describe our approach for applying the MOKE technique to FORC measurements [2]. As an example of the application of MOKE-FORC complementary to conventional hysteresis measurements, we will present here angular dependent studies of two epitaxial FeMn/Co exchange bias (EB) systems with different crystalline orientations ((100) and (111)). With FORC, a clear difference in the magnetic characteristics of both sample types could be identified. The (100)-oriented sample exhibits an asymmetric switching mechanism regarding the ascending and descending hysteresis branches. Distinct influences of the crystalline anisotropy could be identified since also multiple reversal steps via the systems easy-axes were found, resulting in a splitting of the FORC distribution at the respective orientations. When switching the (111)-oriented samples, a strong smearing of the distribution could be observed away from the field-cooling direction as well as a higher symmetry of both hysteresis branches. The influence of the magnetocrystalline anisotropy on the magnetization reversal is weaker; the process is clearly dominated by the unidirectional anisotropy induced by field-cooling. Both results are supported by transverse MOKE measurements exhibiting angular characteristics coinciding with the shape of the FORC distributions. In conclusion, the angular dependent FORC diagrams clearly resolve the different reversal mechanisms in our samples and prove at the same time the feasibility of combining the FORC method with the quick and precise data acquisition process available in MOKE instruments.

Hard-soft exchange-coupled magnetic nanocomposites have gained a lot of intention in recent years due to enhanced magnetic properties compared to the pure phase material. In this study we have used a novel approach to synthesize exchange-coupled magnets based on Sr-ferrites (SFO). A negative charge on the surface of SFO particles was obtained with the adsorbtion of citric acid [1]. Hexadecyl-trimethyl-ammonium bromide adsorbed on the surfaces of CoFe or CoFe2O4 (CFO) nanoparticles provided a positive surface charge at operating pH (=10). Therefore, when mixing both suspensions, the oppositely charged surfaces were attracted and composites consisted of SFO platelets covered with CoFe or CFO nanospheres were formed. Dried composite powders were pressed and sintered with Spark Plasma Sintering (SPS) technique at various sintering temperatures and times. Transmission electron (TEM) and scanning electron (SEM) analysis confirmed the formation of composites consisting of hard SFO and soft CoFe or CFO magnetic phase. The knee in the hysteresis loops of dried powders indicated systems with two different magnetic phases. However, this knee disappeared in the sintered composites, which suggests the exchange interaction between hard and soft magnetic phase. Compared to the pure SFO the remanent magnetization of SFO-CFO composite increased (from 0.36 T to 0.41 T), while slight decrease in coercivity was observed (from 169.8 kA/m to 152.4 kA/m). The remarkable increase was observed also in BHmax, which was 21.9 kJ/m3 for SFO and 26.1 kJ/m3 for the SFO-CFO composite.

Tailoring the size of magnetic particles at the nanometer scale has led to the emergence of new magnetic properties, of great interest in various research topics including magnetic recording. One of the main challenges for the synthesis of such granular materials is the design of organized structures with enhanced tunable physical properties. Particularly, the thermal stability of the nanomaterials magnetization is critical for magnetic recording.
Several recent experimental studies have indicated that exchange coupled ferromagnetic (FM) and antiferromagnetic (AFM) nanostructures exhibit an improved thermal stability of the magnetization and all the features of exchange bias (EB).
Besides, in the case of core-shell FM-AFM exchange-biased nanoparticles (NPs), dipolar interactions may be of great importance and have to be considered. Despite an impressive number of works on exchange-biased systems, few of them deal with the interplay between EB and dipolar interactions. To study the relationships between EB and dipolar interaction, we propose to tune the NP-NP distance by growing polymer brushes on the surface of these nanoparticles.
We prepared, by the polyol process, highly crystallized nanoparticles (NPs) consisting in a Fe3-xO4 core perfectly epitaxied to a polycrystalline CoO shell. We choose to use the grafting from technique to grow poly(methyl methacrylate) (PMMA) chains directly on the surface of the nanoparticles. First, a brominated initiator was anchored to the particle surface. Then, radical polymerization (ATRP) was performed to grow PMMA brushes of controlled lengths.
At low temperature, it appears that increasing the average distance between the NPs increases the coercive field HC and is decreasing the hysteresis loop shift, i.e. EB. These results emphasize the relationships between the dipolar interaction and the hysteresis loop shift in the magnetic NPs presenting EB properties.

Magnetic core/shell nanoparticles (NP's) dispersed in a liquid carrier, present enhanced magneto-thermic effects, which may find their origin in exchange coupling properties of such NPs. We explore low temperature magnetic properties of individual NP's based on a $MnFe_2O_4$ core protected by a γ-Fe_2O_3 shell. Previous studies evidenced in such NPs a well-ordered ferrimagnetic core surrounded by a disordered surface layer frozen in a spin glass-like manner [1]. We investigate their magnetization, surface disorder and magnetic anisotropy properties. Thermal and field dependences of total magnetization are measured at 5T as a function of temperature and at 1.5K in a pulsed field experiment up to 52T. Total magnetization, analyzed as the sum of contributions from core and disordered surface, does not saturate even at very high fields because of misaligned surface spins. The core's magneto-dynamics is probed by FerroMagnetic Resonance (FMR). A theoretical analysis of these results points out the NP's uniaxial symmetry of the magnetic anisotropy energy of the core, which scales as the NPs surface. The deduced uniaxial anisotropy field H_{ani} parallel to the NP magnetic anisotropy axis is confirmed by first magnetization measurements and finds its origin in the exchange interaction at the core/shell interface. Besides, FMR measurements evidence another kind of exchange anisotropy field H_{iso}, which is rotatable, bidirectional and parallel to the applied field (264 kA/m). A third evidence of exchange interactions is found in the shift of hysteresis loops at various field cooling: exchange bias H_{ex}, which is scaling with H_{ani} [2,3].

Exchange-coupled magnets constitute a strategy for designing magnetic materials, not only intended for BHmax enhancement but also to fulfill the specific requirements of a broader spectrum of applications. Theory predicts a considerable improvement by coexistence of two magnetic phases of different nature (hard/soft). Numerous studies on the subject have been reported over the past few years. However, achieving effective exchange-coupling appears to be more challenging than expected. In this work, hydrothermally synthesized CoFe2O4 nanoparticles with an average size of approximately 10 nm were partially reduced through a mild thermal treatment in a reducing atmosphere. The aforementioned procedure gave rise to CoFe2O4 (hard)/CoFe2 (soft) magnetic nanocomposites. Structural coherence of the two phases in case of partial reduction is presumably favored compared with bringing two different starting materials together. Rietveld refinement of high resolution powder x-ray diffraction data allowed quantitative analysis of compositional and microstructural features as function of reduction degree, revealing emergence of intermediate phases before the pure metal is finally formed. Magnetization measurements at room temperature showed a fivefold increase in BHmax with respect to the initial powders. A remanence value of 58 emu/g was preserved in this case, which is significantly higher than expected given the amount of soft phase present (approx. 40% metallic content). Magnetic hysteresis at low temperature and demagnetization curves indicate that an effective exchange-coupling is very likely to be the origin of the enhanced magnetic performance. The potential influence of these intermediate phases on the magnetic behavior is also examined. Research supported by EU-FP7 NANOPYME Project (No. 310516) [www.nanopyme-project.eu].

Mo.I-P16 - Negative rotatable anisotropy as a signature of antiparallel interface exchange coupling in exchange bias systems

The best-known manifestation of the exchange bias (EB) phenomenon, which occurs when a magnetically-hard material (usually an antiferromagnet) is coupled to a softer ferromagnet, is a hysteresis loop typically shifted at a direction opposite to that of the magnetic field applied during either sample growth or a post-deposition treatment. The intriguing positive EB (PEB), i.e., a shift in the applied field direction [1], is attributed to an antiparallel interface coupling. The present work addresses the origin of another fascinating EB feature, namely, the recently discovered negative rotatable anisotropy (RA) [2]. Rotatable uncompensated spins at ferromagnet/antiferromagnet interfaces are assumed to be responsible for the isotropic shift of the angular variation of the resonance field in ferromagnetic resonance (FMR) measurements through a RA field that rotates with the magnetization of the ferromagnet [3]. When the RA is positive, this shift is downward. Here we report on negative RA presented by as-made, annealed and ion-irradiated IrMn/NiFe bilayers. Opposite to the previous observations, an inverse correlation between RA and coercivity is observed. Also, the EB field, determined from hysteresis loop measurements, is higher than that obtained from FMR. All results are explained in terms of antiparallel coupling and magnetic-field-induced transitions, from antiparallel to parallel states, of uncompensated spins at the ferromagnet/antiferromagnet interface. This mechanism is also able to account for previously observed training-induced PEB and partial recovery of training after application of strong magnetic fields. We affirm that FMR-estimated negative RA is a signature of antiparallel interface coupling even in systems presenting conventional EB only.

The exchange bias phenomenon occurs in thin films due to the coupling between a ferromagnetic layer adjacent to an antiferromagnetic one. The main observed manifestations of the exchange bias are the field shift in the magnetization curves and the increase in the coercive field when compared to the uncoupled ferromagnetic material. In this work, we have studied the presence of the exchange bias in Ni81Fe19(100 ┼)/Ir20Mn80(120 ┼)/Ta(30 ┼) multilayers, with different number of trilayers, grown by magnetron sputtering on Si(100) substrates at room temperature. The magnetic properties, such as bias and uniaxial anisotropy field as well as saturation magnetization, were determined through magnetization curves and ferromagnetic resonance (FMR). The magnetization measurements were obtained using an alternate gradient field magnetometer. The FMR dispersion relations were obtained by measuring, with a vector network analyzer (Rohde & Schwarz ZVB 14), the scattering parameter (S11) of a microstrip transmission line loaded with the sample. The measuring frequency range was from 1 GHz to 8 GHz and the in plane magnetic field from -600 Oe to 600 Oe at different orientations relative to the anisotropy axis. The FMR dispersion relations were fitted to the Smit-Beljers equation. In order fit the data, the magnetization equilibrium angles were calculated by the minimization of the free magnetic energy which includes Zeeman, Uniaxial, Unidirectional and Magnetostatic energies. We show that this model fits very well the FMR experimental curves. We found that the anisotropy field values do not depend on the sample. We argue that the strong coupling between ferro and antiferro layers could explain this stationary value of anisotropy field.

Mo.I-P18 - Spring-magnet behaviour in annealed $Fe_{64}Pd_{36}$ thin films: exchange coupling between coexistent soft α-Fe and hard $L1_0$ FePd magnetic phases

S. Bahamida[1,2], A. Fnidiki[2], A. Laggoun[1], M. Coisson[3], G. Barrera [3,4], F. Celegato[3], P. Tiberto[3], A. Guittoum[5]

5. Nuclear Research Centre of Algiers, Algiers, Algeria

$Fe_{64}Pd_{36}$ thin films have been fabricated by thermal evaporation onto single-crystal Si (100) substrates. As-prepared thin films mainly display fcc phase. To promote the transformation to the $L1_0$ phase, samples have been annealed in vacuum at temperatures of 400 °C and 600 °C for one hour. Microstructural properties have been studied by X-ray diffraction. The magnetic properties were measured on a Quantum Design SQUID magnetometer and by ^{57}Fe Conversion Electron Mössbauer Spectroscopy (CEMS), as well as by alternating gradient magnetometry (FORC measurements) and AFM/MFM. X-ray diffraction results show that the as-prepared samples are composed of three magnetically soft phases: α-Fe and two disordered FePd and $FePd_3$ phases. After annealing at 400 °C, only α-Fe and disordered FePd phases are observed. Annealing at 600 °C shows the transformation of the disordered fcc FePd to the tetragonal ordered $L1_0$ FePd phase. The X-ray results are in agreement with Mössbauer measurements: the average hyperfine field decreases with annealing temperature, indicating the transformation from disordered fcc to ordered $L1_0$ phase. The room temperature hysteresis loops and their respective coercive fields, which increase from 56 to 106 and 310 Oe for samples as-prepared, annealed at 400 °C and at 600 °C respectively, confirm the structural transformations. Before and after annealing the saturation magnetization remains the same. After annealing at 600 °C, the hard $L1_0$ phase and the soft α-Fe phase coexist, but the hysteresis loops do not reveal magnetisation reversal occurring in two distinct steps. Conversely, first order reversal curves (FORC) measured on as-prepared and annealed samples show that in the film annealed at 600 °C a bias field might be attributed to exchange coupling between the two α-Fe and L10-FePd crystalline phases connected with each other within the interfaces phases.

Mo.I-P22 - Room temperature metastable behavior of exchange bias systems

R. Cichelero[1], A. Harres[1], J. E. Schmidt[1], L. G. Pereira[1], J. Geshev[1]

1. Instituto de Física, UFRGS, Porto Alegre, Brazil

Although exchange bias (EB) [1] phenomenon has been studied extensively in the past few decades, some of its features still remain unexplained even almost sixty years after its discovery. Nevertheless, the effect is already widely used in spin-valve and magnetic-tunnel-junction devices. It is accepted that its origin lies in exchange coupling between a ferromagnet (FM) and uncompensated spins at the interface with an adjacent anti-ferromagnet (AF). Thus, understanding the role of magnetic interactions in AF/FM interfaces seems to be fundamental for achieving further development in the field. The present study reports on the time dependence of the EB field after the thin films have been subjected to post-deposition treatments such as ion bombardment (IB) and magnetic annealing upon application of a magnetic field. Evidences for such metastable behavior of thin films, observed after either IB [2,3] or annealing [4], have been recently reported. Once initialized the EB, our IrMn/CoFe and IrMn/Co bilayers were exposed to a saturating magnetic field during a certain time interval at room temperature. Subsequently, magnetization hysteresis loops were measured, also at room temperature, and the corresponding magnetic parameters (i.e., remnant magnetization, coercivity, etc.) were extracted. Depending on the EB-induction technique, the systems studied here showed rather distinct behaviors. E.g., after IB the films presented unstable magnetic states, enabling modifications of the EB field for a long time period after irradiation. For low IB fluences, the coercivity remained almost constant. The annealing, from the other hand, enabled energy configurations that eliminate or reduce treatment-induced thermal drift effects in our systems.

4. Research Center for Quantum Nano-Spin Sciences, Fukuoka, Japan

Exchange bias caused by the interaction between the ferromagnetic thin film and anti-ferromagnetic film is utilized to fix the magnetization and is a key element in the operation of the magnetic field sensor and spin-based electric device. Depending on the purpose and situation, a metallic alloy or insulating magnetic oxide has been used as the anti-ferromagnet. On the other hand, the magnetic oxide film has also been used as a core channel for the resistive-switching memory. However, the magnetic properties of the magnetic oxide has not been considered intensively in the operation of the resistive memory. Since the resistance change corresponds to the modification of the electron state, it is natural to expect that the magnetic property is modified with the resistance change. This correlation between the electric and magnetic property may provide new insight in the nano-electronic device. For this purpose, we have investigated the electric field effect in a exchange-coupled CoFeB/NiO film. We have grown a CoFeB/NiO/W multi-layered film by using magnetron sputtering. We have evaluated the electron state of the NiO film from the vertical transport and also evaluated the magnetic property of the NiO from the exchange bias for the CoFeB film. In the vertical transport measurement, we have clearly observed the metal-insulator transition of the NiO film with bipolar signature. The switching voltage for the transition is smaller than other conventional resistive memory. This implies that the spin polarized electrode is effective for the transition. Moreover, the switching voltage is found to depend on the relative angle between the spin direction of the CoFeB and that of the NiO. In addition, the exchange bias was found to be modified by the resistance switching. Thus, these unique observed features strongly suggests that the spin plays an important role in the operation of the resistive memory.

Mo.I-P24 - Direct observation of controllable exchange bias configurations in Ni/FeF2 nanostructures

Confining the dimensions and geometry of magnetic structures down to critical length scales such as the ferromagnetic exchange length or the domain wall width results in intriguing new phenomena not observed in the corresponding bulk material. Recently, ferromagnetic/antiferromagnetic (FM/AF) nanostructures exhibiting both negative and positive exchange bias (EB) have been proposed as model systems for multistate switching memory units [1, 2]. Patterning allows the control of writing fields and the design of the multistate cells [2]. In this work, we combine photoemission electron microscopy (PEEM) with X-ray magnetic circular dichroism (XMCD) to show that a progressive spatial confinement of a FM, either through thickness variation or laterally via patterning, drastically affects the AF domain structure in exchange-biased Ni/FeF2 nanostructures. Imaging the magnetic domains at both sides of the FM/AF interface shows that the spin structure is determined by the balance between the competing FM and AF magnetic energies. For FM layer thicknesses below about 10 nm, competing interactions with the proximal AF system lead to tunable configurations of coexisting EB domains with opposite orientations. Antidot patterning of the Ni/FeF2 heterostructures destabilizes the FM state, promoting the formation of additional inverted Ni domains below a critical antidot separation of the order of a few FeF2 crystal domains. The underlying mechanism of the AF domain formation in Ni/FeF2 may be generic to other magnetic systems with complex non-collinear FM/AF spin structures. A facile chemical approach for the synthesis of Fe2O3/FeO core/shell nanoparticles is reported. The synthesis takes place by thermal decomposition of Fe(Oleat)3in tri-octyl-amine at 320oC. The core/shell morphology was confirmed by transmission electron microscopy (TEM and HR-TEM) analysis. The nanoparticles reveal a near spherical shape with an average diameter of 24 nm and core/shell morphology. The shell thickness was approximately 3.9nm. A progressive oxidation for 40 days caused the shell thickness to increase to 4.8 nm. X-ray diffraction and VSM measurements showed the presence of wustite and maghemite/magnetite phases. Thermomagnetic measurements (M(T)) show an antiferromagnetic to paramagnetic transition at around 200 K which belongs to the wustite (FeO) phase while a minor inflection point in the ZFC M(T) was observed at 120K which indicates the presence of magnetite (Verwey transition). Exchange bias behavior was also observed in the core/shell particles with a 250 Oe shift in the hysteresis loop at 50K. A complete structural and magnetic characterization of the nanoparticles will be reported. Work Supported by IRSES NANOMAG.

Mo.I-P26 - Effects of short post-deposition heat treatment on structure and exchange bias in sputtered FeNi/FeMn system

Exchange anisotropy in layered structures can be created either by depositing an antiferromagnetic (AF) layer on a saturated ferromagnetic (FM) layer in a magnetic field or by cooling down the AF/FM system in a magnetic field after heating above the Néel temperature of the AF layer [1]. However, there is a still remaining challenge to determine the physical processes responsible for the formation of the exchange anisotropy in each one of the above mentioned methods.
In this work, we present a systematic study on the effect of post-deposition annealing in a magnetic field on the properties of Ta(5nm)/FeNi(40nm)/FeMn(20nm) (S1) and Ta(5nm)/FeNi(40nm)/FeMn(20nm)/FeNi(40nm) (S2) films.
It was found that the annealing at 200 °C during 5 min leads to a reduction of exchange field (H_{ex}) from 40 Oe to 27 Oe for S1 sample. A similar H_{ex} decrease was observed for the first FeNi layer in the S2 sample. The H_{ex} for the second FeNi layer is not changed substantially.
Careful analysis of X-ray diffraction patterns shows that such a heat treatment has no effect on the grain size and crystalline texture of the films.
Atomic force microscope studies shows that the samples in as-deposited state have a smoother surface than those after heat treatment which can be related with the increase of the interface roughness. Roughness variation for the S2 sample was more noticeable than for the S1 one. Change in the vacancies and/or dislocation density and formation of the new type of dislocation structures and stress relaxation at low temperature annealing can be responsible for the changes of the surface roughness.
Thus, H_{ex} changes after heat treatment are most likely caused by modification of interfacial roughness and unlikely by changes in the microstructure or/and composition of the antiferromagnetic FeMn layer.

Mo.I-P27 - "Dependence of the exchange bias blocking temperature on the thickness of antiferromagnetic layer in the trilayered Si/Ta/NiFe/IrMn/NiFe/Ta thin-films"

Phenomenon of the shifting of the hysteresis loop along the field axis is called the exchange bias. It remains a topic of active investigation for last fifty years. The key issues are the understanding of the fundamental mechanisms controlling the magnitude of the exchange bias, the nature of exchange bias increasing in multilayered systems with few exchange interfaces and the development of the ways to enlarge the exchange bias blocking temperature. With this aim we have studied unidirectional anisotropy of the samples in the range of temperatures from 100 to 450K. We used thin films of Si/Ta/NiFe/IrMn/NiFe/Ta prepared by magnetron sputtering in magnetic field of 400 Oe. The thickness of the antiferromagnetic IrMn layer was changed from 2 to 50 nm. Magnetic moments of the samples were measured by vibrating sample magnetometer at 9 angles between the magnetization easy axis of samples and the direction of the magnetic field, from 0° to 360° with a step of 45°. Magnetic field was varied in the range of -500 - +500 Oe.
We have found how the exchange bias field depends on the thickness of the antiferromagnetic IrMn layer – it is a non-monotonic dependence with maximum (exchange bias field of 107 Oe) at the antiferromagnetic layer thickness of 10 nm. Also dependence of the exchange bias blocking temperature on the thickness of the antiferromagnetic layer was obtained. We have observed that the decreasing of the antiferromagnetic layer thickness leads to decreasing of the blocking temperature. The thickness of 5 nm is a critical one for appearance of the exchange bias in the studied trilayered structures at room temperature. These results were explained in the terms of sizes of antiferromagnetic grains which were estimated by atomic force microscope.

Mo.I-P28 - Exchange Bias down to the sub-nanometer regime

Since its discovery in 1956, exchange bias (EB) has been commonly used in commercial sensors and memory cells to pin the direction of a ferromagnetic (FM) layer. Quantitative description of its mechanism is still incomplete and is a highly debated subject. In this work we developed a model sample to extend the study to the sub-nanometer regimes for both FM and antiferromagnetic (AFM) layers. This multilayer has the following structure: Si/Ta(5.5 nm)/Pt(2.5 nm)/Co(1.15 nm)/Al(wedge 0-3 nm). A plasma oxidation through the Al wedge allows to control the oxidation in a sub-nanometric scale and to create a Co (0.67 nm)/CoO (0.65 nm) stable magnetic bilayer. Using characterising tools such as VSM-SQUID magnetometry, extraordinary Hall effect and X-Ray reflectivity, we carefully analysed this structure. We evidence the EB effect, HEB=0.65 T at 5 K, which correspond to a surface energy of 0.55mJ/m2. The EB is preserved up to a 70▒5 K blocking temperature, which is only marginally reduced compared to nm-thick layers. We can quantitatively describe this results and by studying the remanence of the sample we could determine that CoO keeps a huge anisotropy (similar to the bulk value of 28 MJ/m3) even in such a 0.65 nm-thick CoO layer. Modeling the complete magnetic response of the sample allows to rule out some EB mechanisms such as the ones assuming domain walls parallel to the interface.

Mo.I-P29 - The role of shape and interface roughness in the exchange bias effect in core-shell magnetic nanoparticles

We study the isothermal magnetic hysteresis of cubical and spherical nanoparticles with FM core/AF shell morphology, in order to elucidate the sensitivity of the exchange bias effect to the shape of the particles and the structural imperfections at the core-shell interface. We use a classical Heisenberg Hamiltonian with local anisotropy for modelling the magnetic structure and the Metropolis Monte Carlo algorithm to study the field-cooled process and the isothermal hysteresis loop. The coercive and exchange bias fields for spherical and cubical nanoparticles with similar nominal sizes are compared. Our simulations at low temperature show that : (i)Cubical particles exhibit higher coercivity than spherical ones, however this situation can be reversed in strongly disordered interfaces. (ii) Cubical particles exhibit lower exchange bias field than spherical ones, owing to the lower number of uncompensated spins, a fact that stems from the geometrical shape of the FM-AF interface. (ii) The presence of interface disorder suppresses the exchange bias field in the case of uncompensated interfaces (spherical or cubical particles), while the opposite trend is observed for compensated interfaces (cubical particles, only). (iii) With increasing degree of interface disorder the differences between spherical and cubical particles are gradually smeared out, rendering the shape effects of minor importance. (iv) The atomic scale details of the interface disorder (alloying or roughness) are of secondary importance in the dependence of the exchange bias and coercive fields on the degree of disorder. Our results shed new light in the interpretation of recent experimental findings on the shape-dependent exchange-bias effect in core-shell nanoparticles.

Solution chemistry methods provide a versatile bottom-up approach for the growth of nanoparticles with tailor-made of sizes, shapes and material combinations. In the present work we use solution chemistry methods to grow Fe2O3/CoO hybrid nanopartices with both the direct (FM grown on AF) and the inverted (AF grown on FM) morphology and various sizes. We use a combination of imaging techniques (TEM), magnetometry (SQUID) and computer simulations to understand the factors controlling the exchange bias effect in these hybrid nanoparticles. We observe an interesting behavior at low temperatures exhibiting strong time dependent phenomena (initial curves lying out of the hysteresis loop) and supression of the exchange bias effect below a certain particle size. We model the morphology of the hybrid nanoparticles by two partialy overlapping spherical particles of FM and AF material, described by a classical classical Heisenberg Hamiltonian with different local anisotropy terms for the core, the (free) surface and the interface region of each constituent spherical particle. We obtain the isothermal magnetic hysteresis after field-cooling using the Metropolis Monte Carlo algorithm and investigate the dependence of the exchange bias effect on the different geometrical lengths characterising the hybrid nanostructure (particle diameters, center-to-center distance) and the material parameters (exchange and anisotropy energy). Our simulations show that the exchange bias field: (i) shows a non-monotonous dependence on the degree of overlap between two spherical particles of fixed radii, following the change of the interface-to-volume ratio. (ii) shows a non-monotonous dependence on the ratio of the particles radii (RFM/RAF) , (iii) vanishes below a critical value of the AF radius. Our simulation results support adequately the experimental measurements.

Exchange bias is a well known effect used in applications such as spintronics, where it provides, e.g., the stability of a fixed magnetic layer. The effect is mainly an interface effect between a ferromagnet (FM) and, mostly, an antiferromagnet (AFM). It is commonly agreed on that at the interface of the FM/AFM system, pinned and unpinned uncompensated moments play the crucial role. Nevertheless, a full picture of all underlying microscopic mechanisms yet has to be developed. The amount and nature of the uncompensated moments depends among others on the interface quality. This influences coercivity enhancement, maximum exchange bias field, and the accordingly required field cooling procedure. We present results on in-plane magnetized Co based FMs on antiferromagnetic thin film containing Mn. The thin films are grown using rf-magnetron sputtering at room temperature. Magnetic characterization has been done using magnetometer measurements as well as X-ray circular dichroism (XMCD) measurements. After a field cooling procedure the magnetometer measurements show that the first hysteresis cycles do not represent the a stable system, but the well known training effect takes place. Over the first hysteresis loop the overall exchange bias changes until saturation is reached. We investigated systems during this training period. The element specific XMCD measurements allow to study the uncompensated moments of the antiferromagnet and their evolution in time when applying an external magnetic field. The amount of uncompensated moments decreases with time. The stronger the applied field and the longer the period it is applied, the more pronounced the decrease. The variation of uncompensated AFM moments is in good agreement with the typical decrease of EB during the training process. We can therefore correlate the EB field to the net amount of uncompensated moments. Different layer thicknesses show the same behavior, supporting the interfacial nature of the effect.

Mo.I-P32 - Comparison between a concentrated and a diluted superspin systems

Superspin glasses (SSG) exhibit slow dynamics which is qualitatively indistinguishable from that observed in atomic spin glasses, and typical glassy properties such as aging, memory and rejuvenation. The non-equilibrium dynamics of two different nanoparticle systems will be discussed:

1) a concentrated nanoparticle system: $MnFe_2O_4$ nanoparticles (<D> @ 2 nm),
2) a dilute nanoparticle system: Co particles (<D> @ 2 nm) embedded in an antiferromagnetic Mn matrix with a volume fraction of 4.7 % (Co@Mn 4.7%).

Zero Field Cooled (ZFC) and Field Cooled (FC) magnetization curves show the typical *SSG* behaviour for both systems, i.e. a sharp maximum at ~ 40 K and ~ 65 K for $MnFe_2O_4$ and Co@Mn (4.7%), respectively.
The $MnFe_2O_4$ system was found to exhibit a superspin glass phase transition, using ac-susceptibility and Mössbauer spectroscopy measurements. Non-equilibrium dynamics of the system has been studied by memory and rejuvenation measurements.
Co@Mn 4.7% represents a very interesting example of glassy behaviour in a dilute system. Generally, for such particle dilution in diamagnetic matrix (e.g. Co embedded in Ag matrix), dipolar interactions are weak and an ordinary blocking process of independent particle moments is observed. Nevertheless, a non-equilibrium dynamics typical of SSG is observed in this system. The reasons for the observation of SSG dynamics relie on the microstructural properties of this system, characterized by a significant Co-Mn alloying. By memory and rejuvenation experiments and Monte Carlo simulations we showed that the memory effects increase with the Co concentration and that both the interface exchange coupling and the dipolar interparticle interactions contribute to the observed dynamical behavior[2].

Recently, bi-magnetic core/shell nanoparticles, where both core and shell are either ferromagnetic (FM), ferrimagnetic (FiM) or antiferromagnetic (AFM), are becoming increasingly appealing.[1] The synergetic combination of the properties of the two constituents and their interactions can enhance their performance. We present a novel mesoscopic method[2] based on a Monte-Carlo approach to simulate dense assemblies of bi-magnetic core/shell nanoparticles by reducing the number of spins to be simulated to the minimum necessary to satisfactorily represent their magnetic structure and introducing the adequate exchange parameters between them. We simulate the hysteresis loops and the temperature dependence of the magnetization, M(T), of a 2D and a 3D random assembly of FM/AFM core/shell nanoparticles with high and low densities. The most prominent result of the simulation is the significant increase of both HC and HE for the large density of nanoparticles, where while HE>HC for high densities, above the percolation threshold, it is opposite for low densities. Similarly, the results for M(T) show that for higher densities the blocking temperature, TB, (i.e., the maximum of the zero field cooled M(T)) increases dramatically. Remarkably, all these features are consistent with the experimental results on Co/CoO nanoparticles assemblies[3].

Mo.I-P34 - Hysteresis properties of exchange coupled Fe-Ni/Tb-Co bilayers separated by ultrathin Ti spacer

N. Kulesh[1], K. Balymov[1], O. Adanakova[1], A. Svalov[1], V. Vas'kovskiy[1]

1. Ural Federal University, Ekaterinburg, Russia

Thin films containing exchange coupled ferromagnetic (FM) and antiferromagnetic (AFM) layers are widely used in magnetic field sensors and spintronics devices. Typically $Fe_{20}Ni_{80}$ is used as a FM material and FeMn or IrMn as an AFM material. In this work we considered similar structures based on the amorphous $Tb_{27}Co_{73}$ ferrimagnetic layer instead of AFM and $Fe_{20}Ni_{80}$ or $Fe_{10}Ni_{90}$ as a material of the FM layer. Unlike antiferromagnetic materials Tb-Co has spontaneous magnetization, can induce large exchange bias field, and potentially has higher blocking temperature. $Fe_{10}Ni_{90}$ alloy was considered due to the large anisotropic magnetoresistance (AMR), relatively high coercivity and magnetostriction, which can potentially be utilized in deformation sensors.

Samples were prepared by ion beam sputtering of mosaic (Tb-Co) and alloyed (Fe-Ni) targets onto the glass substrates. Magnetic anisotropy of the Tb-Co layer was induced by application of the uniform in-plane magnetic field during the deposition process. Thicknesses of the main layers were 100 and 50 nm for Tb-Co and Fe-Ni respectively.

For all samples we observed expected reduction of the exchange bias field (H_{eb}) with thickness of the Ti spacer (L_{Ti}) increasing. Coercivity of both $Fe_{10}Ni_{90}$ and $Fe_{20}Ni_{80}$ layers remained about 0.2 Oe for L_{Ti} below 0.7 nm due to magnetization process taking place by magnetization rotation. As H_{eb} and magnetic susceptibility were modified by introduction of the nonmagnetic spacer and considering low coercivity, 20% higher AMR, and nearly the same magnetic susceptibility as observed for $Fe_{20}Ni_{80}$ layer, $Fe_{10}Ni_{90}$ can be successfully used instead of $Fe_{20}Ni_{80}$ in sensors applications. In order to verify the leading role of the uniaxial anisotropy in the formation of FM layers hysteresis properties, Co/Tb-Co films were obtained, which demonstrated coercivity below 1 Oe and relatively high magnetic susceptibility.

This work was supported by The Ministry of Education and Science of the Russian Federation, project No. 1362.

Mo.I-P35 - Interface exchange coupling in a CoPt/NiO bilayer

S. Laureti[1], L. Del Bianco[2], B. Detlefs[3], E. Agostinelli[1], D. Peddis[1], A. Maria Testa[1], G. Varvaro[1], D. Fiorani[1]

The effects originating from the proximity between the ferromagnetic and the antiferromagnetic phase in a CoPt/NiO bilayer, grown at 670 K by Pulsed Laser Deposition, have been investigated from the point of view of the chemical properties, by Hard X-ray Photoelectron Spectroscopy, HAXPES, and of the magnetic behavior (by measuring hysteresis loops in the temperature range 5-300 K both after cooling in zero external field and after cooling from T=380 K in a field of 1 T). At T=5 K, the coercivity, measured after zero-field-cooling, is ~168 mT, to be compared to that of a reference CoPt layer of ~87 mT. Such magnetic hardening of the ferromagnetic CoPt phase is ascribed to the magnetic exchange interaction at the interface with the antiferromagnetic NiO phase, which is also responsible for the horizontal shift of the loop, observed after field-cooling (exchange bias effect). Actually, the latter effect persists up to room temperature (exchange fields Hex ~60 mT and ~8 mT were observed at T=5 and 300 K, respectively). Hence, it can be deduced that the CoPt and NiO phases are efficiently coupled by the exchange interaction, despite the chemical inhomogeneity observed at the interface region. In fact, the HAXPES analysis reveals that a chemical reduction of the NiO phase takes place in the interface region, resulting in the formation of metallic Ni. On the other hand, the interface chemical inhomogeneity is proposed to be at the origin of the peculiar shape of the field-cooled loop at T=5 K, featuring a double reversal of the magnetization[1].

Mo.I-P36 - Exchange bias Study of Ni50.3Mn36.9Sb12.8/BiFeO3 heterostructures fabricated by magnetron sputtering

R. Barman[1], D. Kaur[2]

1. Indian Institute of Technology Roorkee, Roorkee, India
2. Indian Institute of Technology Roorkee, Roorkee, India

In the present study, we have reported the growth of Ni50.3Mn36.9Sb12.8/BiFeO3 heterostructure onto LaNiO3 (LNO) coated Si (100) substrate by magnetron-sputtering at 5500C. The heterostructure exhibits preferred (220) and (001) orientations of Ni50.3Mn36.9Sb12.8 and BiFeO3respectively. Exchange bias field (EB) ~ 50 Oe was observed at 10 K in Ni50.3Mn36.9Sb12.8 thin film. This value of EB is enhanced to ~ 470 Oe at 10 K for Ni50.3Mn36.9Sb12.8/BiFeO3heterostructure. The shifting of hysteresis loop was decreased with increasing of temperature, which is mainly due to the decoupling of FM-AFM spins at the interface. It is obtained from magnetic hysteresis loop characteristic that Saturation magnetization (Ms) is enhanced to 230 emu/cm3 in our heterostructure. This improvement of magnetization is due to the superexchange magnetic interaction between Fe3+ and Mn3+, occurring at the interface, combined with the compressive strain. On the other hand, a significant result for this heterostructure has been observed, EB~ 67 Oe at room temperature, which makes them a promising candidate for various multifunctional MEMS devices at room temperature.

Mo.I-P37 - Interfacial coupling induced symmetry-breaking of spin-orbit interaction in exchange biased systems

2. D.F.M.C., Universitad Autonoma de Madrid, Madrid, Spain

In transition 3d metal systems the Spin-Orbit (SO) interaction arises from the coupling of the electron spin with its orbital motion. In order to minimize its energy, the system chooses preferential directions for the magnetization, modifying therefore its magnetic anisotropy. Since the SO coupling mixes the electron spin-up and spin-down states in the FM, it gives rise to a magnetization-direction dependent scattering rate, producing an anisotropic magnetoresistance (AMR) signal that depends on the angle enclosed by the magnetization vector and the injected electrical current [1]. In spintronics, the need of stabilizing and controlling the magnetoresistance (MR) output of device, is satisfied by resorting to ferromagnetic/antiferromagnetic (FM/AFM) structures in which the magnetization direction of the FM layer is pinned. In these systems an added anisotropy comes out from frustrated exchange interactions at FM/AFM interface, introducing a interfacial symmetry-breaking along the field axis determining a spin rearrangement in both layer surfaces [2]. Here, we investigate the symmetry-breaking effects of the SO interaction in exchange-biased FM/AFM polycrystalline Co/IrMn bilayer. This is done by performing angular- and field-dependent simultaneous measurements of the magnetoresistance and vectorial-resolved Kerr magnetization hysteresis loops [1,3]. We highlight the role of the exchange-bias induced magnetic anisotropy in determining asymmetric features of the field-driven angular anisotropic magnetoresistance curves, which are directly correlated to the magnetization reversal mechanisms. The experimental field dependent curves, including their asymmetries, gives direct visualization of SO chiral asymmetry which is intrinsic of an exchange-bias system.

3. Dipartimento di Fisica e Astronomia, UniversitÓ di Bologna, Bologna, Italy

A novel approach to model the exchange bias (EB) effect in ferromagnetic (FM)/antiferromagnetic (AFM) continuous films and nanodots is presented. The aim is to study both the EB magnetothermal stability and spatial confinement effects, key features for modern spintronic devices. The EB is due to the exchange coupling at the FM/AFM interface, and is featured by the exchange bias field (Hex), i.e. the horizontal shift of the hysteresis loop. To model the exchange coupling we used the three-dimensional Object Oriented MicroMagnetic Framework. The AFM phase was described as a collection of both fixed and rotatable spins (FSs and RSs, respectively) both interacting with the FM phase: the FSs have the role of pinning centers, i.e. they mirror the presence of regions with high anisotropy energy in the AFM phase, so they increase Hex; the RSs change their orientation following the FM magnetization, so they do not contribute to Hex. The calculations were performed for a continuous film and for squared dots with size (D) ranging from 1200 nm down to 300 nm. By changing the FSs to RSs relative fraction we accounted for confinement effects, confirming a reduction of the anisotropy energy for the AFM grains at the dot border. Moreover, by introducing spatial correlations among FSs we modeled the proven existence of a low temperature frozen collective regime of the interfacial AFM spins and its interplay with D. A good agreement was found between the results of the calculations and the experimental data [1]. Finally, we tested our model for the description of the dynamical properties of the FM/AFM system; we will present our results regarding the spin wave frequency dependence on the external magnetic field. This research was sponsored by MIUR-FIRB2010 project RBFR10E61T/NANOREST and PRIN2010-11 Project 2010ECA8P3/DyNanoMag.

3. Universidade Federal do Espírito Santo - Departamento de Física, Vitória, Espírito Santo, Brazil

Ferromagnetic Resonance (FMR) study of the exchange anisotropy of magnetron sputtered NiFe/IrMn bilayers and NiFe/FeMn/NiFe trilayers reveals that low field absorption modes also are excited by the microwave field. In particular, room temperature FMR experiments at frequency of 9.8 GHz, with swept static field and the usual modulation and phase sensitive detection techniques, reveal the excitation of three absorption modes at applied fields of 80, 86 and 95 Oe, for Ta(7nm)/NiFe(20nm)/IrMn(15nm)/Ta(5nm) bilayer, and at applied fields of 83, 98 and 123 Oe for WTi(7nm)/NiFe(30nm)/FeMn(13nm)/NiFe(10nm)/WTi(7nm) trilayer. The exchange-bias field, given by the angular variation of the in-plane absorption field of the uniform resonance mode, is equal to 85 Oe for the bilayer sample, and 83 Oe for the trilayer sample. For both structures, the spectra exhibit the three narrow and distinct low field absorption lines for the swept static magnetic field anti-parallel to the unidirectional anisotropy axis. They are attributed to spin flop transitions on the antiferromagnetic layer. As the field increases and the Zeeman energy grows, the spins on opposing sub-lattices cant towards the applied field and at a field H1 produce a net moment in this direction, at a field H2 neighboring spins become perpendicular to each other, at a field H3 the Zeeman energy overcomes the anti-ferromagnetic exchange and the antiferromagnetic layer is saturated. The bilayer sample was grown in the presence of a static magnetic field; the trilayer sample was grown in the absence of any applied field, but next subjected to a high field cooling process. The FMR results reveal that they have very similar magnetic parameters and confirm the equivalence of the distinct processes used to set the unidirectional anisotropy axis. The microwave absorption due to spin flop transitions reflects clearly the behavior of spins at the ferromagnetic-antiferromagnetic interface.

Mo.I-P40 - Magnetothermal behavior of the antiferromagnet in exchange-coupled NiFe/IrMn bilayers

E. Bonfiglioli[1], F. Chinni[1], F. Spizzo[1], M. Tamisari[1,2], L. Del Bianco[1,3]

The magnetothermal behavior of antiferromagnetic IrMn layers of different thickness (tAFM = 3, 6, 10 nm) has been studied exploiting the exchange coupling with a ferromagnetic 5nm-thick NiFe layer. We have introduced an original protocol for the measurement of NiFe/IrMn sample magnetization as a function of temperature and time at different values of an external magnetic field Hinv, applied antiparallel with respect to the unidirectional exchange anisotropy [1]. This analysis probes the effective distribution of anisotropy energy barriers of the antiferromagnetic phase, as it is sensed by the coupled ferromagnetic layer. The NiFe/IrMn samples have been grown by DC magnetron sputtering at room temperature in a magnetic field of 400 Oe. At low temperature, T < 100 K, the barrier distribution features a peak, centered at T~20 K, and this value is nearly independent on tAFM and Hinv. For T > 100 K, a large peak is visible, and its position changes with tAFM and Hinv. These results are consistent with the existence of a low-temperature magnetic regime in which the interfacial IrMn spins are frozen in a disordered glassy state and collectively involved in the exchange coupling mechanism. At T ~ 100 K, the collective state breaks up and only the interfacial IrMn spins which are tightly polarized by the IrMn nanograins, forming the bulk of the layer, are effectively involved in the exchange coupling. Therefore, for T > 100 K, the anisotropy energy barriers of bulk IrMn nanograins mainly give rise to the large peak in the distribution. The thermal evolution of the exchange field and of the coercivity in the three samples is discussed and coherently explained in the framework of this description. This research was sponsored by MIUR-FIRB2010 project RBFR10E61T/NANOREST.

Mo.I-P41 - Pressure effect on ferromagnetism and exchange bias in phase-separated (Bi,Ca)$Mn_{1-x}Ru_xO_3$ manganites

A. Wisniewski[1], I. Fita[1], V. Markovich[2], R. Puzniak[1]

1. Institute of Physics, PAS, Warsaw, Poland
2. Department of Physics, Ben-Gurion University of The Negev, Beer-Sheva, Israel

Pressure effect on magnetic state and exchange bias (EB) in phase-separated ferromagnetic/antiferromagnetic (FM/AFM) $CaMn_{1-x}Ru_xO_3$ ($0.06 \leq x \leq 0.15$) and $Bi_{0.4}Ca_{0.6}Mn_{1-x}Ru_xO_3$ (x = 0.1, 0.2) manganites was studied under a pressure up to 11 kbar. For both manganites, complex pressure and Ru-doping effects on EB and coercive fields may be explained with a model of size-variable (depending on Ru content and pressure) nanoscale FM droplets embedded in an AFM matrix. For $CaMn_{1-x}Ru_xO_3$, the observed enhancement of EB with increasing pressure is attributed to the reduction in the FM cluster size, evidenced by both pressure dependence of spontaneous FM moment and EB field dependence upon cooling field. The impact of FM droplet size on the EB was further evidenced by the magnetic field effect, which, in contrast to the pressure effect, leads to a growth of the FM droplets. The intricate coercive field dependencies on both pressure and Ru content are understandable in a view of the transition from the multidomain state to the single-domain one, induced by droplet size decrease with increasing pressure or with doping lowering. For $Bi_{0.4}Ca_{0.6}Mn_{1-x}Ru_xO_3$ charge-ordered manganite, it was found that the x = 0.2 composition is basically ferromagnetic while the low-doped (x = 0.1) one exhibits a FM cluster glass behavior and exchange bias effect at low temperatures. For this compound, both Ru-doping and external pressure act similarly, leading to a growth of the FM clusters and consequently to a suppression of the EB. The results show that for phase-separated FM/AFM manganites the EB effect may be smoothly controlled by pressure because of pressure-dependent size of FM clusters.

Mo.J-P01 - Full-potential KKR calculations for lattice distortion of point defects in al, based on the generalized-gradient approximation

C. Liu[1], M. Asato[2], N. Fujima[3], T. Hoshino[3]

1. Graduate School of Science and Technology, Shizuoka University, Shizuoka, Japan
2. National Institute of Technology, Niihama College, Niihama, Japan
3. Graduate School of Engineering, Shizuoka University, Shizuoka, Japan

In the previous papers [1, 2], we presented ab-initio data for the cohesive energies of Al and X (=Na-Si, Sc-Zn, Zr-Ag) and defect energies such as the solution energies of X impurities in Al, and the X-X and X-vacancy interaction energies in Al. In order to calculate the defect energies in Al, however, we neglected the distortion effect around the defects. It is easily expected that the distortion effect becomes important for the impurities with a large size-misfit, compared with the host atom [3]. We now study systematically the distortion effect. The calculations are based on the generalized-gradient approximation in the density functional formalism and the full-potential Korringa-Kohn-Rostoker Green's function method [4]. We already discussed the lattice distortion effect around single impurities (Sc-Ge) in Al [5].

In the present paper we show the calculated results for the lattice distortion of the two impurities X-X (X=Sc-Ge) in Al, being located at the 1st-nearest neighboring sites. The interatomic distance of the X-X bond lengthens for X=Sc, Mn, Fe, Co, Ni, Ga, and Ge while shortens for X=V, Cu, and Zn. We show that the calculated results for the lattice distortion of the two impurities X-X in Al are understood by considering the atomic sizes of X elements and the stronger Al-X (sp-d) bond compared with the X-X (d-d) bond, obtained by the present ab-initio calculations.

Mo.J-P02 - Magnetism of 4d clusters compared to magnetism of 3d clusters: ab-initio study of free Rh and Fe clusters

O. Sipr[1], H. Ebert[2], J. Vackar[1], J. Minar[2,3]

1. Institute of Physics ASCR, Prague, Czech Republic
2. Ludwig-Maximilians-Universitat Munchen, Germany
3. University of West Bohemia, Pilsen, Czech Republic

A fully relativistic ab-initio study of free Rh clusters of 13-135 atoms is performed to identify general trends concerning their magnetism. Special attention is paid to checking whether concepts which proved to be useful in interpreting magnetism of 3d metals are applicable to magnetism of 4d systems. By comparing theoretical results for free Rh clusters and for free Fe clusters, we demonstrate that some important intuitive concepts which proved to be useful when interpreting magnetism of 3d metals are not applicable for magnetism of 4d systems. In particular, there is no systematic relation between local magnetic moments and coordination numbers. On the other hand, the Stoner model appears to be well-suited as a criterion for the onset of magnetism of Rh clusters and, on the top of that, it can serve as a guide for the dependence of local magnetic moments on the local density of states at the Fermi level. Large orbital magnetic moments antiparallel to spin magnetic moments were found for some sites in Rh clusters, which might explain some earlier experimental results.

Mo.J-P03 - On the edge magnetism and energy gaps in graphenelike nanoribbons

S. Krompiewski[1]

1. Institute of Molecular Physics, Polish Academy of Sciences, Poznan, Poland

This study aims to indicate the main factors responsible for formation of magnetic moments at edges of graphenelike nanoribbons. The attention is focused on the effect of: intrinsic spin-orbit coupling, zigzag nanoribbon's width, and perpendicular electric field. Of particular interest is the interplay of the edge magnetism and the energy band gap. It is shown that, with the increasing electric field, typically the following phases develop: magnetic insulator (with in-plain spins), nonmagnetic semimetal, and nonmagnetic insulator.

Mo.J-P04 - Control of domain wall thickness by introducing spatial modulation of uniaxial anisotropy and exchange stiffness parameters

H. Arai[1,2], H. Imamura[2]

1. Presto, Jst, Tokyo, Japan
2. AIST, Tsukuba, Japan

A magnetic domain wall (DW) has been widely investigated for applications to spintronics devices such as Racetrack memory [1] and microwave oscillators [2]. In these applications, the DW must be pinned at a certain position to prevent undesired translational motion. Also the DW thickness must be controlled to improve device properties such as memory density and oscillation frequency. A common way to pin the DW and control its thickness is to build a geometrical constriction such as a notch. However, precise control of nano-sized notches is difficult without damaging the wire. In this study, we propose another approach to control the DW thickness and DW pinning by introducing spatial modulation of the exchange stiffness (A) and uniaxial-anisotropy (K) parameters to the system. We derived Euler-Lagrange equation and the Landau-Lifshitz-Gilbert equation taking into account of the spatial modulation of A and K. By analyzing the modulation as a perturbation, we showed that the modulation of A is more effective to modify the DW thickness than that of K. We numerically calculated the phase diagram of the DW properties on the wide range of modulation parameters, and showed that it can be classified into three regions: short DW is pinned, long DW is pinned, and DW is not pinned. This study is to appear in Jpn. J. Appl. Phys. (Rapid comm.)

Mo.J-P05 - Imprinting skyrmions in thin films by ferromagnetic and superconducting templates

C. Navau[1], N. Del-Valle[1], S. Agramunt[1], A. Sanchez[1]

1. University Autonomous Barcelona, Bellaterra, Spain

Magnetic skyrmions are promising candidates as information carriers in a new generation of memories. How to nucleate and stabilize skyrmions is essential for their successful application to technology. By solving the dynamic Landau-Lifshitz-Gilbert equation, we theoretically demonstrate that arrays of skyrmions can be imprinted in ultrathin ferromagnetic films in large numbers by bringing a magnetic nanostructured template close to the film. Two kind of templates, allowed by present-day nanotechnologies, are studied: arrays of ferromagnetic nanorods (sources of dipolar magnetic fields) and superconducting vortices (sources of monopolar magnetic fields). Skyrmions are generated when exposing magnetic films to the template fields for short time of nanoseconds and remain stable after removing the template. This idea could open the possibility of to write large quantities of elements of few nanometers size in a fast way, which could be manipulate and read through the free surface of the film, for a future generation of magnetic memories.

Mo.J-P06 - Long-range order of classical dipoles on the kagome lattice

M. Maksymenko [1], V. Ravi Chandra [2], R. Moessner [3]

1. Department of Condensed Matter Physics, Weizmann Institute of Science, Rehovot, Israel
2. School of Physical Sciences, National Institute of Science Education and Research, Institute of Physics Campus, Bhubaneswar, India

We study the role of dipolar interactions in the system of classical spins on the highly frustrated two-dimensional kagome lattice. With a combination of the Luttinger-Tisza approach, numerical energy minimization, spin-wave analysis and parallel tempering Monte-Carlo we investigate the long-range orderings and finite-temperature phase transitions for a Hamiltonian containing both dipolar and nearest-neighbor interactions. We find two distinct low-temperature orderings. For weak and moderate dipolar interactions we observe a three-sublattice 120-degree order while for strong dipolar interactions we uncover a peculiar ferrimagnetic state with continuously varying net moment. For these orderings we study low-temperature excitations and corresponding finite-temperature phase transitions. The critical behavior for 120-degree state is consistent with Ising universality class, while for the ferrimagnetic state we obtain drifting exponents satisfying 'weak universality' hypothesis. Interestingly, the flat band of zero-energy spin-wave excitations in nearest-neighbor kagome antiferromagnet acquires a finite gap and minimal dispersion as dipolar interactions are added.

Mo.J-P07 - Spin glass state (SGS) and other seven fundamental magnetic structures with their symmetry groups in terms of the fibre bundle approach: Application to explain experiments on the temperature dependence of susceptibility in SGS

J. Warczewski [1], P. Gusin [2], D. Wojcieszyk [3]

1. University of Silesia, Institute of Physics, ul. Uniwersytecka 4, Katowice, Poland
2. Wroclaw University of Technology, Faculty of Technology and Informatics, Jelenia Góra, Poland
3. University of Silesia, Institute of Physics, ul. Uniwersytecka 4, Katowice, Poland

We present the description of all the eight fundamental magnetic structures and their symmetry groups including SGS in terms of the fibre bundle approach [1]. It turns out that the SGS structure consists in the appearance of the 3-dimensional Gaussian distribution of the orientations of all the separate atomic magnetic moments in the sample. Therefore, the magnetization vector M is also subject to the Gaussian-like distribution. Thus, the structure of the SGS is presented by M situated along the generatrix of a given cone whose axis coincides with the direction of an internal spontaneous magnetic field H indispensable for the SGS stability in a sample [2]. The axis of the 3-dimensional Gaussian distribution mentioned above coincides with the same direction. Any precession angle of M around H represents the symmetry operation of SGS once the angle between M and H remains constant. This means that the symmetry group of SGS is SO(2). The temperature dependence of susceptibility of SGS in the alloys Cu1-xMnx (x=1.08 and 2.02) [3] can be explained on the basis of aforementioned relationship, namely: at ZFC it corresponds to the gradual degeneration of the Gaussian distribution of the magnetization vector with the increase of temperature, while at FC the effect is dominated by the external field F, which is usually much higher than H and it destroys instantaneously the primary Gaussian-like distribution of magnetic moments. We take in the account the interrelation of both fields and the frustration of orientations of the magnetic moments situated on the separate atoms with their given average kinetic energy depending on temperature.

3. Instituto de Nanociencia de Aragón (INA) Universidad de Zaragoza, Zaragoza, Spain

Magnetic properties of thin films can be controlled by the presence of holes or antidots, through their geometrical parameters such as the antidot diameter, separation between them and thickness of the film. The use of materials with perpendicular anisotropy such as CoPt provides an important route for potential application of these low dimensional nanostructures in magnetic recording, sensor or magnonic devices. In this work we study the magnetic behavior of antidot thin films with perpendicular anisotropy. The combined use of magnetometry, magnetic force microscopy (MFM) and the micromagnetic simulations give us an insight into the coercivity mechanisms of these materials. As a result of the competition between the perpendicular anisotropy and the thin film shape anisotropy, the hysteresis cycles becomes more inclined and the remanence decreases when the thin film thickness increases. To mimic the competition between the two anisotropies, micromagnetic simulations with fixed thin film thickness and varying the strength of the perpendicular anisotropy have been performed. To induce the broken hexagonal ordering symmetry, frequently observed the experimentally measured arrays, we rotated the lattice in half of the simulated array by 30 degrees, and filled the empty spaces by antidots. The numerically obtained values of coercivity grow with the diameter of the antidots for all investigated thicknesses of the arrays. The magnetic configurations at the remanence show the change of the domain structure from small domains localized at antidots to larger stripe domains. The simulated micromagnetic structures resemble those obtained by MFM in antidot thin films, prepared by electrodeposition in alumina membranes with the multilayer structure [Co(0.4nm)/Pt(0.7nm)]x and varying the total thin film thickness.

Mo.J-P09 - First-principles calculations of the spin coupling between lanthanide adatoms and iron islands

We performed a study of the electronic properties of Tm and Lu adatoms over an Fe monolayer on (110)W by using non-collinear spin polarized (SP) DFT-based first principles calculations, where LSDA+U is introduced for including the corresponding corrections when GGA fails, using U = 0.8 eV for Fe d-states and U = 5.0 eV for the adatom's 4f states. The spin-orbit coupling was also included to analyze the dependence of Khon-Sham ground state energy on the direction of the magnetic moments. We performed a fully 3D structural optimization of an "adatom"+ (3x3x1) supercell (217 atoms). Although the electronic structure of Tm adatoms is Tm3+, the 4f orbital and spin momenta are reduced by almost 50 % with respect to bulk Tm, what could be due to the existence of an important uniaxial magnetic anisotropy. The spontaneous 4f spin magnetic moment of Tm is almost fully aligned along [1 -1 0], which is the easy axis direction of the Fe monolayer, and shows a small tilting out of the (110) plane, of about 10‖, towards [1 1 0] direction. On the other hand, we found that the Campbell mechanism proposed for Rare Earth-Transition Metal intermetallics, consisting in the antiferromagnetic (AF) coupling between the 5d Rare Earth spins and the 3d Fe spins, also holds at the single atom limit for both, Tm and Lu adatoms. Further, the analysis of conductance at different bias indicates that the major contribution is coming from dxz+dyz -states. The conductance calculations as well as the obtained AF coupling between 5d and 3d spin moments are in agreement with our spin polarized scanning tunneling microscopy experimental results.

Mo.J-P10 - A Methodology Study of the Hysteresis Loops by Monte Carlo Simulation

Z. Nehme[1], Y. Labaye[1], N. Yaacoub[1], R. Sayed Hassan[1,2], J. Greneche[1]

1. IMMM, Université du Maine, CNRS UMR-6283, Le Mans, France

During the last decades, the study of magnetic nanostructures has been the center of interest among the scientific community because of their increasing number of applications in various fields including catalysis, biotechnology [1], recording media (MRAM, à) [2]. Some magnetic properties are derived from the hysteresis loops the major characteristic of which is the coercive field. It comes into play in the study of various physical phenomena such magnetic anisotropy, exchange bias coupling that induces an additional anisotropy in materials [3], à. We are interested in the study of magnetic and structural exchange biased nanoparticles, as typically core@shell ones. For a detailed microscopic description of such spin system, the Monte Carlo MC method seems to be the most suitable one. But, simulating an hysteresis loop by means of MC can be affected by different numerical parameters such as the intrinsic algorithm dynamic, the field sweep speed, the field direction according to the anisotropy direction, the temperature, the magnetic anisotropy value, the reversal mechanism, à [4,5,6]. So, we need to understand the significance of the obtained numerical coercive field. We focused our study on the impact of varying the effective anisotropic constant on the coercive field for different temperatures by investigating the dynamics of different algorithms. A study of the angular acceptation move distribution has allowed us to check the validity of the implemented algorithm and to compare the dynamics generated by different algorithms in order to keep a good sampling of the phase space and to perform efficient simulations. The results show a linear dependence between the coercive field and the effective anisotropy constant for non-biased conditions. We conclude that the MC coercive field has a physical and numerical significance allowing us to describe correctly the magnetic properties for exchange biased nanoparticles.

2. Petersburg Nuclear Physics Institute, Gátchina, Russia

Artificial spin ice systems have attracted much attention in recent years [1]. They can be used as a model objects for the study of frustration phenomenon and magnetic excitations similar to those observed in pyrochlore spin ice materials. Most of artificial spin ice systems are two dimensional. Inverse opal-like structures (IOLS) are promising candidates to become first 3D artificial spin ice [2]. IOLS can be fabricated from opals by filling the voids between microspheres with another material (Co or Ni in our case). Later microspheres can be removed. Thus IOLS can be considered as a set of submicron metallic particles connected to each other via thin and long crosspieces ("legs"). The shapes of such particles resemble the shapes of the voids of face centered cubic (FCC) structure of opal and have quasi cubic and quasi tetrahedral forms. Such spatially ordered 3D structure of IOLS leads to a complex distribution of the magnetization in the sample [2,3]. One can think IOLS as 3D antidot array. We perform a micromagnetic calculation of magnetization distribution in IOLS unit cell using Nmag software [4]. External magnetic field was applied along IOLS principal axes and corresponding hysteresis curves were calculated. Results are in good quantitative agreement with experimental data (SQUID measurements) and suggest that IOLS exhibit spin ice behavior i.e. spin ice rule is fulfilled in quasicubes and quasitetrahedra in a wide range of magnetic field values.

Mo.J-P13 - Roles of grain boundaries in the coercivity of magnetic thin films investigated by a two-dimensional Ginzburg-Landau model

K. Iwano[1], C. Mitsumata[2], K. Ono[1]

1. High Energy Accelerator Research Organization (KEK), Tsukuba, Japan
2. National Institute for Materials Science (NIMS), Tsukuba, Japan

Magnetic thin films, in which short-ranged exchange interaction and long-ranged dipole-dipole interaction most directly compete with each other, provide us a good stage to explore non-equilibrium physics from both experimental [1] and theoretical sides [2, 3]. Also, we expect that the analyses of hysteresis under various conditions will lead to a clue to increase the so-called coercivity drastically, which is a high demand from industrial fields.
Our model is a two-dimensional Ginzburg-Landau (GL) model, of which the conventional part corresponds to the exchange interaction and an anisotropy effect. Furthermore, it is augmented by terms corresponding to the dipole-dipole interaction and a grain-boundary phase. We apply a fast Fourier transform (FFT) to a discretized version of this continuum model, assuming a periodic boundary condition.
We prepare a regular arrangement of square grains separated by a non-magnetic grain boundary phase and investigate its behaviors under the reversal of the external magnetic field. We particularly find:
1. When the separation distance between the grains exceeds a certain distance, the hysteric curve is almost the same as that for a completely isolated grain.
2. With shorter separation distances, on the other hand, the coercive field decreases monotonically as a function of the distance. We interpret the above separation-distance dependence of the coercive field as due to the two-dimensional dipolar field, which takes the functional form of 1/r2 when it is integrated over a certain angle with keeping the same distance r.

Mo.J-P14 - Laser heating and thermal stresses in the core-shell nanowires

I. Astefanoaei[1], I. Dumitru[1], A. Stancu[1]

1. Alexandru Ioan Cuza University, Iasi, Romania

In the last years, the core-shell nanostructures as nanowires or nanoparticles are intensively used in the heat assisted magnetic recording (HAMR) [1, 2]. This technological procedure uses high anisotropy magnetic systems which can be switched with rather small fields. During the switching process the material is temporarily heated [3]. The induced thermal stress in the heating process becomes an important parameter to be known and controlled in the magnetization process of core-shell nanowires. This paper analyses the thermal stress produced by a laser heating source placed at one end of a core-shell type structure. The thermal field was computed using Fourier heat transport equation in Comsol Multiphysics. The internal stresses are essentially due to thermal gradients and different expansion characteristics of core and shell materials. The stress values computed by the thermo elastic formalism depend on the laser beam parameters (spot size, power etc.) and system characteristics (dimensions, thermal characteristics). The high order of the thermal stress magnitude (GPa) leads to a magnetoelastic energy of $8 \cdot 10^5$ (J/m^3) which is comparable with the magnetocristalline energy of FePt core. As a consequence, magnetic state of the system can be influenced significantly.

Different shell materials lead to different thermal stresses values in the magnetic core. A glass shell ensures a better thermal insulation and lower thermal gradients than alumina shell. The thermal stresses are lower in a system with glass shell, than alumina shell. As a consequence the magnetoelastic energy becomes smaller.

The thermal stress at the end of the laser heating process becomes an important parameter which needs to be carefully analyzed in the heating treatments of the magnetic materials. These results lead to a better understanding of the switching process in the magnetic materials.

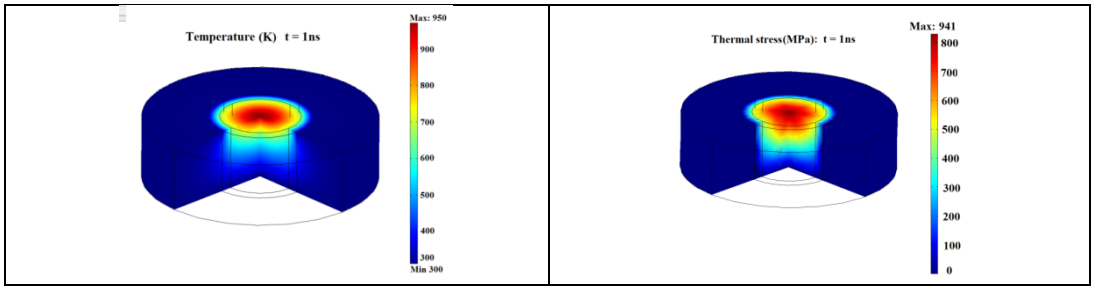

Fig. 1(a) The spatial temperature distribution in the core-shell system at t = 1ns; (b) The radial stress distribution in the system at t = 1ns;

The low temperature magnetic properties of magnetic nanoparticles as the size decreases are governed by surface effects [1]. Work has already been done by means of Monte Carlo (MC) [1] methods and micromagnetic approach, using core-shell type morphology [2], in order to investigate surface effects. In this work a micromagnetic model is presented for ferromagnetic nanoparticles where the surface is treated as a single layer. The model consists of two coupled magnetization vectors for the volume and boundary respectively. The evolution of each one is described by a partial differential equation (PDE) under the influence of an effective magnetic field as, arising from exchange interactions, magnetic anisotropy, Zeeman and dipole energy [3]. The two vectors interchange fluxes, based on the ratio a/lx, where a is the effective width of the surface layer, and lx is the exchange length. Simulations were made by means of the finite element method (FEM), on a spherical uniaxial particle by varying the strength and direction of the surface magnetic anisotropy and it's diameter D. For a more comprehensive study FEM simulations for core-shell type and MC simulations also took place for the same magnetic parameters and assuming a simple cubic lattice by using a classical Heisenberg model [1]. The temperature was set to 0.01J and per external field value 2000MC steps are taken per spin. Results indicate that different anisotropy constant and direction influence Hs, the field where reversal takes place, in manner analogous to 1/(D). Our numerical results are in agreement with the micromagnetic core-shell type and the MC results for very small nano particle sizes and with experimental results. Moreover the computational cost of the effective layer model is lower than the core shell one, mainly due to discretization problems, thus can be easily extended to larger particles where dipole interactions count.

Mo.J-P16 - Temperature-dependent exchange stiffness and domain wall width in hcp Co

R. Moreno Ortega[1], O. Chubycalo-Fesenko[1], M. del C. Munoz[1], L. Szunyogh[2], R. Evans[3], R. Chantrell[3]

Using a hierarchical multi-scale model we have evaluated the temperature dependence of the domain wall width and exchange stiffness in hexagonal close packed (hcp) Co. The exchange parameters were evaluated within the tight-binding approximation obtaining good agreement with previously published ab-initio calculations [1]. The Curie temperature was calculated using the atomistic simulations based on Langevin dynamics and the parameterized Heisenberg Hamiltonian, with good agreement with experimental values. The domain wall was created by imposing anti-periodic boundary conditions at either end of a nanowire of sufficient length to freely contain the domain walls. Our new approach allows the evaluation of the temperature dependence of the domain wall width at all temperatures up to and including the Curie temperature. In hcp Co we find a domain wall width of 30 nm, twice large as frequently assumed and exhibiting a monotonic increase with temperature. The domain wall width also shows some weak anisotropy, being slightly different in directions parallel and perpendicular to the c-axis of the crystal. In the range of low-to-intermediate temperatures the scaling relation of the exchange stiffness with magnetization is obtained both numerically with Langevin dynamics and analytically within a classical spectral density approach. The results constitute a basis for large-scale temperature-dependent micromagnetics, suitable, for example, for modeling heat-assisted magnetic recording or laser-induced magnetization dynamics.

Mo.J-P18 - Magnetic reversal modes in multisegmented nanowire arrays with long aspect ratio

S. Allende[1], E. Rando[1]

1. Universidad de Santiago de Chile, Santiago, Chile

Multisegmented elements have been proposed for device storage, because they can store more than one bit depending on the number of elements and exhibit large magnetic stability of their states[1,2]. In this work a detailed numerical analysis of the magnetization reversal processes in multisegmented nanowire arrays was developed. The nanowires have a long aspect ratio and are formed by magnetic and non-magnetic sections alternately arranged in such a way that the array resembles magnetic layers separated by non-magnetic layers. Attention has been focused on the influence of magnetostatic interaction in the magnetic pattern formation of these magnetic nanostructures. Results from a magnetic correlation function among layers show that three different reversal modes can be detected depending on the number and distance between the magnetic segments. As a consequence of the different reversal modes, a non-monotonic behavior of the annihilation field in function of the distance between the layers is evidenced. Thus, these results are important for the production of magnetic devices with multisegmented nanowire arrays.

The magnetization dynamics in the nanosystems relevant to magnetic recording and spintronics technologies are stochastic in nature due to the presence of thermal fluctuations. This stochastic nature manifests itself in random transitions among coexisting steady states such as metastable magnetic equilibria or self¡oscillatory regimes driven by spin¡polarized currents. In this context there is a growing interest in studying the effects of fluctuations over a wide range of temperature across which the magnetic system undergoes superparamagnetic¡like transitions[1]. In this paper, we carry out the analysis of a single¡domain uniaxial nanomagnet subject to external field and spin¡polarized currents while in contact with a thermal bath. Our starting point is the stochastic Landau-Lifshitz (LL) equation appropriately generalized to take into account the effect of spin polarized currents [2]. We show that key information can be obtained by studying the properties of the noise¡dependent effective potential that naturally arises from the averaging, with respect to rotations around the symmetry axis, of the Fokker¡Planck equation [2] associated with the stochastic LL equation.
This potential contains a fluctuation-dependent part which is related to the presence of a noise¡induced drift in the Fokker¡Planck equation.
The study of bifurcation lines of the effective potential in the fields-temperature plane reveals an Astroid-like curve which enables to computed the values of injected current needed to switch the nanomagnet as function of temperature.
In this paper, the limit of applicability of the theory is studied by comparing the Astroid-like curve with the one determined numerically by estimating the switching values of the injected current computed at different temperatures on a certain time scale which depends by the temperature itself.

The high-speed switching of magnetic particles is a central issue in magnetization dynamics for applications to magnetic recording nanotechnologies[1].
Several strategies have been analysed in recent years in order to circumvent the slow relaxation that occurs in switching an anisotropic nanomagnet through a large enough external field opposite to the initial magnetization. Possible more efficient alternatives include microwave-assisted switching[2] and precessional switching[3]. In the latter case, a field perpendicular to the initial magnetization, directed along the intermediate anisotropy axis, is applied to the particle. This method has been shown, both theoretically and experimentally, to yield much smaller switching times than conventional switching[3]. Nevertheless, in order to guarantee successful switching, an extremely precise timing of the field pulse has to be designed[4]. Recently, it has been also shown that ultra-fast and reliable precessional switching can be realized in anisotropic magnetic nanodots by using applied field pulses with two components: the larger one, directed along the particle hard-axis superimposed to a small bias field of appropriate amplitude[5].
In this work, we propose an analytical study of precessional switching of nanodots driven by hard-axis field pulses. In particular, we analytically derive closed-form expressions for critical fields, magnetization dynamics, pulse durations and timing tolerances for successful switching as function of material and geometrical parameters. Macrospin and micromagnetic simulations are performed to check the accuracy of the theoretical predictions. It is expected that this study will be instrumental to develop novel ultra-fast and reliable magnetization switching strategies.

Magnetization dynamics driven by microwave excitations has been extensively studied in connection with the phenomenon of ferromagnetic resonance[1] and, more recently, in connection with the possibility of using microwave field and microwave injected currents to achieve magnetization reversal under substantially reduced coercive fields[2,3]. In this paper, by using analytical techniques, we study the role of microwave excitations in assisting magnetization switching of a magnetic spin-valve-like nano-structure subject to both DC and microwave fields and injected currents. Magnetization dynamics is analyzed by means of the Landau-Lifshitz equation appropriately generalized to include the effect of spin-polarized currents. It is shown that a special role in the microwave excited dynamics is played by the presence, in the precessional dynamics, of saddle equilibria. The microwave perturbations of the dynamics around these saddle equilibria, at sufficiently large microwave excitations, give rise to homoclinic and heteroclinic phenomena. These phenomena produce chaotic type dynamics and, as a consequence of that, yield an effective reduction of the switching field. The analytical derivation of this reduction is the focus of this paper. The starting point is the characterization of homoclinic and heteroclinic trajectories of the unperturbed conservative dynamics by using elliptic functions. Then, the threshold values of microwave excitation amplitudes for producing heteroclinic and homoclinic entanglement are studied through an appropriate Melnikov function. Finally, by using the concept of lobe dynamics and basin erosion, we connect the reduction of coercive field to the presence of chaotic dynamics. The results of this treatment are instrumental to estimate the switching field by computing and measuring the extension of heteroclinic/homoclinic entanglement and basin erosion.

Mo.J-P22 - Thermal stability and the size- and field-dependence of chiral profiles in ferromagnetic nanoparticles

N. Grisewood[1], H. Braun[1]

1. School of Physics, University College Dublin, Dublin, Ireland

Understanding the behaviour of nonuniform profiles and the nature of size- and field-dependent transitions presents a fascinating challenge in magnetic systems and is of central importance for the design of magnetic recording media. Here we present an analytic model describing the magnetic free energy of a fine ferromagnetic nanoparticle deposited on an in-plane magnetized thin film substrate, and the resultant size-dependent chiral magnetic profiles which have been observed in recent photoemission experiments. As a bistable system, these chiral states may potentially be used for data storage or magnetic sensor purposes so we further consider thermally activated switching between the two chiral states. We analytically calculate the exact prefactor as a function of arbitrary size and field. Remarkably, we find a size-, and field-dependent transition where switching proceeds over a uniform barrier in small sample sizes and over a nonuniform barrier in larger sample sizes. We expect that the observation of such a phase transition should be readily realizable in experiments.

Mo.K-P03 - Magnetocaloric functional properties of $Sm_{0.6}Sr_{0.4}MnO_3$ manganite due to advanced nanostructured morphology

V. Andrade[1], S. Pedro[2], D. Rocco[1], M. Reis[1], A. Campos[3], A. Coelho[4], M. Escote[5], A. Zenatti[5]

The magnetocaloric effect (MCE) is the key concept to produce new, advanced, freon-like free, low cost and environmental friendly magnetic refrigerators. Among several potential materials, $Sm_{0.6}Sr_{0.4}MnO_3$ manganite presents the highest MCE value in comparison to all other known manganites; however, it has a narrow useful temperature range. To overcame this problem we produced advanced nanostructures, namely nanoparticles and nanotubes of that highlighted manganite by using the pore wetting method. High resolution transmission electron microscopy revealed nanoparticle and nanotube diameters of 29 nm and 200 nm, respectively; and, in addition, this technique also showed that the wall of the nanotube is composed of nanoparticles with 15 nm of diameter. In fact, as desired, we could obtain a broader magnetic entropy change (ΔS_M) for the nanoparticles (in comparison to the bulk counterpart); but also an undesired M-shape profile for the nanotube sample was observed, due to the rising of a superparamagnetic behavior. These results also evidenced the existence of a nanoparticle size threshold below which the aim to make the transition wider is no longer valid. Finally, this effort is useful for the present knowledge on this issue and opens doors for deeper research on the evaluation of the magnetocaloric potential of nanostructures.

Mo.K-P04 - Vortex-state Permalloy nanodisks prepared by Colloidal Lithography for Biomedical Applications

M. Goiriena[1], A. García-Arribas[1,2], A. Svalov[2]

1. BCMaterials, Universidad del Pais Vasco (UPV/EHU), Spain
2. Departamento de Electricidad y Electrónica, Universidad del Pais Vasco (UPV/EHU), Spain

Magnetic nanoparticles are extensively studied for biomedical applications because their size are comparable to biological entities, while providing remote capabilities of actuation. Disk shaped ferromagnetic nanostructures display an attractive alternative to the chemically-synthetized oxide nanoparticles that are used normally. First, Permalloy (Py) nanodisks display much higher saturation magnetization and second, with the appropriate dimensions, they can present a spin vortex magnetic configuration, which leads to net zero magnetization at remanence, eliminating the problem of particle agglomeration. Therefore, Py nanodisks present a huge potential for biomedical applications, ranging from cancer cell destroy by hyperthermia or mechanical actuation to MRI contrast enhancement and drug delivery. In fact, micrometric disks has been shown to produce cell apoptosis by their mechanical oscillation under a low ac field. Disks in the nanometer scale might cross cell membrane expanding the biomedical possibilities.
The fabrication methods of nanostructures such as electron beam lithography or deep UV photolithography offer a high control on particle size and geometry, but they imply either a very low yield production or the use of state of the art and expensive equipment. As a satisfactory alternative, self-assembling routes provide high volume and low cost production of Py nanodisks. In this work we demonstrate the excellent capabilities of Hole-mask Colloidal Lithography (HCL) to produce high quality Py nanodisks with a yield adequate for biomedical applications (several micrograms per cm2, approximately 1 miligram in a 2┤ ┤ wafer).
The parameters controlling the HCL process allow us to obtain Py nanodisks with different sizes that are characterized both morphological (SEM and AFM microscopies) and magnetically (SQUID and Kerr magnetometries). A well defined magnetic vortex state appears for dimensions that are compatible with previous phase diagrams. Effective procedures for releasing the fabricated nanodisks from the substrate are under development, which will permit in vitro biomedical experiments.

Mo.K-P05 - Skyrmion state stability in magnetic nanodots with perpendicular anisotropy

K. Gusliyenko[1]

1. Depto. Física de Materiales, Universidad del País Vasco, UPV/EHU

Magnetic skyrmions recently attracted a lot of attention due to their small sizes (1-10 nm) assuming applications to ultra-high density magnetic recording and easy manipulation using spin-polarized currents. The skyrmions were observed in noncentrosymmetric weak ferromagnets MnSi, FeCoSi etc. It was established and widely accepted that the Dzyaloshinskii-Moriya (DM) exchange interaction plays decisive role in stabilization of such skyrmions. However, these materials have low Curie temperatures and need an external magnetic field to stabilize the skyrmions. Question: can the skyrmion state be stabilized in strong ferromagnets like Fe, Co without the DM interaction and bias magnetic field at room temperature? Stabilization of the skyrmion state in magnetic dots, stripes and other patterned nanostructures is of special interest. In this talk we demonstrate that the skyrmions can be stabilized in a nanodot by perpendicular anisotropy in absence of the external field and DM interaction. We consider a thin cylindrical dot with radius R and thickness L. We assume that L is about of the exchange length. We consider competition of the magnetic energies of three distinct magnetization states: perpendicular single domain (SD), vortex (V) and skyrmion (Sk). Then, we determine critical values of the anisotropy fields and dot sizes for transitions between the SD, V, and Sk states by comparing the energies of these stable (metastable) states and choosing a state with the minimal energy. We found that the skyrmion is the ground state of circular ferromagnetic nanodot without the DM exchange interaction and bias magnetic field for moderate perpendicular anisotropy fields Ha=2K/Ms (K is the uniaxial anisotropy constant, Ms is the saturation magnetization) within the range Hc1HaHc2. The critical anisotropy fields Hc1,2(L,R) are functions of the dot sizes, L and R. The obtained Sk stability phase diagrams can serve as a benchmark for calculations of skyrmion dynamics in restricted geometry.

Mo.K-P06 - Instability thresholds for quantized spin waves in ferromagnetic nanowires under microwave pumping

Z. Haghshenasfard[1], M. Cottam[1]

1. Department of Physics and Astronomy, University of Western Ontario, London, Canada

The spin-wave instability thresholds of parametric processes have been studied in ferromagnetic nanowires under conditions of pumping with a microwave field. The quantized spin waves are characterized by a one-dimensional wave vector along the nanowire length and spatial dependences of the amplitude in the transverse directions. The external applied magnetic field is taken be either parallel to the longitudinal axis or in a perpendicular direction. In the latter situation the individual spins cant away from the axis and the static magnetization becomes spatially nonuniform. Both parallel (to the external field) pumping and perpendicular pumping geometries are considered and found to be quite distinct (e.g., the first-order Suhl effect in the latter case depends on three-magnon processes). Much of the previous work on nonlinear spin waves focused on effectively unbounded samples, or on macroscopic spheres or films, together with macroscopic theory. In nanowires with lateral dimensions less than about 200 nm the spatial quantization of the eigenmodes become predominant and our theory employs a microscopic (or Hamiltonian-based) dipole-exchange method analogous to that used recently for ultrathin films [1]. Numerical applications have been made to wires with different sizes and aspect ratios, as well as to magnetic materials with different relative strengths of the magnetic dipole-dipole and exchange interactions, including YIG and Permalloy (strong exchange) and EuO and EuS (weaker exchange). When our nanowire results are compared with those for macroscopic samples or for ultrathin films [1], it is found that the 'butterfly curves' (threshold field vs. applied field) are significantly modified and show more structural features. This is because the quantized spin waves are characterized by a one-dimensional (instead of two- or three-dimensional) wave vector and because of spatial nonuniformity of the magnetization.

Mo.K-P07 - Quantification of nanowire uptake by living cells

M. Bogdan Margineanu[1], E. Jose Perez[1], K. Julfakyan[1], C. Sommer[2], M. Contreras[1], N. Khashab[1], J. Kosel[1], T. Ravasi[1]

1. King Abdullah University of Science And Technology (KAUST), Thuwal, Saudi Arabia
2. Institute of Molecular Biotechnology of the Austrian Academy of Sciences (IMBA) Vienna, Austria,

Nanostructures have become increasingly important for different applications at cellular level. In order to understand how these nanostructures "behave" and for studying their internalization kinetics, several attempts have been made at tagging and investigating their interaction with living cells. In this study, magnetic iron nanowires with an iron oxide layer have been coated with (3-Aminopropyl)triethoxysilane (APTES), and subsequently labeled with a fluorogenic pH-dependent dye pHrodo Red, covalently bound to the aminosilane surface. Time-lapse live imaging of HCT 116 cells interacting with the labeled nanowires has been performed for 24 hours. As the pHrodo Red conjugated nanowires are non-fluorescent outside the cells but fluoresce brightly inside, internalized nanowires could be distinguished from non-internalized ones and their "behavior" inside the cells could be tracked for the respective time period. A computational framework dedicated to automatic analysis of live cell imaging data, Cecog Analyzer, has been adapted and used to classify the cells with internalized and non-internalized nanowires and subsequently determine the uptake percentage by cells at different time points. An uptake of 79 % by HCT 116 cells has been observed after 24 hours incubation at nanowire-to-cell ratios of 200. While the approach of using pHrodo Red for internalization studies is not novel in the literature, this is the first time it has been used for magnetic nanowires. To the best of our knowledge, this study also reports for the first time in the literature a time-resolved automatic analysis pipeline for quantification of nanowire uptake by cells. This pipeline has also been used for comparison studies with nickel nanowires and SPHERO Amino Magnetic particles, both coated with APTES and labeled with pHrodo Red. It has thus the potential to serve as a quantitative tool for studying the interaction of multiple nanostructures types with live cells in diverse experimental designs.

Mo.K-P08 - Magnetization reversal and domain wall motion in magnetic nanotubes

P. Landeros[1], J. Otálora[1]

1. Departamento de Física, Universidad Técnica Federico Santa María, Valparaíso, Chile

We review our recent theoretical predictions on the magnetic properties of ferromagnetic nanotubes [1-6]. We start with a discussion of the actual equilibrium states and its relevance in the nucleation of vortex domain walls [2]. Then we show for long tubes, magnetization reversal is achieved by two mechanisms: propagation of a transverse or a vortex domain wall, which depends on the tube cross section [1]. We then present a theory based on collective coordinates for the field-induced dynamics of vortex domain walls [3,6]. We further propose that the injection either of magnetic field [4] or electric current pulses [5] can be used to control vortex domain walls in metallic ferromagnetic nanotubes. We show that the proper interplay between the tube geometry, and magnitude and duration of a current/field pulse, can be used to manipulate the position, velocity and chirality of vortex domain walls. Our calculations suggest that domain wall velocities greater than 1 km/s may be achieved for tube diameters of the order of 30 nm and increasing with it. We also find that the transition from steady to precessional domain wall motion occurs for very high electric current densities, of the order of 10^13 A/m^2. Furthermore, the great stability displayed by such chiral magnetic configurations, and the reduced Ohmic loses provided by the current pulses, leading to highly reproducible and efficient domain wall reversal mechanisms.

5. Instituto de Química, Universidade de São Paulo (USP), São Paulo, Brazil

The vanadium oxide (VOx) nanotubes (NTs) are multiwall nano-structures constituted by alternating layers of VOx and a surfactant. The V-ions are in different oxidation states: the paramagnetic +4 (3d1) and the diamagnetic +5 (3d0). This coexistence of V oxidation states, with different magnetic behavior, gives rise to interesting and promising physical and chemical properties. Due to these characteristics the doped with other transition metal ions and undoped VOx-NTs, have demonstrated to be very versatile for possible technological-industrial applications such as cathode Li-ion and/or catalysis. In both applications the performance of the material is strongly associated with the ratio V4+/V5+ present in the nanostructure. Consequently, it is important to quantify the fraction of V ions and study different alternatives to vary these proportions. This allows to 'tune' the relationship V4+/V5+ suitable for each application. The possible use of these nanostructures as a technological component, such as batteries cathode, implies that the physico-chemical properties do not change across the time. The study of aging effects results primordial for possible applications and consequently the stability of the initial fraction V4+/V5+ in time. In this work we describe the results of a systematic study of the time evolution of the magnetic properties of VOx-NTs. For this completely characterization, we used electron spin resonance and dc-susceptibility techniques, which were supplemented with TEM microscopy and XANES. We observed that aging in normal environment conditions of pressure, temperature and humidity, that the +4 ions oxidize to +5. Although the multiwall tubular structure is maintained, this oxidation process produces a markedly change in its magnetic properties. Finally, this work allowed us to bring light to the question about the spread dispersion of data reported in VOx-NTs. In the scientific literature some authors reported in their quantifications around 50% of V4+, while others informed values close to 14%.

Mo.K-P10 - Magnetite Nanotubes and Nanorods: Microstructures and Magnetism

Feng Luo [1], Y, Chunjiang Jia [2] N, lingdong Sun [3] N, Kun Zheng [4] N, Xiaodong Han [4] N, Ze Zhang [4] N, Naoaki Hayashi [5] N, Mikio Takano [5] N, Chunhua Yan [3] N, N

1. IMDEA Nanoscience,

3. Beijing National Laboratory for Molecular Sciences, State Key Laboratory of Rare Earth, Materials Chemistry and Applications, PKU-HKU Joint Laboratory in Rare Earth Materials and Bioinorganic Chemistry, Peking University, Beijing, China
4. Institute for Chemical Research, Kyoto University, Uji, Kyoto-fu, Japan
5. Microstructure & Properties of Advanced Materials, Beijing University of Technology, Beijing, China

We present a thermal transformation approach to prepare single crystalline Fe_3O_4 nanotubes and nanorods with α-Fe_2O_3 as precursors. Using various techniques, especially HRTEM, the microstructure of the magnetic Fe_3O_4 nanostructures and the crystallographic orientation-relationships between cubic Fe_3O_4 and trigonal α-Fe_2O_3 was extensively investigated. We got the electron microscopic evidence of all the four relations those are $<111>_{Fe3O4} || <001>_{\alpha\text{-}Fe2O3}$, $<112>_{Fe3O4} || <001>_{\alpha\text{-}Fe2O3}$, $<113>_{Fe3O4} || <001>_{\alpha\text{-}Fe2O3}$, $<115>_{Fe3O4} || (001>_{\alpha\text{-}Fe2O3}$ deduced by Becker et al using X-ray texture goniometry technique in 1970s. (*J. Appl. Crystallogr*. 1977, *10*, 77–78.). Furthermore, new orientation relations of α-$Fe_2O_3 || Fe_3O_4$, such as $<001>_{\alpha\text{-}Fe2O3} || <100>_{Fe3O4}$, $<001>_{\alpha\text{-}Fe2O3} || <110>_{Fe3O4}$, $<001>_{\alpha\text{-}Fe2O3} || <120>_{Fe3O4}$, $<001>_{\alpha\text{-}Fe2O3} || <122>_{Fe3O4}$, $<001>_{\alpha\text{-}Fe2O3} || <123>_{Fe3O4}$, $<001>_{\alpha\text{-}Fe2O3} || <233>_{Fe3O4}$, and $<001>_{\alpha\text{-}Fe2O3} || <351>_{Fe3O4}$ were observed for the first time. In some tubes and rods, multiple fine-scale domains of the Fe_3O_4 were also detected, indicating the complexity of the microstructure of the Fe_3O_4 products. Compare with the Fe_3O_4 nanorods, the Fe_3O_4 nanotubes exhibit quite different magnetic properties due to the hollow geometry. There are two kinks near zero magnetization in the M-H loop of Fe_3O_4 nanotubes at 5K, which indicate the possibility of two vortex states with opposite directions. SQUID and MOKE both clearly indicate that the easy axis of Fe_3O_4 nanotubes is along the tube direction. While for the sample of Fe_3O_4 nanorods, although the magnetic easy axis is along the rod direction obtained from SQUID, both of the in-plane and out-of-plane direction are hard axis obtained from our measurements and due to the limitation of applied field in our MOKE system, we cannot saturate the sample in both directions. Since MOKE is very sensitive to the sample surface, the big difference between the data measured from SQUID and MOKE can be attributed to the imperfect surface microstructure of nanorods samples and also the possible dead layer or spin glass state may play an important role in the nanorods samples.

Mo.K-P11 - Influence of dipolar interactions on the magnetic states and hysteresis of ferromagnetic single-wall zigzag nanotubes

O. Iglesias[1], H. Salinas[2], J. Restrepo[2]

1. Dpt. Física Fonamental and IN2UB, Universitat de Barcelona, Spain
2. Instituto de Física, Universidad de Antioquia, Medellín, Colombia

We have studied the low temperature magnetic equilibrium configurations and hysteretic properties of magnetic nanotubes. The results have been obtained by Monte Carlo simulations of a lattice of Heisenberg magnetic moments residing on the cylindrical lattice of single-wall zigzag nanotubes which interact via competing short-range exchange (J) and long-range dipolar interactions (D). In order to ensure that the low temperature magnetic states correspond to the true ground states, a simulated annealing protocol was followed. Results reveal the occurrence of different low-temperature magnetic states depending of the degree of competition between the exchange and dipolar energies given by the parameter γ=D/J: collinear FM states at low γ, vortex states above a certain threshold γ^*, and interesting non-collinear helical states for intermediate values of γ. Concerning the order parameter, the magnitude of the rotational of the magnetization was computed and its dependence with the external field was analyzed in order to infer the switching fields. Results of the simulated hysteresis loops at low temperatures reveal the occurrence of different magnetization reversal mechanisms depending on orientation (perpendicular to or oriented along the length of the tube) of the external applied magnetic field. In each case, the shape of the hysteresis loops and the reversal mechanism is strongly dependent on γ. In particular, hysteresis loops become elongated and characterized by jumps or discrete steps along the cycle as γ increases and it becomes more competitive. Interpretation of that discrete character is given by direct visualization of the intermediate magnetic configurations in the vicinity of that jumps and analyzed by using convenient order parameters.

Mo.K-P12 - Controllable switching of transverse domain wall polarity in ferromagnetic planar nanowires: A prototype of 2 bits nonvolatile memory cell

S. Leonel[1], D. Toscano [1], P. Coura[1], F. Sato [1], B. Costa[2], M. Vazquez[3]

2. Universidade Federal de Juiz de Fora, Juiz de Fora, Brazil
3. Institute of Materials Science of Madrid, Madrid, Spain

Micromagnetic simulations have been used to investigate the polarity reversal of the transverse domain wall in rectangular magnetic nanowires and the stabilization of the domain wall position after occurring the polarity reversal. One can control the wall position by modifying the local magnetic properties along the wire, which work as traps for pinning or blocking the wall. In order to stabilize the domain wall at predefined positions after a reversal of its polarity occurs, we have proposed the usage of a distribution of magnetic impurities consisting of two clusters. An example of application for this modified magnetic nanowire would be a nonvolatile memory cell, being able to store up to 2 bits of data per cell, which uses 4 states. The wall polarity switching was excited by application of a magnetic field pulse. For our typical pulse duration of 1 ns, we have found that the typical switching time is about 4 ns and the typical time interval from the pulse application to stabilization of the wall position is about 5 ns. Our result for switching time is of the same order of magnitude than the obtained in a previous work [1]. In contrast to previous studies on the polarity control, we showed that the polarity switching can be managed in a Permalloy nanowire with two traps, in our nanowire no local modification of system geometry is required [2] or no additional ferromagnetic layer [1]. Since the position and polarity of the wall can be controlled independently, the modified magnetic nanowire is attractive from a data storage perspective, because it would enable the realization of ultrafast and high-density nonvolatile memory devices.

Mo.K-P15 - Time-dependent factorial cumulants in quantum dots coupled to ferromagnetic leads

P. Stegmann[1], J. König[1], B. Sothmann[2]

1. Theoretische Physik, Universitõt Duisburg-Essen and CENIDE, 47048 Duisburg, Germany
2. Département de Physique Théorique, Université de Genève, Geneva, Switzerland

Recently, theoretical studies have shown that factorial cumulants provide a useful tool to probe interaction in electronic transport through nanostructures [1,2]. Sign changes of factorial cumulants as function of time indicate interaction, whereas in the absence of such sign changes the system can be described by an (effective) noninteracting Hamiltonian. In this sense, we demonstrate that a minimum number of transported electrons is necessary to recognize interaction. Below this critical number, the system appears effectively noninteracting. Furthermore, we derive a criterion for detecting interaction by analyzing the sign of the factorial cumulants in the long time limit. At last, we define a new kind of cumulants being more sensitive to interaction than the commonly used factorial cumulants. We demonstrate our results for a quantum dot and for a mesoscopic Stoner particle [3] weakly tunnel coupled to two ferromagnetic leads.

Iron nanostructures grown by Focused-Electron-Beam-Induced Deposition (FEBID) are promising for applications in magnetic sensing, storage and logic [1-3]. Such applications require precise design and determination of the coercive field (H_C), which depends on the nanostructure shape. In the present work, we have used the $Fe_2(CO)_9$ precursor to grow iron nanowires by FEBID in the thickness range from 10 nm to 45 nm and width range from 50 nm to 500 nm. Such nanowires show Fe content between 80% and 85%, thus giving a high ferromagnetic signal. Magneto-optical Kerr characterization indicates that H_C decreases for increasing thickness and width, providing a route to control the magnetization reversal field via the modification of the nanowire dimensions. Transmission Electron Microscopy experiments indicate that these wires have a bell-type shape with a top-surface oxidation of about 5 nm. Such features are decisive in the actual value of H_C, as micromagnetic simulations demonstrate. These results are relevant to make appropriate designs of magnetic nanowires grown by FEBID.

Three-dimensional (3D) magnetic nanowires have been grown by Focused-Electron-Beam-Induced Deposition (FEBID) using $Co_2(CO)_8$ and $Fe_2(CO)_9$ precursor gases and their magnetic properties characterized by Magneto-Optical Kerr Effect (MOKE) and Electron Holography (EH). Such 3D FEBID structures are being investigated for potential applications in magnetic sensing, storage and logic [1-3]. FEBID techniques are appropriate for the growth of these structures given the flexibility provided in terms of shape, resolution, used substrate, etc. In the present contribution, we will report the optimized growth conditions to simultaneously reach sub-100 nm resolution and high metal content. A pulsed FEBID strategy has been established as the most appropriate one. The role of heating during growth will be highlighted. The magnetic structure in the nanowires and the absolute value of the magnetization have been determined by EH. The magnetization reversal processes have been investigated by means of MOKE measurements in 3D standing nanowires as well as in nanowires felled on the substrate by means of a micro-manipulator.

Among the different geometric types of objects, tubes offer an additional degree of freedom in their design as compared to wires, in that not only the length and diameter can be varied but also the thickness. This time we will show that changes in the diameter of the nanotubes strongly affect the mechanism of magnetization reversal and thereby the overall magnetic response. Our focus on iron oxides results from their unique position among the magnetic materials in terms of abundant availability and biocompatibility. Atomic layer deposition (ALD) of magnetic materials can be applied to ordered porous substrates to yield arrays of smooth tubes with a geometry that is tightly controlled and widely tunable. We have successfully used ALD to create Fe2O3 nanotubes in porous anodic alumina templates. Smooth tubes of 50, 60 and 75 nm outer diameters can be obtained. Subsequent reduction of the Fe2O3 material results in the formation of the strongly magnetic phase Fe3O4. The morphology and composition of the nanotubes were characterized by SEM and EDS analysis, respectively. In addition, hysteresis curves measured at different angles at which the external field is applied were measured using a magnetometer VSM. The dependence of the coercivity on the outer diameter is not monotonic ùcoercivity reaches its maximum at 60 nm outer diameter and then decreases for further increases in the diameter. We interpret this observation as arising from the coexistence of two distinct magnetization reversal modes in our system.

Mo.K-P22 - Skyrmion modes excitations and their hybridization induced by spin Hall effect spin torque

K. Lee[1], T. Shiino[2], B. Park[2]

1. School of Materials Science And Engineering, KIST-UNIST Ulsan Center For Convergent Materials, Ulsan National Institute of Science And Technology (UNIST), Ulsan, South Korea

Skyrmions, a topological magnetic soliton found in a magnetic ultrathin film with large spin-orbit interaction through the interfacial Dzyaloshinskii-Moritya interaction (DMI), have been considered as a promising candidate of the information carriers in future spintronic devices. Recently, several micromagnetic simulation studies have predicted that a magnetic skyrmion can be nucleated and stabilized in a nano-sized ultrathin magnetic disk in the presence of the interfacial DMI. However, it has not been explored so far the current-induced skyrmion motion in a magnetic circular disk. In this study, we report on the micromagnetic simulation studies on excitation of skyrmion dynamic modes and their hybridizations induced by spin Hall effect spin torque (SHE-ST). From our simulations, it has been found that two distinct modes, gyrotropic motions as well as the breathing modes (variations of skyrmion size), can be excited resonantly by applying alternating current (AC) along in-plane direction only. In low frequency regime, 260 MHz for a monolayer nanodisk with 80-nm-diamenter and the DMI constant D = 3.0 í┐ 10-3J/m2, typical gyrotropic mode is excited. Interestingly, the breathing mode was excited by in-plane AC current in our simulations. We found that such breathing modes are excited indirectly; the in-plane AC current excites tiny vibrations of a skyrmion and resonant excitations of breathing modes are mediated by such vibrations of a skyrmion. This is because the distance of the skyrmion from the disk center determines the size of a skyrmion and thus, the vibrations of a skyrmion acts as a driving force of skyrmion breathing mode. Moreover, we found the hybridization of two distinct modes in high frequency regime. This may occur through the dynamical deformation of the skyrmion induced by the in-plane current-induced SHE-ST. Our findings and understandings open up novel methods to manipulate skyrmion dynamics for various applications of data storage and nano oscillator.

Mo.K-P23 - Domain Wall Dynamics in Parabolic Wire

K. Yershov[1,2], V. Kravchuk[1], D. Sheka[3], Y. Gaididei[1], O. M. Volkov[3]

The interaction of curvature and topologically nontrivial magnetization structures~(e.g. domain walls) attract growing interest in fundamental studies and applications. Domain walls are topologically stable structures which can be used as key elements of nonvolatile magnetic memory devices~[1]. In the racetrack domain wall magnetic memory [1] the sequence of bits of information in a nanowire is coded by sequence of magnetic domains separated by the domain walls of head-to-head and tail-to-tail types [2]. However, curvature parameters are an important characteristic of the wire in fabrication of memory devices. Vertical configuration of the racetrack magnetic memory consists of U-shaped nanowires [1] and therefore the domain wall properties on the curvilinear segment of the wire are very important.
Here we study both analytically and numerically the influence of curvature effects on the motion of a domain wall in parabolic curved wire. Using 1D approach developed in [3] we show that the domain wall is pinned by the effective potential induced by the curvature. In the case of infinitesimally small wall width $\Delta\kappa(s_0) \ll 1$ the pinning conditions can be written as $\kappa'(s_0) = 0$ and $\kappa(s_0)\kappa''(s_0) < 0$, where $\kappa(s_0)$ - the wire's curvature in the center of effective potential, Δ - wall width, prime denotes the derivative with respect to the arc length. We established that the domain wall motion frequency can be written as:

$$\omega = \omega_0 \pi \ell^2 \sqrt{|\kappa(s_0)\kappa''(s_0)|},$$

where $\omega_0 = 4\pi\gamma M_s$ with γ being the gyromagnetic ratio. The value of frequency of domain wall oscillations within the pinning potential increases with the increasing of curvature.

In order to verify our analytical predictions we performed numerical simulations of the Landau-Lifshitz equation using the NMAG code [4] and in house-developed simulator for a chain of discrete magnetic moments on the parabolic wire.

Mo.K-P24 - Magnetic properties of nanostructured CoNiFe-B alloy prepared by electroless plating

D. Richardson[1,2], F.M.F. Rhen[1,2]

1. Department of Physics and Energy, University of Limerick, Limerick, Ireland
2. Materials and Surface Science Institute, University of Limerick, Limerick, Ireland

Electroless deposition requires the presence of a catalyst and it is a simple and cheap method for the preparation of metal and alloy. This method has been used for the preparation of non-magnetic nanotubes such as Cu [1] and Au [2]. We previously showed the preparation of electroless plated coaxial nanotubes [3]. Here, we carried out a systematic investigation of the magnetic properties and the nanostructure of electroless plated single wall CoNiFe-B into polycabonate membrane with the formation of nanotubes. We show that the deposition of CoNiFe-B results in a nanostructure comprising nanotubes, nanoparticles and thin films. We prepared CoNiFe-B deposits by electroless plating into porous polycarbonate membranes and investigated the formation of the nanostructure using high-resolution scanning electron microscope images and magnetic measurements. The formation of the nanostructure occurs in five stages: nucleation, particle growth, percolation, film formation and films growth. High-resolution SEM images combined with magnetic measurements reveals that the nanostructure of the deposits consists of nanotubes, nanoparticles and thin film, which is directly linked to the stages of formation. Nanotubes with various lengths were obtained with typical values between 3 to 6 mm and with wall thickness varying from 50 to 90 nm are obtained depending on deposition time. The magnetic measurements show that the nanostructured (Co12Ni60Fe28)88B12 alloys have specific saturation magnetization of (88.6 ▒ 7.7) JT-1kg-1 for samples plated from 2 to 60 min. Acknowledgements We also would like to thank Science Foundation Ireland (12/IP/1692) and IRCSET (RS/2011/270) for financial support.

Mo.K-P25 - Control of Domain Wall Nucleation in Cylindrical Nanowires

H. Mohammed [1], E. Vilanova Vidal [1], I. P. Ivanov [1], J. Kosel [1]

1. King Abdullah University of Science And Technology, Thuwal, Saudi Arabia

Magnetic nanostripes have been a widely researched topic owing to their potential for data storage device applications. Attractive alternatives to nanostripes are cylindrical nanowires due to theoretical predictions showing the absence of Walker breakdown. For the realization of such a nanowire-based device, the controlled manipulation of magnetic domain walls (DWs) is fundamental both from a scientific and technological perspective.

Here we show that an overall reduction in the switching field of a nanowire allows the observation of pinning at internal defects and artificially introduced pinning sites. The reduction of the switching field is carried out by locally modifying the magnetic field at the end of a nanowire, where domain wall nucleation occurs. Pinning is observed via Magnetoresistance measurements (MR).

To demonstrate this, polycrystalline Nickel Nanowires were fabricated by electrodeposition into Anodic aluminium oxide templates. Au electrodes were then patterned onto an isolated nanowire to facilitate magnetoresistance measurements of the nanowire. For the purpose of manipulating the switching field, a permalloy (Py) pad was deposited onto one end of the nanowire.

The MR measurement in the case of the nanowire modified by the Permalloy pad demonstrates a 50% reduction in the switching field. This allows us to observe pinning at internal defects, which could not be detected otherwise. In addition to this, we introduced artificial pinning sites, which were reflected in the MR curve of the Permalloy modified nanowire. Furthermore, simulations confirm our experimental findings.

Mo.K-P26 - Identification and motion of magnetic domain walls in cylindrical nanowires

S. Da-Col[1,2], S. Jamet[1,2], N. Rougemaille[1,2], A. Locatelli[3], T. Onur Mentes[3], R. Afid[1,2], L. Cagnon[1,2], J. Toussaint[1,2], O. Fruchart[1,2]

3. Elettra - Sincrotrone Trieste S.C.p.A., Trieste, Italy

The motion of magnetic domain walls along 1D systems has been an active field of research in the past 15 years. Beyond fundamental interest, an applied background is the search for low-power storage and computing schemes. Another prospect, yet even more challenging, is the concept of a three-dimensional data storage device proposed by IBM ten years ago, the race-track memory. Such a device would be based on dense arrays of cylindrical nanowires, were bits are coded in the form of magnetic domain walls along each wire. So far the focus has been set on flat strips fabricated by lithography, for ease of fabrication . To the contrary, domain walls in cylindrical nanowires was addressed mostly by theory and simulations. In these predictions, the expected physics is drastically different from the one encountered in the more traditional geometry of flat strips investigated so far. We report recent experiments that allowed the formal identification of the two predicted types of domain walls in cylindrical nanowires: of transverse and Bloch-point type, the latter being specific to wiresá[1]. This has been achieved applying XMCD-PEEM in an unusual shadow scheme to get information on the 3D magnetic structure of domain walls. The wires are made of permalloy, electroplated in anodized alumina templates. We also demonstrated that these domain walls may be moved rather easily along the wires, under the stimulus of an applied field. Propagation fields in the range 1-10mT have been evidenced, which is very similar to the strip counterparts. The propagation field at modulations of diameter made on purpose, either constrictions or protrusions, is shown to be several times larger.

In this work, we present a study on the magnetic properties of highly ordered hexagonal arrays of Ni and Co nanowires (NWs) and nanotubes (NTs) electrodeposited in nanoporous alumina templates [1]. In particular, we describe a systematic comparative analysis on the magnetization reversal processes in ordered NW and NT arrays with different diameters (d ~ 30 – 65 nm). For this study we performed analytical calculations and experimental measurements of the angular dependence of the coercivity (Hc), allowing us to determine the reversal modes in NW and NT arrays [2]. The magnetization in Ni and Co NW arrays was found to reverse by means of the nucleation and propagation of a transverse domain wall. While for NT arrays a non-monotonic angular dependent Hc was observed for d ≥ 50 nm, evidencing a transition between the vortex and the transverse reversal mode [3]. The magnetic interactions between NWs/NTs with different diameters were studied using first-order reversal curves (FORCs) [3,4]. From a quantitative analysis of the FORC measurements, we are able to obtain the profiles of the magnetic interactions and the coercive field distributions. In both NW and NT arrays, the magnetic interactions were found to increase with the diameter of the NWs/NTs, exhibiting higher values for NW arrays [3,5]. Finally, we also present experimental evidence of exchange-bias coupling in core-shell Co/CoO nanotubular structures [6].

3. Instituto de Nanociencia de Aragón, Universidad de Zaragoza, Zaragoza, Spain

Nanostructures with a defined geometry are important for the development of technological applications. The patterning processes changes the strain state of the nanostructures, and through the magnetoelastic (ME) contribution to the magnetic anisotropy, can be used to control the domain structure [1]. In this work magnetostrictive Galfenol (FeGa with about 20 % of Ga) strained epitaxial films grown on MgO(001) with thicknesses of 10 nm were patterned as lines using focused ion beam milling. The width w ranges are between 100 nm and 1000 nm, the long axis is along both the [100] and [110] in-plane directions of the film and the line length l is larger than the width (w/l>0.5). Magnetic force microscopy (MFM) has been used to reveal the domain structure. The cubic magnetic anisotropy is small (K about -5 kJ/m3) a value that foresees a domain structure independent of the crystal direction of the wire axis. Nevertheless MFM images show that the domain structures are markedly different for [110] and [100]-wires. For [100]-wires a high remanence single domain structure is present for wires with w up to 1000 nm; similar structures are observed for [110]-wires if w < 300 nm, however above that width a multidomain structure appears. Micromagnetic simulations indicate that a uniaxial anisotropy, that enhances the shape anisotropy, precludes the formation of Landau or Diamond multidomain states in the galfenol wires. The ME contribution, which is proportional to the ME stress coefficient B1 for [100]-wires and B2 for [110]-wires, can address the observed behavior because B1 is larger than B2 and the latter changes its sign depending on slight variations in the range of composition of the film [2].

Mo.K-P29 - Domain Wall annihilation via Phase Correction in Cylindrical Nanowires

S. Goolaup[1], R. Maddu[1], W. Siang Lew[1]

1. Nanyang Technological University, Singapore

Ferromagnetic cylindrical nanowire opens a new avenue for high speed domain wall (DW) memory due to its natural geometry for the 3D design of race track memory and the absence of the Walker breakdown. For memory applications, multiple DWs need to be created and propagated along the nanowire to separate the data. The motion of a transverse DW (TDW) in a cylindrical nanowire is linear and accompanied by the rotation of the transverse component of the DW around the long axis of the nanowire. In planar structures, depending on topological defects associated with the TDW, the interaction between adjacent DWs may lead to annihilation or the formation of a stable bound state. In this work, we show that the TDW interaction in cylindrical nanowires is highly dependent on the phase of the rotational component of the transverse domain wall. The interaction of two TDWs with the same phase of rotation leads to complete annihilation and emission of spin waves within the nanowire conduit. Any mismatch in the phase between the rotational components of two TDWs leads to the formation of a short-lived bound state DW configuration. Depending on the polarity of the phase mismatch, the bound state favours a particular longitudinal motion along the conduit, whereby it eventually annihilates. The maximum length scale over which the bound state is found to be stable occurs when the phase mismatch between the two TDWs is 180°. The annihilation of the bound state happens the TDWs correct the phase mistracking between their rotational components. Our results show that this is achieved via an increase in speed of the rotational component of one of the TDW within the bound configuration.

Mo.K-P30 - Mechanism of magnetic switching in rapidly solidified amorphous nanowires

T. Ovari[1], C. Rotarescu[1], A. Atitoaie[1], H. Chiriac[1]

1. National Institute of R&D For Technical Physics, Iasi, Romania

Amorphous glass-coated nanowires with metallic core diameters from 90 to 900 nm have been recently prepared by glass-coated melt spinning. Here we investigate the magnetic switching in rapidly quenched amorphous nanowires prepared from alloys with the nominal compositions Fe77.5Si7.5B15, with large and positive magnetostriction, and (Co0.94Fe0.06)72.5Si12.5B15, with small and negative magnetostriction. We measured their bulk and surface hysteresis loops, which show a fully bistable magnetic behavior in both cases, with the switching field being one order of magnitude smaller in the nearly zero magnetostrictive samples (hundreds of A/m as compared to kA/m for the highly magnetostrictive ones). The switching mechanism was analyzed in order to understand the key factors that influence the magnetization reversal and to employ them in tailoring the magnetic characteristics of the nanowires for the potential sensing applications. The magnetization reversal mechanism has been also studied by micromagnetic methods, which allowed us to simulate the hysteresis loops and to understand the main contributions to the magnetic anisotropy, i.e. shape and magnetoelastic terms, as well as to visualize the distribution of the magnetic moments at each value of the applied field, and in this way to monitor the possible nucleation of domains with reversed magnetization and the subsequent propagation of the newly formed domain walls along the nanowires. The results show that magnetization switching starts at both ends of the nanowires, irrespective of their magnetostriction. This is for the first time that a detailed analysis of the magnetization switching mechanism was performed for this novel type of magnetic nanowires, the results being essential for their future use in the development of micro and nanosensors, as well as for potential applications in magnetic logic devices. This work was supported by UEFISCDI through contract no. 46/2013 (project PN-II-ID-PCE-2012-4-0424).

Mo.K-P31 - Manipulation of the magnetization reversal in ferromagnetic nanostructures grown by Focused Electron Beam Induced Deposition

R. Córdoba[1], D. Han[1], B. Koopmans[1]

1. Eindhoven University of Technology, Department of Applied Physics, MB Eindhoven, The Netherlands

The manipulation of magnetization is becoming crucial for future applications in spintronics. For instance, the magnetization reversal has been widely investigated for magnetic random access memories. In monodomain nanostructures, this reversal process basically consists of the nucleation of a domain wall and of its propagation, switching the magnetization. The nucleation and propagation processes are governed by magnetic properties of materials as well as structural parameters of the nanostructures. Exploring the magnetization reversal process at the nanoscale may profit from emerging methods for patterning structures at the nanoscale using focused electron or ion beams. As an example, the fabrication of ferromagnetic nanostructures by means of focused electron beam induced deposition (FEBID) has been demonstrated as an attractive alternative method [1,2]. In the present contribution, we report the report the magnetic reversal behaviors in a novel set of magnetic nanostructures fabricated by FEBID. We manipulate the magnetization reversal in Fe FEBID nanostructures varying the scanning strategy of this direct-write technique. In particular, we are able to control their coercive field as a function of the engineered thickness modulation in one direction. The magnetization reversal of these structures has been investigated by magneto-optical Kerr microscopy, where magnetic images are taken as a function of the applied magnetic field, and supported by micromagnetic simulations. This will make possible the investigation of the magnetization reversal processes in complex structures created using this novel strategy, which could have a great potential for the transfer of magnetic information.

Mo.K-P33 - Thermodynamic properties of anisotropic triangular lattices obtained from finite-temperature exact-diagonalization

B. Schmidt [1], P. Thalmeier [1]

1. Max-Planck-Institut für chemische Physik fester Stoffe, Dresden, Germany

We present results of our systematic investigation of the thermodynamic properties of anisotropic triangular lattices with exchange anisotropy J2/J1.
Here J1 is the exchange coupling along two sides of the triangle, different from J2 along the third side. In particular, we discuss the specific heat cV and magnetic susceptibility chi. Our numerical tool is the finite-temperature Lanczos method, which is based on an iterative exact diagonalization (ED) of the model Hamiltonian describing the lattice.
For the ED procedure, we tile the lattice with clusters of size N up to 28 sites where the thermodynamic limit behavior of cV and chi is already stable.
With this unbiased method we are able to investigate the full phase diagram of the model where both constants J1 and J2 can be ferro- and antiferromagnetic. Our description allows in particular for a smooth interpolation between the special cases square lattice (J2 = 0), isotropic triangular lattice (J2 = J1), and one-dimensional chains (J1 = 0). For the latter, our calculations reproduce the well-known infinite-chain results.
For a given anisotropy ratio J2/J1, we determine the temperature dependence of cV and chi with their characteristic broad peaks. We extract peak values and positions Tmax and show their systematic variation as a function of J2/J1, which is very important for the analysis of experimental thermodynamic data, in particular of the susceptibility chi. To demonstrate the usefulness of the FTL method, we apply our findings to the prominent triangular compound Cs2CuCl4. We perform an overall fit to the temperature dependence of its susceptibility and find values J1 = 0.11 meV and J2 = 0.38 meV which are in excellent agreement with those obtained from neutron scattering data above the saturation field.

Mo.L-P01 - Magneto-mechanical property of the $Fe_{55}Co_{17}Ga_{28}$ alloy

S. U. Jen[1], Y. C. Lin[1]

1. Institute of Physics, Academia Sinica, Taipei, Taiwan

$Fe_{55}Co_{17}Ga_{28}$ alloy was made in an induction furnace, and then slowly cooled to room temperature (RT). The structural property of the as-cast alloy was examined by an x-ray diffracto-meter. From the diffraction pattern, we conclude that the major phase in the alloy is the A2 phase, and the minor phases may contain the D03, D019, and L12 phases. The magnetic hysteresis loop was measured by the vibration sample magnetometer: saturation magnetization Ms = 113 emu/g, and coercivity Hc = 4 Oe. Complex permeability ($\mu \equiv \mu R - i\mu I$) as a function of frequency (f) was obtained by using an LCZ meter. At 20 Hz (low-f), μR equals to 280. The mechanical properties, such as Young¡¦s modulus (E), shear modulus (G), flexure damping rate (RF), and torsion damping rate (RT), were measured as a function of magnetic field (H), respectively, by the impulse excitation of vibration (IEV) method. The ΔE or ΔG effect is defined as $\Delta E/E \equiv [Es - Eo]/Es$, or $\Delta G/G \equiv [Gs - Go]/Gs$, where subscript "s" means the near saturation state @H = 3.0 KOe, and the subscript "o" means the zero-field state. Moreover, the flexural magneto-mechanical coupling coefficient (KE) and the torsional magneto-mechanical coupling coefficient (KG) can be calculated from the following definitions: (KE)^2/[1 - (KE)^2] $\equiv \Delta E/Es$ and (KG)^2/[1 - (KG)^2] $\equiv \Delta G/Gs$[1]. Thus, KE = 11.8 to 15.7% and KG = 14.1 to 15.2% for the Fe55Co17Ga28 alloy.

Mo.L-P02 - Magnetocaloric effect studies on MnSb and $MnSbR_{0.05}$ (R: Nd, Er)

R. Pothala[1], Markandeyulu G[1]

1. Indian Institute of Technology Madras, Chennai, India

The search for materials exhibiting second order magnetic transition (SOMT) accompanied by large change in magnetic entropy (ΔS_M) close to transition temperature and at low applied fields has been important in high temperature magnetic refrigeration technology. Magnetocaloric effect studies (MCE) in SOMT materials are helpful to identify materials with high the efficiency of magnetic refrigeration, as they are free from the thermal hysteresis. The study of ΔS_M close to the Curie temperature (T_C) at applied fields ≤ 1.5 kOe in MnSb, $MnSbR_{0.05}$ (R: Nd and Er), materials exhibiting SOMP, are presented in this paper.. Polycrystalline samples of MnSb, $MnSbR_{0.05}$ (R: Nd and Er) were prepared by solid state reaction. XRD patterns reveal that all the samples were crystallized in the hexagonal NiAs-type of structure (space group D_{6h}^4 –$P6_3/mmc$). Magnetic transition was observed from the temperature variation magnetization at 500 Oe. The positive slope at all points of M^2 at and below T_C in the Arrott plot (M^2 vs. H/M) confirms the second-order magnetic transition behavior in all these materials. The temperature dependence of ΔS_M was determined close to T_C (591 K, of all the compounds studied) from isothermal magnetization plots in a magnetic field change from 0 – 15 kOe. The largest values of ΔS_M, $(\Delta S_M)_{max}$ observed in $MnSbNd_{0.05}$, MnSb and $MnSbEr_{0.05}$ at H = 15 kOe are respectively, 0.57 J/kg K, 0.72 J/kg K and 0.99 J/kg K. The $(\Delta S_M)_{max}$ observed at H = 15 kOe, in $MnSbEr_{0.05}$ is relatively large at high temperatures compared with those reported for high temperature MCE materials. On the other hand, a plateau type of behavior is seen at $(\Delta S_M)_{max}$ for MnSb, indicating that MnSb is useful for the practical applications in magnetic refrigeration, over a wide range of temperatures.

Mo.L-P03 - Peculiarities of giant magnetocaloric effect in Ni50Mn35In15 alloys in the vicinity of martensitic transition

I. Rodionov[1], Y. Koshkid'ko[23], J. Cwik[3], A. Quetz[4], S. Pandey[4], A. Aryal[4], I. Dubenko[4], S. Stadler[5], N. Ali[4], I. Titov[1], M. Blinov1, V. Prudnikov1, E. Lähderanta[6], I. Zakharchuk[6], A. Granovsky[1]

.

We present results of direct measurements of magnetocaloric effect in moderate and strong magnetic fields in Ni50Mn35In15 alloys. The polycrystalline samples were obtained by the conventional arc-melting technique, their composition was checked by EDX, the structural properties were studied by XRD, and magnetic properties were investigated with VCM (Lake Shore) and SQUID (Quantum Design). The adiabatic changes of temperature in magnetic fields up to 1.8 T was obtained with MagEq MMS 801set-up. For measurements in the field of 14 T of Bittter magnet we used the extraction method and specially designed home made set-up. We observed the abrupt martensitic transition (MT) from ferromagnetic austenitic state to martensite with low magnetization at 319 K and this temperature does not depend on magnetic field. Magnetic measurements confirm the presence of strong antiferromagnetic correlations in both martensitic and austenitic phases. In the vicinity of MT (H=1.6 T) changes at heating the sample from - 1.1 K to +0.9 K but (14 T) changes from -11 K to +6. The transition region of MT does not exceed 2.5 K. We connect such unusual behavior for this composition with strong antiferromagnetic correlations, which are suppressed by strong magnetic fields. Therefore large values of magnetocaloric effect in Ni-Mn-In alloys may be due to the magnetic field induced MT and by the suppression of intrinsic antiferromagnetic correlations.

2. Laboratório Nacional de Luz Síncrotron, CNPEM, Campinas, Brazil

The magnetocaloric (MCE) and electrocaloric (ECE) effects correspond to a change in temperature of a material upon magnetic field and electric field variation, respectively. Quantitatively, these effects are characterized by the entropy change in an isothermal process ΔS_T and by the temperature change in an adiabatic process ΔT_{ad} upon the field variation [1]. $EuTiO_3$ exhibits a type-G antiferromagnetic structure with strong coupling between electric and magnetic properties around its Néel temperature T_N = 5.5 K. In this work the electrical polarization and the magnetization dependence on temperature, electric and magnetic fields were investigated through a microscopic model. The Hamiltonian of the $EuTiO_3$ system describes the ferroelectric subsystem, the magnetic subsystem and the coupling between the two subsystems. In molecular field approximation, the coupling interaction is embodied by the antiferromagnetic exchange parameter and by the pseudo-electric-spin interaction parameter [2]. The temperature dependence of ΔS_T in $EuTiO_3$ was calculated under simultaneous variations of electric and magnetic field. The peak in the ΔS_T -MCE can be tuned by the electrical field intensity and this process was scribed to the increasing of the antiferromagnetic interaction upon electric polatization. Besides, around T_N , an outstanding result was predicted in which the $EuTiO_3$ can absorbs or eliminate heat, in an isothermal process, upon magnetic field change from zero to 1 T, depending on the electric field intensity.

Mo.L-P07 - Giant reversible rotating magnetocaloric effect in $KEr(MoO_4)_2$

V. Tkáè[1,2], A. Orendáèová [1], M. Orendáè[1], A. G. Anders[3], A. Feher[1]

1. Institute of Physics, P. J. èafárik University, Košice, Slovak Republic
2. Department of Condensed Matter Physics, Faculty of Mathematics And Physics, Charles University, Prague, Czech Republic
3. B. I. Verkin Institute for Low Temperature Physics and Engineering of NASU, Lenin, Kharkov, Ukraine

Experimental and theoretical studies of $KEr(MoO_4)_2$ – a quasi-low-dimensional Ising magnet, were performed at temperatures above 2 K and magnetic fields up to 5 T. Previous studies in magnetic field [1] revealed a shift of a magnetic phase transition down to temperatures far below a zero-field value, T_c = 0.9 K. Thus, the investigation above 2 K excludes any possibility of the interplay between long-range magnetic correlations and crystal field effects (CEF). Correspondingly, magnetization data along the easy axis *a* can be described within a CEF model, while a description along the hard axis *b*, fails due to the occurrence of a field-induced Jahn-Teller effect [2]. In the field applied along the easy axis, large conventional magnetocaloric effect (MCE) was found from experimental data around 10 K ($-\Delta S_{max}$ = 14 J/kg K) for 5 T and even higher values ($-\Delta S_{max}$ = 16 J/kg K) can be expected around 12 K for 7 T, when applying the CEF model. A huge magnetic anisotropy in the *ab* plane leads to a large rotating MCE, $-\Delta S_{R,\,max}$ = 10 and 13 J/kg K obtained by a simple rotating the single crystal within the *ab* plane in the constant magnetic field 2 and 5 T, respectively. The highest anisotropy of MCE was reported in $HoMn_2O_5$ [3] with $-\Delta S_{max} \approx 12.4$ J/kg K for 7 T, but only $-\Delta S_{max} \approx 3$ J/kg K for 2 T. Large ΔS_R values with no hysteresis losses and rather wide working temperature spans imply that $KEr(MoO_4)_2$ may serve as a promising candidate for the implementation of a compact rotary magnetic cryorefrigerator.

The problem of rate of phase transitions (PTs) requires an indispensable solution, because the creation of new technologies based on “giant” effects in vicinity of PTs in magnetic materials is impossibly without solving of this problem. The magnetocaloric effect reaches its peaks near the PTs in magnetics, therefore knowledge of PT’s rate is necessary for creation of new technology of magnetic refrigeration at room temperature. The rate of PT limits the frequency of thermodynamic cycles. Accordingly, the power of refrigeration will depend on the frequency of cycles, and it is difficult to judge the profitability and competitiveness of the creation of this machine without determining the parameters of power. In this paper, we present a new technique for experimental study of the kinetics of the magnetic PTs under low alternating magnetic field, and the theoretical calculations of respective kinetic processes. The new dynamic thermo-magnetometer (DTM) is proposed for solving the problem of the experimental study the rate of the magnetic PT with response time of 10 ms. DTM is designed for measuring the time dependence of the magnetic susceptibility of thin plates of ferromagnets at an abrupt temperature change in water flow. The experimental measurements of the magnetic susceptibility of the samples were carried out with the help of a three-coil differential transformer. An AC signal with a frequency of 1-10 kHz was supplied to the outside coils. The measured signal was taken from the central coil. The temperatures of both samples and water were measured using thin differential thermocouples. As a result of experiments for Gd near Tc = 20 C relaxation time of magnetization is about 50 ms. Then the frequency of the cycles of a magnetic refrigerator with a working body made of Gd plates will be restricted to a value of f = 10 Hz.

Mo.L-P11 - Enhancement of Thermal Stability and Soft Magnetic Properties of High Induction (Fe(1-x)Cox)79Si8.5B8.5Nb3Cu1 (x= 0,0.05, 0.35) Nanocrystalline Alloys

R. K. Roy[1], A. K. Panda[1], A. Mitra[1]

1. MST Division, CSIR-National Metallurgical Laboratory, Jamshedpur, India

The next generation soft magnetic alloys demand higher saturation induction than that of Fe based amorphous alloys (FINEMET) and a low core loss than that of Si steel. The increased thermal stability and high temperature magnetic properties are also prerequisites for their wide application in the harsh environment. In view of this requirement, the phenomena of nanocrystallization and associated high temperature magnetic properties have been investigated in two Co-substituted alloys (#FC05 and #FC35) with nominal compositions of $(Fe_{1-x}Co_x)_{79}Si_{8.5}B_{8.5}Nb_3Cu_1$ (x= 0.05, 0.35), respectively. Alloys were prepared by melt spinning technique and followed by annealing treatment in inert atmosphere to induce nanocrystallization. As-cast alloys are amorphous, and onsets of primary crystallization (Tx_1) and secondary crystallization (Tx_2) temperatures of #FC05 are 443 and 623°C and that of #FC35 are 437 and 582°C, respectively. With more Co incorporation, as examined in #FC35, the drop in TX_2 is far drastic as compared to TX_1. Thus, thermal stability ($\Delta Tx = Tx_2 - Tx_1$) against secondary crystallization and activation energy (Q) for primary crystallization is higher for a minimal amount Co addition (#FC05), evaluated as $\Delta Tx_{\#FC05}$ = 180°C, $\Delta Tx_{\#FC35}$ = 145°C, $Q_{\#FC05}$ = 258kJ/mol and $Q_{\#FC35}$ = 235kJ/mol. Additionally, alloy FC#05 although shows a relatively lower saturation induction (M_s) than #FC35, its coercivity (H_c) is considerably superior than the later [$M_{s\#FC05}$ = 1.46T, $M_{s\#FC35}$ = 1.53T, $H_{c\#FC05}$ =4.4A/m, $H_{c\#FC35}$ =22.4A/m]. Nanocrystallization process of annealed alloy is a consequence of α-FeCo crystallite formation and some non-magnetic phases. Annealing at 500°C confirms comparatively superior magnetic properties of #FC05 (M_s=1.62T, H_c=44.97A/m) than that of #FC35 (M_s 1.69T and H_c of 377.4A/m), which is attributed to more structural instability in annealed #FC35 and better grain refinement of annealed #FC05. Therefore, it is concluded that a small amount of Co addition is advantageous for improving thermal stability and high temperature magnetic properties.

Mo.L-P12 - Structural and magnetic characterization of CoNiA and CoNiGa pseudo-Heusler superelastic alloys

J. Mino[1,2], V. Komanicky[1], M. Ipatov[2], A. Zhukov[2,3], V. Zhukova[2], R. Varga [1], Zuzana Vargova[1]

Magnetic superelastic alloys are perspective materials, which can be used as sensors and actuators [1]. Properties of superelastic change are mostly influenced by martensitic transformation, which can be triggered by stress, temperature and, in the case of magnetic alloys, also by magnetic field change. The CoNiX (X=Al,Ga) superelastic pseudo-heusler alloys are usually prepared by arc-melting with additional annealing [2]. However, with a melt-spinning method annealing can be avoided or significantly reduced, still with good quality of highly textured polycrystalline ribbons [3]. The structural and magnetic properties of melt-spoon CoNiGa and CoNiAl ribbons have been investigated. Structural examination by SEM revealed polycrystalline structure with grain size varied in the orders of micrograms. Magnetic measurements were carried by PPMS. Temperature dependence of magnetization shows martensitic transformation at the temperature around 123K for CoNiGa and 50K for CoNiAl. By measuring the hysteresis loop the relative volume fraction of both phases around the transformation temperature can be estimated.

The usual methods for the determination of the Curie temperature (T_C) are either affected by the value of the applied field (e.g. the inflection point of magnetization curves), depend on the chosen values of the critical exponents (Arrott plots) or they are iterative procedures like Kouvel-Fisher method [1]. Although in the literature the position of the magnetic entropy change peak (T_{peak}) is usually identified as the Curie temperature of the sample, this is only true in terms of a mean field approximation. Actually, T_{peak} can be field dependent. The field dependence of the magnetic entropy change (ΔS_M) can be expressed as a power law of the field $\Delta S_M = aH^n$. It has been previously demonstrated [2] that $n(T_{peak})=n(T_C)$. Making use of this property, in this work we propose an alternative method for the determination of T_C that provides values which are field independent and does not require an iterative procedure: it consists in 1) the determination of T_{peak} from the $\Delta S_M(T)$ curve, 2) evaluate $n(T_{peak})$ and 3) identify the temperature $T<T_{peak}$ for which the $\Delta S_M(T)$ curve reveals the same exponent n for the field dependence, which corresponds to the Curie temperature of the sample. The validity of the method is illustrated with numerically simulated data obtained from the Arrott-Noakes equation of state [3] and experimental results of a Cr containing Fe-based amorphous alloy.
This work was supported by Spanish MINECO and EU-FEDER (project MAT2013-45165-P) and the PAI of the Regional Government of Andalucía. Δ α

Mo.L-P14 - Analysis of the field dependence of magnetocaloric effect at the transition temperatures for biphasic systems

J.J. Ipus[1], L.M. Moreno-Ramirez[1], J.S. Blázquez[1], V. Franco[1], A. Conde[1]

1. Departamento de Física de la Materia Condensada, ICMSE-CSIC, Universidad de Sevilla, Sevilla, Spain

The future application of magnetic refrigeration close to room temperature has increased the interest of the optimization of magnetocaloric materials. Therefore, it is necessary to compare data from different laboratories and acquired at different experimental conditions (e.g. magnetic field, H). In this sense, the study of the field dependence of the magnetic entropy change, $\Delta S_M = aH^n$, and the master curve analysis[1] are useful tools for this comparison. For single phase materials with second order phase transition, n is field independent at the Curie temperature, T_C, and related to the critical exponents of the transition. However, several factors can yield an incorrect determination of n, like the effect of the demagnetizing field and the multiphase character of some alloys. In this work, partially amorphous $Fe_{75}Nb_{10}B_{15}$ alloy was prepared by mechanical alloying[2]. Isothermal magnetization curves were corrected considering a demagnetizing factor of 1/3 and used to calculate ΔS_M. From the analysis of the field dependence of ΔS_M, the individual parameters of each phase were extracted under the approximation of two non-interacting phases (amorphous and bcc-Fe phases). For a constant H, the product $n \cdot |\Delta S_M|$ at T_C of the amorphous phase linearly decreases with increasing crystalline fraction, X_C. From the field dependence of the parameters of the linear fit, the characteristics of each phase are obtained. These agree well with typical ones found for other amorphous materials[1]. The described method can be easily extended to analyze other systems for which pure phase materials are difficult to obtain.

The magnetocaloric effect is extensively studied experimentally and theoretically due to its potential applications for magnetic refrigeration as well as for further understanding the fundamental properties of the new materials. One of the most promising materials for use as a working component of the magnetic refrigerators in wide temperature range are Laves phase intermetallic compounds. This work reports magnetic and magnetocaloric properties of the polycrystalline series of Er-Fe-Al solid solutions. These samples were synthesized using high purity elements. Powder X-ray diffraction study have been performed at room temperature and analyzed using Rietveld refinement. Magnetization measurements were carried out using a vibration sample magnetometer with a step motor in applied fields up to 14 T using a Bitter-type magnet. The heat capacity was measured using Quantum Design PPMS 14 Heat Capacity System in a temperature range of 2-295 K without the magnetic field and in a magnetic field of 1 and 2 T. Structural investigation showed the formation of the cubic C15 structure and the hexagonal C14 structure depends on the composition. The magnetic ordering temperature decreases from 273 K for ErFe1.64Al0.36 to 28 K for ErFe0.5Al1.5. Magnetization measurements in strong magnetic fields showed the complex mechanism of magnetic saturation in the studied compounds. The magnetocaloric effect has been estimated both in terms of isothermal magnetic entropy change and adiabatic temperature change in magnetic fields up to maximum 2 T. The effect of increasing Al amount in ErFe2-xAlx samples on magnetic and magnetocaloric properties will be discussed.

Mo.L-P16 - Shedding light on first-order magnetostructural transitions

M. Boeije[1], F. Guillou[1], Yibole [1], X. Miao[1], P. Roy[2], N. van Dijk[1], R. de Groot[2], E. Brück[1]

Magnetic cooling is a highly efficient refrigeration technique which could replace the traditional vapour compression cycle in the future. The driving force for this effect is a change in entropy between high and low temperature phases and the material can be switched between these states by applying an external magnetic field. For most magnetic materials, only the magnetic entropy plays a role in this transition. In addition to a magnetic contribution, the more promising magnetocaloric materials also show a change in crystal structure. All these transitions are of first order, and range from a small volume changes to changes in crystal symmetry. Apart from the lattice entropy, electronic entropy also plays a role and when the signs of these changes are the same, they can amount to a huge entropy change. Our focus is on materials which exhibit small changes in volume, like found in Fe2P and La(Fe,Si)13 materials. These materials can have very low thermal hysteresis and tend to have better mechanical stability. Unfortunately, these materials are scarce and the mechanism which links the various entropy contributions is not fully understood. We present experimental evidence which show how the coupling between magnetism and crystal structure takes place, with an Fe2P based material as example. Using X-ray absorption and diffraction experiments, it was found that a redistribution of electron density takes place across the transition. The redistribution is consistent with the classical picture of the forming of a covalent bond while losing the magnetization. This discovery provides direct evidence of a predicted form of magnetism, called mixed magnetism. We now understand how these materials work and where to look in finding new promising materials.

Mo.L-P17 - Giant irreversible inverse and large reversible magnetocaloric effect in (Dy0.6Gd0.4)5Pd2 intermetallic compound

T. Paramanik[1], I. Das[1]

1. CMP Division, Saha Institute of Nuclear Physics, Kolkata, India

Detailed structural, magnetic and magnetocaloric study has been performed on polycrystalline (Dy0.6Gd0.4)5Pd2 compound. Magnetic measurement shows large irreversibility both in temperature and magnetic field cycling has been observed in low temperature region. A large reversible magnetic entropy change has been observed over a wide temperature range. The peak value of magnetocaloric entropy change ~7.2 J/kg-K for 7 T magnetic field change has been observed around 87.5 K. Giant positive irreversible magnetic entropy change (~14.8 J/kg-K at 3 K for 7 T magnetic field change) below 25 K from zero-field-cooled isothermal magnetization measurement, which is associated with the internal entropy production. The possibility of the origin of the giant irreversible positive entropy change has been discussed. Validity of Maxwell's relation to evaluate reversible magnetocaloric entropy change from magnetization measurement has been described. An estimation of internal entropy production and its thermal dependence has been presented from thermodynamical analysis.

Mo.L-P18 - Magnetic investigation on $MnNiGe_{0.9}Al_{0.1}$ alloy

P. Dutta[1], D. Das[1], S. Chatterjee[1]

1. UGC-DAE Consortium For Scientific Research, Kolkata Centre, Kolkata, India

We present a systematic magnetic investigation on an Al doped Mn-Ni-Ge magnetic equiatomic alloy (MEA) of nominal composition $MnNiGe_{0.9}Al_{0.1}$.The undoped MnNiGe alloy undergoes first order martensitic phase transition (MPT) from the high temperature hexagonal Ni_2In-type structure to the low temperature orthorhombic TiNiSi-type structure at 470K during cooling and orders antiferromagnetically (AFM) below 346K. Al doping in Ge site results decrease in structural transition temperature and causes changes in lattice parameters that induces ferromagnetism in this intrinsically AFM system. Magnetization vs. Temperature *(M – T)* data in presence of 100 Oe magnetic field reveals that, on cooling, the alloy undergoes paramagnetic (PM) to ferromagnetic (FM) transition around 190K and FM to AFM transition around 115K along with MPT. Observation of clear thermal hysteresis between field cooling and field cooled heating magnetization data around the MPT confirms the first order nature of the transition. Three distinct magnetic regions are clearly observed in the isothermal *M-H* data. The negative slope of the Arrot plot near FM to AFM transition and the positive slope near the PM to FM transition indicate first and second order transitions respectively that prompted us to investigate the magnetocaloric effect (MCE) in the sample. Change in entropy (DS) on application of *H* is a measure of MCE. A large inverse MCE has been observed around the MPT (DS = 15 J/kg-K for 0-50 kOe at 115K), whereas DS is found to be negative around the FM to PM transition (DS = -5 J/kg-K for 0-50 kOe at 190K). Relative cooling powers are found to be -150.4 J/kg and 142.92 J/kg for 0-50 kOe at 115K and 190K respectively.This work reveals that the studied material is a good addition to the list of presently available intermetallic alloys having magneto-functional properties.

Mo.L-P19 - Influence of high pressure oxygenation on the structure and magnetic properties of la-ca-sr-mn-o perovskite ceramic material

K. Zmorayová[1], V. Antal[1], S. Piovarèi[1], V. Kaveèanský[1], J. Kováè[1], L. Vojtková[1], P. Diko[1], M. Kañuchová[2]

1. Institute of Experimental Physics, Slovak Academy of Sciences In Košice, Košice, Slovakia
2. The Technical University of Košice, Košice, Slovakia

In this contribution, the influence of high pressure oxygenation on the structure and magnetisation behaviour of La0.67Ca0.3Sr0.03MnO3 (LCSM) perovskite ceramics was investigated. The LCSM perovskite ceramic material was prepared by conventional solid state synthesis in air and subsequently sintered at 1520°C. The sample for study of oxygen influence was additionally treated by high pressure oxygenation (HPO) at following conditions: 800°C for 1 hour, cooling to room temperature at 95 bar pressure of pure oxygen atmosphere. The purity and grain size of studied sample was checked by a scanning electronic microscope (SEM) and analysis by energy dispersive spectrometer (EDS) which confirmed the uniform distribution of elements in the sample. The formation of the LCSM perovskite ceramic material and changes in the oxidation states of elements were studied by X-ray photoelectron spectroscopy (XPS) and by thermogravimetric measurement (TG). XPS measurements showed changes in the valence of Mn3+ to Mn4+ after high pressure oxidation caused by the mass changes of the oxygen content in the samples, which was confirmed by TG measurement. For determination of the Curie temperature the small sample pieces were measured by a Magnetic Property Measurement System (MPMS). The magnetization measurements showed that the high-pressure oxidation shifts the thermomagnetic curves toward lower temperatures.

Mo.L-P20 - Structural, optical and magneto-optical studies of martensitic tansformation in magnetic shape memory alloy Ni2MnGa

P. Cejpek[1], L. Beran[1], R. Antoš[1], V. Holý[1], M. Veis[1], O. Heczko[2]

1. Charles University In Prague, Prague, Czech Republic
2. Institute of Physics, Academy of Science of Czech Republic, Prague, Czech Republic

Magnetic shape memory alloys have the outstanding property, which allows their straining [1] in moderate magnetic fields (< 1T). Among these alloys Ni_2MnGa is a good model system in which the macroscopic deformation occurs due to magnetically induced structural reorientation of martensite. Therefore the martensitic transformation to low symmetry phase is a key for the existence of the shape memory effect and its deep understanding is necessary for future applications of these alloys. In this work, the structure of the $Ni_{50.1}Mn_{28.4}Ga_{21.5}$ was systematically studied by X-ray diffraction, especially with the reciprocal space mapping. The structure is monoclinic, which slightly differs from the tetragonal martensite. Measured reciprocal maps contain more diffraction spots, which occur due to the mosaic blocks and the twinning. The satellite maxima have been measured too. There were four of them between each of the proper diffraction spots. That proofs the 10M modulated structure. Temperature dependent reciprocal maps around 040 diffraction peak have been measured. The structure transition to cubic austenite phase was observed with notable hysteresis. The transition occurs at 68°C during the heating and at 56°C during the cooling. To get the information about the changes in electronic structure during the transformation, optical and magneto-optical methods were employed as well. Namely the spectroscopic ellipsometry and Kerr magneto-optical spectroscopy in the photon energy range from 1.2 to 5.6 eV. Magneto-optical spectra of polar and longitudinal Kerr rotation as well as spectra of ellipsometric parameters Ψ and Δ exhibited significant changes when crossing the transformation temperature. These changes correlated with XRD observations and were explained by change of optical properties of Ni_2MnGa due to differences in electron density of states at Fermi energy in martensite and austenite phases.

Mo.L-P23 - Magnetic and magnetothermal properties of the melt-spun $(Gd_{1-x}Tb_x)_{75}Co_{25}$ and $(Gd_{1-x}Y_x)_{75}Co_{25}$ alloys

D. Shishkin[1,2], A. Volegov[2], A. Chirkova[1,2,3], K.i Nenkov[3], N. Baranov[1,2]

1. Institute of Metal Physics, Russian Academy of Science, Ekaterinburg, Russia
2. Institute of Natural Sciences, Ural Federal University, Ekaterinburg, Russia
3. IFW Dresden, Dresden, Germany

This work aims to study the magnetic and magnetothermal properties of melt-spun $(Gd_{1-x}Tb_x)_{75}Co_{25}$ and $(Gd_{1-x}Y_x)_{75}Co_{25}$ alloys. The samples were prepared by a melt-spinning technique. The isothermal magnetic entropy change, ΔS_M, was calculated from the temperature dependences of the magnetization measured in magnetic fields up to 50 kOe by using the thermodynamic Maxwell relation.
The Gd_3Co compound is an antiferromagnet with the Néel temperature $T_N \approx 131$ K and with zero magnetic moment on Co atoms. The amorphization of Gd_3Co modifies its magnetic state to the ferromagnetic-like behavior, leads to the appearance of a magnetic moment on Co atoms and improves the magnetocaloric properties in comparison with the crystalline counterpart [1]. Specific heat measurements performed in the present work have revealed that the liquid-quenched $Gd_{75}Co_{25}$ alloy exhibits a lower value of the electronic specific heat coefficient than the crystalline sample (257 mJ kg^{-1} K^{-2} and 319 mJ kg^{-1} K^{-2}, respectively). Unlike the metallic character of the resistivity behavior in the crystalline Gd_3Co the $\rho(T)$ dependence for the liquid-quenched sample shows a weak thermally activated behavior. For the melt-spun $(Gd_{1-x}Y_x)_{75}Co_{25}$ alloys, the substitution of Y for Gd reduces the magnetic ordering temperature and ΔS_M value. The amorphous $(Gd_{1-x}Tb_x)_{75}Co_{25}$ alloys are found to exhibit the ΔS_M value about of 8.7±0.5 J kg^{-1} K^{-1} in the wide temperature range between 75 K and 170 K. Moreover, amorphous samples show much higher refrigerant capacities in comparison with their crystalline counterparts.
This work was supported by the program of the Ural Branch of RAS (Project No 15-17-2-22) and RFBR (Grant No. 14-02-31865).

Mo.L-P24 - Magnetic behaviour of martensite in metamagnetic Ni-Co-Mn-Ga alloys

C. Seguí[1], E. Cesari[1], P. Lázpita[2]

1. Departament de Física. Universitat Illes Balears, Palma de Marllorca, Spain
2. Departamento de Electricidad y Electrónica. Universidad del Pais Vasco, Leioa, Spain

Ferromagnetic Ni-Co-Mn-Ga shape memory alloys show, for a certain range of Co content, metamagnetic behavior, as they undergo martensitic transformation (MT) between ferromagnetic austenite (Aferro) and paramagnetic -or weak magnetic- martensite (mpara). The temperatures of the structural and magnetic transitions depend on composition and atomic order. The austenite L21 order degree can be modified by selected thermal treatments; namely, quenched-in disorder after quench raises the MT temperatures, and lowers both austenite and martensite Curie temperatures, whereas order improvement during post-quench ageing promotes recovery of all transformation temperatures. Such opposite changes make that, for a given composition, the transformation sequence on cooling/heating depends on the atomic order; for example, poorly ordered high e/a alloys display Apara-mpara MT, evolving to Aferro-mpara as ordering improves, while for low e/a the MT changes from Aferro-mpara to Aferro-mferro. Consequently, combined composition and thermal treatment allows for MT between any magnetic state of austenite and martensite. In previous works we have made progress in understanding the mutual influence between atomic and magnetic order and its effect on the transformation entropy. However, there are still several issues that require detailed analysis to be well understood. These include the magnetic nature of martensite. At low magnetic fields, magnetization in martensite is small but seemingly not zero; this could be due to antiferromagnetic rather than paramagnetic behavior of martensite, as suggested for some metamagnetic alloys including Ni-Co-Mn-Ga, but this is still a matter of discussion. In the present work, the magnetic state of martensite has been studied in detail for the Ni43Co7Mn30Ga20 alloy. Its evolution as a function of atomic order shows that the magnetic order of the -as called- paramagnetic martensite increases as the austenite switches Apara to Aferro; in the ordered state, the martensite is ferromagnetic (or ferrimagnetic) rather than paramagnetic, as revealed by the magnetization vs field curves.

Mo.L-P25 - Rotational Electromagnetic Energy Harvesting System

D. Dinulovic[1], M. Haug[1], T. Petrovic[2]

1. Wurth Elektronik EiSos, Germany
2. University of Nis, Niš, Serbia

Abstract
This paper presents development of a rotational electromagnetic energy harvesting transducer. Transducer is driven mechanically by pushing the button; therefore, a mechanical energy will be converted in to an electrical energy. The energy harvesting (EH) transducer consists of multilayer planar coils embedded in to PCB, of multipolar NdFeB hart magnets, and of mechanical system for movement conversion. The EH transducer generate an energy of 3mJ at load of 10Ω. The maximal open circuit output voltage is higher as 2V and maximal short circuit output current is higher as 800mA.

Introduction
Main advantage of rotational electromagnetic transducers regarding to oscillatory electromagnetic transducers is independence to the oscillating frequency.
The harvester will be powered by pushing the button. The linear movement of the button will be transformed into a rotational movement by movement conversion mechanism. On this way, a rotor consisting of hart magnets will be rotated above the stator with coils. Therefore, an electrical voltage will be induced. These transducers are capable to achieve higher energy density as other electromagnetic transducers [1].

Design
The whole energy harvester system is modular and consists of 3 modules: (A) mechanism for motion conversion, (B) electromagnetic energy harvesting part, (C) power management system (PMS) with RF transmitter.
The electromagnetic transducer consists of movable part (rotor) and stationary part (stator). The rotor consists of 8 multi-pole hart magnet segments of NdFeB mounted on soft magnetic Co-alloy sheet metal with high saturation flux density. As a stator serves one coil system consisting of 8 coils divided in two phases. Coils are embedded into PCB.
Both parts, the stator and the rotor, are mounted on axis forming a defined air gap between.
An induced voltage will be “managed” using power management system. The AC voltage will be converted into DC voltage and set to a regulated output voltage i.e. 1.8V. This voltage will be used for power an RFID transmitter.

Hexagonal Mn-Fe-P-Si compounds are known to represent an extremely attractive rare-earth-free system for applications in room-temperature magnetic refrigeration [1]. The giant magnetocaloric effect (MCE) associated to a magneto-elastic first-order phase transition has been studied in this system with particular emphasis on the tuning of critical temperature, entropy change and thermal hysteresis as a function of the chemical composition [2]. MCE properties are also extremely sensitive to the preparation route [3, 4]. A systematic comparison between three bulk samples, with composition Mn1.3Fe0.65P0.5Si0.5, prepared respectively by conventional sintering and by spark plasma sintering (SPS) under different pressures, and a powder of the same composition prepared by high-energy ball milling is presented. Here we focus on the behavior of samples after the first cooling (i.e. the so-called virgin effect will be treated elsewhere). We show that the magnetic entropy change, derived from isothermal magnetization curves measured in a magnetic field up to 5 T, and Arrott plots are strongly affected by the preparation route. The observed differences are interpreted with emphasis on the role of microstructure and porosity. The way in which microstructure can affect the transition due to magneto-elastic coupling is discussed.

Mo.L-P27 - Pressure induced magnetic and magnetocaloric properties in Mn rich Mn-Ni-Sn Heusler alloys

J. Sharma[1], K. G. Suresh[1], A. A. Coelho[2]

1. Indian Institute of Technology Bombay, Mumbai, India
2. Instituto de Física "Gleb Wataghin", Universidade Estadual de Campinas-UNICAMP, Sao Paulo, Brazil

In recent years Ni-Mn-Z (Z= Ga, Sn, Sb and In) Heusler alloys have attracted enormous attention owing to their multifunctional properties such as giant magnetocaloric effect (MCE) and large magnetoresistance, at their first order magnetostructural (martensitic) transition. Magnetic properties of these alloys are strongly influenced by Mn-Mn exchange interaction, which can be altered by either chemical substitution or applying pressure. Recently effect of pressure has been reported in many Ni rich Ni-Mn-Z alloys. However, no such reports are available for Mn rich Mn-Ni-Z alloys. In this paper, we have investigated the effect of pressure on the martensitic transition, magnetic and magnetocaloric properties of Mn rich $Mn_{50}Ni_{39+x}Sn_{11-x}$ (x=0 and 2) Heusler alloys. Polycrystalline samples were prepared by arc melting method. Magnetization measurements at different applied pressures have been performed using SQUID attached with a Cu–Be clamp type pressure cell. Both alloys undergo the martensitic transition and the transition temperature (T_M) has been found to increase with increase of pressure, whereas it decreases with increase in field. For x =2, T_M ~299 K (RT) at ambient pressure (P= 0) and becomes ~339 K for P=10.4 kbar, which is attributed to the stabilization of the martensite phase. A splitting between ZFC and FC curves has been observed at low temperatures, which is attributed to the coexistence of antiferromagnetic and ferromagnetic exchange interactions. Pressure effect on MCE has been studied by isothermal magnetic entropy change (ΔS_M). ΔS_M has been found to increase with increase of x, and a large value of ΔS_M ~6.45 J/kg.K has been observed at ~RT (at P = 0) for x = 2. However it has been found to decrease with increase of pressure, but the peak temperature of ΔS_M vs. T peak increases. Therefore, hydrostatic pressure can be used to tune magnetic and magnetocaloric properties over a wide temperature span around RT in these alloys.

Mo.L-P28 - Enhancement of coercivity through Nd-Cu eutectic reaction for Nd-Fe-B thin films

R. Nakagawa[1], T. Shima[1]

1. Tohoku-Gakuin University, Sendai, Japan

In this study, in order to enhance a hard magnetic properties and microstructure modification for the Nd-Fe-B thin films through Nd-Cu eutectic reaction, Nd-Fe-B/ Nd-Cu multilayer thin films have been prepared and their structure and magnetic properties have been investigated. The samples were prepared by using an UHV compatible magnetron sputtering system. The base pressure is below 5×10^{-8} Pa. First of all, a epitaxial Mo buffer layer of 20 nm was deposited onto MgO (100) single crystal substrates at room temperature (R.T.) Subsequently, the substrates were cooled to 500 ºC and the Nd-Fe-B layer and the Nd-Cu cap layer were deposited. The nominal thickness of the Nd-Fe-B layer was fixed at 16 nm and Nd-Cu layer was fixed at 0.75 nm. Then, the samples were annealed from 500 ºC to 600 ºC for 60 min for the crystallization of Nd-Fe-B/ Nd-Cu layer. Finally, a protective Mo layer of 10 nm was deposited at R.T.. In order to see the effect of annealing temperature, T_a was varied. All the films were measured in the perpendicular direction to the film plane and in the in-plane direction. Nd-Fe-B layer began to crystallize at T_a = 500 ºC and highest H_c of 29.2 kOe and good squareness were obtained at T_a = 550 ºC. The alloy composition of Nd and Cu is close to eutectic point, and H_c is thought to increase by the diffusion of the Nd-Cu alloy layer to the grain boundary phase. However, remarkable reduction of H_c was observed at T_a = 600 ºC.

Mo.L-P29 - Microstructural control of Nd-Fe-B materials sintered using electric Field Assisted Sintering Techniques (FAST)

E. Castle[1], S. Grasso[1], M. Reece[1], R. Sheridan[2], A. Walton[2]

1. Queen Mary, University of London, London, United Kingdom
2. University of Birmingham, Birmingham, United Kingdom

In order to address the growing need for high coercivity, Dy-free Nd-Fe-B permanent magnets for automotive applications, it has long been recognised that enhanced microstructural control over the grain size, alignment and grain boundary phase distribution and composition will be key [1,2]. In the present work, electric Field Assisted Sintering Techniques (FAST) have been employed in order to rapidly consolidate both commercially available melt-spun materials and recycled hydrogenation, disproportionation, desorption, recombination (HDDR) processed materials. The effect of starting material, pre-sintering preparation method and sintering conditions on the density, final microstructure and magnetic properties has been investigated. It is shown that a good degree of microstructural control can be achieved as well as consolidation to full density. Consequently, it is shown that a range of magnetic properties can be achieved, including both isotropic and anisotropic magnets; using fabrication techniques which require much less time and energy as compared to conventional processing methods.

Refrigeration based on magnetic cooling *via* the magnetocaloric effect offers potential as an alternative to conventional gas-compression systems [1]. MnCoGe-based compounds show promise for magnetic refrigeration and have been extensively investigated over the last decade [*e.g.* 2]. These compounds have two crystallographic structures: nominally low temperature TiNiSi-type orthorhombic structure (P*nma*) and the high temperature Ni_2In-type hexagonal structure (P6_3/*mmc*). When the structural transition temperature between the two structures is 'tuned' between the respective Curie temperatures of the phases (~345 K for the orthorhombic phase and ~275 K for the hexagonal phase in MnCoGe [2]), a direct change from a ferromagnetic orthorhombic phase to a paramagnetic hexagonal phase can result [2]. For a such a magneto-structural transition, the lattice and magnetic entropy changes occur simultaneously, thereby providing scope for observation of a large magnetocaloric effect [3].
The crystallographic structures and magnetic properties of annealed $Mn_{1-x}Ni_xCoGe$ (x = 0.03, 0.04, 0.05, 0.06 and 0.07) have been investigated using x-ray diffraction (T = 18-310 K) together with neutron diffraction measurements carried out for $Mn_{0.95}Ni_{0.05}CoGe$ in the range T = 5-320 K in addition to magnetisation measurements (T = 5-340 K). The outcomes from our experiments demonstrate the formation of magneto-structural transitions within the series. The magnetic entropy changes have been derived in the conventional way from a series of isothermal magnetisation experiments, *e.g.* $-\Delta S_m$ ~ - 8.8 J kg^{-1} K^{-1} for a magnetic field change of ΔB = 0-5 T in $Mn_{0.95}Ni_{0.05}CoGe$.

Mo.L-P32 - Direct and inverse thermal magnetocaloric effect obtained from non-adiabatic measurements: $Gd_{0.5}Pr_{0.5}Al_2$ compound case

A. Carvalho[1], C. Salazar Mejía[2], A. Gomes[2]

1. Laboratório Nacional de Luz Síncrotron, CNPEM, Campinas, Brazil
2. Instituto de Física, UFRJ, Rio de Janeiro, Brazil

In the last two decades, there was an increasing interest on the research of the magnetocaloric effect (MCE), mainly due the possibility of applying it to heat up or cool down objects, using different thermomagnetic cycles, such as, Ericsson, Stirling or Brayton cycles. Direct measurement of the MCE is usually referred only to the adiabatic temperature change (ΔT_S), and in this case, the magnetic material is directly attached to a temperature sensor and its response is monitored while the applied magnetic field is altered. Although the direct measurement of ΔT_S seems to be a trivial task, it is not the case in terms of experimental procedures.
In this work, we apply to $Gd_{0.5}Pr_{0.5}Al_2$ compound a new methodology to obtain the ΔT_S curve from non-adiabatic temperature changes measurements. Around the magnetic transition temperature, we have obtained positive ΔT_S values (direct MCE). Below 60 K, we have obtained negative ΔT_S values (inverse MCE), in great agreement with results from calorimetric measurements [1]. Above 60 K, the divergences between MCE from calorimetry and MCE from direct measurements increase with temperature, which is an indication of any kind of problem with the calorimetric measurements in Ref. [1].

Mo.L-P33 - Giant Magnetic Entropy Change in $La_{0.6}Ce_{0.4}Fe_{11.5}Si_{1.5}$ Alloy Exhibiting First- and Second-Order Phase Transitions

T. D. Thanh[1], W. Z. Nan[1], B. Y. Jeon[2], T. S. You[2], T. L. Phan[3], S. C. Yu[1]

1. Department of Physics, Chungbuk National University, Cheongju, South Korea
2. Department of Chemistry, Chungbuk National University, Cheongju, Korea
3. Department of Physics, Hankuk University of Foreign Studies, Yongin, South Korea

In this work, a polycrystalline alloy ingot $La_{0.6}Ce_{0.4}Fe_{11.5}Si_{1.5}$ was prepared by an arc-melting method. Magnetic measurements versus temperature (50-300 K) and magnetic field (0-30 kOe) were performed on a vibrating sample magnetometer. The magnetic results reveal the sample exhibiting a ferromagnetic-paramagnetic phase transition at T_C = 170 K. Interestingly, the H/M versus M^2 curves at low-field ($H \leq 10$ kOe) show a positive slope, corresponding to the second-order phase transition (SOPT), whereas, a negative slope corresponding to the first-order phase transition (FOPT) was observed at high-field ($H > 10$ kOe). These suggest that a coexistence of FOPT and SOPT properties in $La_{0.6}Ce_{0.4}Fe_{11.5}Si_{1.5}$. Basing on $M(H)$ isotherms, $\Delta S_m(T)$ data for sample under the maximum magnetic field change H = 5-30 kOe (with step of 5 kOe) were calculated. As a result, $|\Delta S_m(T)|$ reaches the maximum ($|\Delta S_{max}|$) around T_C and increases with an increasing H. With H = 10, 20, and 30 kOe, $|\Delta S_{max}|$ values are 13.2, 26.0, and 33.2 $J \cdot kg^{-1} \cdot K^{-1}$, respectively. On the other hand, the magnetic cooling efficiency of refrigerants can be, in simple cases, evaluated by RCP = $|\Delta S_{max}| \times \delta T_{FWHM}$, where δT_{FWHM} is the full width at half maximum of $\Delta S_m(T)$ curve. Depending on H, the RCP value is found to be 59.4, 130.0, and 199.2 $J \cdot kg^{-1}$ for H = 10, 20, and 30 kOe, respectively. Also, the results reveal that all $\Delta S_m(T)$ curves at low-field ($H \leq 10$ kOe) are collapsed into a universal curve, which is obtained by normalizing $\Delta S_m(T)/\Delta S_{max}$) versus $\vartheta = (T - T_C)/(T_r - T_C)$; here, T_r is the reference temperature. In contrast, $\Delta S_m(T)/\Delta S_{max}$ versus ϑ curves in the high-field case ($H > 10$ kOe) do not overlap into a universal curve, indicating an existence of the FOPT property. This nature of the observed phenomena is discussed thoroughly.

Mo.L-P35 - 3D nano-architectured multiferroic CuO electrodes for high-performance supercapacitors

K. Lu[1], M. Deng[1], C. Song[2], C. Wang[2], Y. Tseng[2], J. Chen[1]

1. National Synchrotron Radiation Research Center (NSRRC), Hsinchu, Taiwan
2. Department of Materials Science and Engineering, National Chiao Tung University, Hsinchu, Taiwan

We prepared nano-architectured multiferroic CuO electrodes with a 3D hierarchically porous structure and an excellent supercapacitive performance. These nano-architectured CuO electrodes were processed through co-deposition of a Ni–Cu layer on Ni foam, selective etching of Cu from the Ni–Cu film (leaving tentacle-like nanoporous Ni), and anodic deposition of CuO nanoribbons (NRs) on the tentacle-like nanoporous Ni/Ni foam substrate. Because of its unique nano-architecture, the prepared CuO nanoribbon-on-Ni-nanoporous/Ni foam (CNRNP) electrode shows exceptional performance of energy storage relative to a conventional version of the electrode. The CNRNP electrode has also a superior kinetic performance relative to CuO nanoflake-on-Ni foam (CNFNF) and flake-like CuO (FLC) electrodes. Besides its excellent cyclic stability, an exceptionally large specific capacitance of 880 and 800 F g^{-1} (deducting the substrate capacitance from the total) for the CNRNP electrode is obtained at scan rates of 10 and 200 mV s^{-1}, respectively. The excellent pseudocapacitive characteristics of CNRNP electrodes associated with the variation of the Cu oxidation state during charge and discharge cycles were elucidated with *in situ* X-ray absorption near-edge structure (XANES) spectra.

Mo.L-P37 - Direct measurements of the crucial characteristics of MCE refrigeration in high magnetic fields in a Gd sample

E. Dilmieva[1], V. Koledov[1], A. Kamantsev[1], V. Shavrov[1], A. Mashirov[1], I. Tereshina[2], V. Nizhankovskii[3]

2. International Laboratory of High Magnetic Fields & Low Temperatures of PAN, Wroclaw, Poland
3. Baikov Institute of Metallurgy and Material Science of RAS, Moscow, Russia

The coefficient of performance (COP) of cooling process is the relation of heat transferred from a cold body to a hot body of the refrigerator to the mechanical work spent for one thermodynamic cycle. For the purpose of experimental study of the process of magnetic cooling by Gd working body and direct estimation the COP the new technique was developed. It allows to determine at the same time the magnetocaloric effect (MCE) and the magnetization (M) of materials versus magnetic field (H) in quasiadiabatic mode. The full cycle of magnetic cooling was tested on Gd sample in the field of the Bitter magnet up to 12 T. The temperature growth is equal to $deltaT_{on}$ = 13,5 K at turning on magnetic field 12 T. The temperature drop is equal to $deltaT_{off}$ = -19 K at turning off the magnetic field. The resulting temperature change of the sample under cycle of magnetic field turning on/off is equal to $deltaT_{total}$ = - 5,5 K. $DeltaT_{total}$ is a consequence of the process of magnetic cooling. The *in situ*measurement shows that M(H) dependence of the Gd sample during the process has hysteretic character. The calculation of integral of HdM on a closed loop allows one to determine the work of magnetic field during cooling cycle and to calculate the COP of magnetic cooling process. By calculating COP it is found that at initial sample temperature T_0 = 298 K and the magnetic field change 12 T, COP = 15. By reducing the magnetic field to H = 2 T, COP increases COP = 92. The fundamental restrictions on COP are imposed by Carnot's theorem. COP_{Carnot} (T_0=298, H=2T)= 600, COP_{Carnot} (T_0=298, H=12T)= 60. The reasons for which the COP found by experimental estimation is significantly lower than COP_{Carnot} are discussed.

Mo.L-P39 - Magnetocaloric effect of La(Fe,Si,Co)13 compounds as measured in pulsed magnetic fields

M. Ghorbani-Zavareh [1,2], Y. Skourski [1], K.P. Skokov [3], J. Wosnitza [1,2], O. Gutfleisch [3]

1. Hochfeld-Magnetlabor Dresden (HLD-EMFL), Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany
2. Institut für Festkörperphysik, TU Dresden, Dresden, Germany
3. Technische Universität Darmstadt, Institut für Materialwissenschaft, Darmstadt, Germany

We report on direct measurements of the magnetocaloric effect (MCE) and magneto-volume effects of $La(Fe,Si,Co)_{13}$ compounds, which are promising candidates for magnetic refrigeration applications as they undergo a metamagnetic transition associated with considerable entropy change. The nature of the transition can be changed from first to second order as well as the temperature of the transition can be tuned by varying the Co concentration. The MCE of two compounds with different Co concentrations and transition temperatures of 199 K (first order) and 254 K (second order) have been measured in pulsed magnetic fields up to 50 T. The compound with first-order transition shows half of the net magnitude of the MCE already at low fields (2-10 T). Whereas the MCE of the compound with second-order transition grows gradually. The MCE in both compounds reaches similar values of about 18 K at maximum field of 50 T. Results obtained in pulsed magnetic fields of 2 T are in a good agreement with data from quasi-static-field measurements. These phenomena are driven by an itinerant-electron metamagnetic transition accompanied by a volume change of the sample. Magnetostriction measurements performed in both static and pulsed magnetic fields show an irreversible magnetovolume effect of about ~1%. The entropy change, ΔS, was evaluated from specific-heat measurements in static fields. Pulsed-field magnetization of both compounds was measured in fields up to 60 T in a nearly adiabatic regime and compared to steady-field isothermal measurements. The differences between the two are discussed and explained involving the measured MCE values.

Mo.L-P40 - Influence of structural disorder on normal and inverse magnetocaloric effect in Y1-xGdxCo2 (0 ≤ x ≤ 1) compounds

N. Pierunek [1], Z. Śniadecki [1], V. Franco [2], B. Idzikowski [1]

1. Institute of Molecular Physics Polish Academy of Sciences, Poznań, Poland
2. Condensed Matter Physics Department, Sevilla University, Spain

YCo_2 compound is an exchange-enhanced Pauli paramagnet on the verge of being magnetic. Ferromagnetic long-range ordering can be induced by topological or chemical disorder [1]. The influence of Gd substitution and quenched-in free volumes and vacancies on the magnetic properties of as cast and annealed $Y_{1-x}Gd_xCo_2$ ($0 \le x \le 1$) compounds is studied by means of X-ray diffraction and vibrating sample magnetometry. Investigated systems crystallize in the $MgCu_2$-type Laves phase ($Fd\bar{3}m$ space group) [2]. Magnetic entropy changes $\Delta S_M(T,\mu_0 H)$ and refrigerant cooling power *RCP* parameter were determined on the basis of *M(H)* curves and results have been correlated to the presence of structural disorder [3]. Changes in values of ΔS_{Mpk} (maximum of ΔS_M peak), δT_{FWHM} (full width at half maximum) and *RCP* parameters with structural ordering (after isothermal annealing procedure) are clearly visible. For $Gd_{0.6}Y_{0.4}Co_2$ compound (T_C = 282 K) in as-quenched state the ΔS_{Mpk}, δT_{fwhm} and *RCP* are equal to 2.12 J/kgK, 75 K and 122 J/kg, respectively for magnetic field changes from 0 to 5 T. Through isothermal annealing (T = 700°C, τ_a = 60 min.) crystalline structure reaches lower free energy level, which directly affects the MCE properties. ΔS_{Mpk} is equal to 2.15 J/kgK, but δT_{fwhm} value drops with annealing by *ca.* 15% as well as *RCP* parameter. Structural disorder significantly broadens the magnetic transition and the temperature-dependent magnetic entropy changes in investigated compounds.

Heusler-type ferromagnetic shape memory alloys have attracted much attention over the last two decades due to their magnetoelastic, megnetocaloric and thermoelectroric effects. Martensitic phase transition (MPT) is a key factor responsible for the unique properties. The Ni-Fe(Co)-Ga alloys are known to show a good ductility in sharp contrast to the most famous Ni-Mn-Ga alloys. Moreover, Curie temperature can be raised to by doping the ternary Ni-Fe-Ga alloys with Co. To unveil the underlying mechanism of MPT for Ni-Fe(Co)-Ga alloy film from the electronic structure viewpoint, we have done a bulk sensitive hard X-ray photoelectron spectroscopy (HAXPES), element-selective soft X-ray magnetic circular dichroism (XMCD) and first-principles calculations. The HAXPES and XMCD measurements were performed at BL15XU and BL23SU of SPring-8, respectively. First-principles calculations were done for the parent Ni2FeGa alloy by using WIEN2k program package. The HAXPES results showed a drastic change of the electronic structure near Fermi energy (EF) and the observed hysteretic behavior was confirmed a close relation with the MPT. Moreover the spectral weight near EF was transferred to higher binding energy on cooling through the MPT. Namely, a pseudo-gap appeared in the low temperature phase. In addition, the Ni 3d, Fe 3d and Co 3d spin magnetic moments increased across the MPT. Especially, the Ni 3d moment increased to approximately 2 times larger value. The first-principles calculations also explained the formation of the pseudo-gap and the enhanced Ni 3d spin magnetic moment in the tetragonal phase. Thus we can conclude that the band Jahn-Teller distortion is the key mechanism of the MPT. The experiments at BL15XU and BL23SU were performed with the approval of NIMS and the approval of JAEA at SPring-8 (Proposal Nos.2013B3880, 2013B4910, 2014A3880, and 2014A4903).

Mo.L-P42 - The magnetic and magnetocaloric properties of $CoMnGe_1$-x$GaxB_{0.015}$

I. Dincer [1], G. Durak [1], E. Yüzüak 2, Y. Elerman [1]

1. Department of Engineering Physics, Faculty of Engineering, Ankara University, Besevler, Ankara, Turkey
2. Department of Nanotechnology Engineering, Faculty of Engineering, Recep Tayyip Erdogan University, Rize, Turkey

The increasing attention has been attracted the magnetic cooling technologies due to its high efficiency and environmental friendliness. Recently, many experimental and theoretical studies are performed to investigate the magnetocaloric materials show first-order magnetostructural phase transition. CoMnGe alloy has particular interested because this alloy undergoes martensitic structural transition from hexagonal structure (space group: $P6_3/mmc$) to orthorhombic structure (space group: Pnma) at 420 K. The Curie temperature of this alloy is 355 K. The magnetic and structural phase transitions cannot overlap for CoMnGe alloy. There are so many methods to decrease the structural phase transition down to room temperature and overlap with Curie temperature because magnetic and magnetocaloric properties are very sensitive to interatomic distance in CoMnGe alloy. The $CoMnGe_{0.95}Ga_{0.05}$ alloy exhibits simultaneous structural and magnetic phase transitions around 310 K and the temperature dependent Synchrotron measurements reveal that (ΔV/V) of alloy is 3.9% which is comparable to the $CoMnGeB_{0.02}$ system (ΔV/V=4.2%). Due to the presence of coinciding structural and magnetic phase transitions, huge magnetocaloric effect and also giant ΔV/V, this alloy is considered to have a high potential for magnetic cooling applications. The magnetic and magnetocaloric properties of $CoMnGe_{1-x}Ga_xB_{0.015}$ (x=0.05 and 0.06) alloys have been investigated by using calorimetric, X-ray diffraction and magnetic measurements. Our results show that the structural and magnetic phase transitions in alloys are tailored by the substitution of Ga for Ge. The alloys exhibit a giant magnetocaloric effect due to coexistence of magnetic and Martensitic phase transitions at the same temperatures. The entropy change values range from −22.1 (x =0.05) to −27.1 J/kg.K (x =0.06) for ΔH = 7 T and are proportional to the volume differences of the phases involved in the transition. These results on boron doped CoMn(Ge-Ga) alloys would set a good example for other types of magnetocaloric materials and could open up new possibilities for searching new magnetocaloric materials.

Mo.L-P43 - The Effect of the Substitution of Cu and Al for Mn on Magnetic and Magnetocaloric Properties of $Ni_{50}Mn_{34}In_{16}$

Y. Elerman [1], M. Kaya [1], M. Mirac Cicek [1], I. Dincer [1]

1. Department of Engineering Physics, Faculty of Engineering, Ankara University, 06100 Besevler, Ankara, Turkey

Recent experimental and theoretical researches reveal that in $Ni_{50}Mn_{34}In_{16}$ Heusler alloy, extra Mn atoms partially occupy In sites and they exhibit antiferromagnetic coupling [1, 2]. According to *ab-initio* calculations and Monte Carlo methods, decreasing of magnetic exchange interactions in this alloy can lead to increase magnetic cooling properties around structural transition region, doping the alloy with nonmagnetic atoms. In accordance with these results, we investigated the influence of Cu and Al substitution for Mn on magnetic and magnetocaloric properties has been investigated by using calorimetric and magnetic measurements. We found that martensitic transition temperature ($T_m=(A_f+M_s)/2$) shifts to higher temperatures with Cu and Al substitutions as a result of decreasing of the magnetic exchange interactions with respect to the $Ni_{50}Mn_{34}In_{16}$. The isothermal magnetization curves around the martensitic transition temperatures show a typical metamagnetic behavior. Associated with that, large positive values of magnetic entropy changes around structural transition region are determined by using the Maxwell relation. The maximum magnetic entropy change values are found to be 25.2 and 13.0 $J.kg^{-1}.K^{-1}$ for $Ni_{48.8}Mn_{34.3}Cu_{1.7}In_{15.2}$ (S1) [1] and $Ni_{51.67}Mn_{31.84}Al_{1.32}In_{15.17}$ (S2) in a magnetic field change (ΔH) of 2 T, respectively. Furthermore, it is necessary to take into account that magnetocaloric materials are desired to have a large relative cooling power (RCP). The calculated RCP values are found 91.5 and 85.8 $J.kg^{-1}$ under ΔH=2 T for S1 and S2, respectively. In summary, the results show the general tendency of increasing T_m from 200 K [3] to 266.5 and 278 K for S1 and S2 with the substitution of Cu and Al for Mn in $Ni_{50}Mn_{34}In_{16}$, respectively. It is observed that Cu and Al doping in $Ni_{50}Mn_{34}In_{16}$ alloy has not only shifted the T_m and improved magnetocaloric properties towards higher temperature, but has also increased the RCP values [1, 3].

Mo.L-P44 - Visualization of crack evolution in field cycled $LaFe_{11.8}Si_{1.2}$

A. Funk [1], A. Waske [1], J. Eckert [1,2]

1. Institute for Complex Materials, IFW Dresden, Helmholtzstraße, Dresden, Germany
2. Institute for Material Science, TU Dresden, Helmholtzstraße, Dresden, Germany

Based on solid state materials with a high magnetocaloric effect (MCE), magnetic refrigeration is a promising alternative to conventional gas-compression cooling techniques [1]. Such materials, e.g. La(Fe,Si)13, Mn-Fe-P-X and Heusler alloys, commonly show a 1st order phase transition with simultaneous structural and magnetic changes that can be induced by an external magnetic field or temperature. The resulting volume change of La(Fe,Si)13 can reach up to 1,5 vol.% in a moderate magnetic field (μ0H = 2 T) [2]. Field or temperature cycling leads to cracks in bulk material, therefore its mechanical stability and refrigeration performance suffer drastically over time. However, Waske et al. observed an intermediate state before the material falls apart: Interlocked particles of thermally cycled La(Fe,Si)13, conserve the 1st order MC behaviour of the bulk material after 40 cycles [3]. In this work, the transition of $LaFe_{11.8}Si_{1.2}$ close to its transition temperature is magnetically induced in a field up to μ0H = 2 T over several cycles. X-ray computed tomography (XCT) as a non-destructive imaging technique was applied to observe the crack evolution of a $LaFe_{11.8}Si_{1.2}$ bulk sample after certain cycling steps. Since field cycling was performed in a SQUID, magnetization behaviour is correlated to CT-microstructure comprehensively. Moreover, the degradation of the entropy change with decreasing particle cohesion was observed by magnetometry of a reference sample for different cycling numbers. The presented results help to understand the crack mechanism and the correlation to the giant MCE in La(Fe,Si)13 and 1st order MC materials. This understanding is crucial in order to develop new material combinations, i.e. composites, in order to retain both, the large MCE and mechanical integrity for long term stability.

Mo.L-P45 - Magnetic properties of magnetostrictive galfenol nanowires

I. Ivanov [1], M. Alnassar [1], M. Vazquez [2], J. Kosel [1]

1. King Abdullah University of Science And Technology (KAUST), Thuwal, Saudi Arabia
2. Institute of Materials Science of Madrid, CSIC, Madrid, Spain

Magnetostrictive nanowires (NWs) have attracted increasing attention due to their potential applications as functional elements in advanced nanoscale sensors, actuators or energy harvesters. Galfenol $Fe_{80}Ga_{20}$ is one of the most promising magnetostrictive materials. Single-crystal bulk Galfenol exhibits magnetostriction constants up to 400 ppm and attractive mechanical properties (high elastic modulus and tensile strength). Therefore, developing single-crystal Galfenol as NWs could lead to extremely efficient NW-based devices. Among various fabrication methods, electrodeposition into porous aluminum oxide templates (AOT) is a competitive, simple technique for the controlled preparation of high-quality NWs. 50 nm FeGa NWs were fabricated by DC electrodeposition. Electrodeposition was carried at a bias of between –1.1V and –1.5V to achieve the desired Ga content. For studies of individual NWs by transmission electron microscopy (TEM) and magnetic force microscopy (MFM), the AOT was dissolved. As observed by TEM the NWs are straight with a uniform diameter, smooth surface and single-crystal structure along the whole NWs' length (a few um). The alloy composition is $Fe_{86}Ga_{14}$ (Energy dispersive X-ray analysis). Electron diffraction patterns confirmed the bcc structure with a lattice parameter of 2.95 A and an angle of 20 deg between the NW's long axis and the strongest magnetostrictive axis <100>.
Vibrating sample magnetometer measurements of the NWs array revealed the strong effect of shape anisotropy on magnetic properties. The magnetization curve perpendicular to the NWs axis exhibits two distinct regimes of low and high permeability which is typical for single-crystal bulk galfenol. A single domain magnetic structure at remanence has been observed by MFM. The coercivity of individual NWs measured by MFM and Lorenz microscopy is a bit higher than the one measured by VSM for the array, as expected. A variable magnetic field MFM study revealed two interesting remanence states depending on the strength of the external magnetic field.

Mo.L-P47 - Effects of pressure on the magnetic, structural, and Griffiths-like transitions in magnetocaloric R5(SixGe$_1$-x)4 (R= Tb and Dy)

The discovery of the giant magnetocaloric effect in $Gd_5Si_2Ge_2$ has attracted a strong interest in the study of other R5(SiGe)4-type (R= rare earth) compounds in order to understand the relationship between their structural and magnetic properties. The R5(SiGe)4 compounds are known for the appearance of a Griffiths-like phase (GP) at characteristic temperature T* above the long-range order temperature (TN,C). The GP has been reported in several R5(SiGe)4 compounds with either the monoclinic $Gd_5Si_2Ge_2$-type (M) or the orthorhombic $Sm5Ge_4$-type (O(II)) of crystal structure [1]. Two interesting examples are Dy_5Si_3Ge and $Tb_{4.925}La_{0.075}Si_2Ge_2$. At room temperature both compounds crystallize in the M structure. As the temperature decreases they show a GP phase below T*>TN,C. The long-range ordered phase is antiferromagnetic (AF) for Dy_5Si_3Ge [2] and ferromagnetic (FM) for $Tb_{4.925}La_{0.075}Si_2Ge_2$ [3]. At TS they show a structural transition from the M-type to the orthorhombic O(I)-type structure. The hydrostatic pressure (P) strongly affects both TS and TN,C. In this work we report on a study of the pressure effect on the different phase transitions in Dy_5Si_3Ge and $Tb_{4.925}La_{0.075}Si_2Ge_2$ by measuring the magnetization under different applied magnetic field protocols up to 50 kOe and P up to 10 kbar in the temperature range 5 K< T <300 K. At low applied magnetic field Ts strongly increases with increasing P, whereas TN and TC show a weak increasing dependence on P. Such difference in the pressure dependence enables the coupling of the magnetic and structural transitions above a critical pressure. The Griffiths-like phase temperature T* shows a weak temperature dependence increasing linearly with pressure.

Refrigeration based on the magnetocaloric effect (MCE) is considered to be environmentally friendly, due to reducing the energy consumption and therefore improving the energy efficiency of cooling devices. La-Fe-Si based materials are a promising candidate, because of its good magnetocaloric properties, a comparatively low material price and Curie temperatures that can be tuned by varying the alloying components. In Active Magnetic Regenerators (AMR) often plate-shaped magnetocaloric materials are used. This geometry can easily be realized by producing composites of magnetocaloric particles in an epoxy matrix.
Epoxy-bonded magnetocaloric composites with different particle sizes of magnetocaloric La-Fe-Co-Si were characterized by determining their magnetic properties, as well as the temperature- and field-dependent specific heat capacity ($c_P(T,H)$). For comparison, sintered La-Fe-Co-Si was measured. Entropy change ΔS and adiabatic temperature change ΔT_{ad} was calculated and compared with calculations from magnetic measurements (ΔS_{mag}) and direct measurements (ΔT_{direct}). Furthermore, by using X-ray Computed Tomography (XCT) exact volume fractions of the active magnetocaloric material, the epoxy and the porosity were studied. Moreover the particles of active magnetocaloric material were analyzed concerning their size and shape. We will discuss the magnitude of the magnetocaloric effect with respect to the fraction of active magnetic material in the composite as well as anisotropies originating from the manufacturing process. This is shown in the particle orientation within the composite and hence in the anisotropy of the properties. Additionally, the thermal conductivity, which is an often underestimated property in the development of MCE devices, was investigated in experiment and simulation. For this purpose, the structural data determined by XCT was used to feed FEM calculations with real geometry data. By simulation, anisotropic thermal conductivity of the plates was revealed.

Mo.L-P49 - Magnetocaloric properties of purified Gd: assessing structural and impurity aspects

I. Tereshina [1,2], G Burkhanov [2], E. Tereshina [3], G. Politova [2], V. Chzhan [2], O Chistyakov [2], N. Kolchugina [2], H. Drulis [4], M. Paukov [5], L. Havela [5]

The magnetocaloric, thermal and manufacturing properties of Gd make it currently the best material for room-temperature magnetic refrigeration [1]. Here we study high-purity Gd samples with the structure variation from coarse-grain to nanocrystalline obtained as a result of distillation procedure. Samples cut out of structurally inhomogeneous regions consisting of needle-shaped crystals of cross section 0.5-2.5 micrometers with near-c-axis orientation embedded in a matrix of nanosized (30 - 100 nm) grains [2] demonstrate strong anisotropy of electrical and magnetic properties. Further, several a-GdHx solid solutions were obtained by hydriding the parent pure metal to different hydrogen concentrations. The maximum hydrogen content determined volumetrically reached 0.22 +/- 0.02 at.H/f.u. For the end sample GdH0.22, the relative volume change upon hydrogenation DV/V is about 1%. As shown by Atomic Force Microscopy, the grains increased in size to 200-400 nm after hydrogenation. Magnetocaloric effect was studied using direct and indirect methods. Opposite trends in the MCE response to hydrogen charging with respect to the crystal's orientation within the samples was observed and the mechanisms interrelating the unique inhomogeneous structural morphology with the impurity behavior were proposed. As an overall assessment, the Curie temperatures of a-GdHx solid solutions increase from 291 K up to 295 K when increasing hydrogen concentration x from zero to 0.22. Hydrogenation is found to broaden the ferromagnetic-to-paramagnetic phase transition and strongly increases the relative cooling power of Gd. The Curie temperature increase upon hydriding of pure Gd together with large MCE at elevated temperatures ensure avenue to application in future magnetic refrigeration, heat pump and power generation devices.

Mo.L-P51 - Effect of Fe substitution on $Ni_{50}Mn_{35}In_{15}$ Heusler alloys

M. Halder [1], Penkey Suresh [1] N, K. G. Suresh [1]

1. Department of Physics, Indian Institute of Technology Bombay, Bombay, India

The off-stoichiometric Ni-Mn-In Heusler alloys have drawn significant research interest in the resent years. The properties of these alloys are strongly affected by composition, magnetic field, etc., and some of the compounds exhibit multifunctional properties such as exchange bias, giant magnetocaloric effect, and magnetic shape memory effect, by virtue of the martensite phase transformation (MPT). The phase diagram of the $Ni_{50}Mn_{50-y}In_y$ system has been studied in details in literature [1]. These alloys undergo a first order austenite to martensite phase transformation with lowering of temperature, particularly in the composition range y = 15 to 16 [1]. $Ni_{50}Mn_{35}In_{15}$ is reported to show MPT and large magnetocaloric effect [2].

We have investigated structural and magnetic properties of $Ni_{50}Mn_{35}In_{15}$ and effect of Fe substitution in $Ni_{50}Mn_{35}In_{15}$ *i.e.* $Ni_{48}Fe_2Mn_{35}In_{15}$. Room temperature x-ray diffraction shows that $Ni_{50}Mn_{35}In_{15}$ has two phases, cubic and other (which we were unable to index) phase *i.e.*, both austenitic and martensite phases coexist [2], while $Ni_{48}Fe_2Mn_{35}In_{15}$ shows pure cubic structure *i.e.* austenitic phase [3]. From magnetization measurements, in $Ni_{50}Mn_{35}In_{15}$, we observe MPT at about 311 K. The Curie temperatures of the austenite and the martensite phases are 313 and 189 K, respectively. In the case of $Ni_{48}Fe_2Mn_{35}In_{15}$, there is only one magnetic transition at 316 K with no MPT. This indicates that the martensite phase, which is present in $Ni_{50}Mn_{35}In_{15,}$ gets suppressed when Ni is substituted by Fe, which stabilizes the austenite phase. The absence of MPT in the case of $Ni_{48}Fe_2Mn_{35}In_{15}$ has been explained on the bases of valence electron concentration *e/a*. The magnetic entropy change has been evaluated and the maximum value is found to be 7.6 and 2.7 J kg^{-1} K^{-1} for $Ni_{50}Mn_{35}In_{15}$ and $Ni_{48}Fe_2Mn_{35}In_{15}$, respectively, for a field variation of 20 kOe.

Mo.L-P52 - Structural and magnetic properties of $FeRh_{1-x}Co_x$

K. Takahashi [1], K. Ohtake [1], K. Koyama [2], K. Watanabe [1]

1. Institute For Materials Research, Tohoku University, Sendai, Japan
2. Graduate School of Science and Engineering, Kagoshima University, Kagoshima, Japan

Ordered FeRh alloys around the equiatomic composition with an ordered B2 (CsCl-type) structure exhibit peculiar magnetic and structural properties. The compound shows a first-order transition from the antiferromagnetic (AFM) to the ferromagnetic (FM) phase accompanied by an isotropic volume expansion of about 1%. In this study, $FeRh_{1-x}Co_x$, substituting Co for part of Rh to control the AFM-FM transition temperature to around room temperature, was studied in order to investigate the relationship between magnetic and structural properties affected by the magnetic field. The magnetization was measured using a conventional SQUID magnetometer in magnetic fields up to 7 T and in the temperature range from 10 to 400 K. X-ray diffraction measurements with FeKα radiation were performed in magnetic fields up to 5 T and at temperatures ranging from 10 K to room temperature. The isostructural transformation due to the field-induced AFM-FM phase transition was directly observed by the X-ray measurements, and the lattice parameter was found to be expanded by 0.3% at the phase transition. The magnetocaloric property was also evaluated from the magnetization measurements, which shows excellent capability comparable to that of FeRh.

Mo.L-P53 - Magnetocaloric effect in Ni-Fe-Ga-Co-Al Heusler alloys

F. Tolea [1], M. Sofronie [1], A. Daniela Crisan [1], M. Valeanu [1]

1. National Institute of Materials Physics, Magurele, Romania

The magnetocaloric effect (MCE) around room temperature is an environmentally friendly alternative to conventional refrigeration. In recent years, ferromagnetic shape memory alloys (FSMA) have received much attention as new magnetic materials with high magnetocaloric characteristics. The functionality of the FSMA is related to the martensite and magnetic order-disorder transformations; both, the martensitic (T_M) and Curie temperatures (Tc), may be tailor by doping the alloys with other elements (to change the electronic concentration, e/a) or by suitable thermal treatments (to change the atomic order) so that, alloys with concomitant or sequential structural and magnetic phase transition may be obtained. Recent studies have shown that the entropy change associated to the martensite transformation in FSMA increase as the temperature difference between Tc and T_M decreases.
The off-stoichiometric Ni-Fe-Ga based Heusler alloy have been found good candidate to replace the brittle Ni-Mn-Ga in various applications including magnetic refrigeration. The presence of the secondary phase responsible for its better ductility, may be prevent by suitable quenching preparation techniques, like melt spinning, ribbons preserving a relative good malleability. In addition, concerning the magnetocaloric applications, it is assumed that the thin melt-spun ribbons assure a more efficient heat transfer.
In the present work we investigate the entropy changes and the relative cooling power (RCP) in $Ni_{52}Fe_{20}Ga_{23}Co_3Al_2$ based Heusler alloy with concomitant or sequential structural and magnetic phase transition prepared as bulk (Tc = 373 K, T_M = 253 K) and as ribbons in as prepared state (Tc = T_M = 378 K) or subjected to a thermal treatment (Tc = 388 K, T_M= 334 K) for atomic ordering . For a magnetostructural transformation the as prepared ribbons show almost the same entropy variation with that obtained in bulk alloy (between -8 and -10 J/KgK) but the RCP is much enhanced.

Mo.L-P54 - Magnetic properties of soft magnetic thin ribbons prepared by an electroplating method

T. Yanai [1], Y. Watanabe [1], M. Otsubo [1], N. Shimoya [2], K. Fujisaki [2], M. Nakano [1], H. Fukunaga [1]

1. Nagasaki University, Nagasaki, Japan
2. Toyota Technological Institute, Chicago, United States

As it is well-known that a reduction in thicknesses of soft magnetic materials is one of effective methods to reduce an eddy current loss, soft magnetic thin ribbons are widely used for high-frequency driven electric machines. Typical soft magnetic thin ribbons, such as amorphous ones and nano-crystalline ones, are produced by rapid quenching methods, and their thickness are approximately 0.02 mm. In present study, we fabricated Fe-Ni-based thin ribbons (< 0.02 mm) prepared by an electroplating method, and evaluated the magnetic properties of the toroidal core prepared from the thin ribbons. We electroplated Fe-Ni-based thin films on a Cu sheet (L350 ~ W5 ~ T0.3 mm), and then the films were peeled off physically from the Cu sheet. Consequently, we obtained the ribbon-shaped Fe-Ni thin films with Fe composition of approximately 22 at.%. The Fe-Ni thin ribbon (0.0092 mm-thick) were formed into toroidal core (D = 48 mm), and ac magnetic properties of the toroidal core were evaluated at Bm = 0.9 T in the frequency range from 50 Hz to 200 kHz. In order to compare high frequency properties, we also evaluated ac magnetic properties of a toroidal core prepared from a 0.025 mm-thick amorphous ribbon (2605HB1, Hitachi Metals, Ltd.). Although the amorphous core showed low iron loss in low frequency region, the loss of the amorphous core showed higher value compared with that of the Fe-Ni one in high frequency region (> 50 kHz). As an eddy current loss in a typical metric soft magnetic material becomes dominantly in the high frequency region, we found that the prepared Fe-Ni thin ribbon is an effective material for high frequency driving.

Mo.L-P55 - A new method for maximizing magnetic refrigeration efficiency in antiferromagnets

R. Tamura [1], S. Tanaka [2], T. Ohno [3], H. Kitazawa [4]

Magnetic refrigeration is a promising candidate as a next-generation cooling technology that can solve environmental and noise problems. The key to the magnetic refrigeration is the change of behavior of magnetic entropy in magnetic materials under different magnetic fields, which is known as the magnetocaloric effect (MCE). It has been recognized that ferromagnets are the most suitable materials for magnetic refrigeration because of their large magnetic field response near the phase transition temperature. Recently, the MCEs in nonferromagnets such as antiferromagnets and random spin systems have been studied experimentally. However, the fundamental theory relating MCE to the magnetic structure was not established. The purpose of this work is to formulate a fundamental theory for the relationship between MCE and magnetic structure, and to propose a method for maximizing the magnetic refrigeration efficiency. We consider the A-, C-, and G-type antiferromagnets that are typical ordered antiferromagnetic structures and compare the MCE in nonferromagnets with that in the ferromagnets by the Monte Carlo simulations and the mean-field treatments. In the isothermal process, the magnetic entropy monotonically increases as the magnetic field decreases in the ferromagnets. On the other hand, in the antiferromagnets, the magnetic entropy exhibits nonmonotonic behavior as a function of the magnetic field. Based on the fact, we propose a new protocol for applying magnetic field to obtain the maximum magnetic entropy change in the antiferromagnets. By using the same proposed protocol, the adiabatic temperature change and the cooling capacity such as the relative cooling power (RCP) are also maximized. We emphasize that the proposed protocol can be widely applied to any magnetic materials to achieve the maximum efficiency of magnetic refrigeration, not just antiferromagnets.

Mo.L-P56 - Mechanical and corrosion properties of La(Fe,Si)13 for magnetic refrigeration technology

B. Kaeswurm [1], S. Sharma [1], A. Barcza [2], P. Geiger [1], M. Vögler [1], K.E. Johanns [1], N. Wilson [3], M. Katter [2], O. Gutfleisch [1]

2. Vacuumschmelze GmbH & Co. KG, Hanau, Germany
3. Camfridge Ltd, Cambridge, United Kingdom

Magnetic refrigeration is an environmentally friendly and efficient technology which may replace conventional vapour cycle refrigeration in the near future. In order for a magnetocaloric material to be used as a heat exchanger, it needs not only to show the appropriate magnetocaloric properties and high thermal conductivity, but also mechanical and chemical stability as well as ease of machinability. We investigate the corrosion and mechanical properties of Co containing $La(Fe,Si)_{13}$. While water provides efficient heat transfer, it causes $La(Fe,Si)_{13}$ to corrode easily. In order to investigate the corrosion properties, heat exchanger plates were submerged in various testing fluids and removed for testing at regular intervals. For reference, samples were kept in air and argon atmosphere. A range of testing fluids with thermal conductivity k= 0.1 to 0.6 W/mK and specific heat capacity c= 1 to 4.2 J/kg K were chosen.
Samples of different Co content with different Curie Temperatures T_C near room temperature and well-defined geometry were used to investigate the mechanical properties of the material. The flexural strength σ was examined using four point bending under ASTM C1161. For increasing Co content, which corresponds to a higher T_C, a lower σ was observed. Resonance frequency damping analysis (ASTM E 1879-99) was applied in order to study the Youngs modulus as a function of temperature. The data correlates to the temperature dependence of the magnetic and crystallographic properties of the material.
The research leading to these results received funding from the EC FP 7/2007-2013 under grant agreement n°310748 (DRREAM).

Mo.L-P57 - EBSD analysis of {111}-Conjugated Interfaces in Mn-Al-C permanent magnetic materials

F. Bittner [1,2], L. Schultz [1,2], T. George Woodcock [1]

1. IFW Dresden, Dresden, Germany
2. Department of Materials Science, TU Dresden, Dresden, Germany

Mn-Al based materials have the potential for application as rare earth free permanent magnets. Coercivity strongly depends on microstructure and the presence of defects in the Mn-Al materials is particularly important. In order to optimise the coercivity, it is therefore necessary to have detailed knowledge of the microstructural features which appear in these magnets, especially the types of defects, their formation mechanisms and the effect of processing on their fractions. MnAl and MnAl-C have the L10 crystal structure and planar defects, conjugated on {111} planes, similar to twins, are well known in these materials from the results of transmission electron microscopy (TEM). Electron backscattered diffraction (EBSD) offers an advantage over TEM for the analysis of interfaces as much larger areas can be studied, yielding more representative data. Mn-Al-C materials have therefore been studied in the heat treated and hot worked states using EBSD. Three crystallographically different {111}-conjugated twin-like defects, distinguished by different rotation angles about the normal to {111}, were found to be the dominant interfaces in the heat treated material. Previously only one of these interfaces has been reported in similar materials by TEM. In the hot worked sample, {111}-conjugated interfaces characterised by a rotation of 180^{o} about the normal to {111} appeared frequently, probably as a result of the associated dynamic recrystallization, while the other two interfacial types were suppressed.

Mo.L-P58 - Influence of Nb content on high temperature magnetic properties of FeCo based high induction alloys

R.K. Roy [1], A. K. Panda [1], A. Mitra [1], M.E. McHenry [2]

1. NDE & Magnetic Materials Gr., MST Division, CSIR-National Metallurgical Laboratory, Jamshedpur, India
2. Department of Materials Science and Engineering, Carnegie Mellon University, Pittsburgh, United States

Research on the enhancement of soft magnetic properties in high induction alloys has been extensively studied in last two decades due to their potential use of transformers, motors and sensors for use in energy, transportation, defense and aerospace sectors. Prior research targeted reaching inductions of silicon steels and high temperature magnetic properties so that these materials can effectively perform in severe environments. In this work, Nb influence has been investigated in FeCo based alloys with nominal compositions of $(Fe_{0.65}Co_{0.35})_{85-y}Si_{2.8}B_{11.2}Nb_yCu_1$ (y= 0, 1, 2 and 3) extending the composition range reported in [1]. Alloys were prepared in the form of ribbons by a single roller melt spinning technique, and subsequently annealed in inert atmosphere to induce nanocrystallization. The increasing Nb content increases not only amorphization of alloys but also the onsets of primary crystallization (Tx_1) and secondary crystallization (Tx_2) temperatures of alloys. Thus, thermal stability (Tx_2 - Tx_1) and activation energy (Q) for primary crystallization are increased with more Nb addition. Higher Nb containing alloy (y=3) demonstrates saturation induction (M_s) of 1.62-1.68T and coercivity (H_c) of 66-82 A/m within temperature ranges of 400–550°C, whereas Nb free alloy exhibits very high M_s of 1.86-1.91T and H_c of 407-452A/m at the same temperature range. The hindrance of crystallite growth through higher Nb content and resulting fine (~20nm) crystallites are main reasons for enhanced soft magnetic properties in the former alloy. With increasing Nb, the residual amorphous phase is stabilized at high temperature and, therefore, amorphous Curie temperature (T_c) increases for those alloys. We conclude that an optimum amount Nb content is prerequisite for the enhancement of thermal stability and high temperature magnetic properties of FeCo based high induction alloys.

Mo.L-P59 - Magnetocaloric effect and Magnetothermopower in $Pr_{0.5}Sr_{0.5}MnO_3$

R. Mahendiran [1], D.V. Maheswar Repaka [1]

1. National University of Singapore, Singapore, Singapore

Materials that show more than one magnetic phase transition can be exploited for magnetic refrigeration over a wide temperature range. The manganite, Pr0.5Sr0.5MnO3 upon cooling from room temperature undergoes a second order ferromagnetic transition (TC= 260 K followed by a first-order antiferromagnetic transition around 135 K. We have studied magnetocaloric effect and magnetothermopower in this compound. It is found that the magnetic entropy change at the ferromagnetic- antiferromagnetic transition (DSm = 7 J/Kg. K for DH = 5 T) is three times larger than its value at the ferromagnetic transition. The results are compared with $Pr_{0.46}Sr_{0.54}MnO_3$ which undergoes a paramagnetic to antiferromagnetic transition without an intermediate ferromagnetic state.

The effect of magnetic field on thermopower is more dramatic. Magnetothermopower of nearly 100% is found at the ferromagnetic -antiferromagnetic phase boundary whereas the magnetothemopower changes by 40% around the paramagnetic-ferromagnetic phase boundary. We discuss possible connection between the magnetic entropy change and magnetothermopower. Coexistence of large magnetothermopower and magnetocaloric effect make this compound interesting for energy saving applications.

Mo.L-P60 - Enhanced electrical resistivity after rapid cool of the specimens in layered oxide LixCoO2

K. Miyoshi [1], K. Manami [1], G. Motoyama [1], K. Fujiwara [1], J. Takeuchi [1], R. Sasai [1], S. Nishigori [2]

2. Department of Materials Analysis, ICSR, Shimane University, Matsue, Japan

$LixCoO_2$ is practically used as a high energy cathode material in commercial Li ion batteries, having a structure consisting of CoO_2 layers and interlayers of Li atoms alternatively stacked along c-axis. In $LixCoO_2$, charge ordering of Co3+/Co4+ occurs below TS=155 K and is closely linked with ordering of Li ions via Coulomb interactions below TF=120 K, above which Li ions begin to diffuse as in a liquid state. Recent observations by scanning tunneling electron microscope and density functional theory for $Li_{0.66}CoO_2$ have revealed that the surface CoO_2 layer shows a metallic electronic state with a characteristic ordering pattern of Co3+/Co4+ (=2:1) but also shows an insulating state with disordered structures, depending on the location of the surface.

The latter disordered state is produced by inhomogeneity in Li-ordering patterns, which is thought to be enhanced by cooling rapidly from a liquid state down to the temperature far below TF, as in an amorphous metal. Thus, it is expected that the sample after rapid cool shows an enhanced resistivity. In the present work, we have performed the measurements of electrical resistivity as a function of temperature for LixCoO2 using single crystal specimens in order to confirm whether or not electrical resistivity depends on the cooling rate of the sample as mentioned above. It has been found that electrical resistivity after rapid cool becomes 30-50% larger compared with that after slow cool below Ts=155 K especially for the specimens with x=0.6-0.7.

Mo.L-P61 - Effect of the induced internal stresses on the martensitic transition and magnetic properties of Ni-Mn-Ga glass-coated microwires

S. Shevyrtalov [1], A. Zhukov [2, 3], V. Zhukova [2], V. Rodionova [1]

1. Institute of Physics & Technology, Immanuel Kant Baltic Federal University, Kaliningrad, Russia
2. Dpto. Fisica de Materiales, Fac. Quimicas, sUPV/EHU, San Sebastian, Spain
3. IKERBASQUE, Basque Foundation for Science, Bilbao, Spain

Heusler alloys with Ni-Mn-X (Ga, In, Sb, Sn) composition have attracted significant attention due to their functional properties that are originating from the coupling between the magnetic and structural ordering. Thin glass-coated microwires might be of interest in this aspect because of the possibility to tune the strength of the internal stresses in the metallic nucleus by changing the diameters ratio (d/D – define the mechanical stresses inside the metallic nucleus) and by the thermal treatment. Both theoretically [1] and experimentally [2] there was demonstrated the possibility to change the temperatures of the structural transition by external pressure.
In this abstract we report on the results of investigation of the glass-coated microwires with different ratios of the diameters d/D 0.4÷0.8 prepared by the Taylor-Ulitovsky technique from $Ni_{49,5}Mn_{25,4}Ga_{25,1}$ Heusler alloy. Fabricated microwires were annealed at 773 K for 30 min to establish the structural ordering. Magnetic properties of the annealed microwires were investigated by vibrating sample magnetometer in the temperature range 77-450 K in the magnetic fields up to 12 kOe. Hysteresis loops were observed for two positions of the microwire (with the axis directed along and perpendicular to the magnetic field direction). Martensitic transitions were detected by differential scanning calorimetry method in the temperature range 150-450 K and by collecting magnetization vs temperature curves in the different magnetic fields (10 Oe, 1 kOe and 10 kOe).
All measurements were repeated for the same piece of the microwire after the glass-coating removal to determine the influence of the internal stresses induced by the glass coating.
It has been shown that the internal stresses affects considerably magnetic properties of the microwires that results in the decreasing of the magnetization and in the shifting down of the Curie temperature for about 10 K and of the temperature of the structural transition by 8 K.

Mo.L-P62 - Influence of Pr substitution for La on the structural, magnetic and magnetocaloric properties of (La1-xPrx)2/3Ba1/3MnO3 manganites

A. Bezergheanu [1], C. Bazil Cizmas [1], I. Grigore Deac [2], R. Tetean [2]

1. Transilvania University of Brasov, Dept. Electrical Engineering & Applied Physics, Brasov, Romania
2. Babes-Bolyai University, Faculty of Physics, Cluj-Napoca, Romania

Structural, magnetic and magnetocaloric properties of $(La_{1-x}Pr_x)_{2/3}Ba_{1/3}MnO_3$, (x=0; 0.2; 0.4; 0.6; 0.8 and 1.0) manganites with perovskite type structure are reported. The samples were prepared by the conventional ceramic method, noting that the final sintering was carried out in air at 1300 ^{0}C. The crystal structure was checked by X-ray diffraction (XRD). The XRD patterns showed the presence of a majority rhombohedral phase (GS: $R\bar{3}c$, Z=6), for all compounds. The lattice parameters decrease by increasing the Pr content and therefore the cell volume decrease linearly from 413.8 Å^3 for x=1 to 408.9 Å^3 for x=0. The magnetic measurements were performed in the temperature range 4.2-700 K and external magnetic fields up to 7 T. The Curie temperatures (T_C), determined by thermomagnetic analysis, linearly decrease from ~350 K for x=0 to 197 K for x=1. The Arrots plots shows a second order magnetic phase transition at T_C, for all compounds. The saturation magnetic moments at 5 K also decreases from 3.7 μ_B/f.u. for x=0 to 3.4 μ_B/f.u. for x=1. The magnetic entropy changes, $|\Delta S_m(T, 0\text{-}B)|$, were determined from magnetization isotherms measured around T_C, using the Maxwell equation. Large $|\Delta S_m|$ value has been obtained for all samples. As example, for a magnetic field change from 0T to 5T, we have obtained $|\Delta S_m|$=2.6 J/kgK with relative cooling power *RCP*=172 J/kg for x=0 and respectively, $|\Delta S_m|$=4.5 J/kgK with *RCP*=232 J/kg for x=1. Considering the possibility to tune the transition temperatures with composition the potential use of these materials in magnetic refrigeration is also discussed.

Mo.L-P63 - Study of the magnetocaloric effect in (Pr,Dy)2Fe17 and Pr2(Fe,Al)17 intermetallic compounds

K. Zehani [1], R. Guetari [1,2], N. Mliki [2], L. Bessais [1]

1. CMTR, ICMPE, UMR7182, CNRS-UPEC, Thiais, France
2. LMOP, Faculté des Sciences de Tunis, Université Tunis El Manar, Tunis, Tunisia

The Pr_2Fe_{17} compound is a potential candidate for low cost magnetocaloric materials with a significant relative cooling power (RCP) around room temperature (280 K).
In this work, we present the results of the substitution of dysprosium for praseodymium and of the substitution of aluminum for iron in Pr_2Fe_{17}. The polycrystalline $Pr_{2-x}Dy_xFe_{17}$ (x = 0.125, 0.25, 0.375, and 0.5) and $Pr_2Fe_{17-y}Al_y$ (y = 0, 0.25, 0.5, 0.75, 1) were prepared by arc melting under a high purity argon and homogenized at 1373K to minimize the amount of other possible impurity phases. The samples were characterized using powder X ray diffraction and were refined using Rietveld method with Fullprof program. All the samples crystallize in the $R\bar{3}m$ of the rhombohedral Th_2Zn_{17} type structure. The lattice parameters increase with the Al and Dy content. The Curie temperature increases with Dy content (from 285 K at x = 0 to 314 K at x = 0.5) and Al content (from 285 K at y = 0 to 361 K at y = 1). This variation is due to an electronic effect.
The magnetic entropy change ΔS_m was estimated from isothermal magnetization curves for all samples. For $Pr_{1.75}Dy_{0.25}Fe_{17}$, the magnetic entropy increases up to a maximum T_C = 305 K of ΔS_m = 7.5 $J.kg^{-1}K^{-1}$ (T_C = 305 K and ΔH = 5T). However, for $Pr_2Fe_{17-y}Al_y$, ΔS_m decreases with Al content from 5.5 $J.kg^{-1}K^{-1}$ (x = 0) to 4.2 $J.kg^{-1}.K^{-1}$ (x = 1) at $\mu_0 H$ = 5T.
The analysis of the magnetic ordering transition using the Landau theory and the Arrott's plots have been carried out.
Keywords: Rare-earth intermetallics, Curie temperature, Magnetization, Magnetocaloric effects

Mo.L-P64 - Large magnetocaloric effect and magnetic properties in ErCoAl

D. X. Li [1], Y. Homma [1], F. Honda [1], T. Yamamura [2], D. Aoki [1]

1. Institute for Materials Research, Tohoku University, Oarai, Ibaraki, Japan
2. Institute for Materials Research, Tohoku University, Sendai, Japan

Recent years, exploration of magnetic refrigerant material used in different temperature ranges has been attracted much attention. We are particularly interested in the magnetic materials that exhibit large magnetocaloric effect (MCE) and high relative cooling power (RCP), and can be used for liquefaction of hydrogen. Intermetallic compound ErCoAl is a worthwhile material, which crystallizes in the hexagonal $MgZn_2$-type structure and undergoes a ferromagnetic (FM) transition at the temperature near 20 K. As a potential magnetic refrigerant material for liquefaction of hydrogen, large MCE is expected for this alloy.
We have carried out a systematic study on magnetic properties and MCE of polycrystalline ErCoAl by measuring the temperature dependences of magnetic susceptibility, electrical resistivity and specific heat in various magnetic fields, and the field dependence magnetization in various temperatures. The experimental results indicate that ErCoAl undergoes a second-order FM transition at T_c = 16 K. The low field susceptibility curve shows a sharp rise around T_c while a rapid decrease in resistivity curve and a large peak in specific heat curve are clearly observed in zero field at the temperatures just below T_c. The important finding in this work is that both magnetic and calorimetric measurements reveal a large MCE for ErCoAl around 16 K. The maximum magnetic entropy change, adiabatic temperature change and relative cooling power are determined to be 15.5 J/kg/K, 6.0 K and 284 J/kg, respectively, for a field change of 5 T. It is worth emphasizing that the large MCE can be observed for ErCoAl even in a small field change (~2 T) that can be generated by a permanent magnet. These results indicate that ErCoAl has better refrigeration performance at the temperatures near 20 K, and thus can be considered as the potential magnetic refrigerant material for liquefaction of hydrogen.

Mo.L-P65 - New synthetic route for HoN particles as magnetic refrigerant in hydrogen re-liquefaction system

D. Kim [1], J. Ahn [1], C. Choi [1]

1. Korea Institute of Materials Science, Changwon, Republik of Korea

For hydrogen energy system, liquefied hydrogen is suitable for storage and transportation, because it provides the highest hydrogen densities with respect to both mass and volume. In order to establish this refrigeration technology, it is necessary to obtain the efficient and reliable magnetic refrigerant that possesses a large magnetocaloric effect (MCE) near the boiling point of hydrogen. Rare-earth (RE) nitrides such as ErN, HoN, TbN etc have low transition temperatures and show high magnetic entropy change in cryogenic temperature. So, RE-nitrides have been studied for the application to magnetocaloric materials in low temperature considering re-liquefaction system in hydrogen storage. Among them, Holmium nitride (HoN) was selected from its excellent MCE around 20 K and successfully synthesized to nanoparticles by plasma arc discharge process and microwave-assisted sol-gel method respectively. X-ray diffraction patterns showed the six sharp peaks exactly corresponded to each plane of crystallographic structure of HoN in both cases. Also, the nanocrystallite depicts a clear lattice arrangement that belongs to the planes (111) with 0.28 nm interplaner spacing of HoN cubic crystal structure. Physical Property Meas-urement System (PPMS) was employed to measure the magnetic properties at various temperatures and applied fields. Magnetic entropy changes for as-synthesized particles calculated from the magnetization data set reached maximum value to 27.5 JK-1kg-1 by plasma arc discharge process and 36.6 JK-1kg-1 by microwave-assisted sol-gel method, which are comparable or superior to that of intermetallic compounds having a transition temperature around 20 K such as DyNi2, HoAl2 and $(Gd_{0.1}Dy_{0.9})Ni2$. Accordingly, HoN particles prepared in this work can be a promising candidate for magnetic refrigerant in hydrogen re-liquefaction system.

Mo.L-P66 - Field-induced Martensitic Transformation in $MnCo_{0.92}Fe_{0.08}Ge$

K. Ozono [1], Y. Mitsui [1], R. Umetsu [2], K. Takahashi [2], M. Hiroi [1], K. Koyama [1]

1. Departmaent of Physics and Space, Graduate School of Science and Engineering, Kagoshima University, Kagoshima, Japan
2. Institute for Materials Research, Tohoku University

Ferromagnetic materials, which show martensitic transformation, have attracted considerable attention as magnetic field-controlled materials, because some of them exhibit magnetic-field-induced martensitic transformation, giant magneto-resistance effect, magneto-caloric effect, etc. [1, 2] MnCoGe is a ferromagnet with Curie temperature TC of 335 K. It has been reported that MnCoGe causes the martensitic transformation from hexagonal Ni2In type austenitic phase to orthorhombic TiNiSi type martensitic phase in the vicinity of 420 K. Recently, Li et al. and Lin et al. have been reported that the martensitic transformation temperature and TC of MnCo1-xFexGe compounds are decreasing with increasing the substitution contents x. [3, 4] In our previous studies, it was found that $MnCo_1$-xFexGe for $0.07 < x < 0.10$ shows the magnetic phase transition from paramagnetic to ferromagnetic and is accompanied by the martensitic transformation. This result suggests that $MnCo_1$-xFexGe for $0.07 < x < 0.10$ shows the field-induced martensitic transformation in the vicinity of TC. In this work, we have studied the magnetic and structural properties of $MnCo_{0.92}Fe_{0.08}Ge$ by using a high-field X-ray diffraction (XRD) system in magnetic fields up to 5 T. The obtained XRD patterns shows the diffraction peaks of the hexagonal phase with paramagnetic decrease and the peaks of the orthorhombic phase with ferromagnetic increase with increasing magnetic fields at 276 K. Consequently, we observed a field-induced martensitic transformation from hexagonal to orthorhombic by applying magnetic fields for $MnCo_{0.92}Fe_{0.08}Ge$.

Mo.L-P67 - Effect of Mn-deficient on magnetocaloric effect in non-stoichiometric $La_{0.8}Ca_{0.2}MnO_{3+\delta}$

D. Nanto [1], B. Kurniawan [2], N. Chebotaev [3], A. Telegin [3], S.C. Yu [4]

1. Dept. of Physics Education, Syarif Hidayatullah State Islamic University, Banten, Indonesia
2. Dept. of Physics, University of Indonesia
3. Institute of Metal Physics, UB of RAS
4. Dept. of Physics, Chungbuk National University

In present work, influence of Mn-deficient on magnetocaloric effect (MCE) in Oxygen-excessive polycrystalline $La_{0.8}Ca_{0.2}MnO_{3+\delta}$ and $La_{0.8}Ca_{0.2}Mn_{0.975}O_{3+\delta}$ samples has been investigated. Both samples were prepared by conventional solid-state reaction method. Detail Oxygen treatment on the samples could be found elsewhere [1]. Magnetic properties for those samples were investigated by means of a vibrating sample magnetometer (VSM). Excessive Oxygen led to T_C decrease for $La_{0.8}Ca_{0.2}MnO_{3+\delta}$ compared to $La_{0.8}Ca_{0.2}MnO_3$ [2]. Figure 1 shows thermo-magnetization curves, M(T), for Mn-deficient samples with T_C~144 K for $La_{0.8}Ca_{0.2}Mn_{0.975}O_{3+\delta}$ and T_C~190 K for $La_{0.8}Ca_{0.2}MnO_{3+\delta}$. Maximum magnetic entropy change of Mn-deficient $La_{0.8}Ca_{0.2}Mn_{0.975}O_{3+\delta}$ ($-\Delta S_{M\ max}$ = 0.67 $Jkg^{-1}K^{-1}$) decreases significantly compared to the maximum entropy change of $La_{0.8}Ca_{0.2}MnO_{3+\delta}$ ($-\Delta S_{M\ max}$ = 1.34 $Jkg^{-1}K^{-1}$) under external field of 10 kOe as shown in Fig. 2. Even the maximum magnetic entropy change of $La_{0.8}Ca_{0.2}MnO_{3+\delta}$ much higher than $La_{0.8}Ca_{0.2}Mn_{0.975}O_{3+\delta}$, however, refrigerant capacity of $La_{0.8}Ca_{0.2}Mn_{0.975}O_{3+\delta}$ (37.4 J/kg) higher than $La_{0.8}Ca_{0.2}MnO_{3+\delta}$ (26.8 J/kg). H/M versus M^2 curve shows that both cases exhibit second order magnetic phase transition due to positive slope. Interestingly enough, we find $M(T)$ curve has the magnetization of Mn-deficient $La_{0.8}Ca_{0.2}Mn_{0.975}O_{3+\delta}$ increases than the case of $La_{0.8}Ca_{0.2}MnO_{3+\delta}$ under low applied fields less than 100 Oe but decreases under high applied fields greater than 7 kOe, which is considered to be caused by excessive Oxygens. Moreover, the maximum entropy change of Mn-deficient $La_{0.8}Ca_{0.2}Mn_{0.975}O_{3+\delta}$ decreases than that of $La_{0.8}Ca_{0.2}MnO_{3+\delta}$ as well as the T_C without changing the second order behavior of the magnetic phase transition.

Mo.L-P68 - Critical exponents and EXAFS study of Non-stoichiometric $Nd_{0.5}Sr_{0.5}MnO_3$ Single Crystalline

D. Nanto [1], B. Kurniawan [2], S. Telegin [3], A. Telegin [3], S.C. Yu [4]

1. Dep Syarif Hidayatullah State Islamic University, Jakarta, Indonesia
2. Dept. of Physics, University of Indonesia, Indonesia
3. Institute of Metal Physics, UB of RAS, Ekaterinburg, Russia
4. Dept. of Physics, Chungbuk National University, Cheongju,South Korea

Non-stoichiometric $Nd_{0.5}Sr_{0.5}MnO_3$ (NSMO) single crystalline has been grown by the floating zone method. The slight non-stoichiometric NSMO single crystalline system raises the Curie temperature around 30 K towards room temperature without degradation of the refrigerant capacity (*RC*) and temperature span corresponding to the full width at half maximum of ΔS_{max} (ΔT_{FWHM}) compared to pure single crystalline NSMO system.[1] Here we study in detail critical behavior of non-stoichiometric NSMO. By using the modified Arrott plot method, the critical parameters were obtained to be T_C 267.05 K, β=0.488 ± 0.007, and γ= 1.005 ± 0.048 as shown in figure 1. The values of β obtained is close to expected the mean-field theory (β = 0.5 and γ = 1). Compared to pure single crystalline NSMO system the critical parameters obtained are relatively similar those are β =0.58 and γ = 1.02 [2]. Such the results demonstrate an existence of ferromagnetic long-range order in both pure single crystalline and nonstoichimetric NSMO system. To find out other perspective, we perform local structure study around the central atom of Mn by using extended X-ray absorption fine structure (EXAFS) measured at Pohang Accelerator Laboratory (PAL), South Korea. Figure 2 shows absorption of photon energy NSMO non-stoichimetric compare to Mn-foil.

Mo.L-P69 - Investigation of Structural, Magnetic and Magnetocaloric Properties of (La1-xPrx)0.85Ag0.15MnO3 (x = 0.0, 0.2) Perovskites

A.O. Ayaş [1], M. Akyol [2], S. Kılıç Çetin [2], G. Akça [2], A. Ekicibil [2], Bekir Özçelik [2]

1. Department of Mechatronic Engineering, Faculty of Technology, Adıyaman University, Adıyaman, Turkey
2. Department of Physics, Faculty of Sciences and Letters, Çukurova University, Adana, Turkey

We study the Pr substitution into the La-site effect on magnetocaloric properties in $(La_{1-x}Pr_x)_{0.85}Ag_{0.15}MnO_3$ (x=0.0 and 0.2) polycrystalline compounds prepared by the sol-gel method. The structural and magnetic properties of both polycrystalline compounds are investigated by X-ray Diffraction (XRD), Scanning Electron Microscope (SEM) and Energy-Dispersive X-ray spectrum (EDX) methods. The crystal structures of both samples have been found hexagonal, closed packed structure determined from XRD analysis. SEM images showed that the particles are closely packed with each other in both samples. In addition, the average particle size dropped from 1.23 to 1.03 µm when the Pr added into the structure. We also performed EDX measurement for elemental analysis of each sample. The EDX spectrum showed that there is no any impurity elements coming from the producing and/or sintering process in both samples. Temperature dependence of magnetization , $M(T)$ measurements were performed to determine the Curie temperatures, T_C of both samples. External magnetic field dependence of magnetization, $M(H)$, measurements were performed to determine the magnetic entropy changing (ΔS_M) and saturation magnetizations, *Ms* of both samples. The critical transition temperatures from ferromagnetic to paramagnetic phase are found as 262 and 216 K in $La_{0.85}Ag_{0.15}MnO_3$ and $(La_{0.8}Pr_{0.2})_{0.85}Ag_{0.15}MnO_3$, respectively. In addition, the magnetic entropy changing, is calculated at around this transition temperature by using $M(H)$ data. It is found that the values are decreased from 7.90 to 4.96 J/kgK under 5T external magnetic field when Pr substituted into the structure. Furthermore, the relative cooling power (RCP) values are found as 213.32 and 263.02 J/kg in $La_{0.85}Ag_{0.15}MnO_3$ and $(La_{0.8}Pr_{0.2})_{0.85}Ag_{0.15}MnO_3$, respectively. These findings could potentially be used to engineer of magnetocaloric cooling systems with comparatively high magnetic entropy changing and cooling power in $(La_{1-x}Pr_x)_{0.85}Ag_{0.15}MnO_3$ (x=0.0 and 0.2) samples.

Mo.L-P70 - Relaxation dynamics across the first-order metamagnetic phase transition in magnetocaloric La(Fe,Mn,Si)13

E. Lovell [1], M. Bratko [1], A.D. Caplin [1], L.F. Cohen [1], A. Barzca [2], M. Katter [2]

1. Blackett Laboratory Imperial College London United Kingdom, London, United Kindom
2. Vacuumschmelze GmbH & Co. KG, Hanau, Germany

$LaFe_{13}$-xSix is of considerable interest due to their large magnetic entropy and adiabatic temperature changes and small magnetic hysteresis when field-driven through their first-order metamagnetic transition [1]. This transition is easily tuned by introduction of hydrogen interstitially [2] or by substitution of appropriate elements. Recently it has been shown that $LaFe_{13}$-xSix shows significant long-time magnetic relaxation across the phase transition related to the first order nature of the transition, with a strong dependence on internal demagnetising fields [3,4]. In addition we have observed in one composition x = 1.4, the magnetic relaxation rate slows down as the temperature is increased from Tc towards a tri-critical point (Tcrit) known to exist in the H-T phase diagram, indicating that the dynamics are not Arrenhius or athermal [4]. We have speculated that these observations suggest that the dynamics are governed by the degree of superheating or supercooling. In order to investigate this further we have examined the magnetic relaxation rate in a series of $LaFe_1$-x-yMnySix samples as a function of Mn concentration. We also use a sensitive ac calorimetry probe to separate the heat capacity from the latent heat, in order to characterise the strength of the first order character [5]. We report on the relaxation dynamics across this series of samples and report the correlation with the magnitude of the latent heat. This work is in part funded by the European Community's 7th Framework Programme under Grant agreement 310748 "DRREAM" and also the EPSRC EP/G060940/1.

Much attention has been paid to the ferromagnetic shape memory alloys (FSMAs) due to their application potential as actuators, sensors and magnetocaloric materials. Heusler alloy Ni_2MnGa is a well-known FSMA with the Curie temperature (T_C) of 376 K and the martensitic transition temperature (T_M) of 202 K [1]. T_C and T_M depend on the kind and quantity of the doping atoms as reported in $Ni_2Mn_{1-x}M_xGa$ (M=Co, Ni, and Cu) alloy system [2-4]. Some researchers have reported that T_M is mapped to the average number of valence electrons per atom (e/a) [2]. Co, Ni and Cu atoms have the more valence electrons than Mn atom, but Cr atom has less. As far as we know, there is no data for T_C and T_M of the Cr-doped Ni_2MnGa.
In this study, the temperature dependence of the electrical resistivity r of $Ni_2Mn_{1-x}Cr_xMnGa$ (x=0 - 0.15) has been measured. Two anomalies on the r-T curves for all samples are observed. These anomalies correspond to the magnetic and structural phase transition at T_C and T_M, respectively. On the basis of the experimental results, the T-x phase diagram of $Ni_2Mn_{1-x}Cr_xGa$ is given.

Mo.L-P72 - Magnetic structure and magnetocaloric properties of $Ho(Co_{1-x}Fe_x)_2$ quasibinary intermetallic compounds

M. Anikin [1], E. Tarasov [1], A. Pirogov [1], N. Kudrevatykh [1], A. Zinin [1]

1. Ural Federal University, Ekaterinburg, Russian Federation

We have studied crystal and magnetic structures, magnetic and magnetocaloric properties of $Ho(Co_{1-x}Fe_x)_2$ isostructural compounds (x = 0.00, 0.04, 0.07, 0.12) and made an assessment of a possibility of their application as material for a working body of magnetocaloric refrigerators.

Magnetic properties were measured with SQUID-magnetometer under the magnetic field up to H = 70 kOe over temperature range 5 ÷ 400 K. Neutron diffraction (ND) experiments were carried out with the D-2 diffractometer, mounted on the reactor IVV-2M (Zarechny, Russia). The neutron wave length is 1.805 Å.

It was found that temperature dependencies of the magnetic entropy change $\Delta S(T)$, calculated from magnetization isotherms, demonstrate a broadening of their maximums at temperatures below Curie point. The broadening rises both under magnetic field increasing and Fe-content. At H = 50 kOe the cooling capacity of the sample with x = 0.12 was found to be 583 J/kg, that is much higher than that 299 J/kg determined for $Tb(Co_{0.7}Fe_{0.3})_2$ in [1].

These unusual $\Delta S(T)$ dependences could be explained by a canted magnetic ordering in the Ho sublattice of doped compounds. This assumption is confirmed by results of ND-experiments at T = 78 K on the sample with x = 0.12, in which the average magnetic moment of Ho-atoms was found to be 7.8 μ_B instead of 10.0 μ_B for the Fe-free sample. Thus, it was possible to infer that Ho-magnetic moments near the Fe-atoms positions in $MgCu_2$ lattice are deflected from the global easy axis [100] at the large angles. The average angle of this deflection for all Ho-magnetic moments was assessed as 38º.

This work has been supported by the UrFU State contracts № 1362 and № 2582.

Mo.L-P73 - Hydrogen-induced magnetic anisotropy and magnetocaloric effect in SmFeCo

N. Mushnikov [1], A. Protasov [1], V. Gaviko [1], V. Lazukin [1]

1. Institute of Metal Physics UB RAS, Ekaterinburg, Russian Federation

Quasi-binary $Sm(Fe_{1-x}Co_x)_2$ intermetallics with the fcc $MgCu_2$-type lattice are ferromagnets with the Curie temperatures 208-667 K depending on *x* value. The samarium sublattice provides a large anisotropic magnetostriction, and the crystal lattice undergoes rhombohedral magnetoelastic distortions which can be registered by x-ray diffraction. A characteristic feature of these intermetallics is their high activity to hydrogen. Powdered samples spontaneously absorb hydrogen from the atmosphere and form hydrides $Sm(Fe_{1-x}Co_x)_2H_{0.1-0.05}$. Hydrogen orders in the distorted lattice, which in turn enhances the rhombohedral distortions. The arrangement of the hydrogen ions can be modified by heating in magnetic field, which causes a uniaxial magnetic anisotropy.

We studied the magnetic and magnetothermal properties and structure of the SmFeCo compound containing spontaneously absorbed hydrogen. The compound has the Curie temperature 613 K and the room-temperature specific magnetization 45 Am^2/kg. After heating up to 350-450 K and subsequent cooling in magnetic field, the magnetization curves measured along the direction of thermomagnetic treatment and perpendicular to it were found to be substantially different because of an induced magnetic anisotropy. We determined optimum values of the temperatures and magnetic fields which provide the induced anisotropy energy up to 5.2×10^5 J/m^3 at room temperature. It decreases down to zero with increasing temperature up to 350 K. Near this temperature, due to increasing of hydrogen mobility, we observed strong magnetic relaxation.

Using the results of temperature and field dependences of magnetization, we estimated the magnetocaloric effect caused by changing of mutual orientations of the easy axis and magnetic field direction. The MCE is positive, appeared in relatively weak magnetic fields and has a maximum at ~ 320 K. The maximum value of the isothermal entropy change amounts to 1.8 $J\,kg^{-1}K^{-1}$. The adiabatic temperature changes for the hydrogen-containing SmFeCo are currently under study.

This work is partially supported by RFBR 13-02-96022 and UB RAS 15-17-2-22 grants.

Mo.L-P74 - Specific heat, magnetostriction and magnetocaloric effect in $Fe_{48}Rh_{52}$ alloy

A. Aliev [1], A. Batdalov [1], L. Khanov [1], A. Kamantsev [2], E. Dilmieva [2], A. Mashirov [2], V. Koledov [2], V. Shavrov [2], M. Topic [2]

2. Kotelnikov Institute of Radio-engineering and Electronics of RAS, Moscow, Russia

In the modern literature, there are no comprehensive data on the role of different mechanisms responsible for metamagnetic phase transition of the 1st order from antiferromagnetic (AFM) to ferromagnetic (FM) state observed in the alloys Fe-Rh. There is no theory satisfactorily describing the nature of this transition. The most popular idea is of an electronic nature of the transition, based on differences in the density of electronic states near the Fermi level in the FM and AFM- phases. The basis for this assumption is the experimentally observed difference in the coefficients of the electronic specific heat γ=Ce/T in FM and AFM-states ($\gamma_{FM}>\gamma_{AFM}$) [1,2]. Since the direct measurement of γ_{FM} is not possible, the procedure was carried out by measuring the specific heat at low temperatures in magnetic fields exceeding the critical values. The experimentally measured value of the specific heat just before the AFM-FM transition and just after the transition must undergo a jump $\Delta C=(\gamma_{FM}-\gamma_{AFM})T_{cr}$. Using data on $\Delta\gamma\approx0.048 J/kgK^2$ [1,2] and $T_{cr}=318K$, one can get $\Delta C_e=15.26$ J/kgK. Our experimental data $C_P(T)$ show that the expected discontinuity of ΔC cannot be observed.
Direct measurements of MCE were conducted using magnetic field modulation technique, with high ΔT accuracy measurements [3]. The temperature hysteresis, a significant difference in the magnitude of the effect at heating and cooling, as well as the splitting of the maximum of the effect in weak magnetic fields were detected. The observed phenomena are explained by the coexistence of FM and AFM-phase and low heterogeneity of the studied sample. Temperature hysteresis of MCE in strong magnetic fields demonstrate a qualitatively different form.

Mo.L-P75 - Predictions of large magnetocaloric effects in Co- and Cr-substituted Heusler alloys using first-principles and Monte Carlo approaches

V. Sokolovskiy [1], V. Buchelnikov [1], M. Gruner [2], P. Entel [2]

1. Chelyabinsk State University, Chelyabinsk, Russia
2. Duisburg-Essen University, Essen, Germany

Ferromagnetic (FM) compounds with first-order magnetic phase transition and simultaneous structural changes have attracted interest due to emerging magnetocaloric effects (MCE) and their possible application in magnetic refrigeration technology [1]. Nowadays, Ni-Z-Mn-In (Z = Co, Fe, Cr, Si etc.) Heusler alloys have been widely investigated because of their potential applications as intelligent FM materials [1-3]. The additional element Z can bring a transformation sequence from martensite having low magnetization to FM austenite with high magnetization giving rise to better magnetocaloric properties. In this work we theoretically studied MCE in Ni-Co-Mn-Cr-In Heusler alloys by combining first principles with Monte Carlo approaches. We discuss the resulting complex spin configurations, temperature behavior of entropy as well as critical temperatures of phase transitions. Three types of composition with substitution of 5at.% Cr for Mn, In, and Ni have been discussed. The ab initio calculations have been carried out by using two kinds of 16-atom supercell Ni7Co1Mn6In2 with different both spin configurations and distributions of Mn and In at the In-sublattice. We have shown that different spin configurations lead to the small respective large magnetic moments of martensite and austenite. As a consequence, the substitution of 5% Co for Ni and 5% Cr for Mn results in a magnetostructural transition from FM austenite to antiferromagnetic martensite, which is accompanied by a spin-flip transition upon cooling. Large magnetization drop and giant inverse magnetocaloric effect can be achieved of $\Delta T_{ad} \sim -9$ K under magnetic field change of 2 T field across the structural transition.

3. Institut für Werkstoffe, Ruhr-Universität Bochum, Bochum, Germany

The search for materials that exhibit a large magnetocaloric effect (MCE) near room temperature endorses the systematic investigation of entire material classes with varying chemical composition. For this purpose material libraries can be prepared by thin film deposition on wafers. However, the direct measurement of the adiabatic temperature change ΔT in thin film samples is difficult due to the fast heat diffusion on small length scales.
We present direct measurements of ΔT in low volume and thin film samples [1]. Our newly developed experimental setup combines magnetomodulation with non-contact temperature measurements via detection of the sample's thermal radiation. The setup reaches sub-mK sensitivity and gives insights into the low-field behavior of the MCE, which is not accessible by standard calorimetry.
For the measurements of ΔT on a thin film, a 1.4 µm thick layer of Gd was deposited on a 1.1 µm thick membrane fabricated by micro-electro-mechanical systems technology. Temperature dependent measurements show a clear peak at 294K, as expected in the region of the ferromagnetic-paramagnetic phase transition.
Measurements on bulk metamagnetic $LaFe_{11.05}Co_{0.91}Si_{1.04}$ in magnetic field amplitudes of 4 mT to 45 mT show a strong broadening of the peak with increasing field amplitude. Different values for the temperature change are observed upon heating and cooling the sample, indicating a thermal hysteresis. Magnetic field dependent measurements on all samples show a quadratic dependence of ΔT at the peak temperature for weak external fields, contradicting earlier predictions. An analytic expression is derived from Landau-theory that correctly describes both the quadratic dependence of ΔT at low fields and the well known $H^{(2/3)}$ behavior at high fields.

Mo.L-P77 - Phase transformations and magnetocaloric effect in Ni-Mn-(Co)-In Heusler alloys

V. Buchelnikov [1], R. Fayzullin [1], A. Mashirov [2], V. Koledov [2], V. Shavrov [2], S. Taskaev [1]

1. Chelyabinsk State University, Chelyabisk, Russia
2. Kotelnikov Institute of Radioengineering and Electronics, Moscow, Russia

The magnetocaloric effect (MCE) is a phenomenon of adiabatic temperature change of the magnetic material induced by change of external magnetic field. Recent experimental studies have shown that Ni-Mn-(Co)-In Heusler alloys are also attractive for magnetic refrigeration [1, 2]. In this work, we study experimentally MCE in Ni1.81Mn1.64In0.55, Ni1.73Mn1.80In0.47 and Ni1.72Mn1.51In0.49Co0.28 Heusler alloys. Polycrystalline ingots with nominal compositions were prepared by an arc-melting method. The MCE measurements were performed by the setup produced by AMT&C [3]. The temperatures of phase transitions were determined from the thermomagnetic dependences in the temperature range of 50–400 K. The latent heat connected with the first-order transformation were determined by differential scanning calorimetry.
The magnetostructural transformation from the antiferromagnetic-like martensite to the ferromagnetic austenite phase in the all compositions was found. The giant inverse MCE (DTad = -3.72 K) is observed at the magnetostructural phase transition temperature (Tm=230 K) in Ni1.81Mn1.64In0.55 alloy. For Ni1.73Mn1.80In0.47 and Ni1.72Mn1.51In0.49Co0.28 alloys maximum values of MCE are somewhat smaller: DTad are -2.1 K (at Tm=292 K) and -2.4 K (at Tm=311 K) for DH=2 T, respectively. Maximum positive value of MCE in Ni1.81Mn1.64In0.55 and Ni1.72Mn1.51In0.49Co0.28 (DTad = 1.8 K at Tc=320 K and DTad = 1.4 K at Tc=327 K, respectively) observed at Curie temperature. This work was supported by RFBR (Grant No. 14-02-01085, preparation of samples), RSF (Grants No. 14-12-00570, MCE measurements, No. 14-22-00279, magnetic measurements) and Ministry of Education and Science RF (Grant No. 3.2021.2014/K, DSK measurements).

Mo.L-P78 - MAGNETIC and structural analysis of MN rich MN-NI-SN alloys

J.J. Suñol [1], R. Coll [1], L. Escoda [1], M. Ipatov [2]

1. University of Girona, Girona, Spain
2. SGIKer, University of Basque Country, Leioa, Spain

In this work we analyse the thermomagnetic response and the structure transformation of three Mn rich alloys of the Mn-Ni-Sn system: $Mn_{50}Ni_{40}Sn_{10}$, $Mn_{50}Ni_{42.5}Sn_{7.5}$ and $Mn_{50}Ni_{45}Sn_5$ (at. %). Previous studies concluded that these materials are prospective for the development of magnetically driven sensors, actuators and working substances for magnetic refrigeration. Characteristic temperatures of the martensitic transformation were determined from differential scanning calorimetry (DSC) measurements. Structure and microstructure was examined by X-Ray diffraction (XRD) and scanning electron microscopy (SEM) linked with an energy dispersive X-ray spectrometry (EDX) device. Temperature and field dependences on magnetization were measured with a vibrating sample magnetometer (VSM) and PPMS. The temperature dependence of the magnetization M(T) was measured at our values of applied magnetic field from 50 Oe up to 50 kOe. Martensitic transformation temperatures decrease as the intensity of the applied magnetic field increases. Thus, magnetic field stabilizes the high temperature austenite phase. Magnetization values of 40 emu/g were obtained (austenite phase). The Curie temperature ranged from 250 to 350 K. Complementary AC magnetic susceptibility measurements were also performed. Transformation temperatures are lower than those obtained in Ni rich Ni-Mn-Sn alloys.

Magnetocaloric effect (MCE) is the isothermal entropy change or adiabatic temperature change induced by external magnetic field and it forms the basis for solid state refrigeration near room temperature. For successful application, large MCE is required in relatively small fields below 2 T. $La(Fe,Si)_{13}$ based compounds are promising candidates exhibiting large MCE associated with a first-order metamagnetic phase transition above the T_c. Importantly, the T_c can be shifted to near room temperature by hydrogen absorption while sustaining the large MCE [1].
The effect of hydrogenation on the metamagnetic phase transition is not fully understood. Here we investigate the impact of hydrogenation on the first order nature of the phase transition in $LaFe_{11.33}Mn_{0.37}Si_{1.30}$, where Mn doping has been used to tune the T_c of fully hydrogenated state to 283 K. We use our unique microcalorimeter which operates in two distinct setups allowing us to measure the latent heat and the reversible changes in heat capacity separately. Thus we can quantify the first order and the second order contribution to the entropy change. We do so in the dehydrogenated and fully hydrogenated state showing significant decrease in the first order contribution to the total MCE in the hydrogenated state. In the dehydrogenated state we perform this analysis across a series of $La(Fe,Mn,Si)_{13}$ compounds with increasing Si and Mn content showing a transition from relatively strongly first order phase transition to a second order phase transition. Across the series we observe tricritical points where the metamagnetic phase transition becomes fully second order. The tricritical points appear closer to the T_c with the suppression of first order phase transition by composition.

Mo.L-P80 - Magnetocaloric effect in Gd - Y alloys

M. Drobosyuk [1], S. Taskaev [1], M. Ulyanov [1], D. Bataev [1], R. Fayzullin [1], V. Buchelnikov [1]

1. Chelyabinsk State University, Chelyabinsk, Russian Federation

The magnetocaloric effect (MCE) is the ability of magnetic materials to heat up or cool down then they are placed in or removed from an external magnetic field. The magnetic materials with large values of MCE can be applied as work substances in magnetic cooling devices. In this work, we study experimentally MCE of Gd - Y alloys.

Polycrystalline ingots with Gd - Y nominal compositions were prepared by a conventional arc-melting method. Samples were cut from the middle part of the ingots.

The magnetocaloric measurements were performed by the Magnetocaloric Measuring Setup produced by Advanced Magnetic Technologies and Consulting Ltd (AMT&C). The adiabatic temperature change ΔT_{ad} was measured by a direct method in this setup. . Magnetic field up to 2 T was created by Halbach permanent magnet magnetic field source. Signals from the thermocouple and Hall probe were recorded simultaneously what allowed us to measure ΔT_{ad} as a function of magnetic field H. Temperature was stabilized with accuracy of ~ 0.05 K. The measurements were performed in a temperature interval from 220 to 290 K.

Temperature dependencies of ΔT_{ad} for one of $Gd_{100-x}Y_x$ alloys for the magnetic field change ΔH = 2 T are shown in Figure 1. It is seen that all the alloys exhibit the positive MCE typical for 2nd order transition. The maximal MCE is observed at the Curie point and it's value of ΔT_{ad} is 2.68 K.

Mo.L-P81 - Thermal and rheological properties of water based ferrofluids and their applicability as quenching media

J. Župan[1], M. Majiæ Renjo [1]

1. University of Zagreb, Faculty of Mechanical Engineering And Naval Architecture, Quenching Research Centre (QRC), Zagreb, Croatia

Water based ferrofluids present a new energy transfer fluid with tunable properties. Previous research has shown the increase in thermal conductivity of water based nanofluids with the addition of iron oxide. Such increased thermal properties show great potential for use in heat transfer. In this paper, several nanofluids were prepared with two step method. Iron (II,III) oxide nanoparticles with average paerticle size less than 50 nm were added to deionized water in following concentration: 0.01, 0.1, 0.5 and 1 g/L. Their thermal and rheological properties were measured at 20, 40 and 60 °C. Results showed increase in thermal conductivity and viscosity with increase in the addition of nanoparticles at all three temperature levels. The biggest increase was observed at 20°C. For this research, all of the prepared nanofluids were tested as immersion quenching liquid according to ISO 9950 standard. Besides still conditions, quenching experiments were conducted under the magnetic field at two levels, 500 and 1000 Gauss. The magnetic field effect was least present at 60°C with almost no influence on the cooling curve and cooling rates. At lower temperature levels quenching under the magnetic field shortened the full film boiling phase and increased the maximum cooling rate.

Mo.L-P82 - Two Dumbbell-shaped M_5Gd_4 Herterometallic Clusters exhibiting well magnetocaloric effect

J.P. Tong [1], X.J. Xu [1] Y, D.J. Yang [1] Y, K. Zhang [1], J. Tao [2]

1. Xiangyang Noncommissioned Officers School, Xiangyang, China
2. Xiamen University, Fujian, China

Heterometallic 3d-4f complexes have been intensively studied owing to the rapid development in molecular magnetic properties. Many Gd-containing complexes display fascinating magnetocaloric effect due to spin multiplicity of Gd(III) ions. So far, lots of Gd-containing complexes have been synthesized, in which tetranuclear cuboidal species are highly concerned because intracluster ferromagnetic exchanges and thus high-spin ground states are often obtainable so that they are potential candidates used in low-temperature refrigeration.

Herein, we obtained two dumbbell-shaped herterometallic clusters **Co5Gd4** and **Ni5Gd4**. The skeleton can be viewed as two $\{M_2Ln_2\}$ cubanes connected via an M(II) ion. The magnetic entropy changes of **Co_5Gd_4** and **Ni_5Gd_4** are calculated from magnetization data according to the Maxwell equation. The largest $-\Delta S_m$ values at 3.5 K for 7 T are 31.0 J Kg^{-1} K^{-1} for **Co_5Gd_4** and 37.3 J Kg^{-1} K^{-1} for **Ni_5Gd_4**, respectively. Ni5Gd4 shows large MCE taking advantage of intramolecular ferromagnetic interactions and considerable metal-to-ligand mass ratio.

Mo.L-P83 - Direct measurements of giant adiabatic temperature change in FeRh alloys under cyclic conditions

Materials exhibiting a large magnetocaloric effect (MCE) can be exploited for solid-state magnetic refrigeration. The presence of a first order metamagnetic transition in a material has the disadvantage of a hysteresis, which can reduce the MCE. It is very important to carefully estimate the MCE under cyclic conditions close to those in a potential magnetic refrigerator [1] in order to avoid the overestimation that happens when only the first application of the magnetic field is considered. FeRh exhibits one of the largest MCE displayed at a metamagnetic transition from an antiferromagnetic (AF) to ferromagnetic (FM) state near room temperature and this is characterised by a large adiabatic temperature change (ATC). FeRh has a large hysteresis (about 20 K in 0.5T) and is an ideal model system for magnetocaloric materials with a hysteretic transition. It has been estimated that the magnetic entropy change in FeRh does not decrease significantly even after repeated applications of a magnetic field [2], however so far direct measurements of the MCE under cyclic conditions have not been reported. In the current work, direct measurements of the ATC during cycling of binary Fe-Rh have been carried out. The results showed that in $Fe_{49}Rh_{51}$, the ATC was 9.2 K on the first application of the 2T field and it remained constant at 6.2 K during repeated cycling. Despite the presence of the hysteresis at the AF-FM transition, this directly measured value of the ATC is higher than in Gd and demonstrates the potential of materials with a first order metamagnetic transition for application in magnetic refrigeration technology.

Mo.L-P84 - $(Mn_{55}Al_{45})_{100}B_2$ and $Mn_{55}Al_{45}Ga_5$ - promising permanent magnetic materials

Sofia Kontos [1], Klas Gunnarson [1], H.ailiang Fang [2], P. Svedlindh [1], Martin Sahlberg[2]

1. Uppsala University, Engineering Sciences, Uppsala, Sweden
2. Uppsala University, Chemistry, Uppsala, Sweden

Due to magnetic properties potentially superior to ferrites and lack of rare earth contents, Mn-Al alloys are promising candidates for permanent magnets. Besides, they show good mechanical properties, machinability and corrosion resistance. The ferromagnetic tetragonal τ-phase has a strong uniaxial anisotropy which is a prerequisite for achieving a high coercivity. τ-phase is usually formed from the nonmagnetic hexagonal ε-phase by annealing a quenched alloy with 50-60% of Mn. Since both phases are metastable at room temperature, different alloying elements are used to stabilize the phase.
Magnetic and crystallographic properties were obtained by X-ray diffraction and vibrating sample magnetometry measurements. By alloying $Mn_{55}Al_{45}$ with B or Ga to $(Mn_{55}Al_{45})_{100}B_2$ and $Mn_{55}Al_{45}Ga_5$, respectively, τ-phase was achieved from high temperature synthesis methods. Subsequently the samples were annealed at 1000˚C and quenched in water. The magnetization was measured as a function of applied field up to 7.2 MA/m at room temperature before and after a relaxation process.
For $(Mn_{55}Al_{45})_{100}B_2$ and $Mn_{55}Al_{45}Ga_5$, the saturation magnetizations are 0.42 MA/m and 0.50 MA/m and the coercivities 0.26 MA/m and 0.22 MA/m, respectively. The quantities were measured directly after annealing and quenching. After relaxation, the saturation magnetizations are slightly increased to 0.50 MA/m and 0.51 MA/m, however, at the expense of coercivities which decreased to 0.15 MA/m and 0.11 MA/m. The squareness factor M_r/M_s of the samples were 0.3-0.4 for all samples.

Mo.L-P85 - Ab-initio based analytical evaluation of entropy in magnetocaloric materials with first order phase transitions

M. Piazzi [1], V. Basso [1], J. Zemen [2], K. Sandeman [2,3]

1. Istituto Nazionale di Ricerca Metrologica, Torino, Italy

The possibility to predict first order magnetic phase transition from first principles would boost the theory-led discovery of novel compounds with enhanced magnetocaloric effect. However this task is a challenging one. Spin polarised density functional theory (SDFT) can foreshadow Curie points [1], but can say little about first order transitions where magnetoelastic effects and spin disorder at finite temperature play relevant effects. Possible solutions include the application of the disordered local moment (DLM) picture [2], that has been recently applied to antiferromagnets [3]. Here we investigate an approach complementary to Ref. [3], based on multilevel modeling: ab-initio SDFT and mean field thermodynamic theory (MFT) [4]. On the one hand SDFT provides the local moments, the ground state energy and the electronic density of states. On the other hand MFT allows for the analytical evaluation of the magnetic entropy and magnetoelastic contributions. In this way we evaluate by SDFT the magnetic configurations of a system and we derive by MFT the temperature dependence of the free energy. We test this approach with relevant magnetocaloric compounds: La(Fe,Si)13 [5] and Mn-based antiperovskites (AXMn3, with X=C, N and A metal element) [6]. For the antiperovskites we find that adding the localized spin contribution is necessary to achieve good agreement with the measured Tt, since the electronic entropy alone would overestimate the value. The research leading to these results has received funding from the EC FP7 under Grant agreement 310748 'DRREAM'.

Mo.L-P88 - Ferrites in the low-power wireless power transfer systems

B. Stergiou [1], V. Zaspalis [1]

1. Laboratory of Inorganic Materials, Centre for Research and Technology – Hellas, Thessaloniki, Greece

The emerging trend of wireless charging in electronic device market has revived the research interest in wireless power transfer systems and pushed magnetic materials design towards certain specifications. In typical inductive power transfer applications, the demand for efficient inductive coupling and elaborate manipulation of magnetic fields indicate the critical role of magnetic materials. Thus, the main objective of this investigation is to monitor the impact of magnetic material properties on the basic characteristics of a low-power wireless power transfer system.

For this examination, two different compositions of NiZn and NiCuZn spinel ferrites were fabricated with the conventional solid-state reactions route. Specifically, disc and toroidal specimens were pressed at the constant density of $3gr/cm^3$ and sintered at different top temperatures from 1000°C to 1300°C. The varying composition and sintering temperature ensured the appearance of different material properties, which facilitated the derivation of their influence on the overall performance. To this end, the ring-shaped ferrite samples were initially characterized in terms of the saturation magnetization B_{sat}, complex permeability μ^* and power loss density P_v in various frequency ranges from 20kHz to 1GHz. The variations of these properties were clearly correlated with the recorded structural and microstructural aspects of the materials. Moreover, by employing the produced disc-shaped ferrite specimens, we have measured their shielding effectiveness in the near field and studied their effect as substrate material on the inductance L and quality factor Q of standard planar spiral coils with emphasis on the 100-200kHz frequency range, which is defined by the respective prevalent standards. Finally, the impact of high saturation and permeability planar ferrite on the coupling efficiency was verified and quantified by means of an evaluation low-power wireless power transfer module.

This work was supported by the IKY fellowships of excellence for postgraduate studies in Greece - Siemens program.

Mo.L-P89 - Magnetocaloric effect in some magnetic materials in alternating magnetic fields

A. Aliev [1], A. Batdalov [1], A. Gamzatov [1], L. Khanov [1], V. Koledov [2], V. Shavrov [2]

1. Amirkhanov Institute of Physics of Daghestan Scienti fic Center, RAS, Makhachkala, Russia
2. Kotelnikov Institute of Radio-engineering and Electronics of RAS, Moscow, Russia

The creation of magnetic refrigerators remains an actual and alluring idea. Today the compact sources of high magnetic fields exist; the alloys with large values of magnetocaloric effect (MCE) are obtained. But an important questions is scarcely explored. The magnetocaloric materials in refrigerators will be affected by external alternating magnetic field. But it is not clear how will the magnetocaloric effect behave under alternating magnetic fields. Whether a magnetocaloric material will have time to exchange energy with surrounding heat exchanger under such conditions?
In this work we present the modulating method of the direct measurement of magnetocaloric effect, alternating magnetic field source, and experimental results of magnetocaloric effect in different materials, including gadolinium, some manganites, and Heusler and FeRh alloys under alternating magnetic fields up to 25 Hz. In some of the studied materials no significant dependence of the MCE on frequency of magnetic field change is observed. In some Heusler alloys and manganite compounds, MCE strongly depends on the frequency of magnetic field changes, and can even vanish at high frequencies.
Possible reasons for the frequency dependence of MCE could be the long time relaxation processes at magnetic phase transitions and irreversibility around the first order magnetostructural phase transitions. The results show that the frequency dependence of MCE should be considered for the choice of materials for magnetic refrigerators.

Mo.L-P90 - Anodic iron oxide nanotubes: Structural and magnetic characterization

A. Apolinário [1], C. T. Sousa [1], A. M. Pereira [1], M. P. Fernandez [1], G. Oliveira [1], J. Azevedo [1,2], J. Ventura [1], L. Andrade [2], A. M. Mendes [2], J.P. Araújo [1]

1. IFIMUP-IN - Universidade Do Porto, Porto, Portugal
2. LEPABE - Universidade Do Porto, Porto, Portugal

Highly-ordered hematite (α-Fe2O3) nanotubes (NTs) have gained relevance for application in hydrogen production by water splitting (photoelectrochemical cells) [1] due to its narrow band gap about 2.0-2.2 eV, which collects up to 40% of the solar spectrum energy. However, the hematite materials have poor electron mobility that results into high electron-hole recombination rate and, short hole diffusion length. In order to overcome these drawbacks, nanostructuring techniques have been proven useful for increasing the performance of the hematite's photoresponse [2]. In this work, we synthesized iron oxide NTs starting from an iron foil in fluoride containing electrolytes via an electrochemical anodization method. The NTs' geometry depend on different anodizing parameters (electrolyte type, concentration, pH, time, temperature and applied potential) that determine the relevant tube features (length, pore diameter and wall thickness). Fast-growth of iron NTs arrays were obtained with an anodization potential of 50 V in an ethylene glycol solution containing NH_4F (0.5 wt%) and H_2O (2 wt%) at 45^{o}C. Through scanning electron microscopy (SEM) it was determined the NTs morphology, unveiling NTs features, diameter and length. Afterwards, the as-prepared NT samples were annealed under different conditions, time and temperature, in an oxygen atmosphere in order to obtain crystalline iron oxide NTs. It was observed that after 1h the iron oxide NTs start to crystallize at temperatures above 400^{o}C. The X-ray diffraction spectrum discloses that 2 iron oxide phases are always present: magnetite (Fe_3O_4) and α-Fe_2O_3. These achievements were further corroborated by the temperature dependence of magnetization measurements, namely by the presence of a breakdown of magnetization magnitude at T_V~120 K, arising from the electronic transition of Fe_3O_4 (Verwey transition). Additionally, and one anomaly at T_M ~190 K is also presented due to the antiferromagnetic spin flop transition of the α-Fe2O3 (Morin transition). The isothermal hysteresis loop proves that all the oxide NTs are ferromagnetic at room temperature with coercive fields ~ 150 Oe and up to 400 Oe for low temperatures.

Mo.L-P92 - Influence of quenching and heat-treatment parameters on the antiferromagnetic-ferromagnetic phase transitions in $Fe_{49}Rh_{51}$ alloys

V. Rodionov [1], V. Rodionova [1], S. Shevyrtalov [1], M. Annaorazov [1]

1. Immanuel Kant Baltic Federal University, Kaliningrad, Russia

The nearly equiatomic Fe–Rh alloys when heated without an external influences to critical temperature suffer the first-order antiferromagnetic–ferromagnetic transition. The reverse transition takes place at lower temperature. The width of thermal hysteresis can be varied by the changing of alloy's chemical content, preparation technique of the samples, heat- and mechanical treatment in wide range of temperatures. To decrease the hysteresis - it is important for technical applications. Moreover, each subsequent measurement leads to changing of the antiferromagnetic–ferromagnetic transition temperature. This research work was aimed to find quenching and heat-treatment parameters of equiatomic Fe–Rh alloy for achieving of the extremely narrow thermal hysteresis and repeatable results. The quenching was performed in different temperature range: from 1370 K down to 990 K, from 1208 down to 790, from 1073 down to 278 K. At highest temperatures (temperature of exposition) the alloy was kept for 5-400 min. The heat-treatment was performed at 1273 K for 20-72 hours and 1100 K for 20-72 hours with cooling rate of 10 K/hour. Vibrating sample magnetometer by Lake Shore was used for measurements of magnetic moment versus temperature in range of 100-950 K. The optimal parameters of quenching and heat-treatment were determined to observe thermal hysteresis of 15 K. The increasing of the temperature of exposition time leads to decreasing of temperature of transition на 14 K.

Mo.L-P93 - Ni-Mn-Sn-Co metamagnetic shape memory thin films

I.R. Aseguinolaza [1,2], A.V. Svalov [1], V.A. Chernenko [1,2,3], J.M. Barandiaran [1,2]

Magnetic shape memory alloys (MSMAs) represent a promising kind of smart materials because of their ability to undergo large strains (>10%) under a moderate external magnetic field. This effect arises from the magnetostructural coupling in the martenstitic phase. Among these compounds, metamagnetic shape memory alloys (MMSMAs) [1] show additionally the magnetic field induced reverse martensitic transformation due to the big and sudden magnetization increase from the martensite to the austenite. Such phenomenon enables the large inverse magnetocaloric and large magnetoresistance effects, making these materials appropriate for applications like magnetic refrigeration. Beyond their bulk applicability, their micro- or nanoscale functionality is especially interesting in view of the enhanced properties of the MMSMAs when they are reduced to those dimensions, as in the case of thin films [2]. On the one hand, the high area/volume ratio of the films increases the heat transfer rate per unit mass allowing high-frequency temperature actuation. On the other hand, the magnetically controlled resistivity through phase transformation permits a potential implementation in microelectronic systems. In this work, Ni-Mn-Sn-Co MMSMA 1 µm-thick films have been sputter-deposited from two pre-alloyed Ni46.1Mn38.9Sn10.1Co4.9 and $Ni_{44.8}Mn_{37.7}Sn_{10.8}Co_{6.7}$ targets, using a 150 W power and a 500 °C substrate temperature for both Si/SiO2 and single-crystalline MgO (001) substrates. The film compositions have been studied as a function of the Ar pressure exhibiting a systematic increase of Ni and decrease of Mn contents as the pressure increases. The martensitic transformation of the films has been characterized by means of magnetic and electric resistivity measurements as a function of temperature, taking place near the room temperature and revealing a narrower transformation interval as the Ni content increases. The observed magnetization drop upon direct transformation reaches up to 42% while the electric resistivity changes by 64%, making these films suitable for the mentioned applications.

TU.A-P01 - Magneto-electric coupling, magnetoreistance and magnetocaloric effect in Ba rich quantum paraelectrics : $Eu_{0.4}Ba_{0.6}TiO_3$

R. Mahendiran [1]

1. National University of Singapore, Singapore, Singapore

While $BaTiO_3$ is a well known ferroelectric of displacive type, ferroelectric transition is impeded in $EuTiO_3$, presumably by quantum fluctuations. We have synthesized Eu1-xBaxTiO3 for a wide x from x = 0 to 1 and studied magnetism, magnetoelectric coupling, dc and ac magnetoresistance , magnetothermopower and magnetocaloric effect. Giant magnetic entropy change (> 20 J/kg.K) at below 20 K has been found. Resistivity and dielectric studies indicate that charge carries are coupled to Eu^{2+}:4f local spins . Our results indicate a correlation between magnetocapacitance and magnetoresistance in the Ba- rich compound x = 0.6. I will give overview of the physical properties of the Ba rich compositions investigated.

TU.A-P03 - Photostriction in multiferroic $BiFeO_3$

B. Kundys [1]

1. Institut De Physique Et De Chimie Des Matériaux De Strasbourg, Strasbourg, France

The multiferroic BiFeO3 belongs to the group of photostrictive materials [1] where the photovoltaic effect [2] linked with elastic interactions induces the deformation by light [3]. In this work we study the wavelength dependence of photostriction in $BiFeO_3$ and its correlation with photocurrent. As light energy decreases, the photostriction effect in a single crystal of $BiFeO_3$ shows amonotonous dependence and follows the photocurrent with a some delay. The light-induced charge excitation mechanism and direct light coupling to ferroelectric polarization can be used to understand such a correlation. By increasing excitation energy at the given wavelength some remnant strain levels can be observable after light is off. Therefore it appears to be extremely important to distinguish between the photostriction in spontaneous and saturated ferroelectric states. Based on recent experiments [4,5], the analogy to remnant strain effects can also be seen in photostriction. Depositing ferromagnetic film on such a photostrictive material results in its interesting photo-magneto-resistive behaviour that can be used for the light-controlled logic and memory applications in both optics and magnetic straintronics with photostrictive elements.

TU.A-P07 - Physical properties of Single Crystals of A-site ordered manganites $REBaMn_2O_6$ (RE = rear earth)

S. Yamada [1], K. Higuchi [1], T. Sasaki [1], H. Aoki [1], H. Sagayama [2], T.H. Arima [3]

1. Department of Materials System Science, Yokohama City University, Kanagawa, Japan
2. Institute of Materials Structure, High Energy Accelerator Research Organization, Ibaraki, Japan
3. Department of Advanced Materials Science, The University of Tokyo, Chiba, Japan

We have succeeded in growth of single crystals of A-site ordered perovskite manganites, $REBaMn_2O_6$ (RE = Sm, Eu, Tb, Gd, Dy, and Y), and investigated the physical properties. We categorize the materials into three groups in terms of the difference in magnetic properties between the single crystals (SCs) and the Pulverized samples (PSs). The first group is the compound with RE = Sm and Eu which has small magnetic moments. In contrast to the temperature dependence of magnetization of the SCs, that of the PSs does not exhibit an anomaly at ~ 200 K which is the charge rearrangement temperature and has a broad peak between the charge ordering (~ 400 K) and the rearrangement (~200 K) temperature. The second group is the compounds with RE = Y which has no magnetic moment. The temperature dependence of magnetization of the SC is the same as that of the PS. The last group is the compound with RE = Tb, Gd and Dy which has large magnetic moments, the temperature dependences of magnetization of the SCs are also same as that of the PSs. However, these magnetizations are not mainly caused by the magnetic moments manganese ions but those of rear earth ions. These results indicate when the rare earth ions have small magnetic moments in comparison with that of the manganese ions, these temperature dependence of magnetization strongly depend on the size of the samples.
We can clearly observe anomalies in temperature dependence of magnetization and electrical resistivity of the single crystals, which enable us to determine the magnetic and electric phase transition temperatures. In particular, the obtained Neel temperatures are different from the ones proposed by previously studies using polycrystalline samples. We revise the magnetic and electric phase diagram of $REBaMn_2O_6$.

TU.A-P08 - Structural and physical properties of multiferroic $Bi_{1-x}RE_xFeO_3$ powders (RE = Nd^{3+}, Eu^{3+}) synthesized by the sol-gel method

Interrelation of magnetic and electric properties allow to manipulate transport and create new devices for writing and saving of information. Among the substances with the strong correlation between the magnetic and electrical properties are the disordered systems. Electron doping of manganese monoselenide of $Mn_{1-x}Gd_xSe$ ($0 \le x \le 0.7$) solid solutions may cause the chemical phase separation and nonuniform magnetic states. The aim of this work is to study the mechanism of the electrical resistivity and interrelation between the electric and magnetic subsystems depend on compounds, temperature and magnetic field. Solid solutions, as well as limit compounds MnSe and GdSe, have an antiferromagnetic ordering with T_N=136 K and T_N=34 K. The magnetic susceptibility was measured in the 77-900 K temperature range. The Neel temperature is monotonically decreased with gadolinium concentration and achieve to T_N =88 K for $Mn_{0.3}Gd_{0.7}Se$. The magnetic permeability and relaxation time were studied in the range of frequencies 10 Hz-100 kHz at temperatures 80 K < T < 400 K. Prehistory dependence of magnetic moment at cooling without magnetic field and in magnetic field is found. The electrical resistance of $Gd_xMn_{1-x}Se$ solid solutions has been measured at magnetic field H=0.8 T and at zero magnetic field within the 100 K < T < 500 K temperature range. The resistance minimum is observed at two temperatures. On heating, the composition with x = 0.05 exhibits the change of magnetoresistance sign from negative to positive and the magnetoresistance peak near the transition to the magnetically ordered state and at T=375 K. The experimental data are interpreted in the framework of the model involving the orbital ordering of electrons and the arising electrical polarization leading to the changes in the spectral density of states for electrons in the vicinity of the chemical potential in the applied magnetic field.

TU.A-P09 - Magnetic properties of the $CaBaCo_3FeO_7$

J. Blasco [1], V. Cuartero [2], J. García [1], G. Subías [1], J. A. Rodríguez-Velamazán [1,3]

1. Instituto De Ciencia De Materiales De Aragón, CSIC-Universidad De Zaragoza, Zaragoza, Spain

3. Institute Laue Langevin, Grenoble, France

We here report the magnetic properties of $CaBaCo_3FeO_7$, an isostructural compound of the ferrimagnetic pyroelectric $CaBaCo_4O_7$. The structure is non-centrosymmetric with Co/Fe atoms in tetrahedral coordination in four non-equivalent sites. The Co(Fe)-O sublattice is composed by $Co(Fe)O_4$ tetrahedra sharing corners giving rise to a geometrically frustrated network (Kagomé layer) regarding magnetic interactions. Replacing a quarter of Co atoms by Fe leads to a drastic change in the magnetic properties of the system. $CaBaCo_4O_7$ undergoes a ferrimagnetic transition at TC~64 K coupled to the occurrence of spontaneous electric polarization along the c-axis. The partial substitution of Co with Fe leads to a strong magnetization decrease and the disappearing of spontaneous magnetization at low temperature. In addition, the magnetic susceptibility of $CaBaCo_3FeO_7$ between 5 and 300 K does not obey a Curie-Weiss law and shows a rounded anomaly close to 160 K. In order to disentangle these differences, neutron diffraction measurements were performed in both samples. $CaBaCo_3FeO_7$ shows a magnetic structure below ~64 K with a propagation vector k=0 and the Co moments lie in the ab-plane forming zigzag chains along b-axis with a ferromagnetic component in the whole Kagomé layer in agreement with previous studies. The neutron thermodiffractograms of $CaBaCo_3FeO_7$ reveals an antiferromagnetic contribution below 160 K. The new magnetic Bragg peaks follow the propagation vector k= (1/3, 0, 0) and moments mainly lie in the ac-plane forming a conic arrangement, new for this family of compounds. Refinements of neutron patterns performed above the magnetic transition indicate that the replacement of Co by Fe is not random but the Fe atoms preferentially occupy two of the four crystallographic sites. This may agree with an isovalent substitution of Co^{3+} with Fe^{3+} and changes in the magnetic interactions in Co(Fe) sublattice leading to the stabilization of a different magnetic structure.

TU.A-P10 - Metamagnetic transitions in R_2CoMnO_6 (R=Yb, Lu) magnetoelectric double perovskites

J. Blasco [1], J. García [1], G. Subías [1], J. Stankiewicz [1], J.L. García-Muñoz [2], C. Ritter [3], J.A. Rodríguez-Velamazán [1,3]

1. Instituto De Ciencia De Materiales De Aragón, CSIC-Universidad De Zaragoza, Zaragoza, Spain
2. Institut de Ciència de Materials de Barcelona, CSIC, Campus univ. de Bellaterra, Bellaterra, , Spain
3. Institute Laue Langevin, Grenoble, France

R_2CoMnO_6 compounds, with R = Yb or Lu, adopt the crystal structure of a double perovskite with an almost perfect ordering of Co and Mn atoms in the B-position. The crystal structure is strongly distorted and the competitive magnetic interactions between neighbor atoms and next-neighbor atoms lead to the development of an E-type antiferromagnetic ordering at low temperature. This feature differentiates these compounds from La_2CoMnO_6 where a collinear ferromagnetic order is observed. Magnetic transition in distorted R_2CoMnO_6 samples is coupled to a large anomaly in the real part of the electric permittivity suggesting that these materials are very close to improper multiferroics. We have found that the dielectric anomaly disappears under a magnetic field of 5 T revealing a negative magnetocapacitance for these compounds. In order to identify the causes of this behavior, neutron diffraction patterns were collected in different conditions of temperature and external magnetic field for three selected samples: Yb_2CoMnO_6, $YbLuCoMnO_6$ and Lu_2CoMnO_6.
Above a critical value the external magnetic field induces similar changes in the neutron patterns of the three samples: The E-type magnetic peaks vanish whilst the intensity of some nuclear peaks increases. This fact reveals that these samples undergo a metamagnetic transition from E-type antiferromagnet into collinear ferromagnet. The critical field to produce this transition depends on the composition (higher for Lu than for Yb) and on the temperature (decreases as temperature increases). Measurements of the isothermal magnetization as function of magnetic field also show turning points at the critical field where the phase transition is produced. These measurements show hysteresis loops revealing spontaneous magnetization and an increase of coercivity as the temperature decreases. The combination of both hysteresis loops and neutron diffraction patterns allowed us to outline the H-T phase diagram that reveals the magnetic states present in these samples.

TU.A-P11 - Optical activity in multiferroic ferroborate

A.M. Kuzmenko [2], A. Shuvaev [1], V. Dziom [1], A. Pimenov [1], M. Schiebl [1], A.A. Mukhin [2], V.Y. Ivanov [2], L.N. Bezmaternykh [3], A. Pimenov [1]

1. Vienna University of Technology, Vienna, Austria
2. Prokhorov General Physics Institute, Russian Academy of Sciences, Moscow, Russia
3. L.V. Kirensky Institute of Physics Siberian Branch of RAS, Krasnoyarsk, Russia

In contrast to well-studied multiferroic manganites with a spiral structure, the electric polarization in multiferroic borates is induced within collinear antiferromagnetic structure and can easily be switched by small static fields. Because of specific symmetry conditions, static and dynamic properties in borates are directly connected, which leads to giant magnetoelectric and magnetodielectric effects. Here we prove experimentally and theoretically that the giant magnetodielectric effect in samarium ferroborate $SmFe_3(BO_3)_4$ is of intrinsic origin and is caused by an unusually large electromagnon situated in the microwave range. This electromagnon reveals strong optical activity, which leads to a nonreciprocal propagation of the terahertz light.

TU.A-P12 - Giant Magnetoelectric Effect in FeCo and FeCo/Ag films on (011) oriented PIN-PMN-PT

M. Staruch [1], P. Finkel [1]

1. Naval Research Laboratory, Washington, United States

To engineer large magnetoelectric coupling in composites, it is necessary to optimize the properties of both the magnetic and ferroelectric components. There has recently been much interest in single crystals of relaxor ferroelectric Pb(In1/2Nb1/2)O3-Pb(Mg1/3Nb2/3)O3-PbTiO3 (PIN-PMN-PT) due to high piezoelectric coefficient with larger linear range and temperature stability than binary relaxors, which could provide for large tunability of the magnetization. In this work, thin films of FeCo and FeCo/Ag multilayers were deposited on (011) PIN-PMN-PT crystals. The coercive field was significantly decreased in the multilayer film, which also showed a larger piezomagnetic coefficient at a lower magnetic field as compared to FeCo. Angular dependence measurements of the magnetization show an in-plane easy axis that is rotated with an electric field applied to the PIN-PMN-PT crystal. Giant converse magnetoelectric coupling up to 2 x 10-6 s m-1 were observed in heterostructural composites with both FeCo and FeCo/Ag.
This work was funded by the Office of Naval Research (ONR) through the Naval Research Laboratory Basic Research Program.

TU.A-P13 - Role of Tb single ion Ising-nature on the magnetic anisotropy on $TbMnO_3$ under applied magnetic fields

V. Cuartero [1], S. Lafuerza [1], G. Subias [2], J. Garcia [2], E. Schierle [3], J. Blasco [2], J. Herrero-Albillos [2,4]

4. CentroUniversitario de la Defensa, Universidad de Zaragoza, Zaragoza, Spain

TbMnO3 is a prototypical spin driven multiferroic material: magnetic competing interactions lead to a noncollinear ordering of Mn_3+ moments oriented in the bc plane below 27 K and to the appearance of a spontaneous electric polarization (Ps). The short range ordering of Tb moments occurs at TN(Tb)=7 K. The inversion symmetry breaking due to the anisotropic magnetic interactions of Mn moments is commonly ascribed to be responsible for ferroelectricity. However, in an applied magnetic field, the strong magnetic anisotropy from Tb-spins appears to be important for the flop of the Mn cycloid with magnetic field and therefore, the flop of Ps from c- to a-axis. In order to disentangle the magnetic contributions responsible for the macroscopic magnetic anisotropic behavior under applied magnetic fields on $TbMnO_3$, the differentiated role of Mn and Tb ions has been investigated by soft x-ray magnetic circular dichroism (XMCD) at Tb M4,5 and Mn L2,3 edges, as a function of temperature and the intensity and direction of the applied magnetic field. Integrated XMCD signals at the Tb M4,5-edge as a function of the magnetic field highly reproduce the macroscopic magnetic anisotropy at low temperatures, with the Tb moments staying along their Ising axis within the ab plane. However, a weak XMCD signal is observed at the Mn L2,3-edge. These results point out that Tb_3+ single ion anisotropy is the only responsible for the magnetic anisotropy on this multiferroic compound at high magnetic fields. Moreover, we found a negligible magnetic coupling between Mn and Tb at low temperatures under an applied magnetic field. We conclude that Tb_3+ single-ion anisotropy is responsible for the magnetic anisotropy on $TbMnO_3$ at high magnetic fields and also plays a highly relevant role on its magnetic field-induced electric polarization flop.

TU.A-P14 - Theoretical prediction of spin-valley coupling in 5d transition-metal oxides

K. Yamauchi [1], P. Barone [2], T. Shishidou [3], T. Oguchi [1], S. Picozzi [2]

Spin-orbit coupling plays a considerably important role in spintronic phenomena, such as magnetoelectric effects, magnetic anisotropy, etc. Among them, the Rashba effect, which removes the spin degeneracy in non-magnetic materials, has appealing potential for spin-FET applications. Although the Rashba effect commonly occurs at interfaces or surfaces where inversion symmetry is broken, it was recently suggested that Rashba splitting might also occur in non-centrosymmetric (polar or ferroelectric) bulk materials, such as BiTeI or GeTe. When the Rashba splitting extends over two valleys in k space and results in two non-degenerate spin states, it is called spin-valley coupling. For example, a monolayer of MoS_2 shows a valley Hall effect due to a strong spin-valley coupling. Based on an ab initio materials-design approach, we study “bulk spin-valley coupling” in newly designed perovskite oxides. Aiming at a sizable spin splitting, low-spin 5d transition metal ions are embedded in host ferroelectric oxides with $LiNbO_3$-type structure. Our calculations clarified that the spin-orbit coupling splits t2g orbital states of the transition metal ion into jz=+1/2 and jz=-1/2 states at the valence-band top around K and K’ points in the hexagonal Brillouin zone. In this talk, the microscopic mechanism for the spin-valley coupling in our novel oxide system will be discussed and compared with the monolayer MoS_2 case.

4. Materials Science Division, Inter University Accelerator Centre, New Delhi, India

Magnetism in zinc ferrite nanoparticles has been topic of great understanding due to presence of different magnetic ordering like ferromagnetic, ferromagnetic and antiferromagnetism [1]. In this work zinc ferrite nanoparticles were investigated, which exhibit superparamagnetic as well as paramagnetic behaviour. Zinc ferrite nanoparticles of different sizes (61 nm (ZF61), 32 nm (ZF32), 19 nm (ZF19), and 13 nm (ZF13))were synthesized by nitrate method. The samples ZF61 and ZF32 exhibit paramagnetic nature, while samples ZF19 and ZF13 are superparamagetic [2]. Crossover from paramagnetism to superparamagnetism has been studied using NEXAFS spectra at Fe L-edge and O K-edge (figure not shown). Fe L-edge spectra exhibit spectral features at 709, 711, 722, 724 eV, which occurs due to Fe (2p) core level in effect of spin-orbit coupling give rise to degenerate state 2p3/2 (~708 eV)and 2p1/2 (~721 eV). Presence of octahedral crystal fields lifts the degeneracy of the 2p3/2 and 2p1/2 levels so that two levels with t2g and eg symmetry [2]. The spectral features present in the spectra favors the ferromagnetic high spin 3d5 configuration of Fe. In ferrites, Fe L-edge spectra occur due to Fe (2p) core level. Though the shape of spectral features of Fe L-edge spectra for all samples is almost same however spectra for samples ZF32 and ZF61 have more intense spectral features. These spectral features are more distinguished in difference spectra. O K-edge spectra exhibit spectral features ~ 527 eV (A2), 530 eV(B2), 534eV (C2), 538 eV (D2), 545 eV (E3). The variation of eg and t2g feature in O K-edge is varied with respect to the annealing (size) effect. The behavior is also supported by Fe L-edge spectra. Spectral features for ZF61 and ZF32 are enhanced than that of ZF19 and ZF13. It may be contemplated that the strengthening of the local electronic structure of zinc ferrite nanoparticle and successfully correlated the spin-orbit coupling with the magnetic properties and hence strengthening of density of states.

TU.A-P16 - Charge ordering, Ferroelectric, and Magnetic Domains in LuFe2O4 Observed by Scanning Probe Microscopy

Y.H. Jeong [1], I. Yang [1]

1. Dept of Physics, POSTECH, Kyungbuk, Republic of Korea

$LuFe_2O_4$ is a multiferroic system which exhibits charge order, ferroelectricity, and ferrimagnetism simultaneously below ~230 K. The ferroelectric/charge order domains of LuFe2O4 are imaged with both piezoresponse force microscopy (PFM) and electrostatic force microscopy (EFM), while the magnetic domains are characterized by magnetic force microscopy (MFM). Comparison of PFM and EFM results suggest that the proposed ferroelectricity in $LuFe_2O_4$ is not of usual displacive type but of electronic origin. Simultaneous characterization of ferroelectric/charge order and magnetic domains by EFM and MFM, respectively, on the same surface of $LuFe_2O_4$ reveals that both domains have irregular patterns of similar shape, but the length scales are quite different. The domain size is approximately 100 nm for the ferroelectric domains while the magnetic domain size is much larger and gets as large as 1 *f*Ým. We also demonstrate that the origin of the formation of irregular domains in $LuFe_2O_4$ is not extrinsic but intrinsic.

TU.A-P17 - Polarization modulation induced by a magnetic field in polar oxide alpha-$Cu_2V_2O_7$

Y.H. Jeong [1], Y. Lee [1], S. Lee [2]

1. Dept of Physics, POSTECH, Kyungbuk, Republic of Korea
2. Dept of Physics, Univ of Virginia, Charlottesville, United States

α-$Cu_2V_2O_7$ is a complex oxide material with an unusual polar structure and antiferromagnetic ground state. We have investigated the variation of induced electric polarization under a magnetic field in this canted antiferromagnet with flux grown single crystalline samples. We have also thoroughly examined the currently available theoretical models to account for the magnetically induced polarization variation in α -$Cu_2V_2O_7$.

The crystal structure of α-$Cu_2V_2O_7$ adopts a orthorhombic structure with space group *Fdd2* (no. 43), and the lattice parameters of a = 20.66 Å, b = 8.39 Å, and c = 6.44 Å. α-$Cu_2V_2O_7$ consists of cross-linking chains of CuO_5 polyhedra with one chain parallel to the [011] direction and another parallel to [0-11] direction. These chains are then separated by V_2O_7 anion groups. While all copper atomic positions are equivalent above Neel temperature T_N, but below T_N four Cu sites must be considered independently since the spin directions are different in each Cu ion. Of five oxygen ions surrounding the Cu ion, four oxygen ions show shorter bonds of 1.91~1.94 Å to Cu and one oxygen a longer bond of 2.56 Å.

Currently there are several available microscopic models for magnetically induced ferroelectricity. The most prevailing model is the spin current mechanism, or equivalently the inverse Dzyaloshinskii-Moriya mechanism. In a crystal which contains multiple inequivalent magnetic sites, the collinear spin structure may also induce ferroelectricity due to magnetostriction. The third one, which is less known, is the magnetic-metal-ligand *p-d* hybridization mechanism. While the magnetically induced polarization modulation of a-$Cu_2V_2O_7$ cannot be accounted for by the spin current model nor by the exchange striction mechanism, it is adequately described by the spin-dependent *p-d* hybridization between the transition metal Cu and ligand O via the spin-orbit interaction. We discuss the implication of the present result from the viewpoint of multiferroics materials search.

TU.A-P18 - The magnetic properties of $SrCo_2Ti_2Fe_8O_{19}$ compound

M. Mihalik [1], M. Mihalik [1], M. Zentková [1], V. Eremenko [2], V. Sirenko [2], A. Mikhailovich Balbashov [3]

An increasing degree of interest has been paid to hexaferrites since their discovery in 1950s due to their interesting magnetic, ferroelectric and multiferroic properties which determine application potential of hexaferrites in the field of permanent magnets, microwave or data storage devices. We present the magnetic measurements performed on M-type hexaferrite $SrCo_2Ti_2Fe_8O_{19}$ single crystal. We have found that the compound orders magnetically at a little bit higher temperature (TC = 768 K) than the parent, $SrFe_{12}O_{19}$ compound (TC = 732 K) [1]. $SrCo_2Ti_2Fe_8O_{19}$ undergoes another order-to-order magnetic phase transition at T1 = 380 K and the magnetization data exhibit additional maximum at 329 K. The bifurcation point of zero-field-cooled (AFC) and field-cooled (FC) curves was found to be Tb = 763 K, but at lower temperatures the ZFC curve crosses FC curve two times: at 384 K and 345 K. The hysteresis loops measured at T = 350 K with magnetic field applied in basal plane reach magnetization 36 Am2kg-1 at applied magnetic field of 5 T and the hysteresis loop has coercivity of -800 Am-1. At temperature T = 500 K (above T1) the hysteresis loop has coercivity of 3.2 kAm-1, but the highest-reachable magnetization at field of 5 T amounts 11.5 Am2kg-1.
The imaginary part of AC susceptibility exhibit frequency-dependent maximum, which occurs at temperature below 40 K at frequency 1 Hz and increases to 75 K for frequency 884 Hz. This observation might signal the dynamics and the complexity of the magnetic structure.
Concluding, the magnetization data suggest that $SrCo_2Ti_2Fe_8O_{19}$ compound can have application potential at room temperature and elevated temperatures. This compound can be used also for basic studies of magnetic dynamics of M-type hexaferrites.

TU.A-P19 - Magnetic and magnetodielectric behavior of $GdCrTiO_5$ and its implications

T. Basu [1], K. Singh [1], K.K. Iyer [1], E.V. Sampathkumaran [1]

1. Tata Institute of Fundamental Research, Mumbai, India

The compound $NdCrTiO_5$, consisting of two magnetic sub-lattices (Nd and Cr), shows magnetodielectric (MDE) coupling and magnetism induced ferroelectricity around magnetic ordering temperature (TN =21 K) [1]. It is believed that Cr sublattice orders at TN, whereas Nd sub-lattice orders near 11 K.
Here, we report the results of our investigation of dc magnetization (M), heat-capacity (C), and dielectric behavior of the Gd analogue $GdCrTiO_5$ down to 2K. We do not find any evidence down to 2 K for the long-range magnetic ordering of the Gd sub lattice; however, M(T) and C(T) data reveal some features around 10 K, attributable to magnetic ordering from Cr. Thus, TN for the sub-lattice in the Gd case is suppressed with respect to that in the Nd case. Another point of emphasis is that, at the same temperature, dielectric constant exhibits a weak anomaly, which gets stronger with the application of external magnetic fields, supporting the existence of MDE coupling. This relative weakness of MDE behavior in comparison with that in the Nd case is surprising considering larger magnetic moment on Gd. On the basis of these results, we speculate that 4f-anisotropy and/or 4f-hybridization (which is stronger in light rare-earths) play a dominant role over the magnitude of the rare-earth magnetic moment in deciding TN as well as MDE coupling in this series.

TU.A-P20 - Magnetic ordering in multiferroics $Ba(Fe,Nb)O_3$ AND $Pb(Fe,Nb)O_3$ observed by míssbauer spectrometry

T. Kmjec [1], J. Kohout [1], K. Zaveta [1], D. Kubaniova [1], V.V. Laguta [2], I.P. Raevsky [3]

1. Faculty of Mathematics and Physics, Charles University in Prague, Prague, Czech Republic
2. Institute of Physics, Academy of Sciences of the Czech Republic, v. v. i., Prague, Czech Republic
3. Department of Physics and Research Institute of Physics, Southern Federal University, Rostov on Don, Russia

The multiferroic materials $Ba(Fe,Nb)O_3$(BFN) and $Pb(Fe,Nb)O_3$(PFN) studied in this work belong to the family of single-phase perovskites exhibiting high value of dielectric permittivity [1]. The aim of our study was to estimate the value of the transition temperature to magnetically ordered state from the temperature dependences of the hyperfine parameters. Tablets of ceramics of BFN and PFN were prepared by solid state reaction.
Our samples were characterized by XRD to check phase composition, crystal structure and lattice constant(s). Their chemical composition and homogeneity were confirmed by SEM and XRF. Sample BFN is single phase whose crystal structure at room temperature was found to be cubic (Pm-3m) with a=4.06(3) A [2]. Two phases were identified in PFN sample: pure monoclinic (C1m1) PFN (~97.2%) with a=5,67(6) A, b=5,67(3) A, c=4,02(8) A, beta=89.826(5)°, [3] and as impurity FCC (F4/m-32/m) alfa-LiFeO2 (~2.8%) with a=4,16(1) A. The Mössbauer spectra were acquired in the temperature range 4.2-300 K with in-field spectra taken in external fields up to 6 T at 4.2 K. In summary, magnetic ordering transition was found in a relatively wide range of temperatures around 30 K (BFN) and 40-80 K (PFN). The spectra of both BFN and PFN at 4.2 K are consistent with random distribution of Fe and Nd atoms. In-field spectra of BFN indicate antiferromagnetic ordering while in PFN two sublattices with magnetization oriented parallel and antiparallel to the applied field exist. Temperature dependences of Isomer Shift above the magnetic transition temperature correspond to the second order Doppler shift.

The b-axis oriented orthorhombic $YMnO_3$ (o-$YMnO_3$) epitaxial films on a $YAlO_3$ (010) substrate were fabricated with pulsed-laser deposition. The anisotropic orbital occupation and Jahn-Teller (JT) distortion of an o-$YMnO_3$ film were investigated with polarization-dependent x-ray absorption spectra and configuration-interaction multiplet-cluster calculations. A significant energy difference, ~3.8 eV, for the main white line along E//b and E//a in polarization-dependent Mn K-edge spectra of o-$YMnO_3$ indicates an extraordinary JT distortion and significant anisotropic Mn-O bonding within the ab plane in the o-$YMnO_3$ film. Most importantly, although the orbital occupation of 3d electrons in o-$YMnO_3$ films is almost the same as that in single crystalline o-$DyMnO_3$, the JT distortion of o-$YMnO_3$ films is larger than that of single crystalline o-$DyMnO_3$, deduced from the multiplet calculations. We speculate that this JT distortion predominantly contributes to the origin of the cycloidal spin deformation in bulk o-$YMnO_3$, because of a suppressed nearest-neighbor (NN) superexchange interaction and an enhanced next-nearest-neighbor (NNN) superexchange interaction. These complementary results provide insight into the origin of the E-type magnetic configuration of o-$YMnO_3$.

TU.A-P22 - Uniaxial-stress control of spin-driven ferroelectricity in multiferroic $Ba_2CoGe_2O_7$

T. Nakajima [1], Y. Tokunaga [1,3], V. Kocsis [1,2], Y. Taguchi [1], Y. Tokura [1,4], T.H. Arima [1,3]

4. Department of Applied Physics and Quantum-Phase Electronics Center, University of Tokyo, Tokyo, Japan

We demonstrate that spin-driven ferroelectricity in a tetragonal multiferroic $Ba_2CoGe_2O_7$ is controlled by applying uniaxial stress. This system is known to exhibit a simple collinear antiferromagnetic order, in which the magnetic moments are aligned along the a or b axis, below TN =6.7 K [1]. By applying a magnetic field of ~0.4 T along the [110] direction, the magnetic moments are rotated so as to be perpendicular to the magnetic field. This rotation breaks the fourfold rotoinversion symmetry of the crystal, and consequently spontaneous electric polarization appears along the c axis [2]. In the present study, we performed pyroelectric measurements under applied compressive uniaxial stress of up to 100 MPa along the [110] direction, in zero magnetic field. As a result, we found that the field-induced ferroelectric phase is also induced by the application of uniaxial stress, which can affect the magnetic anisotropy of the Co2+ ions through tiny deformation of the crystal. We have also demonstrated that magnetic-field variations of the spin-driven electric polarization can be tuned by the application of the uniaxial stress. These results suggest that an application of `anisotropic' stress, which is the simplest way to control symmetry of matter, can induce a variety of cross-correlated phenomena in spin-driven multiferroics.
This work has been published as Phys. Rev. Lett. 114, 067201 (2015).

$CuFe_2O_4$ is a highly interesting material as a ferrimagnet with an unusual high ordering temperature up to 780 K, while $ZnFe_2O_4$ is a frustrated spin system with antiferromagnetic order below 10 K. High and high intensity neutron powder diffraction were applied to study the crystallographic and magnetic phase transition in $Cu_{1-x}Zn_xFe_2O_4$ from 4 K to 750 K, combined with magnetization measurement from 10 K to 950 K. Fully inverse $CuFe_2O_4$ was obtained with all the Cu^{2+} occupying the octahedral sties. Structural phase transition from cubic to tetragonal phase was observed, which is caused by Jahn-Teller Cu^{2+} ions with two-fold e_g orbital degeneracy, resulting in the stretching of CuO_6 octahedra along c axis. Ferrimagnetic order was observed with spin ordered along c axis in $CuFe_2O_4$. Short-range antiferromagnetic scattering peak was observed below 10 K in cubic $ZnFe_2O_4$ and this ordering is strongly restrained by addition of slightly amount of Cu^{2+} ions. All the doped $Cu_{1-x}Zn_xFe_2O_4$ (x = 0.2 - 0.8) samples crystallize cubic structure and form ferrimagnetic spin configuration. Upon doping, ferrimagnetic order temperature was gradually reduced from 789 K. Collinear spin setting was observed and no indication of frustration was found even up to doping rate of x = 0.8. Highly frustrated $Cu_{0.04}Zn_{0.96}Fe_2O_4$ and $ZnFe_2O_4$ behave short-range antiferromagnetic order, as well as high curie-weiss temperature (T_{CW} = 112 K and 43 K, respectively) induced by the competing between ferromagnetic interaction from first-nearest neighbour and antiferromagnetic interaction from the third-nearest neighbour in tetrahedron formed by Fe ions on B sites.

TU.A-P24 - Strain-induced multiferroicity in antiferromagnetic $SrMnO_3$ thin films

Multiferroic materials exhibiting two or more ferroic orders have gained a lot of interest owing to the development of new mechanisms that increase the coupling between their properties. This development is expected to give rise to new devices where the electric control of the magnetic properties would open new concepts in the field of the data storage. One very promising mechanism is by means of strain engineering, where the artificial expansion of the unit cell in the perovskite system $AMnO_3$ (where A is an alkaline-earth cation such us Ca, Sr or Ba) is predicted to bring the system into a multiferroic state[1]. Two different approaches have been chosen to induce multiferroicity in this system: first of all, theoretical calculations[2] predicted a ferroelectric state in epitaxially strained $SrMnO_3$ thin films; secondly, above 45% Ba doping in bulk $SrMnO_3$ was shown to induce a ferroelectric behavior[3]. In this work we have used pulsed laser deposition to grow strained epitaxial $SrMnO_3$ thin films, and X-ray diffraction and transmission electron microscopy to show their high crystal quality and strain state. Then, through second harmonic generation measurements we have shown the emergence of a polar state induced by epitaxial strain. Furthermore, in agreement with theoretical studies in similar materials[4], we have found that epitaxial strain induces the formation of oxygen vacancies, concomitantly increasing the unit cell volume more than expected by the elastic deformation alone. Our observations using scanning probe microscopy, together with first-principle calculations, show that these defects get ordered and give rise to oxygen-deficient insulating walls separating conducting polar nanodomains.

The possibility of controlling the magnetization (polarization) by an electric (magnetic) field in materials displaying ferroelectric and magnetic order in the same phase, so-called multiferroic materials, has triggered great amount of research in the last few years. However, very few of them have been proved to show strong magnetoelectric coupling, mainly due to the different mechanisms of ferroelectricity and magnetism in these compounds. Exception could be found, though, in perovskite $AMnO_3$ system (A = Ca, Sr, Ba), in which Mn^{4+} is expected to be able to drive both the magnetic order and the required non-centrosymmetric distortion for ferroelectric order. Yet ferroelectricity is allowed in this system, solely, when the unit cell volume is large enough to promote Mn off-centring [1], which may be achieved by using increasingly larger A cation, as partially replacing Sr with Ba [2]. However, increasing the size of the A-cation also destabilizes the perovskite structure, becoming different hexagonal polymorphs the ground state phase [3].
Here, we report the pseudocubic phase stabilization of $(Sr_{1-x}Ba_x)MnO_3$, $0.1 \leq x \leq 0.5$, (SBMO) epitaxial thin films grown by pulsed laser deposition from bulk polycrystalline hexagonal phase targets onto (001)-oriented perovskite substrates. X-ray diffraction measurements show that, under appropriate deposition conditions, the perovskite pseudocubic phase with cube-on-cube growth is stabilized over the non-ferroelectric hexagonal phase. Moreover, we have managed to grow epitaxial tensile strained SBMO films, ranging from 0% to 4% strain. Selected films were observed by aberration corrected scanning transmission electron microscopy, which proves the homogeneity and defect-free crystal quality of the films, and corroborate the epitaxial coherent growth and the pseudocubic structure of the films.

4. Department of Materials Science and Technology, Niigata University, Niigata, Japan

Electric control of a local-magnetic moment is studied in multiferroics $Ba_2CoGe_2O_7$ by using a polarized-neutron-diffraction technique. Below 6.7 K, $Ba_2CoGe_2O_7$ exhibits a collinear-antiferromagnetic structure with the easy axis along <100> directions and an antiferroelectric order with the polarization axis along [001] direction. The magnitude and direction of the electric polarization depend on the local relationship between the Co spin and the O ions in a local CoO_4 tetrahedron, which is explained by the spin-dependent d-p hybridization mechanism. The result of the neutron experiment shows that the magnetic intensities at the Q-points with $h > 0$ and $k > 0$ decrease with applying an electric field along the c-axis. In contrast the magnetic intensities at the Q-points with $h > 0$ and $k < 0$ increase with the field. On the assumption that the polarization direction does not deviate from the c-axis, the spin-dependent d-p hybridization mechanism leads to the constraint that the magnetic moment is confined in the c-plane. Then, the electric-field dependence of the intensities is consistent with the model that the direction of the magnetic moment rotates from <100> to [110] with the field. The present study revealed the novel magnetoelectric effect that the direction of the local-magnetic moment is controlled continuously by the electric field.

TU.A-P28 - Tunable metamagnetic transitions in a mixed-valent ferromagnet

N. Lee [1], H.Y. Choi [1], M.S. Seo [2], S.Y. Park [2], Y.J. Jo [3], Y.J. Choi [1]

2. Korea Basic Science Institute, Seoul, Republic of Korea
3. Kyungpook University, Daegu, Republic of Korea

Metamagnetic transition which undergoes an abrupt increase of magnetization in a magnetic field is a crucial subject in magnetism, motivated by a desire to enhance certain functionalities utilizing different means of tuning parameters. Here we present remarkable controllability of metamagnetic transitons in our first-synthesized double perovskite single crystals of Eu_2CoMnO_6 in which ferromagnetic order emerges below T_C=122 K along the crystallographic c axis. In an as-grown crystal, magnetic susceptibility exhibits a pronounced peak at ~117 K indicating a spin-glass behavior, and isothermal magnetization at 5 K reveals a metamagnetic transition. We demonstrate the control of relative portions of ferromagnetic and spin-glass states by annealing the crystals in different gas environments, resulting in the retardation (after Ar-annealing) and bifurcation (after O2-annealing) of the metamagnetic transition. This remarkable variation offers an efficient approach of manipulating metamagnetic transitions.

TU.A-P29 - Strong ferromagnetic-dielectric coupling in multiferroic Lu_2CoMnO_6 single crystals

N. Lee [1], H.Y. Choi [1], Y.J. Jo [2], M.S. Seo [3], S.Y. Park [3], Y.J. Choi [1]

1. Yonsei University, Seoul, Republic of Korea
2. Kyungpook National University, Daegu, Republic of Korea
3. Korea Basic Science Institute, Seoul, Republic of Korea

We have grown single crystals of multiferroic double-perovskite Lu_2CoMnO_6 and studied the directional dependence of their magnetic and dielectric properties. The ferromagnetic order emerges below T_C=48 K along the crystallographic *c* axis. Dielectric anomaly arises along the *b* axis at T_C, contrary to the polycrystalline work suggesting ferroelectricity along the *c* axis. Through the strongly coupled ferromagnetic and dielectric states, the highly non-linear variation of both dielectric constant and magnetization was achieved in application of magnetic fields. This concurrent tunability provides an efficient route to manipulation of multiple order parameters in multiferroics.

TU.A-P30 - Key features of the magnetic and magnetoelectric properties of rare-earth multiferroic $HoFe_3(BO_3)_4$

Y.F. Popov [1], A.I. Popov [2,3], G.P. Vorob'ev [1], V.Y. Ivanov [4], A.A. Mukhin [4], N. Kostyuchenko [2,4], A.K. Zvezdin [2,4]

4. A. M. Prokhorov General Physics Institute of Russian Academy of Sciences, Moscow, Russia

Recently a new class of multiferroics, rare-earth $RFe_3(BO_3)_4$ ferroborates have been discovered [1]. Among them holmium iron borates $HoFe_3(BO_3)_4$ is of substantial interest due to its rich magnetic and magnetoelectric properties including low temperature spontaneous spin-reorientation as well as quite a large (in terms of potential applications) value of the magnetoelectric effect [1-3].
In the present work, we have studied experimentally and theoretically the magnetic and magnetoelectric properties of rare-earth iron borates using holmium iron borate as an example. We measured magnetization, magnetic susceptibility and polarization of $HoFe_3(BO_3)_4$ single crystals. The measurement of the field dependences up to 200 kOe of the magnetoelectric polarization along the a axis, Pa revealed that the longitudinal, Pa(Ha) and transverse, Pa(Hb) magnetoelectric effects have the opposite signs and magnetically induced polarization changes its sign in a field close to the field of exchange between Ho3+ and Fe3+ ions. These dependences agree well with theoretical predictions based on the symmetry of the compounds. Energy levels and wave functions Ho^{3+} ion were defined. A self-consistent description of the magnetization, magnetic susceptibility and electric polarization has been made. The quantum theory of the magnetoelectric effect developed in [4] has been applied to $HoFe_3(BO_3)_4$. We show that the leading role in the origins of the magnetoelectric effect belongs to the single-ion mechanisms: the electron mechanism linked to the magnetic field-induced electric dipole moment in the 4f -electron shell, and the ion mechanism connected to electric polarization arising from the relative spatial shift of the ions in magnetic field.

TU.A-P33 - Large low field room temperature magneto-dielectric response from $(Sr_{0.5}Ba_{0.5})Nb_2O_6$ / $Co(Cr_{0.4}Fe_{1.6})O_4$ bulk 3-0 composites

S. Vitta [2], S. Rathore [1]

1. Indian Institute of Technology Bombay, Mumbai, India

Bulk magnetodielectric composites with a 3-0 configuration comprising of ferroelectric-magnetostrictive phases have been synthesized using $(Sr_{0.5}Ba_{0.5})Nb_2O_6$ / $Co(Cr_{0.4}Fe_{1.6})O_4$ as the two constituents respectively. The ferroelectric phase made by a dual stage sintering process has a uniform grain size of 15 µm while the magnetostrictive phase has a grain size of 2 - 3 µm. Composites synthesized by conventional solid state processing using these two constituents exhibits large magnetodielectric coupling at room temperature which increases with increasing magnetic field. The composite with 30 % magnetostrictive phase distributed uniformly in the ferroelectric phase has the most desirable microstructure and exhibits a large coupling with 3.2 % change in the dielectric constant at 1 kHz and 8 kOe magnetic field. This change in dielectric constant decreases when the fraction of magnetostrictive phase is varied, indicating that 30 % is the optimal value to realize large coupling between the two phases. The change in magnetodielectric constant upon application of an external magnetic field could be due to the inherent magnetoresistance of the magnetic component. These result however confirm that 3D percolation causes the coupling to decrease in composites.

TU.A-P34 - Effect of magnetic and non-magnetic substitution on properties of magnetoelectric $Ba_3NbFe_3Si_2O_{14}$

S.S. Rathore [1,2], S. Vitta [1]

1. Indian Institute of Technology Bombay, Mumbai, India
2. University of Petroleum and Energy Studies, Dehradun, India

The effect of partial substitution of Fe with magnetic and non-magnetic Mn and Cu respectively has been studied in the magnetoelectric compound $Ba_3NbFe_3Si_2O_{14}$. The variation in crystal and magnetic structure with temperature studied using neutron diffraction in the temperature range 6 K to 300 K shows that substitution does not change the crystal structure. The magnetic structure is observed to be similar to the parent compound with triangular and spiral arrangement of Fe_3+ moments along a-b plane and c-axis respectively. However, a small change in pitch of the magnetic spiral has been observed due to substitution which leads to a change in interaction strength. The susceptibility shows that up to 10 at. % Cu substitution no change in antiferromagnetic ordering temperature TN ~26 K is observed whereas for 10 at. % Mn substitution it is reduced to ~21.5 K. The effect on magnetic properties is more evident in field dependent magnetization studies. The parent compound exhibits a ferromagnetic component along with paramagnetic and antiferromagnetic phases. A partial and nearly complete suppression of the ferromagnetic component was observed for Mn and Cu substituted $Ba_3NbFe_3Si_2O_{14}$ respectively. The change in magnetic properties is attributed to the variation in exchange path length which changes the interaction strength and hence the magnetic properties.

TU.A-P35 - Dielectric and Magnetic Properties of Two-Phase Composite System: Mn-Zn or Ni-Zn ferrites in Dielectric Matrices

M. Salem [1], L. Panina [1], A. Morchenko [1], V. Kostishyn [1], O. Hemeda [2], A. El-Raouf Tawfik

1. National University of Science And Technology, Islamabad, Pakistan
2. Faculty of Science, Physics Department, Tanta University, Tanta, Egypt

Novel two-phase powder composites of Zn-substituted spinel ferrites $Cu_{0.6}Zn_{0.4}Fe_2O_4$(CZF) and ferroelectric barium titanate (BT) $BaTiO_3$ were prepared by high energy ball milling technique [1] starting from raw materials. Increasing the milling time, it was possible to obtain powders with micrograins having a nanocrystalline structure. The structural parameters of the composite system (1-x) CZF + (x) BT (where x changes from 0 to 1) were deduced from the analysis of X-ray diffraction patterns which were consistent with the existence of two piezoelectric and piezomagnetic phases. The magnetoelectric (ME) effect is due to the mechanical coupling between the ferrite and ferroelectric phases. The maximum of the ME coefficient of about 0.25 mV/cm/Oe is observed at 400 Oe for 40% BT phase. Very similar values for ME are also seen for 80% BT phase. In the latter case, a clear electrical dipole hysteresis is detected as well, demonstrating the ferroelectric properties of the prepared composites. Further increase in the ferrite phase leaded to irregular hysteresis loops because of decrease in resistivity causing the leakage current problems. As expected, the magnetic permeability of the composites decreases when increasing BT content but less than twice when the ferrite phase is decreased from 100% to 20%. The permeability increases with frequency for all concentrations. When increasing BT content, the dielectric constant at room temperature increases, while the dielectric loss decreases. These properties suggest the potential for applications in tunable high frequency materials and devices such as electrically controlled microwave phase shifters, ferromagnetic resonance devices, and magnetically controlled electro-optic or piezoelectric devices [2].

A phase boundary of competing phases has played a key role in exotic phenomena such as colossal magnetoresistance (1), morphotropic phase boundary (2), and metal-insulator transition (3). Bismuth ferrite ($BiFeO_3$, BFO) has been heavily studied due to its multiferroicity at room temperature. A highly-elongated tetragonal-like BFO shows a concurrent phase transition of multiple order parameters near room temperature (4). In this work, we applied the phase proximity concept into the highly-elongated tetragonal-like BFO. By introducing chemical substitution into the tetragonal-like BFO, the concurrent transition temperature decreases simultaneously, and then bifurcates, thereby producing a multiferroic triple phase point. Near the triple phase point, the as-grown spin disordered state can be switched into a spin ordered state by means of an electrical writing. Phenomenological theory was employed to understand how the phase proximity in multiferroic system can offer a non-volatile spin order transition by an electric field in a reversible way. Our findings offer a promising route toward enhancing inter-coupled phenomena in multiferroic systems.

TU.A-P37 - XANES: A probing tool for mixed valence, modified magnetism

H. Singh [1], M.N. Singh [1], A.K. Sinha [1]

1. Indus Synchrotrons Utilization Division, Raja Ramanna Centre for Advanced Technology Indore, India

X-ray Absorption Near Edge Structure (XANES) is extremely sensitive to the oxidation state, hybridization effect of orbitals and electronic state of the probed element in the sample. Mixed valence manganites, cobaltites etc. have already drawn great attention to the fundamental as well as application based science. We, on the other hand, show the effect of mixed valency of transition metals (TM) in TM (Co/Mn) based oxides using XANES. For this, we have taken two samples Co_3TeO_6 (CTO) and $Co_{2.5}Mn_{0.5}TeO_6$ (CMTO) prepared by conventional solid state reaction route. In the former, observations of Co2+/3+ using XANES agrees well with the high field dc magnetization as well as first principles total energy calculations (Singh et al., JAP 116 (2014)). Existence of Co3+ in ceramic CTO does not diminish multiferroic property observed earlier in single crystal (with Co2+), but actually enhances some of the observables. For example; the magnetization on our ceramic sample under 1 T is comparable to that measured for single crystal in a magnetic field of 14 T. While, the observation of $Co^{2+}/^{3+}$ and $Mn^{2+}/^{3+}$ using XANES in CMTO not only enhances the Neel temperature from 26 K (CTO) to 45 K (CMTO) but also short range robust ferromagnetism is observed at around 185 K (Singh et al., JAP 116 (2014)). This spectroscopic technique can also be used as a tool to extract the concentration of the corresponding mixed valence states, where linear combination fit of the unknown sample as a combination of the corresponding standards provides the quantitative information. Not only the oxidation state but one can easily observe the coordination geometry (tetra/octahedra) of the probed element which plays a significant role in most of the ferroelectrics and/or multiferroics. Aforementioned XANES measurements (transmission as well as fluorescence mode) has been done at BL-12, Indus -2 Synchrotron Source India.

TU.A-P38 - A comparison in multiferroic coupling between triangular lattice polytypes of hexagonal and rhombohedral AgFeO2

N. Terada [1], D. Khalyavin [2], P. Manuel [2], Y Tsujimoto [1], A. Belik [1]

1. National Institute For Materials Science, Tsukuba, Japan
2. ISIS facility, STFC Rutherford Appleton Laboratory, Harwell Oxford, United Kingdom

In order to study an influence of a parent symmetry on coupling between spin order and ferroelectricity in spin-order-driven multiferroics, we have investigated magnetic and ferroelectric orderings of a triangular lattice antiferromagnet 2H-$AgFeO_2$ by neutron diffraction, magnetic susceptibility, specific heat, pyroelectric current, dielectric constant measurements. This compound has the space group of hexagonal $P6_3/mmc$, and is known as a polytype of rhombohedral 3R-$AgFeO_2$ (*R-3m*) with multiferroic behaviors that has been reported in our previous work. *(N. Terada et al, Phys. Rev. Lett.* ***109*** *097203 (2012))* Although these compounds have similar triangular lattice structures, the magnetic orderings and ferroelectricity of 2H-$AgFeO_2$ are significantly different from those of 3R-$AgFeO_2$.
Ferroelectric polarization, $P \sim 5$ mC/m^2 appears below 11 K in 2H-$AgFeO_2$, concomitant with a polar nature of the magnetic ordering. For 11 K ≤ T ≤ 18 K, an incommensurate spin density wave ordering (ICM1) (magnetic point group *mmm1'*) is realized. Below 14 K, a proper screw ordering (ICM2) appears as a minor phase, which is coexistent with other phases. No ferroelectric polarization associated with the ICM2 phase was observed due to the nonpolar point group *2221'*. The spiral order with cycloid and proper screw components (ICM3) emerges below 11 K. Based on the deduced magnetic point group *21'* in the ICM3 phase, we conclude that the ferroelectric polarization in 2H-$AgFeO_2$ is parallel to the hexagonal *c* axis and is yielded by the inverse Dzyaloshinskii -Moriya effect with $\boldsymbol{p}_1 \propto \boldsymbol{r}_{ij} \times (S_i \times S_j)$. Unlike polytype rhombohedral 3R-$AgFeO_2$, the additional contribution, $\boldsymbol{p}_2 \propto S_i \times S_j$, does not exist due to the symmetry constraint in the hexagonal 2H-$AgFeO_2$.

TU.A-P39 - Negative magneto-dielectric coupling in ceramic multiferroic Co_3TeO_6

H. Singh [1], G. Sharma [2], H. Ghosh [1], S. Patnaik [2], A. K. Sinha [1]

1. Indus Synchrotrons Utilization Division, Raja Ramanna Center for Advanced Technology, Indore, India
2. School of Physical Sciences, Jawaharlal Nehru University, New Delhi, India

The coupling phenomena among various ferroic order parameter e.g. mutual control of P by M, in multiferroics have attracted great attention due to their promising potential applications as spintronics and magnetic data storage devices, in future. We have made an attempt to find out the microscopic mechanisms (exchange-striction, spin-current model and the p-d hybridization) for magnetically driven ferroelectricity in type II multiferroic Co_3TeO_6 (CTO) which shows interesting physical as well as low temperatures magnetic properties (Singh et al., JAP 116 (2014)). To probe the same, magneto-dielectric measurements are performed. Our dielectric constant shows a sharp peak at around T2 = 17.4 K (at zero magnetic field). This anomaly in dielectric constant shows suppression in magnitude with the application of magnetic fields. With fields, this T2 (= TN2, the Neel temperature, observed in magnetization) shifts towards lower temperature indicating strong coupling between magnetic and electrical order. There are several reports on magneto-dielectric coupling which deal with the nature of the magnetic ordering and the role of the magnetic phases can be employed to explain the magneto-dielectric behaviour of our ceramic CTO. Following similar observations, our CTO shows negative magneto-dielectric shift i.e. lowering of overall magnitude of dielectric constant in higher magnetic fields, a behaviour expected for AFM transition, and could be related to the spiral spin structure (in the frame of spin current model - spin current induced by two non collinear spins realizes a nonzero electric dipole moment). This also supports the observation by Wang et al., PRB 88 (2013) that the spontaneous polarization is not caused purely by the incommensurate magnetic order. However, till date there is no report which deals with ferroelectric nature of CTO in term of spiral magnetic order. This could also explain the change in the polarization and dielectric constant with magnetic fields in CTO.

TU.A-P40 - Magnetoelectric effect in diamagnetic sillenites

K. Filar [1], V.I. Nizhankovskii [1]

1. International Laboratory of High Magnetic Fields And Low Temperatures, Wroclaw, Poland

The magnetoelectric effect - an electric polarization induced by a magnetic field - is observed in ferromagnetic or, at least, paramagnetic structures [1,2].
But if an elementary cell is non-centrosymmetrical then it's possible to see the magnetoelectric effect even in a diamagnetic crystal [3]. Such observations haven't been published till now.
Measurements were done for $Bi_{12}TiO_{20}$ (BTO), $Bi_{12}SiO_{20}$ (BSO) and $Bi_{12}GeO_{20}$ (BGO) single crystals, that have non-centrosymmetrical cubic structure and they belong to the I23 space group [4]. The BTO was doped with chromium at level of 0.0015 wt%, whereas BSO and BGO were pure crystals.
The magnetic moment measurements were made by using VSM magnetometer in 14 Tesla superconducting magnet (Oxford Instruments), while measurements of the magnetoelectric effect were done by means of field modulation technique and Keithley 642 electrometer.
Measurements of magnetization vs. magnetic field show that both materials are diamagnetic, but with some paramagnetic contribution for Cr-doped BTO. Results for dependence of polarization derivative vs. magnetic field demonstrate that magnetoelectric effect exists in both materials, but is much bigger for Cr-doped BTO. It is caused by chromium doping in BTO and only by some magnetic impurities in BSO. Actual polarization was received after integration *dP/dH* signal.
Moreover, for these two single crystals, the influence of light exposure on the magnetoelectric effect was investigated. It has been shown that, the longer the exposure time is, the effect become smaller, especially after annealing in vacuum. It is caused by traps generated by oxygen vacancies in crystal.

TU.A-P41 - Cone→Planar→Uniaxial transitions in $Sr_{(3-x)}Ba_xCo_2Fe_{24}O_{41}$ multiferroics

Y. Santos [1], B. Andrade [2], M. Macedo [1]

1. Federal University of Sergipe - Physics Department, São Cristóvão, Brazil
2. Instituto Federal de Alagoas – Piranhas, Piranhas, Brazil

Multiferroics were produced by proteic sol-gel process. The effect of the replacement of the Sr^{2+} ions with Ba^{2+} ions in Cone→Planar→Uniaxial transitions was investigated by magnetometry and structural analysis obtained with the Rietveld refinement. The volume expansion and the distortion of the unit cell were observed as a function of the amount of Ba^{2+} ions, as the ionic radius of Ba^{2+} (1.35 Å) is higher than that of Sr^{2+} (1.12 Å). The MxT magnetization curves showed changes in the magnetocrystalline anisotropy of the samples as a function of the amount of Ba^{2+}. The cone→planar transition was observed in the temperature range of 375–400 K, and occurred at lower temperatures as the amount of Ba^{2+} increased. The planar→uniaxial transition of the easy magnetization axis was found in the temperature range of 500–563 K. The temperature at which this transition occurs is proportional to the amount of Ba^{2+} ions. The Cone→Planar→Uniaxial transitions are also related to the behavior of the effective magnetic moment of the Co ions. The MxH curves at room temperature showed an increase of the coercive field Hc and the remanent magnetization Mr in the range of 10.4–14 emu/g and 1.1–1.7 emu/g, respectively; the saturation magnetization Ms, approximately equal to 47 emu/g, remained identical for all the concentrations. A strong magnetic anisotropy was found when the applied field was parallel or perpendicular to the sample, with Mr ranging from 0.9 to 3.3 emu/g. The substitution induced a change in the bond angle Fe(4)–O(2)–Fe(5) stabilizing the spiral magnetic order, contributing to the changes observed in Hc, and also facilitating the superexchange interaction. Controlling the amount of Ba can be an efficient mechanism to produce multiferroics that are best suited for this type of application.

TU.A-P42 - Magnetodielectric frequency behavior in nanoparticulated BTO-CFO multiferroic composites

4. Instituto de Ciencia y Tecnología de Materiales, Universidad de La Habana, Havana, Cuba

Magnetodielectric (MD) effects in different materials have exhibited many contributions, from purely magnetoresistance and Maxwell-Wagner effects, to induced stress arising from direct magnetoelectric coupling [1-3]. In this work, we report an investigation of the MD response (or magnetocapacitance MC) in nanoparticulated BTO-CFO composites consolidated by Spark Plasma Sintering (SPS). The electrical conductivity was measured simultaneously as a function of magnetic field (- 1200 to + 1200 kA/m), temperature (40-210°C), and as a function of frequency in the 5 Hz-1 MHz range, as typically in impedance spectroscopy. By using the Jonscher┤s universal relaxation law, the activation energies for long-range conductivity and hopping conductivity could be resolved [4]. Both activation energies exhibited a critical behavior for values about the coercive field of CFO, and also about the Curie point for BTO, thus confirming the magnetoelectric coupling in the nanoparticulated BTO-CFO.

The interest for spintronic and spins/charges controls motivates material science research in the field of multiferroicity, magnetoelectric effect, and magnonics. Signatures of dynamical magnetoelectric coupling have already been observed in the form of magnons dressed with electric charges, hence excitable via an electric field [Pimenov et al. Nat. Phys, 2, 97 (2006)]. Coupling two complementary experimental techniques, THz/FIR spectroscopy on synchrotron source and inelastic neutron scattering, we have focused of two members of the multiferroics hexagonal manganites $RMnO_3$, with R=Er and Ho. These compounds order electrically below 800 K and magnetically around 80 K with a 120° frustrated arrangement of the Mn_3+ ions. We have fully characterized the low energy spectra (magnon, phonon, crystal field transitions) of these compounds and their excitation rules as regards the electric and magnetic fields of the THz wave. In $ErMnO_3$, we have observed the complete loss of the magnetic character of a magnon transmuted into an electroactive excitation [Chaix, et al. Phys. Rev. Lett. 112, 137201 (2014)]. We attribute this magnetoelectric dynamical process to the hybridization between a crystal field level transition of the Er magnetic rare earth and a Mn magnon. In $HoMnO_3$, spectacular modifications of the Mn spin waves and Ho crystal field level transitions are observed at a temperature of 40 K when a spin reorientation of the Mn magnetic moments occurs, together with the ordering of some Ho ions [Fabrèges et al. Phys. Rev. Lett. 103, 067204 (2009)]. At lower temperature, the spin waves dispersion perpendicular to the Mn triangular planes vanishes, the Mn ordered structure being maintained in the molecular field of the rare earth ions. Both studies highlight the crucial role of the strong coupling between the Mn and rare earths in the dynamical properties of these hexagonal manganites.

TU.A-P44 - Effects of in-plane strain on charge/orbital ordering in $La_{0.5}Ca_{0.5}MnO_3$ thin films

J.Y. Juang [1], J.W. Mi [1], T. Tsai [1], Y.F. Hsiao [1], Y.W. Jiang [1], Y.M. Chang [1], C.W. Luo [1], K.H. Wu [1], J.Y. Lin [2], T.M. Uen [1]

2. Institute of Physics, National Chiao Tung University, Hsinchu, Taiwan

A series of 20-nm-thick perovskite (010)-$La_{0.5}Ca_{0.5}MnO_3$ (LCMO) thin films were grown on $SrTiO_3$ (110) and $LaAlO_3$ (110) substrates by pulsed laser deposition. Depending on the in-plane strain state of the films, the charge/orbital ordering (COO) behavior, manifested as resistivity hysteresis near the COO temperature, was found to appear only when measuring along certain crystalline orientation. Moreover, the orientation along which COO occurs can be changed when the in-plane strain state was changed from tensile to compressive. The results suggest that there exist two versions CE state, namely the “charge stacked” and “Wigner crystal”, in LCMO films grown on different substrates. These results suggest that the strain-induced variations in Mn 3*d* orbitals may have altered the competition between super-exchange and double-exchange interactions in the CE-type phases.

TU.A-P45 - Direct observation of polar state in multiferroic $(Sr_{1-x}Ba_x)MnO_3$

R. Guzman [1], E. Langenberg [2], L. Maurel [2,3], P.A. Algarabel [3,4], J.A. Pardo [2,5], C. Magen [1,2,6]

6. Fundación ARAID, Zaragoza, Spain

Multiferroic materials showing simultaneous magnetic and ferroelectric ordering have become the subject of intensive research in the last decade. Recent theoretical predictions and experiments suggest that paraelectric $SrMnO_3$ with the cubic ABO_3 perovskite structure could become ferroelectric upon artificial expansion of the unit cell, either by epitaxial strain [1] or partial substitution of Sr for Ba [2]. This would give rise to a new class of multiferroic perovskites where ferroelectricity would be driven by off-centering of the magnetic cation Mn^{4+}.
In this work we show pseudocubic $(Sr_{1-x}Ba_x)MnO_3$, $0.1 \leq x \leq 0.2$, (SBMO) epitaxial thin films grown by pulsed laser deposition from bulk polycrystalline hexagonal phase targets onto (001)-oriented perovskite substrates. Strain analysis of High Angle Annular Dark Field (HAADF) images by aberration-corrected Scanning Transmission Electron Microscopy (STEM) confirms the epitaxial coherent growth and the pseudocubic structure of the films. By simultaneous HAADF and Annular Bright Field (ABF) imaging we have confirmed the polar state of the SBMO films. This technique reveals significant displacements of the Mn atomic positions in addition to a strong shift of the oxygen atoms, leading to distorted MnO_6 octaedra. Quantitative mapping of local atomic displacements with picometer resolution is carried out by the precise structural analysis of atomic resolution ABF images [110]. Displacement mapping of large areas reveal extended domain walls due to the progressive spatial variation of the O-Mn relative positions in $Sr_{0.8}Ba_{0.2}MnO_3$ samples.

Multiferroics, where spontaneous long-range magnetic and dipolar order coexist, show a rich fundamental physics with potential for multifunctional applications. $TbMnO_3$ is a multiferroic compound, exhibiting magnetic ordering of Mn ions, with a sinusoidally modulated collinear magnetic structure along the a-axis (Pnma space group) below TN = 41 K. This magnetic structure changes to a cycloidal phase below Ts = 28 K, which is accompanied by the emergence of a spontaneous electric polarization along the b-axis, accordingly to Dzyaloshinskii-Moriya model. On further cooling, Tb_3+ spins order independently from the Mn_3+ sublattice at T1 = 7 K [1, 2]. In order to tune the balance between the competitive ferro- and antiferromagnetic interactions leading to frustrated magnetic structures, we have studied the effect of Fe_3+ substitution for Mn3+ on selected physical properties of $TbMn_{1-x}FexO_3$, with x=0 to 0.05. Fe_3+ has the same radius as Mn3+ but while Mn_3+ is Jahn-Teller active, Fe_3+ is not. In our work we present a detailed characterization of the structural, thermal, magnetic, polar and magnetoelectric properties of the $TbMn_{1-x}FexO_3$ system as well as a lattice dynamical study at low temperatures by Raman spectroscopy. We have found that already at x=0.05 ferroelectricity is lost and below this concentration there is a strong dependence of the magnetoelectric response on Fe concentration. The temperature dependence of the Raman modes of MnO_6 units has revealed a shift relative to the pure anharmonic temperature dependence of the phonon frequency. The relation between spin-spin correlation function and anomalous Raman mode frequency behaviour is evidenced enabling the determination of spin-phonon coupling. A phase diagram for this system is proposed.

3. Institute for Solid State Physics, University of Tokyo, chiba, Japan

3R-$AgFeO_2$ and alpha-$NaFeO_2$ are two-dimensional triangular-lattice antiferromagnets with rhombohedral symmetry. Recently, it has been reported that the both compounds have non-collinear magnetic phases accompanied by a dielectric polarization. In spite of several powder studies, there have been no investigations on single crystals. We succeeded in growing single crystals of 3R-$AgFeO_2$ and alpha-$NaFeO_2$ by a hydrothermal method. Using them, anisotropic measurements of the magnetic susceptibilities, the magnetizations and the dielectric properties were carried out under high magnetic field up to 60 T. The magnetic susceptibility of 3R-$AgFeO_2$ under a magnetic field along the c axis reveals two-step magnetic phase transitions at 15 and 7 K. The magnetization curve of 3R-$AgFeO_2$ at 1.3 K exhibits anomalies corresponding to the 1/5 and 1/3 magnetic plateaus at 12.5 T and 27 T, respectively when the field is applied along the c axis. On the other hand, the magnetization curve under magnetic fields along the a axis is almost linear except for a small bend at 40 T. alpha-$NaFeO_2$ undergoes two-step phase transitions at 9 and 5 K. The decrease in the magnetic susceptibility below 9 K is more pronounced under magnetic field along c axis. The magnetic susceptibility steeply drops at 5 K with a thermal hysteresis. These behaviors are consistent with the neutron results. The magnetization curve of alpha-$NaFeO_2$ exhibits multi-step phase transitions under the field along the both c and a axes. Field-induced transitions are detected at 5.2, 8.5 and 13.5 T under the c-axis fields, 3.3, 8.5 and 13.6 T under the a-axis fields. A dielectric polarization is observed under magnetic fields between 5.2 and 13.5 T along the c axis.

TU.A-P49 - Effect of partial substitution of of Fe^{3+} with Al^{3+} on the magnetic and dielectric properties of Z-type hexaferrite, $Sr_3Co_2Fe_{24}O_{41}$

S. Tiwari [1], S. Vitta [1]

1. Indian Institute of Technology, Bombay, India

Hexaferrites have non-collinear magnetic structures which facilitate multiferroicity to be induced at elevated temperatures. A Z-type compound, $Sr_3Co_2Fe_{24}O_{41}$ has been chosen for investigation as it has cycloidal or conical magnetic structure at room temperature. Partial substitution of Fe^{3+} with Al^{3+} allows tuning of the magnetic structure and hence magnetoelectric coupling. In the present work $Sr_3Co_2(Fe_{1-x}Al_x)_{24}O_{41}$ with x=0 and 0.019 compounds have been synthesized using standard solid state techniques. Structural characterization shows that both the compounds are single phase with a hexagonal crystal structure, $P6_3/mmc$. Secondary and backscattered electron images show the presence of plate like grains with no secondary phases. The variation of magnetization M with temperature T at different external fields, 100, 500 and 1000 Oe has been measured under two different conditions, ZFC and FC, to determine magnetic structural changes. In the unsubstituted compound a single hump in the magnetization was observed at ~370 K while the substituted compound exhibits additional peak at lower temperature. The position of these peaks in the substituted compound has been found to shift with changing magnetic field. These peaks indicate that the magnetic structure undergoes modification on changing either the T or external field. The room temperature hysteresis shows that the x=0 compound has a simple ferromagnetic behavior while the substituted compound exhibits discontinuities – a step like M variation indicative of successive evolution of the magnetic structure at different fields. The dielectric permittivity and resistivity of the two compounds at room temperature has been investigated in the frequency range 1Hz to 1MHz. In both the compounds permittivity and resistivity decrease with increasing frequency. The permittivity of unsubstituted compound however is higher compare to the substituted compound at low frequency. The resistivity of x=0 compound decreases from 10^6 Ωm to 6×10^4 Ωm while for x=0.019 it decreases from 10^7 Ωm to 6×10^4 Ωm.

TU.A-P50 - Magnetostriction of $Cu_3Mo_2O_9$ under the pulsed magnetic fields

S. Nishikawa [1], Y. Hirata [1], H. Kuroe [1], T. Sekine [1], S. Kawachi [2], A. Miyake [2], M. Tokunaga [2], M. Hase [3], K. Oka [4], T. Ito [4]

2. Institute for Solid State Physics, The University of Tokyo, Tokyo, Japan
3. National Institute for Materials Science (NIMS), Ibaraki, Japan
4. National Institute of Advanced Industrial Science and Technology (AIST), Ibaraki, Japan

We report some anomalies due to magnetically induced phase transitions, e.g., the plateau states, in the magnetostriction curve of $Cu_3Mo_2O_9$.
$Cu_3Mo_2O_9$ is a multiferroic material which exhibits the slightly canted antiferromagnetic and ferroelectric phase below TN = 8 K [1, 2]. The cross correlation effects between the spin and the charge systems and the magnetically induced phase transitions, including the one to the magnetization plateau state above 50 T, are observed in $Cu_3Mo_2O_9$ [3]. Our main focus is the cross correlation effects between the spin and the lattice systems under pulsed magnetic fields up to 57 T. We measure the longitudinal magnetostriction at 1.6 K by using the capacitance technique [4].
When H//a, the lattice constant decreases with increasing magnetic fields up to 19 T and shows sudden increase with hysteresis at 19 T, where the magnetization also increases suddenly [3,5]. And it shows the magnetostriction plateau above 52 T, where the magnetization plateau is observed [3]. Also, when H//c, the lattice constant increases with increasing magnetic field up to 8 T and turns to decrease at the magnetic fields above 8 T. It shows a small anomaly at 18.6 T, where the magnetization jump is observed [3,5]. It also shows the magnetostriction plateau at the magnetic fields where the magnetization plateau is observed. The magnetic-field dependence of magetostriction resembles that of the squared magnetization, suggesting the cross correlation effects between the lattice and the spin systems in $Cu_3Mo_2O_9$.

TU.A-P52 - Multiferroic properties of $(Cu,Zn)_3(Mo,W)_2O_9$

Y. Hirata [1], S. Nishikawa [1], K. Aoki [1], R. Kino [1], H. Kuroe [1], T. Sekine [1], M. Hase [2], K. Oka [3], T. Ito [3], H. Eisaki [3]

1. Sophia Univ., Tokyo, Japan
2. National Institute for Materials Science (NIMS), Ibaraki, Japan
3. National Institute of Advanced Industrial Science and Technology (AIST), Ibaraki, Japan

The substitution effects on $Cu_3Mo_2O_9$ is presented. The parent material has a distorted tetrahedral quasi-one-dimensional spin structure made from the Cu^{2}+ ions with the spin moments of S = 1/2. From this spin structure, geometrical frustration and quantum fluctuation are expected to appear simultaneously. We have found that $Cu_3Mo_2O_9$ is a multiferroic material, where the weak ferromagnetic component of the spin moments and the ferroelectricity coexist below TN = 8 K [1,2].
In $(Cu,Zn)_3Mo_2O_9$, the direct substitution of the nonmagnetic Zn^{2}+ ions for the magnetic Cu2+ ones introduces the spin defects into the spin system [3,4]. In the case of $Cu_3(Mo,W)_2O_9$, the nonmagnetic Mo^{6}+ ions replace the nonmagnetic W6+ ones. The disorder is introduced indirectly into the spin chain through the lattice system. We have synthesized the single crystals of $(Cu,Zn)_3(Mo,W)_2O_9$ with the continuous solid state crystallization [5]. We have studied these direct and indirect substitution effects on $(Cu,Zn)_3(Mo,W)_2O_9$ and have published some results in the Zn-substituted systems [3,5,6]. In this report we present our recent results of the magnetization, the specific heat, and the dielectric constant in $(Cu,Zn)_3(Mo,W)_2O_9$. I explain the similarity and difference between W- and Zn-substitution effects.
I focus the temperature-impurity-concentration-ratio phase diagram. In both of the W- and the Zn- substituted systems, the phase transition temperature decreases linearly. The efficiency of the W substitution is much weaker than that of the Zn substitution.

5. National Institute of Advanced Industrial Science and Technology (AIST), Ibaraki, Japan

The muon spin relaxation/rotation/resonance (mSR) measurements under electric field give helpful information to study the electrically induced magnetism, *e.g.*, the cross correlation effects in multiferroic materials.
In this presentation, we report the electric-field application system up to 500 V newly developed for Dolly spectrometer at PSI. We also present, as a main subject of this research, the electric-field effects on the mSR spectrum in $Cu_3Mo_2O_9$.
This compound has a multiferroic phase below T_N = 8 K [1, 2]. Below T_N, a slightly canted antiferromagnetic long-range magnetic order appears. Two kinds of the internal magnetic fields at the muon stopping sites are clearly observed as the beating oscillation in the muon-spin rotation spectrum below T_N [3]. The mSR spectrum is related to the phase transition at T_N because the temperature dependence of the averaged internal-field amplitude reflects the order parameter of this phase transition. In this presentation, we clarify that the mSR spectrum depends on the electric fields along the *c* axis of the crystal. In this direction, the spontaneous electric polarization appears.
From the fitting of the mSR spectra in time and frequency domains, we conclude that the observation of the electric-field dependence on mSR spectra clearly demonstrates the change of the internal electric fields induced by the application of the external electric fields.

TU.A-P54 - Interplay between electronic correlation and charge transport properties of self-doped multiferroic oxides $CuCr_{1-x}O_2$ (0 < x < 0.1)

D.C. Ling [1], S.B. Singh [1], L.T. Yang [1], Y.F. Wang [1], Y.C. Shao [1], C.W. Chiang [1], K.T. Lin [1], W.F. Pong [1]

1. Dept. of Physics, Tamkang University, Taipei, Taiwan

We have performed x-ray absorption near-edge structure (XANES), extended x-ray absorption fine structure (EXAFS), valence-band photoemission spectroscopy (VB-PES) measurements on layered multiferroic oxides $CuCr_{1-x}O_2$ with $0 < x < 0.1$ to elucidate the interplay between electronic correlation and charge transport properties. The Cu L3,2- and O K-edge XANES spectra reveal a gradual increase in the valence state of Cu from Cu^1+ to Cu^2+ and the presence of excess holes at the O sites due to the generation of Cu^2+, indicative of a strong hybridization between Cu 3d and O 2p states. VB-PES spectra show that the spectral weight of the occupied O 2p valence states shifts about 3 eV toward delocalized O 2p-Cu 3d hybridized states with increasing Cr deficiency, accompanied by a decrease of the density of states of the Cu 3d and O 2p valence states near the Fermi level. These findings provide direct evidence that the increase in the p-type conductivity over a wide range of temperature predominantly arises from Cr-deficiency-induced changes in the electronic structures.

TU.A-P55 - Oxygen vacancy mediation of magnetoelectric coupling in W-type strontium hexaferrites doped with Ce^{3}+ ion

B. Andrade [1], M. Macedo [2]

1. Instituto Federal De Alagoas – Piranhas, Piranhas, Brazil
2. Federal University of Sergipe - Physics Department, São Cristóvão, Brazil

W-type strontium hexaferrite was prepared by proteic sol-gel process. The effects of the Ce substitution on the structural and magnetic properties were investigated by X-ray diffraction, X-ray fluorescence, scanning electron microscopy, magnetometry, differential scanning calorimetry, and impedance spectroscopy. The results revealed the increase of lattice parameters and unit cell volume in function of Ce^{3}+ concentration in W-type hexaferrite. This finding indicated the complete substitution of Sr^{2+} by Ce^{3+}. The value of the saturation magnetization of all the samples was approximately 66.3 ± 0.7 emu/g, whereas the Curie temperature was invariant with the doping (Tc = 475 ºC). The remanence, coercivity, and activation energy increased with the Ce^{3}+ doping. The insertion of a dopant ion led to the creation of oxygen vacancies and the reduction of Fe^{3+} to Fe^{2+} in the octahedral site. Thus, the concentration of cerium ions indicated a possible coupling between the electric and magnetic fields. The Mr/MS ratio suggested that W-type hexaferrites doped with Ce^{3+} have multiple domains and coercivity lower than 100 Oe. As a result, this material is a potential candidate for magnetoelectric and electromagnetic devices.

TU.A-P56 - Structural and magnetic properties of M-type $Sr_{1-x}MgxFe_{12}O_{19}$

M. Macedo [1], B. Andrade [2], Y. Santos [1]

1. Federal University of Sergipe - Physics Department, , São Cristóvão, Brazil
2. Instituto Federal de Alagoas – Piranhas, Piranhas, Brazil

$Sr_{1-x}MgxFe_{12}O_{19}$ nanocrystals were obtained via proteic sol-gel process with the molar ratio $Fe/Sr_{1-x}Mgx$ = 12 (x = 0.0-1.0). The materials were characterized by scanning electron microscopy (SEM), X-ray diffraction (XRD), and magnetometry. XRD results showed: for $x \leq 0.2$ a hexagonal phase; for $0.2 < x < 0.8$ a mixture of $Sr_{1-x}MgxFe_{12}O_{19}$ and few traces of alpha-Fe_2O_3; and for $x > 0.8$, the phase alpha-Fe_2O_3. The c/a ratio falls 3% for $x < 0.8$, due to the different ionic radii between $Mg^{2}+$ and $Sr^{2}+$. SEM results showed a morphological structure with wide distribution in particle size. The FC-ZFC curves obtained from the magnetization versus temperature with a field of 100 Oe for $x > 0.8$ showed a marked elevation of 250 K. This transition was attributed to the reorientation of spins typically found in the hematite, which gradually disappeared as the hexagonal phase formed. The maximum values of Ms, Mr, Hc and Mr/Ms found at x = 0.2 were 66.0 emu/g, 30.0 emu/g, 538.0 Oe and 0.5, respectively. For $x > 0.2$ a sharp drop in these quantities was observed, reaching saturation at x = 0.8. The increase of the magnetic properties for x = 0.2 can be explained by hyperfine field of the 12k- and 2b-site as a result of superexchange interaction energy for Fe-O-Fe. Above this doping, the reduction of the magnetization can be explained by magnetic dilution. The reason Mr/Ms suggests that the presence of $Mg^{2}+$ in the structure leads to the formation of single domain particles to multiple magnetic domains. This study showed that low magnesium doping leads to an increase of the magnetic properties of strontium hexaferite.

TU.A-P57 - Magnetic and Magneto-optical properties of films of multiferroic $GdMnO_3$ grown on $SrTiO_3$ (100) and LSAT (100) and (111)

H. Albargi [1], H. Blythe [1], A.M. Fox [1], G. Gehring [1], V. Chichkov [2], N. Andreev [2]

1. The University of Sheffield, Sheffield, United Kindgdom
2. National University of Science and Technology "MISiS"

Bulk GdMnO3 is a canted antiferromagnet below ~ 40K and ferroelectric below ~8K and is orthorhombic with axes $a = 5.310$ Å, $b = 5.840$ Å, $c = 7.430$ Å. The magnetization is expected to depend strongly on strain because of the coupling between the spin structure and the ferroelectricity. We investigate the effects strain on films that are grown epitaxially on LSAT(100) and (111) and compare the results with epitaxial films grown on $SrTiO_3$ (100) [1]. The magnetic properties have been studied using a SQUID magnetometer to obtain ZFC/FC and hysteresis loops data for magnetic fields both in and out of the plane. The strain due to the substrates causes substantial differences in the magnetic properties. The canting of the Mn moments is enhanced and a strong easy plane anisotropy is induced by the strain caused by the LSAT(100) that is larger than that induced by $SrTiO_3$ (100) due to the extra compressive strain in plane. The saturation magnetization of the film grown on LSAT(111) are reduced and almost isotropic. The Curie constant found by fitting the ZFC plot to a Curie law is also smaller for the films grown LSAT(111). The in-plane compression of the film grown on LSAT(100) causes a strong enhancement of the strength of the inter-site transition between Mn ions and a large enhancement of the magnetic circular dichroism (MCD) around 2eV relative to the films grown on $SrTiO_3$ (100). In contrast the MCD is suppressed for the film grown on LSAT(111). Thus large changes may be induced in GdMnO3 by growing thin epitaxial films on suitably chosen substrates. In particular a marked enhancement of the saturation magnetization and the coercive field may be obtained by growing on LSAT (100).

TU.A-P58 - Anisotropy, Magnetostriction and Inverse Magnetoelectric effect in Dy substituted Ni Ferrite

A. Majumder [1], K. Ugendar [1], A. Baby K. B. [1], V. Chunchu [1], M. G [1]

1. Indian Institute of Technology Madras, Chennai, India

$NiFe_2O_4$ and $NiFe_{1.9}Dy_{0.1}O_4$ compounds prepared by solid state reaction were found to crystallize in the cubic inverse spinel phase as confirmed by XRD and Raman studies. The saturation values of magnetization (M_s) of $NiFe_2O_4$ and $NiFe_{1.9}Dy_{0.1}O_4$, at 300 K, are 50.1 emu/g and 44 emu/g respectively and at 20 K, the respective values are 56.4 emu/g and 53.2 emu/g. The M-H data were fit to the law of approach to saturation (LAS) and K_1(T), the first order magnetocrystalline anisotropy constant, was obtained. The values of K_1 of $NiFe_2O_4$ and $NiFe_{1.9}Dy_{0.1}O_4$ at 20 K are 42.2 kJ/m^3 and 121.2 kJ/m^3 respectively and K_1 at 300 K are 33 kJ/m^3 and 55.1 kJ/m^3 respectively. The observed increase in K_1 is attributed to the large negative anisotropy value of Dy. From the ln K_1(T) *vs* ln M(T) plot, the anisotropy of $NiFe_{1.9}Dy_{0.1}O_4$ is seen to be more sensitive to temperature than $NiFe_2O_4$, explaining the lower value of M_s of the former, at 20 K. The saturation magnetostriction (λ_s) values at 300 K of $NiFe_2O_4$ and $NiFe_{1.9}Dy_{0.1}O_4$ are -32×10^{-6} and -35×10^{-6}, respectively, the increase being contributed by that of the Dy^{3+} ion. Ferroelectricity, magnetocapacitance and magnetoelectric effect have been reported on Dy substituted Ni ferrite. All the above made possible the observation of inverse magnetoelectric effect in $NiFe_{1.9}Dy_{0.1}O_4$. A circular pellet of the sample was electrically poled in a field of 0.3 kV/cm and the magnetic field was determined by measuring a change in impedance of a soft magnetic ribbon kept above the pellet. The impedance was measured at 5 MHz, the frequency at which, the magnetoimpedance of the ribbon was the largest (28%). The magnetic field developed due to poled $NiFe_{1.9}Dy_{0.1}O_4$ was determined as 1.2 Oe (~96 A/m or 0.1 mT).

TU.A-P59 - 'One-way transparency of light' in multiferroic CuB_2O_4

S. Toyoda [1], N. Abe [1], S. Kimura [2], Y. Matsuda [3], T. Nomura [3], A. Ikeda [3], S. Takeyama [3], T.H. Arima [1]

3. Institute for Solid State Physics, University of Tokyo, Chiba, Japan

The response of matter to light is described in terms of electric response and magnetic response. In multiferroic materials, the responses can interfere with each other, resulting in a change in optical absorption with the reversal of the propagating direction of light. If the electric response is as large as the magnetic response, the material should be transparent for the light propagating in one direction, while it should absorb light propagating in the opposite direction. It has been reported that CuB2O4 shows giant directional dichroism at 1.40 eV which corresponds to the intratomic d_(x^2-y^2)-d_xy transition of Cu2+ holes in the canted antiferromagnetic phase below 21 K [1]. The optical absorption coefficient changes by a factor of three with the reversal of the propagation direction of light. In this study, we investigate the directional dichroism in high magnetic fields up to 52 T. The directional dichroism is enhanced with magnetic field. The ratio of the optical absorption coefficient is as large as 1000 % at 52 T for the light E // [110] and B // c-axis. The enhancement of the directional dichroism is explained by a modification of the electric and magnetic transition dipole moments with the canting of the spin direction of Cu^2+. Furthermore we predicted that the electric dipole transition should be as large as the magnetic dipole transition at 52 T by rotating the sample around [110] axis by 45 degrees, because the magnetic dipole transition decreases with reduction of the c-component of the magnetic field of light. In fact, the absorption peak disappears for the light propagating in one direction. In other words, we succeeded in realization of 'one-way transparency of light'.

TU.A-P61 - Weak ferromagnetic transition induced by structure phase transition in chiral antiferromagnet $Ba_3Fe_2O_5Cl_2$

N. Abe [1], S. Shiozawa [1], N. Netsu [1], K. Nguyen [1], K. Matsuura [1], H. Sagayama [2], A. Nakao [3], Y. Tokunaga [1], T.H. Arima [1]

Coupling of the crystal chirality and the magnetism in material causes interesting phenomena such as chiral soliton lattice, skyrmion, and magnetochiral dichroism. $Ba_3Fe_2O_5Cl_2$ is a chiral magnetic insulator of space group I213. Each magnetic Fe^3+ ion is located at the center of oxygen tetrahedron. Neighboring FeO_4 tetrahedra connected by sharing a corner, which leads to fairly strong antiferromagnetic superexchange interaction. Because of a previous study provided no information about magnetic and dielectric properties, we grow large single crystals and reveal the physical properties of $Ba_3Fe_2O_5Cl_2$.
We succeeded in growing large single crystals by using floating zone method. A magnetization measurement shows that weak ferromagnetic moment appears below 137K. Dielectric constant also shows an anomaly at the magnetic transition temperature. In ordered to clarify the mechanism of the phase transition, we performed a single crystal structure analysis by using synchrotron x-ray diffraction at BL-8A, Photon Factory, Japan, and single crystal magnetic structure analysis by using pulsed neutron diffraction at BL-18, MLF, J-PARC, Japan. The crystal structure clearly shows that the crystal structure changes from cubic to orthorhombic at the magnetic phase transition temperature. From the result of the crystal structure analysis, Fe sites are split into two un equivalent sites in the low temperature phase. We also performed a magnetic structure analysis for the high temperature phase. We found that Fe magnetic moments are arranged antiferromagnetically. Therefore we can conclude that antiferromagnetic to weak ferromagnetic transition is induced by the structure phase transition. This phase transition would be controlled by applying uniaxial pressure or magnetic field.

TU.A-P62 - Strain induced phase separation in thin films of half-doped $La_{0.5}Sr_{0.5}MnO_3$ manganites: 55Mn NMR studies

M. Wojcik [1], E. Jedryka [1], G. Radaelli [2,3], D. Gutiérrez [2], F. Sánchez [2], J. Fontcuberta [2]

1. Institute of Physics, Polish Academy of Sciences, Warsaw, Poland
2. Institut de Ciència de Materials de Barcelona (ICMAB-CSIC), Bellaterra, Spain
3. Istituto Italiano di Tecnologia, Smart Materials, Nanophysics Department, Genova, Italy

Half-doped manganites $La(1-x)A(x)MnO_3$ (where A is a divalent ion and x=0.5) recently attracted a renewed attention because their ground state (ferromagnetic or antiferromagnetic, metallic or insulator) can be easily modified by engineering the bandwidth or modifying the carrier density. The aim of this study is to explore how epitaxial strain affects the magnetic and electric ground state in films of $La_{0.5}Sr_{0.5}MnO_3$ (LSMO-05) by using 55Mn NMR resonance as probe to local magnetism and charge localization. Various oxide substrates with a different lattice mismatch to LSMO-05 were used in order to induce different strain effect (tensile or compressive strain). 55Mn NMR spin echo experiments have been carried out at 4.2 K on films with thickness of 20 and 35 nm. The NMR spectra consist of the Mn4+ line and the resonance line corresponding to Mn in a mixed valence state revealing the presence of hole localized and hole itinerant states, respectively. The analysis of NMR data leads to the following conclusions: (1) Strain induces a separation into antiferromagnetic and ferromagnetic phases rather than reducing an overall magnetization of a film, which could be suggested by the macroscopic magnetization measurements. (2) A degree of phase separation depends on the film thickness and on magnetic history of the film. (3) 55Mn NMR frequency (55Mn hyperfine field) observed at manganese ions participating in the double exchange interaction is surprisingly high compared to that expected for this composition (x=0.5) and similar to the frequency observed for the optimally doped composition (x=0.3). This observation strongly suggests that besides phase separation also the electronic charge redistribution takes place between the ferromagnetic and the antiferromagnetic phases.

TU.A-P63 - Overlayer-induced reconstruction of Mn orbitals in manganite thin films studied by 55Mn NMR

M. Wojcik [1], E. Jedryka [1], D. Pesquera [2], F. Sánchez [2], G. Herranz [2], J. Fontcuberta [2]

2. Institut De Ciència De Materials De Barcelona (ICMAB-CSIC), Bellaterra, Spain

Optimally doped manganite $La_{2/3}Sr_{1/3}MnO_3$ (LSMO) is prospective for use in spintronic devices, which involve contact of a manganite layer with other materials (mainly other perovskite oxides -ABO_3), leading to deterioration of magnetic and conducting properties of manganite film. Here, we use ^{55}Mn NMR as a probe of charge distribution and of Mn spin state in LSMO ultra thin films to study the effect of strain and bonding at the interface between manganite and ABO_3 capping layer. A series of LSMO thin films were grown by PLD deposition on the (001) STO-TiO_2 terminated substrates. Three of these films were respectively capped with $SrTiO_3$ (STO), $SrZrO_3$ (SZO) or $LaAlO_3$(LAO), while the fourth remained uncapped and served as a reference. Based on the characteristic features of ^{55}Mn NMR spectra, the contributions from the two interfaces (with substrate and with capping) have been disentangled. The NMR line around 375 MHz corresponds to the mixed valence state of Mn ions within the main ferromagnetic and metallic phase (FMM) governed by double exchange (DE) interaction. Intensity of this line varies with the capping material and reveals a dramatic role of an open surface in breaking degeneracy of Mn e_g(3d) orbitals, diminishing the strength of DE and converting a few upper atomic layers of the manganite film into antiferromagnetic (AF) phase. Depending on the capping material, parameters such as lattice mismatch to manganite, symmetry (s, d) and space expansion (3d, 4d) of the wave function of the B atom (Al, Ti, Zr), the local symmetry of Mn atoms in the upper layers is altered. In case of capping with LAO and STO (to less extend), this brings back the degeneracy of Mn e_g(3d) orbitals and recovers the DE phase, whereas in case of SZO, the asymmetry of the Mn e_g(3d) orbitals is strengthened, leading to expansion of the AF phase.

TU.A-P65 - Peculiar Magnetoelectric Coupling in $BaTiO_3$:Fe_{113}ppm

C. De Oliveira Amorim [1], F. Figueiras [1,2], J. de Sequeira Amaral [1,2], P. Tavares [3], M.d.R. Correia [4], E. Alves [5], J. Rocha [5], V.d.S. Amaral [1]

Multiferroics is one prominent area of Physics due to the outstanding applications that arise from these materials which led to the study of composites of ferroic materials, namely composites of ferromagnetic and ferroelectric archetypes.
We show results regarding polycrystalline $BaTiO_3$ which contained an overall 113 ppm of Fe. Despite this tiny concentration, abrupt variations in the magnetization (≈600%) are seen in temperature dependent magnetic curve around T≈330K and T≈373K.
This result is correlated with the $BaTiO_3$ ferroelectric phase transitions. Such effect was never seen even in works where bulk $BaTiO_3$ was doped/mixed with higher concentrations of Fe (similar effects were only seen in thin films composites). Raman Spectroscopy analysis of the 520cm^{-1} and the 487cm^{-1} vibrational modes confirms this correlation, revealing a magnetoelectric coupling in the BaTiO3:Fe_{113ppm} phase transitions.
EDS mapping reveals that Fe distribution through the $BaTiO_3$ is quite inhomogeneous, tending to aggregate in specific locations we believe being in the vicinity (around/between/inside) of the grain boundaries which should have a preponderant role in the reported magnetoelectric coupling.
$BaTiO_3$ thermal treatments show that the magnetoelectric coupling persists for temperatures as high as 1200ºC. Although, for T≥1300ºC treatments the abrupt variations of the magnetization vanish and the magnetic curve assumes the shape of a typical paramagnetic Curie curve, suggesting the dispersion of the Fe ions all over the $BaTiO_3$ matrix.
Fe ion implantation in $BaTiO_3$ single crystals was made to confirm the importance of grain boundaries and in fact even for local Fe concentrations as high as 1% do not show any signs of a magnetoelectric coupling in the magnetization curve, having instead a magnetization behavior similar to the one obtained for the T≥1300ºC thermal treatments.
We also discuss DFT calculations as well as others' experimental data to suggest possible mechanisms for this peculiar magnetoelectric coupling.

TU.A-P66 - Huge Resistive Change in Tunnel Junctions Using the Multiferroic BiFeO3 Barrier

T. Ichinose [1], H. Naganuma [1], M. Oogane [1], Y. Ando [1]

1. Tohoku University, Japan

Tunnel electroresistance (TER) effect in ferroelectric tunnel junctions has attracted much attention because the high resistance change was achieved ~106% by switching ferroelectric polarization [1]. If we use multiferroic materials as a tunneling barrier having magneto-electric (ME) coupling, an extremely weak magnetic field can be detected through both of ME effect and TER effect; which is a noble concept of high-sensitive magnetic field sensors. In this study, (001)-La:SrTiO3 sub./BiFeO3(0.8-3.2)/CoFe(4)/Ru(5) (in nm) tunnel junctions were prepared by r.f. magnetron sputtering, and its structural, ferroelectric, and electric conductive properties were systematically investigated. TEM observation using pattern analysis of nano-beam diffraction revealed that the BiFeO3 barrier has rhombohedral structure even though the film thickness was only 3.2 nm. It should be noted that the rhombohedral symmetry of BiFeO3 has ME effect above room temperature. Switching spectroscopy PFM confirmed that the ferroelectric polarization of BiFeO3 barrier was switched. The current-voltage (I-V) curves for the junctions with various BiFeO3 barrier thicknesses were asymmetric, and the current was drastically decreased at negative bias; which indicated that the junction resistance strongly depended on the polarization direction. The resistance ratio between upward-polarization-state and downward-polarization-state was estimated to be 107%. 10 times larger resistance ratio than that of the previous report should be caused by extremely low resistance in downward-polarization-state. The barrier height lowering in downward-polarization-state should lead the conduction of the electrons with high energy than that of barrier height. The asymmetric I-V curves were observed even if the BiFeO3 thickness was decreased from 3.2 to 0.8 nm. This study was partly supported by KAKENHI (No. 25600067, 24226001) and JST ASPIMATT.

TU.A-P67 - Tests for electromagnetic effects on a toroidal magnetic ordered state of UNi_4B

H. Saito [1], K. Uenishi [1], N. Miura [1], C. Tabata [1], H. Hidaka [1], T. Yanagisawa [1], H. Amitsuka [1]

1. Graduate School of Science, Hokkaido University, Hokkaido, Japan

Toroidal moment is one of the parameters that describe the strength of the magnetoelectric effect. In the last several years, the toroidal order, which is the ordered periodic array of toroidal moments, has attracted much interest in connection with multiferroic insulating materials. Last year, S. Hayami et al. showed theoretically that such an exotic order can occur in metallic systems, and electric currents can induce magnetization in such the toroidal ordered metal [1].

UNi_4B crystalizes in the orthorhombic structure with the symmetry *Cmcm* and U ions form a slightly distorted triangular lattice [2]. Below T_N (= 20.4 K), 2/3 of U ions gain ordered magnetic moments and make the vortices in each triangular planes [3]. This magnetic structure is the same as the structure assumed in the above theory, so that UNi_4B may show the exotic electromagnetic phenomena predicted by the theory. To test the reality of the theoretical predictions, we performed the magnetization measurements with the electric currents applied in the toroidal magnetic ordered state of UNi_4B.

Magnetization parallel to [01-10] was measured with applying the electric current parallel to [1000] and [0001]. In our measurements, a variation of magnetization ΔM due to applied electric current was found in the direction of [01-10] below T_N for each setup of I || [1000] and [0001]. ΔM increases by cooling or applying larger currents. Reversing the current direction, ΔM changes its sign. ΔM is mostly independent of magnetic field. Those experimental results indicate that the electric currents in both the directions induce spontaneous magnetization parallel to [01-10] below T_N, confirming basically the theoretical predictions.

TU.A-P72 - Strain effect and multiferroic properties of Sr_2CrReO_6 / $Ba_xSr_{1-x}TiO_3$heterostructures

J. So [1], F. Xu [1], K. Ito [1], T. Hajiri [1], K. Ueda [1], H. Asano [1]

1. Nagoya University, Dept. of Crystalline Materials Science, Graduate School of Engineering

Multiferroic heterostructure composed of ferromagnetic (FM) half-metal and ferroelectrics (FE), in which the coexistence of tunneling electroresistance (TER) and tunneling magnetoresistance (TMR) effects can be confirmed, are promising for future high-density memory devices. Double-perovskite ferrimagnetic half-metal Sr_2CrReO_6 with a high curie temperature (TC = 635 K)[1] exhibits large magnetocrystalline anisotropy[2], making it favorable to generate perpendicular magnetization. Therefore it is expected for spintronics applications at room temperature. However, there has been no study that utilized Sr_2CrReO_6 in multiferroic heterostructures. In this study, in order to evaluate the potential of Sr_2CrReO_6 as an electrode of multiferroic tunnel junctions, we used $Ba_xSr_{1-x}TiO$ (x = 0.2-0.7) as buffer layers to induce strain and perpendicular magnetization in Sr_2CrReO_6 films. Then we grew $Ba_{0.7}Sr_{0.3}TiO_3$ as a dielectric layer on Sr_2CrReO_6 epitaxially and also systematically investigated the influence of strain on dielectric properties of $Ba_{0.7}Sr_{0.3}TiO_3$ layers.
Thin films of Sr_2CrReO_6 and $Ba_xSr_{1-x}TiO$ (x = 0.2-0.7) were grown on LSAT (001), LAO (001) substrate by magnetron sputtering. The buffer layer $Ba_xSr_{1-x}TiO$ has larger lattice constant than Sr_2CrReO_6 and induces larger tensile strain as x becomes bigger. We have confirmed the c/a value of 80nm Sr_2CrReO_6 goes smaller (c/a = 0.998, 0.994 and 0.991) as x increases (x = 0.2, 0.4 and 0.7). It was found that Sr_2CrReO_6 showed different longitudinal and perpendicular magnetization properties depending on its c/a value. Then we investigated electric properties of Ba0.7Sr0.3TiO3 thin film on the Sr_2CrReO_6. We obtained the 2Pr values of $Ba_{0.7}Sr_{0.3}TiO_3$ are 28, 40, and 62 â‡C/cm2 for thickness of 100, 50, 40 nm, respectively. The dielectric measurement result of $Ba_{0.7}Sr_{0.3}TiO_3$ with different thickness shows that as $Ba_{0.7}Sr_{0.3}TiO_3$ layer becomes thinner, its property becomes better. The negative mismatch of -1.5% induced greater strain effect when $Ba_{0.7}Sr_{0.3}TiO_3$ becomes thinner. Therefore, $Sr_2CrReO_6/Ba_xSr_{1-x}TiO_3$ü@heterostructure is a very potential substitute for multiferroic tunneling junctions aiming for the coexistence of TER and TMR effects at room temperature.

TU.A-P73 - Magnetic- and electric-field control of magnetoelectric properties of $CaBaCo_4O_7$

R. Oda [1], R. Kajihara [1], K. Nishida [1], M. Akaki [2], H. Kuroe [1], H. Kuwahara [1]

1. Department of Physics, Sophia University
2. Center for Advanced High Magnetic Field Science, Graduate School of Science, Osaka University

The so-called "114" family compounds focused in this study have been intensively investigated as a novel magnetic system. One of these 114 compounds, CaBaCo4O7 with polar space group Pbn21, has recently attracted much interest owing to its giant change of electric polarization ΔP associated with the ferrimagnetic ordering below Tc=64K. One possible origin of ΔP is proposed to be magnetosriction, which is supported by the large change of lattice parameters at Tc. For further understanding of the large ΔP of magnetic origin, we have systematically investigated the magnetoelectric properties of pristine CaBaCo4O7 and its impurity-substituted derivative (Cal-xYx)BaCo4O7, (Cal-xSrx)BaCo4O7, Ca(Bal-xSrx)Co4O7, and CaBa(Col-xFex)4O7 single crystals in magnetic and/or electric fields.
By applying magnetic fields, magnetic and dielectric transition temperature for CaBaCo4O7 increases, which is due to the stabilization of the ferrimagnetic phase. We have observed the large magnetocapacitance and magnetic-field-induced ΔP near above Tc. In addition, we have tried to detect the electric-field-induced magnetization by using a magnetometer with customized system. This is because the nonzero components, α23 and α32, of linear magnetoelectric tensor are expected from a symmetry analysis for the magnetic point group of m'm2'. As a result, we have successfully observed the discernible change of magnetization within the ab plane as a function of applied electric field along the c axis up to ±2.0MV/m below Tc, which is the first demonstration expressed as Mb=α32Ec. We have measured lattice striction for CaBaCo4O7 in magnetic fields by using a strain gauge attached along each principal axes. Then we have confirmed the large change of lattice striction: the magnetic easy ab plane expands, whereas the hard c axis shrinks at Tc with decreasing temperature. The observed large ΔL/L of about 10-4 also supports that the magnetostriction plays an important role in the appearance of large ΔP.

TU.A-P75 - Charge-Ordering induces magnetic axes rotation in organic materials (TMTTF)2X (X=PF6, AsF6, SbF6)

C. Dutoit [1], S. Bertaina [1], M. Orio [2], M. Dressel [3], A. Stepanov [1]

2. Aix-Marseille Université, CNRS, iSm2 UMR7313, Marseille, France
3. Physikalisches Institut Universität Stuttgart, Stuttgart, Germany

Charge-ordering (CO) phenomenon, also named charge disproportionation, has been intensively studied in the last decade in antiferromagnetic quantum spin chains (TMTTF)2X with X = SbF6, AsF6, and PF6. (TMTTF) molecules are arranged in a zig-zag configuration, forming stacks along the a direction. Above TCO, the charge is equally distributed between two TMTTF molecules. Below TCO, there is a charge disproportionation between two molecules TMTTF and the symmetry center is broken. All (TMTTF)2X salts crystallize in the triclinic structure P-1. Experimentally, we studied the g tensor electron spin resonance (ESR) at 9.7GHz and the temperature dependence of the g tensor principal axes position was examined. We observed a rotation of up to 18° of the g-tensor principal axes around a direction in the temperature range from 300 to 15K for (TMTTF)2SbF6 salt. We discuss the possible origin of this rotation by comparing experimental results with the quantum-chemical calculation performed by DFT (using ORCA). g-tensor were obtained using the hybrid functional B3LYP and the EPR-II basis set. Considering only thermal contraction of TMTTF structure [2] as temperature decreases, the numerical calculation shows a rotation of only 2° between 300K and 4K. If one considers additionally a uniform anion displacement, experimentally reported in (TMTTF)2PF6 salt [1], one obtains a rotation of about 22° between 300K and 4K, which is in good agreement with the experimental value.

4. IMEM-CNR, Parma, Italy

Improper ferroelectrics, where the electric polarization is induced by a magnetic order, typically exhibit modest values of polarization, P ~ 0.1 µC cm^{-2}, which prevents their use as multiferroic materials. Here we report on values up to ~1 µC cm^{-2} in the single-valent compound $LaMn_3Mn_4O_{12}$ [1], which belongs to the family of quadruple perovskites $AA'_3B_4O_{12}$ [2,3]. This value is ~4 times larger than the previous record value reported on the related mixed-valence compound $CaMn_3Mn_4O_{12}$ [4,5]. Our analysis of neutron diffraction, magnetization and pyroelectric current measurements shows that, in $LaMn_3Mn_4O_{12}$, the polarization is induced at $T_{N,B}$ = 78 K by a *C*-type antiferromagnetic order of the Mn^{3+} ions at the octahedral *B* sites. The simplicity of the nuclear and magnetic structures and the observation of a sudden increase of the monoclinic b-angle at $T_{N,B}$ enable us to establish that the polarization is parallel to the *ac*-diagonal, which indicates that the magnetoelectric coupling is driven by exchange striction. An abrupt ~2 cm^{-1} softening of all Raman modes at $T_{N,B}$ and a 40% reduction of the specific heat by a 9 T field confirm the existence of a very large magnetoelastic coupling. Finally, the single-valent Mn^{3+} characteristics enable us to rule out the possible contribution of the charge ordering to the polarization.

TU.A-P77 - Using pinned domain walls to implement magnetic logic gates in ferromagnetic-ferroelectric heterostructures

D. López González [1], A. Casiraghi [1], S. van Dijken [1]

1. NanoSpin, Department of Applied Physics, Aalto University School of Science, Aalto, Finland

Local magnetic anisotropy modulations in continuous ferromagnetic films can be realized using pre-patterned substrates [1] or focused ion beam irradiation [2]. Alternatively, strain coupling between a ferroelectric substrate and a magnetic film can be used to induce regular magnetic stripe domains [3]. Because of strong pinning of magnetic domain walls onto ferroelectric boundaries, versatile control over the formation of magnetically charged and uncharged domain walls in an applied magnetic field can be achieved in such systems [4]. Here, we report on the effect of pinned magnetic domain walls on the magnetization reversal in a Co40Fe40B20 wedge film on a ferroelectric BaTiO3 substrate. We show that the distinctive energies of the two types of domain walls cause either a lateral modulation or a synchronization of magnetic switching, depending on field direction. Based on these findings, we propose a magnetic logic device consisting of three stripe domains, whereby the central domain reads out the magnetic state of the two adjacent domains. Depending on the applied bias field, AND, NOR, and NOT gates can be implemented. The concept is experimentally demonstrated and further supported by micromagnetic simulations.

TU.A-P78 - Exotic ferromagnetic ordering of polar magnetic PbVO3 epitaxial thin films

S. Hee Oh [1], H. Jin [1], J. Cha [2], S. Hong [2], W. Jo [1]

1. Department of Physics, Ewha Woman University
2. Department of Physics and Graphene Research Institute, Sejong University

Tetrahedron-based perovskite PbVO3 (PVO) is an intriguing polar magnetic material because its strong tetragonal distortion allows VO5 square-pyramidal structure rather than VO6 octahedron. Bulk PVO is known to show the unique features of 2-dimensional antiferromagnetic ordering and large pyroelectric polarization. The c-axis lattice parameter of the PVO films epitaxially grown on LaAlO3(001) and SrTiO3(001) substrates is abnormally elongated by 5% and 6.5%, respectively [1]. Atomic ordering of Pb and V shows an interesting configuration onto La and Al or Sr and Ti. In a single-crystal bulk, the ground state of magnetic ordering of PVO is degenerated by C- and G-type configurations [2] and its transition temperature is reported as TN = 47K [3]. In our theoretical study using the first-principle calculations, a ferromagnetic ordering is found to be stable in the elongated PVO thin-films. Our magnetic measurement exhibits a clue for this exotic phase at low temperature, which is a direct evidence for change of the exchange interaction between two adjacent dxy electrons of the V+4 ions. The phenomenon is attributed to the elongation of the c-axis lattice parameter of the PVO thin-films.

TU.A-P79 - Magnetic properties and Magnetoelectric coupling of vacancy doped hexagonal $LuMn_xO_{3+/-delta}$ ceramics

A. Baghizadeh [1], J.M. Vieira [1], J.S. Amaral, M.P Grþa

1. CICECO, Dep. of Materials And Ceramics Engineering

Vacancy doping on A-site or B-site of the h-$LuMn_xO_{3+/-delta}$ (x=Mn/Lu) ceramics were used to explore the dependency of the lattice parameters and magnetic properties to doping. Ceramics samples were sintered via solid state route in the range of 0.92 <=x<=1.12, and the study extended to investigate the effect of sintering time. The concomitant occurrences of planar defects, nano-scale domains inside the crystalline grains of the main phase and secondary phases as impurities are further investigated by electron microscopy for samples on either sides of the stability range of hexagonal LuMnxO3+/-delta phase. It is found that within the solid stability limit and different sintering conditions studied in this work, the lattice structure preserves the hexagonal P63cm crystalline structure. Shrinkage of the lattice parameters as x goes from 0.92 to 1.12 is found. The AFM transition with Neel ordering temperature around 90 K is observed for all samples under study. The trend of change in TN is decreasing as the x value is increased, showing higher values for lower x values. The irreversibility observed in FC and ZFC magnetization measurements of all samples starts at TN and is independent from sintering conditions. Magneto-electric coupling could be revealed for all samples in measurements of the complex dielectric constant. Measured dielectric and magnetic properties coupled to lattice change are connected to the vacancy doping of either A-site or B-site.

This work was developed within the project CICECO-Aveiro Institute of Materials (Ref. FCT UID/CTM/50011/2013)

TU.A-P81 - Excitonic Multipole Order in a d-p Model with Parity Mixing

Y. Sugita [1], S. Hayami [1], Y. Motome [1]

1. Department of Applied Physics, University of Tokyo, Tokyo, Japan

Multipole orders have attracted much attention in condensed matter physics, as they lead to exotic electronic, transport, and optical properties. Recently, unconventional multipole orders associated with conventional electronic symmetry breaking have been of great interests. A typical example is found in several pyrochlore compounds, such as Os and Ir pyrochlores. In these compounds, a noncoplanar all-in/all-out type magnetic (dipole) order was discussed as a magnetic octupole order. Similar multipole orders (magnetic toroidal and quadrupole orders) were discussed on a zigzag chain and a honeycomb lattice, paying attention to the effects of the atomic spin-orbit coupling and the mixing of different parity orbitals. In these previous works, however, multipole orders always appear subsidiary to the lower-rank electronic orders. Thus it is important to explore the possibility of pure, primary multipole ordering for deeper understanding of the multipole physics. In order to search such primary multipole orders, we consider a simple d-p model on a zigzag chain, which incorporates the spin-orbit coupling and the parity mixing. The model is considered as an extension of the multi-orbital Hubbard model discussed for excitonic orders. Using the Hartree-Fock approximation, we obtain the ground-state phase diagram of this model at half filling in a wide range of intra and interorbital Coulomb interactions. The result shows that a pure multipole ordered phase appears as an intermediate phase between the band insulating phase with the d-p hybridization gap and the antiferromagnetic phase caused by the strong intraorbital Coulomb interaction. The intermediate phase has a magnetic quadrupole order with an excitonic nature from the orbital mixing, which is stabilized by the spin-orbit coupling and the parity mixing. We also find that the multipole ordered phase exhibits a peculiar band deformation with a shift of the band bottom in the momentum space in an applied magnetic field.

TU.A-P82 - Effect of Fe doping on magnetic properties of RMnO3 single crystals (R = Gd and Dy)

J. Laz·rovß [1], V. Viktor [1], M. Mihalik [1], M. Mihalik [1], M. Zentkovß [1], J. BrianÞin [2], K. Uhlí°ovß [3], M. Kratochvílovß [3], M. Fitta [4]

4. Institute of Nuclear Physics, Polish Academy of Sciences, Kraków, Poland

In our work we study effect of Fe doping on thermal and magnetic properties of GdMnO3 and DyMnO3 single crystals. In GdMnO3 a ferroelectric phase appears in magnetic field H = 1 T and DyMnO3 shows a ferroelectric order even at H = 0 [1]. GdMnO3 orders magnetically below TN(Mn) = 43 K and undergoes the second transition at TN(Gd) ~ 6.5 K [1]. DyMnO3 exhibits magnetic ordering below TN(Mn) = 41 K, where Mn-spins order in a longitudinal spin density wave propagating along the b-direction; this structure changes to a cycloidal phase below Ts(Mn) = 18 K and another ordering appears at TN(Dy) ~ 6.5 K [1, 2]. The cycloidal Mn-spin structure, with the inverse Dzyaloshinskii-Moriya interaction is the driving force for ferroelectric order and frustration is mechanism of multiferroicity [3]. Magnetic frustration can be tuned by modifications of exchange interactions e.g. by substitution. Single crystals of RMn1-xFexO3, where R = Gd, Dy and x = 0.00, 0.01, 0.02, 0.05, 0.1, were grown by optical floating zone method in order to verify this assumption. All crystals adopt the orthorhombic crystal structure, space group Pbnm. The crystal lattice parameters change linearly and volume of the elementary cell decreases with Fe doping. Temperature of all characteristic transitions decreases with doping as it is indicated e.g. by the decrease of the maximum in heat capacity at TN(Mn) from 38.5 K to 33 K and from 41.5 K to 31.5 K for Dy and Gd samples, respectively. No sign of transition to the cycloidal phase was observed for x > 0.02. Magnetization measurements confirmed that c-axis is the hard magnetic axis. [1] T. Kimura et al.: Phys. Rev. B 71 (2005) 224425. [2] T. Kimura et al.: J. Phys.: Condens. Matter 20 (2008) 434204. [3] S-W. Cheong et al: Nat. Mater. 6 (2007) 13.

TU.A-P83 - Determination of incommensurate magnetic structures using symmetry arguments

I. Urcelay-Olabarria [1], J.M. Pérez-Mato [1], E. Ressouche [2], J.L. García-Muñoz [3]

1. Departamento de Física de la Materia Condensada, Facultad de Ciencia y Tecnología, Universidad del País Vasco, UPV-EHU, Leioa, Spain

3. Institut de Ciència de Materials de Barcelona, ICMAB-CSIC, Campus universitari de Bellaterra, Bellaterra, Spain

Determining a magnetic structure from neutron diffraction data can be a rather tough problem, and frequently the data analysis is manually constrained in order to achieve a satisfactory convergence. Nevertheless, in most of the cases those constraints are made using arbitrary criteria, and this is more evidenced in the field of incommensurate magnetic structures (ICMS). In this work we show how the use of the superspace symmetry formalism allows to rationalize not only the data treatment, but also the physical properties induced by a magnetic ordering.
The ICMSs in $Mn_{1-x}Co_xWO_4$ have been studied using symmetry arguments. $MnWO_4$ is a multiferroic material in which the magnetic order of one of its magnetic phases induces ferroelectricity. Like most multiferroic materials MnWO4 is extremely sensitive to small perturbations. It turned out that doping with Co^2+ is particularly interesting since it strongly stabilizes the multiferroic phase at low temperatures, and moreover, by increasing the cobalt amount in the crystals its properties change (electric polarization flops from the b axis to the ac plane) . This change of orientation is linked to a symmetry change. The ICMS of the x = 0 and x = 0.10 compounds, have been studied thoroughly. We have found, not only the symmetry of the magnetic structures and their intrinsic restrictions, but also information about the tensor properties, such as ferroelectric and magnetostructural properties: in the paramagnetic state, there is a unique independent magnetic atom in the crystallographic unit cell in both cases, but when the system enters into the multiferroic phase, this is no-longer true. In the multiferroic phase of $MnWO_4$, the two Mn atoms in the unit cell become symmetry independent, whereas in the x = 0.10 substituted compound, they are still symmetry-related. This difference is related to the change of the electric polarization.

TU.A-P85 - Phase transisions ans magnetoelectric coupling in bi1-xaxfeo3 (a=la, nd) multiferroic ceramics

A. Amirov [1], I. Kamilov [1], D. Yousupov [2], L. Reznichenko [2], O. Razumovskaya [2], I. Verbenko [2]

1. Institute of Physics, Dagestan Scientific Center of Russian Academy of Sciences, Makhachkala, Russia
2. Institutes of Physics, South Federal University

Compounds on base of $BiFeO_3$ are very perspective multiferroic materials due to high temperature of magnetic and ferroelectric phase transitions, bad conductivity and simple chemical structure [1-2].
High quality ceramics were synthesized on the basic of $Bi_{1-x}A_xFeO_3$ (A=La, Nd; x=0-0.2) solid solutions. Their crystal and grain structure, Mossbauer spectra, dielectric, magnetic, thermal characteristics were studied. The ac-susceptibility vs. temperature curve of $BiFeO_3$ has a sharp peak at 646 K which corresponds to the antiferromagnetic phase transition T_N and it is confirmed by literature data [3]. The anomalies of dielectric permeability, spacing parameter, thermal conductivity and heat capacity near temperature of antiferromagnetic order T_N were observed in all samples and it is related with correlation between magnetic and ferroelectric subsystem which is typical for multiferroics. The magnetization of pure $BiFeO_3$ is small and grows linearly with magnetic field. The substitution Bi by La or Nd changes the temperature of the antiferromagnetic order and increases the magnetization of $BiFeO_3$. The magnetic properties change occurs not only on account of magnetic moment and ionic radiuses, but also because of La and Nd ions magnetic moments anisotropy.
The samples were also studied for the presence of the magnetodielectric effect (magnetocapacitance), which is a change in the permittivity of the sample caused by the application of a magnetic field

$$\frac{\Delta\varepsilon(H)}{\varepsilon(0)} = \frac{\varepsilon(H)-\varepsilon(0)}{\varepsilon(0)},$$

where ε(*H*) and ε(0) are the permittivities in a magnetic field and in the absence of it, respectively. The measurement results showed an increase in magnetodielectric effect is associated with an increase in the degree of interaction between the dipole and magnetic subsystems. The slower increase of magnetocapacitance in the range $0.05 \le x \le 0.1$ associated with the change of predominant mechanism in the solid solutions, as in $0.15 \le x \le 0.2$ - with the existence of invar effect due to the appearence of a new monoclinic phase.

In multiferroic heterostructures magnetoelectric coupling between a ferroelectric material and a ferromagnetic film has been extensively studied during the last decade and various interaction mechanisms have been identified as promising routes towards exclusively electric-field controlled magnetism. In strain-coupled systems, direct correlations between the polarization direction within ferroelectric domains and the locally-induced magnetic anisotropy have been demonstrated [1-2].We have fabricated bilayer thin films of the ferromagnetic (FM) $La_2/3Sr_1/3MnO_3$ (tLSMO=100 nm) and ferroelectric (FE) $BaTiO_3$ (tBTO=100 nm) on (001) oriented $SrTiO_3$ (STO), $(LaAlO_3)_{0.3}(Sr_2TaAlO_6)_{0.7}$ (LSAT) and $LaAlO_3$ (LAO) substrates as a possible route to design heterostructures with artificial magnetoelectric coupling. Reciprocal space map analysis revealed that, while the LSMO grew epitaxially strained, the BTO film grew relaxing its single-crystal structure through dislocations formed in the LSMO-BTO interface. Magnetization-temperature curves prove the ferromagnetic order for all bilayers at room temperature, with magnetization between 280-320 emu/cm3, making possible a multiferroic behaviour at room temperature. Magnetic anisotropy analysis through magnetization hysteresis loops performed at 300 K, with the magnetic field applied along different in-plane crystallographic directions, showed that the bilayer grown on STO (001) substrate presented a change in the magnetic anisotropy from biaxial magnetic ordering (observed in the LSMO/STO (001) single-layer) to uniaxial magnetic ordering (BTO/LSMO/STO (001) bilayer) due to strain induced by the BTO layer on the top of LSMO layer. This effect has not been observed in the bilayers grown on LSAT and LAO substrates. This result revealed that the superficial strain effect only induced a uniaxial anisotropy when the LSMO film was grown with a tensile strain.

Rare-earth iron borates with general formula $RFe_3(BO_3)_4$ (R = Y, Pr-Er) have a structure of the natural mineral huntite (SG R32). Iron borates with an ionic radius of R smaller than that of Sm undergo a structural phase transition into the SG P3121 at the temperature TS inversely proportional to the ionic radius of R^3+. $EuFe_3(BO_3)_4$ has the lowest TS. TS=88K and TS=58K were reported for powder samples prepared by solid-phase synthesis [1] and for a single crystal [2], respectively. In the present work we study how and why the method of sample growth influences structural, magnetic, and spectroscopic properties of $EuFe_3(BO_3)_4$. We compare optical spectra of $EuFe_3(BO_3)_4$ crystals grown by flux-melting technique using (i) $Bi_2Mo_3O_{12}$ and (ii) Li_2WO_4 based fluxes. The spectra clearly evidence TS=58K for the sample (i) and TS=83K for the (ii) one, whereas TN=34K for both samples. Obviously, lower TS for the sample (i) is connected with entering of a “big” Bi^{3+} ion from the flux into positions of Eu^3+. Our estimate gives 7±2 % for Bi concentration in the sample (i). Bi impurity manifests itself also by a presence of extra lines in the spectra, due to Eu^3+ located near Bi impurities. Using high-resolution polarized spectra of the “pure” (ii) crystal, we have determined energies and symmetries of the Eu^3+ crystal-field (CF) levels for both R32 and P3121 phases. CF calculations were performed and CF parameters were determined. To describe the spectral data for a magnetically ordered state, the anisotropic orbitally-dependent exchange Hamiltonian was considered. These results form a basis for a correct description of magnetic and magnetoelectric properties of $EuFe_3(BO_3)_4$.

TU.A-P88 - New dipolar ordering of $(C_2H_5NH_3)_2CuCl_4$ below 26 K

T. Sakami [1], T. Ohtani [1], X. Xi [1], T. Suzuki [1]

1. Department of Quantum Matter, ADSM, Hiroshima University, Higashi-Hiroshima, Japan

Perovskite-type layered structure compounds with the chemical formula $(C_2H_5NH_3)_2MeCl_4$ (Me = Transition metal) have been intensively investigated due to the interests in the mechanism of successive transition. Many of these compounds show not only magnetic order but also ferroelasticity. We have studied dielectric properties of $(C_2H_5NH_3)_2CuCl_4$ (hereafter EACuC) known as antiferromagnet below 10 K and found out a clear anomaly at 26 K in the temperature dependence of the dielectric constant. To confirm this transition, we carried out the x-ray diffraction experiments of single-crystalline samples and found that the centrosymmetry was lifted below 26 K. These experimental results strongly suggests that EACuC has a new dipolar ordering at low temperatures.

TU.A-P89 - Jahn-Teller distortions study in Sm(Nd)MnO_3 Manganites

Manganites and their exquisite electronic properties have been extensively studied in the last decade due to both fundamental interest and possible applications of colossal magnetoresistance, magnetocaloric and multiferroic properties [1,2]. Additionally, low-cost AMnO3 and doped manganites have shown promising results for catalysts solutions [3,4]. In these systems orbital occupancy of the metal ion, orbital order and the Jahn-Teller effect have a critical role on the macroscopic material's properties.
In this work it will be presented the evolution of the local Jahn-Teller distortion across the Jahn-Teller phase transition as function of temperature studied with the perturbed angular correlation technique. In the case of $NdMnO_3$ a single phase scenario is proposed. In addition, ab initio calculations were performed and the results will be discussed in light of the experimental electric field gradient (EFG) measurements.

The rare-earth ferroborates $RFe_3(BO_3)_4$ (R = rare-earth metal) are a new series of multiferroic compounds containing R^3+ and Fe^3+ (3d5 S = 5/2) as magnetic ions. Variety of the magnetic anisotropy of the R^3+ moments (R = Y, Pr, Nd, Sm, Gd and Tb) and that of the interaction between the Fe^3+ and R^3+ moments, f-d coupling, induce diverse magnetoelectric effects with respect to the R^3+ ions [1]. In these compounds the mechanism of the magnetoelectricity is explained by the spin-dependent metal-ligand hybridization model [2,3]. We performed inelastic neutron scattering experiment to explore the magnetic excitations in $NdFe_3(_{11}BO_3)_4$. The obtained spectra are analyzed by the spin-wave calculation to identify the magnetic Hamiltonian. It is revealed that Fe^3+ chains along the c - axis are weakly coupled and that they strongly interact with Nd^3+ moments. The anisotropy of Fe^3+ moment is easy-axis type and that of Nd^3+ moment is easy-plane type. The origin of the Fe^3+ anisotropy is discussed in terms of single-ion anisotropy, magnetic-dipole interaction, and the polarization interaction in the framework of the crystal symmetry. None of the three explains the direction of the anisotropy, suggesting that undetectably small distortion is the origin of the anisotropy.

The interfacial exchange coupling between a ferromagnetic (FM) and a multiferroic $BiFeO_3$ (BFO) layer is investigated. FM/BFO bilayers with different FM intrinsic anisotropy and BFO film with different structure have been used, in order to explore the influence of the intrinsic FM anisotropy and the magnetic configuration of the BFO film. BFO and 5%-Mn doped BFO (BFO-Mn) thin films were grown by pulsed laser deposition onto (001)-oriented $SrRuO_3$ (SRO) and $SrTiO_3$ (STO) surfaces [1]. Co, Fe, Ni, and CoFeB thin films were sputtered in a separate chamber at 300K in a magnetic field of 200 Oe, after a short plasma cleaning. The samples were capped by 10 nm of Au layer for ex-situ characterization. The BFO films are fully strained epitaxial heterostructures [2] and display an antiferromagnetic (AFM) behaviour at room temperature, as derived by the non-negligible exchange bias values found for any FM/BFO bilayer. High resolution vectorial magneto-optic Kerr effect (v-MOKE) measurements have been performed at room temperature by using a v-MOKE setup with simultaneous and quantitative determination of the two in-plane magnetization components [3]. The angular dependence of the hysteresis phenomena, remanence, coercivity, exchange bias, and magnetization reversal processes, as well as the accurate determination of the characteristic magnetization directions and magnetic anisotropies are discussed. The data show that the angular-dependent properties are strongly affected by the intrinsic anisotropy of the FM layer and the structure of the BFO layer. The largest exchange bias effects are found for CoFeB films exchange-coupled with BFO films grown onto oriented-(001) metallic SRO sufaces. Numerical simulations based on a modified Stoner-Wohlfarth model confirm that the competition between the unidirectional anisotropy, due to the interfacial coupling, and the anisotropy of the FM layer is the key parameter to understand the experimental observations.

We have investigated a variety of coupled magnetic and ferroelectric phase transitions in $Mn_{1-x}Co_xWO_4$ multiferroics by single crystal and powder neutron diffraction, symmetry analysis and polarization measurements. The competition between the magnetic anisotropy and the isotropic exchange interactions or the external field produces a rich variety of competing multiferroic magnetoelectric phases, in which the anisotropy of the ferroelectriciy behaves according to the inverse Dzyaloshinskii-Moriya model.
Spin-orbit coupling effects associated to the presence of $Co^{+2}O_6$ octahedra strongly modify the magnetic anisotropy and produce changes in the magnetic structures. Up to five distinct collinear and non-collinear spin orders (commensurate and incommensurate) compete in $Mn_{1-x}Co_xWO_4$ multiferroics with Co concentrations in the range $x\approx0.12$-0.15.
Here we report the investigation of the magnetic and ferroelectric properties of these frustrated oxides in the highly-doped regime ($0.15\leq x\leq0.50$, above the complex $x\approx0.15$ composition). The evolution of the magnetic behavior has been investigated and described up to the composition with $x=0.50$. The results obtained allow to extend our understanding of the magnetic and ferroelectric phase diagram up to $x=1$. We have found that the magnetic and ferroelectric properties in the high doping range can be rationalized in terms of the influence of Co atoms on the competition between commensurate collinear (AF4) and incommensurate cycloidal (AF2) spin structures. Finally, powder and single-crystal neutron results are faced to previous resonant magnetic x-ray scattering studies using soft x-rays and full polarization analysis.

TU.A-P94 - Magnetoelectric effect in CoFe alloy/Piezoelectric/CoFe alloy three-layered structures

Multiferroic materials are interesting from both applied and fundamental points of view: there are many applications in microelectronic, magnetic memory devices, sensor technologies and energy harvesting area and at the same time there are few challenges related, for example, interactions between electric and magnetic properties in these materials. Recently much attention has been paid to studies of magnetoelectric effect in layered multiferroic structures, which consist of ferroelectric and ferromagnetic phases. In this work we investigated the magnetoelectric effect in planar composite structures consisting of 3 layers: piezoelectric layer located between two ferromagnetic layers. Piezoelectric material was the same for all structures - Vibrit 1100. Three different types of cobalt-iron alloys were used as ferromagnetic layers. Three-layered structures based on different magnetic materials had various thicknesses: Vacoflux 48 - 0,2 mm, Vacoflux 50 - 0,35 mm and Vacodur 50 - 0,3 mm. The magnetoelectric properties of the three-layered structures with cobalt-iron alloys were compared with three-layered structure with nickel. Magnetoelectric effect was measured using the technique of harmonic modulation of magnetic field. Constant magnetic field was varied in range from 0 to 3000 Oe, amplitude of applied alternating magnetic field was 0-10 Oe and frequency range was 0,1-223 kHz. Resonances were observed at a frequencies of 212,38 kHz, 206,36 kHz, 217,5 kHz and 217,12 kHz for the structures with Ni, Vacoflux 48, Vacoflux 50 and Vacodur 50 layers, respectively. The values of magnetoelectric effect were found to be larger for three-layered structures with cobalt-iron alloys. The magnetoelectric effect magnitude for structure with Ni-ferromagnetic layer was only 0,41 V/(cm*Oe) while the largest magnetoelectric effect value for cobalt-iron alloys structures was 10,25 V/(cm*Oe) - for multiferroic based on Vacoflux 48 material.

TU.A-P95 - Enhanced magnetism and electrical behavior of Co-doped $KNbO_3$

6. Universidad del Cauca, Departamento de Física, Laboratorio de Bajas Temperaturas, Popayán, Colombia

Polycrystalline $KNb_{1-x}Co_xO_3$ (x = 0, 0.05, 0.1) samples were synthesized by standard solid-state reaction and their electrical and magnetic properties carefully studied. Special attention is paid to the thermal treatments in order to obtain a single-phase compound. In this regard, the $KNb_{1-x}Co_xO_3$ pellets have been preheated at 850° C for 12 hours, and then sintered at 900° C for 12 hours in air atmosphere. The X-ray diffraction patterns of the Co-doped samples show a systematic shift of their peaks to the right side as compared to those of the pristine compound (x=0). Morphological analysis of the compounds evidences that the crystallite size increases by increasing Co content. The magnetic response of the pellets is detected by sensible measurements of the magnetization as a function of the temperature and external magnetic field. An increased ferromagnetism by Co-doping is observed at temperatures as high as room temperature. In turn, measurements of the resistivity as a function of the magnetic field show high values of the magnetoresistance. In adition, the dielectric and conducting properties of the samples were studied by means of complex impedance spectroscopy at temperatures above 300 K. Measurements of the electric polarization as a function of the electric field indicate the presence of ferroelectricity in the analyzed samples.

TU.A-P97 - Electric tuning of magnetization dynamics and negative magnetic permeability in nanoscale composite multiferroics

C. Jia [1]

1. Lanzhou University, Lanzhou, China

Steering magnetism by electric fields upon interfacing ferromagnetic (FM) and ferroelectric (FE) materials to achieve an emergent multiferroic response bears a great potential for nano-scale devices with novel functionalities.
FM/FE heterostructures allow, for instance, the electrical manipulation of magnetic anisotropy via interfacial magnetoelectric (ME) couplings. A charge-mediated ME effect is believed to be generally weak and active in only a few angstroms. Here we present an experimental evidence uncovering a new magnon-driven, strong ME effect acting on the nanometer range. For Co$_{92}$Zr$_{8}$ (20 nm) film deposited on ferroelectric PMN-PT we show via ferromagnetic resonance (FMR) that this type of linear ME allows for electrical control of simultaneously the magnetization precession \emph{and} its damping, both of which are key elements for magnetic switching and spintronics. The experiments unravel further an electric-field-induced negative magnetic permeability effect, pointing so to a new class of optical negative-index metamaterials based on multiferroics.

TU.A-P98 - Stabilization of the multiferroic spin cycloid in Ni_3V_2O by light Co-doping

Multiferroic lightly Co-doped $Ni_3V_2O_8$ was investigated by macroscopic measurements and neutron diffraction on single-crystal samples. Doping Co into the parent compound suppresses the sequence of four magnetic phase transitions [1], and only two magnetically ordered phases - the paraelectric high-temperature incommensurate (HTI) phase and the ferroelectric low-temperature incommensurate (LTI) phase - can be observed. Interestingly, the LTI multiferroic phase with a cycloidal magnetic structure is stabilized down to at least 1.8 K. The resulting symmetry-adapted magnetic structures of both phases show subtle differences to those observed in the parent compound. The stabilization of the LTI phase together with a wider temperature stability range of the HTI phase in comparison to Ni_3V_2O can be explained by a simple model [2], which takes into account the interplay between the single-ion easy-axis anisotropy due to Co doping and the ratio between the competing next-nearest-neighbor and nearest-neighbor interactions.

We have explored the preparation of different transition metal oxides with double perovskite structure with the aim of obtaining insulating materials with ferromagnetic order with high Curie temperature. New ferromagnetic insulating (FM-I) materials are interesting as candidates for active insulating barriers in spin filters. We have started with two known systems: La2CoMnO6 and La2NiMnO6. The first one was prepared by solid state reaction and the second one by the sol-gel method in order to favor cationic ordering and reducing sintering temperature. In both cases, x-ray diffraction measurements disregard the presence of impurities. The degree of cationic ordering has been estimated from low temperature magnetic properties. The use of alternative 3d cations is currently under investigation with the aim to prepare new FM-I materials with Curie points above RT.

TU.A-P100 - Local electrical control of the Ferromagnetic/Antiferromagnetic transition in FeRh just above room temperature

Coupling between different ferroic orders in artificial multiferroic structures might allow electrical control of macroscopic magnetic properties such as for example magnetization and coercive field. Here we show by means of element specific X-Ray PEEM microscopy the possibility to locally switch (isothermally) by means of a voltage between the ferromagnetic and antiferromagnetic phase of epitaxial FeRh thin films grown on top of ferroelastic BaTiO3 [Ref. 1]. The resultant magnetoelectric coupling is larger and more reversible than previously reported from macroscopic measurements [Ref. 2]. Our results emphasize the importance of nanoscale ferroic domain structure and the promise of first-order transition materials to achieve enhanced coupling in artificial multiferroics.

TU.B-P01 - Study of d-electron correlations in skutterudite-related $Ce_3M_4Sn_{13}$ (M = Co, Rh, and Ru)

Andrzej Ślebarski [1], J. Goraus [1], P. Witas [1], L. Kalinowski [1], M. Fijałkowski [1]

1. Institute of Physics, University of Silesia, Katowice, Poland

In the past few years, the number of intermetallic compounds based on rare earth and transition metals and having coexistence of f- and d-electron correlations increases [1]. We present the electric transport, thermodynamic properties and electronic structure of $Ce_3M_4Sn_{13}$ heavy fermions, where M is d-electron metal (Co, Rh, and Ru). A comparison of DFT electronic structure calculations and the XPS data gives evidence for strong Coulomb correlation among metal M d-electron states. We note the large impact of d-electron correlation, which is clearly observed in the change of Ce 5p states located about 18 eV in the valence bands. The influence of the d-electron correlations is also manifested by the positive magnetoresistivity of $Ce_3Rh_4Sn_{13}$, $Ce_3Ru_4Sn_{13}$ and the La-doped alloys, and strong enhancement of the low-temperature electronic specific heat coefficient in C(T)/T data.

In this work, we report Electron Spin Resonance (ESR) studies on the α-$YbAl_{1-x}Fe_xB_4$ (x < 0.55) heavy fermions series and on their reference compound α-$LuAlB_4$.
For all studied compounds, the observed ESR signal strikes as a Conduction Electron Spin Resonance (CESR) response in the entire temperature range (10 K ≤ T ≤ 300 K). This observation is in clear contrast to the behavior found in the heavy fermion superconductor (T_c ~ 0.8 K) β-$YbAlB_4$, for which a striking and unprecedented ESR signal was found. This unusual ESR response (named *Kondo quasiparticles spin resonance* (KQSR))[1] behaves as a CESR at high temperatures and acquires characteristics of the Yb^{3+} local moment ESR at low temperature. We discuss the difference between the ESR responses in β-$YbAlB_4$ and α- $YbAl_{1-x}Fe_xB_4$ (x < 0.55) considering the fact that proximity to a quantum critical point may be essential to the occurrence of a KQSR signal.

6. Max Planck Institute for Solid State Research, Stuttgart, Germany

The microscopic magnetic nature of a novel A-site ordered chromium perovskite, $LaCu_3Cr_4O_{12}$, has been studied with muon-spin rotation and relaxation (\muSR) measurements down to 1.8 K using a powder sample. Here, the sample was synthesized with a high-pressure technique above 6 GPa and 1200 C [1]. In the $LaCu_3Cr_4O_{12}$ lattice, the 3/4 of the A site are occupied by Cu2+ ion so as to make isolated CuO4 planes [2]. Since the related compounds, $CaCu_3Ru_4O_{12}$ [3] and $CaCu_3Ru_4O_{12}$ [4], show a heavy-fermion like behavior without magnetic order down to the lowest temperature measured, the A-site ordered perovskites are thought to be a candidate for exhibiting a quantum phase transition.
Magnetization and resistivity measurements indicated the presence of a magnetic transition at Tm=220 K together with a metal-to-metal transition [1]. Moreover, since the magnetization versus temperature curve showed a step-like decrease at Tm with decreasing temperature, it was thought that a spin-singlet like state is formed below Tm. However, \muSR measurements demonstrates the appearance of static antiferromagnetic (AF) order below Tm, i.e. Tm=TN. Thus, both negative chemical pressure and electron-doping due to the substitution for Ca by La is found to induce AF order, implying the presence of a quantum phase transition in this system.

The local electronic structure of the f electrons in Kondo-insulating materials is known to be of major importance for transport and magnetic properties, and in particular for the generation of the hybridization gap. CeNiSn, one of the first narrow-gap Kondo semiconductors, has been intensively studied in the past [1] and many explanations for the low-temperature behavior have been suggested, all of which stress the significance of the 4f crystal-field ground state [2-4]. However, an unambiguous direct experimental detection of the ground state is still pending. By exploiting the potential of polarization-dependent x-ray absorption spectroscopy at the Ce M4,5 edge at low temperature [5], we have determined the crystal-field ground-state wave function of CeNiSn. Furthermore, the energies of the excited Kramers' doublets can be estimated from the temperature dependence of the linear dichroism. The obtained crystal-field scheme is in good agreement with a possible solution found for Cu-doped CeNiSn [6] and supports the theoretical framework of Moreno and Coleman [4] for the understanding of the narrow pseudo-gap and the low-temperature characteristics of the Kondo-insulating behavior.

TU.B-P08 - Transport properties of Field-Insensitive Heavy-Fermion Compound $SmTa_2Al_{20}$

A. Yamada [1], R. Higashinaka [1], T.D. Matsuda [1], Y. Aoki [1], H. Sato [1]

1. Department of Physics, Tokyo Metropolitan University, Tokyo, Japan

RT2X20 (R: rare earth, T :transition metal, X :Al and Zn) crystallizing in the cubic $CeCr_2Al_{20}$-type structure with the space group #227, have attracted much attention due to their novel physical properties. In SmT2Al20 family, Kondo-like behaviors unusually insensitive to magnetic field (such as -logT dependent resistivity and large mass enhancement) were found, suggesting a non-magnetic mechanism of the formation of the heavy-fermion state. In order to reveal the origin of the field-insensitive nature, we performed detailed studies of electrical transport properties in $SmTa_2Al_{20}$, putting emphasis on the field dependence, and those of La-substitution for Sm site. We found transverse magnetoresistance (MR) roughly follows H^2 dependence in low-field condition in $SmTa_2Al_{20}$, which indicates that the suppression of Kondo scattering by magnetic field is quite small compared with the positive ordinary MR due to the cyclotron motion of conduction electrons. We also found strong deviation from Kohler's rule (i.e. strong enhancement of MR with decreasing temperature down to the lowest temperature, 0.5 K). In the same temperature range between 2 and 50 K, Hall coefficient shows evident temperature dependence. These facts indicate that the scattering probability of conduction electrons has a huge wave-number dependence in the ground state. Furthermore, we have confirmed that such field-insensitive behaviors appear even in the Sm-diluted system.

TU.B-P09 - Powder x-ray diffraction study of caged magnetic compound $DyFe_2Zn_{20}$ at low temperature

N. Kishii [1], S. Tateno [1], M. Ohashi [1], Y. Isikawa [2]

1. Kanazawa University, Kanazawa, Japan
2. Toyama University, Tayoma-Takaoka, Japan

High-angle X-ray powder diffraction measurements show that the crystal structure of the caged magnetic compound $DyFe_2Zn_{20}$ is tetragonal while almost all RT2X20 compounds are cubic. The lattice parameters were estimated at temperatures between 14 K and 300 K. No structural transition was observed and the ratio between the a- and c-axes was found to be almost constant, i.e. $c/a \sim 0.989 \pm 0.0034$ between 14 K and 300 K. The large magnetic anisotropy observed may be related to the low structural symmetry of $DyFe_2Zn_{20}$.

TU.B-P10 - Itinerant-Localized Transitions in Magnetic Phases of the Periodic Anderson Model

K. Kubo [1]

1. Advanced Science Research Center, Japan Atomic Energy Agency, Ibaraki, Japan

In recent years, Fermi-surface reconstruction, which is called a Lifshitz transition, has been discussed as a possible origin of anomalies in magnetic phases of several f-electron materials. To clarify the characteristics of the Lifshitz transitions, we investigate magnetically ordered states of the periodic Anderson model by applying the variational Monte Carlo method. As variational wavefunctions, we use the Gutzwiller wavefunctions for the paramagnetic, antiferromagnetic, and ferromagnetic states. For each state, we evaluate energy and determine the variational parameters in the wavefunction which minimize energy. Then, we compare energy between different magnetic states.
Around half-filling, we find an antiferromagnetic phase, and far away from half-filling, we find a ferromagnetic phase as the ground state. Inside the both magnetic phases, Lifshitz transitions take place. At the Lifshitz transitions, the sizes of the ordered moments change. In order to understand the transitions further, we also analyze the f-electron contribution to the Fermi surface by evaluating the jumps in the momentum distribution function at the Fermi momenta. Then, we find that, in the large ordered-moment states, the f-electron contribution to the Fermi surface becomes small. This observation clearly shows that these Lifshitz transitions are itinerant-localized transitions of the f electrons.

TU.B-P11 - Double-k commensurate magnetic order in $NdFe_2Al_{10}$

J. Robert [1], F. Damay [1], K. Saito [1,3], A.M. Bataille [1], F. Porcher [1], G. André [1], A. Gukasov [1], J.M. Mignot [1], H. Tanida [2], M. Sera [2]

1. Laboratoire Léon Brillouin, CEA-CNRS, CEA/Saclay, Gif sur Yvette, France
2. Department of Quantum Matter, ADSM, Hiroshima University, Higashi-Hiroshima, Japan
3. Present address: Institute of Materials Structure Science, KEK, 1-1 Oho, Tsukuba, Ibaraki, Japan

The orthorhombic compound NdFe2Al10 has been studied by powder and single-crystal neutron diffraction [1]. Below TN = 3.9 K, the Nd3+ magnetic moments order in a double-k [k1 = (0, 3/4, 0), k2 = (0, 1/4, 0)] collinear magnetic structure, whose unit cell consists of four orthorhombic units in the b direction. The refinements show that this structure consists of (0 1 0) ferromagnetic planes stacked along b, in which the moments are oriented parallel to a (the easy anisotropy axis according to bulk magnetization measurements) and nearly equal in magnitude (approx. 1.7–1.9 Bohr magneton). The alternating eight-plane sequence providing the best agreement to the data turns out to be that which yields the lowest exchange energy if one assumes antiferromagnetic near-neighbor exchange interactions with J1 >> J2, J3. With increasing temperature, the single-crystal measurements indicate the suppression of the k2 component at T = 2.7 K, supporting the idea that the anomalies previously observed around 2–2.5 K correspond to a squaring transition. In a magnetic field applied along the a axis, the magnetic Bragg satellites disappear at Hc = 2.45 T, in agreement with earlier measurements. Comparisons are made with related magnetic orders reported previously for CeT2Al10 (T = Ru, Os) [2] and $TbFe_2Al_{10}$ [3].

TU.B-P12 - $CeRh_6Si_4$: An intermediate valent cerium compound

T. Gruner [1], C. Geibel [1]

1. Max Planck Institute for Chemical Physics of Solids, Dresden, Germany

The ternary Ce-Rh-Si system comprises a huge number of compounds crystallising in different structure types and with a broad spectrum of properties. Particularly interesting is the change of the Ce-valence from stable trivalent Ce with completely localized 4f electrons, as e.g. in $CeRh_3Si_2$ [1], to a strongly intermediate valence state with fully delocalised 4f electrons, as e.g. in CeRh3. While the binary Ce-Si and Ce-Rh compounds show a continuous evolution of the valence as a function of Rh or Si content, presently available results for ternary compounds do not indicate a simple relation between composition and valence. Here we present a study of the compound $CeRh_6Si_4$. It crystallises in a rather simple hexagonal structure [2], in which the Ce sublattice presents some quasi-one-dimensional character which might lead to interesting properties. The presence of four different CeRhxSiy compounds in a very small composition region makes the preparation of pure $CeRh_6Si_4$ delicate. By starting from a slightly off-stoichiometric composition, we were able to prepare rather pure samples as evidenced by energy-dispersive X-ray spectroscopy, powder X-ray diffraction, and a comparatively high residual resistivity ratio of 31. Analysis of magnetic susceptibility and X-ray LIII absorption edge measurements indicate an intermediate valent state, with a Ce valence of approximately 3.2 and a characteristic energy of about 260K. Thus the f-hybridisation is much stronger in $CeRh_6Si_4$ than in the nearby $CeRh_3Si_2$. We analyse the expected relation between distance to ligands and 4f-hybridisation by comparing a number of Ce-Rh-Si compounds.

TU.B-P13 - Thermodynamic properties of $CeRh_2Si_2$: Evidence for a meta-orbital transition?

P. Kushwaha [1], N. Caroca-Canales [1], D.V. Vyalikh [2], C. Geibel [1]

1. Max Planck Institute for Chemical Physics of Solids, Dresden, Germany
2. Institute of Solid State Physics, Dresden University of Technology, Dresden, Germany

$CeRh_2Si_2$ is an intensively studied antiferromagnetic Kondo lattice system, which presents a striking duality in the properties of the 4f electrons: The large 4f entropy of Rln2 just above TN = 35 K and the large value of the ordered moment mAF = 1.4 muB points to a fully localized 4f electron, while other properties, e.g. the width of the quasi elastic line in inelastic neutron scattering (INS), indicate a Kondo scale of about 33 K implying a significant 4f hybridization. We have determined the 4f specific heat of $CeRh_2Si_2$ up to 300 K and analyzed the data using a standard approach with three crystal electric field (CEF) doublets subject to different Kondo scales. This analysis confirms the contradiction between TK = 33 K as deduced from INS and the large entropy just above TN, and indicates that the excited CEF levels are very broad in energy. It implies a strong hybridization for at least one of the excited CEF level, as recently suggested by photoemission spectroscopy. Our analysis indicate that the simple standard picture for Kondo lattice is not applicable for $CeRh_2Si_2$. By combining our results with previous ones obtained under pressure, we show that the Kondo scales has to increases strongly within the small pressure range between P = 0 and the critical pressure Pc at which antiferromagnetism is suppressed, in contrast to other Kondo lattice systems. This indicates that the simple Doniach scenario is not applicable, and that a further mechanism is needed to account for the properties of $CeRh_2Si_2$ near Pc. The combination of large entropy at TN, strong hybridization of an excited CEF level, and large increase of TK in the small pressure range up to Pc suggest the occurrence of a meta-orbital transition.

TU.B-P14 - Heavy fermion behavior in itinerant ferromagnet $CeCrGe_3$ and possible existence of a quantum bi-critical point in $CeCr_{1-x}Ti_xGe_3$

Z. Hossain [1], D. Das [1], T. Gruner [2], C. Geibel [2]

1. Department of Physics, Indian Institute of Technology, Kanpur, India
2. Max-Planck Institute for Chemical Physics of Solids, Dresden, Germany

New and exotic phases including unconventional superconductivity are often discovered near quantum critical point (QCP). It is widely believed that magnetic fluctuations near the QCP play a key role in stabilizing the superconductivity in a wide class of materials like heavy fermions, pnictides, high Tc cuprates etc. Ce based intermetallic compounds are of particular interest for studying quantum phase transition as the magnetism of Ce-compounds can quite conveniently be tuned by doping or by applying pressure. Many Ce-based compounds have been investigated and tuned toward QCP. However, ferromagnetic (FM) QCPs in Ce-compounds are quite rare. In this context, our discovery of heavy fermion behaviour in the trivalent Ce compound $CeCrGe_3$ is quite remarkable. It exhibits enhanced value of Sommerfeld coefficient (~ 130 mJ/mol/K2) and FM ordered state due to the ordering of itinerant Cr moments (Tc=70K)[1]. Moreover, our attempt to suppress the FM ordering of Cr by Ti substitution strongly suggests a possible existence of a quantum bi-critical point in this system[2]. We have performed a systematic study on polycrystalline $CeCr_{1-x}Ti_xGe_3$ ($0 < x < 1$) using magnetic susceptibility, isothermal magnetization, specific heat and electrical resistivity measurements[1,2]. Our results also show that upon Ti substitution the Cr- ordering temperature is gradually suppressed down to TC = 7K for x = 0.7K beyond which Ce moment ordering starts to dominate and a crossover between Cr and Ce moment ordering is observed[2].

Photoemission spectroscopy (PES) has been shown to be very powerful in determining valences and configuration interaction parameters of heavy fermion compounds. However, the surface sensitivity has always been a big drawback [1]. Using hard x-rays which are available at third generation synchrotrons increases the probing depth so that bulk representative results can be obtained [2]. We have performed such hard x-ray core level PES (HAXPES) experiments at the Taiwan beamline BL12XU at Spring-8 in Japan with incident photon energy of 6.47 keV. Several heavy fermion and intermediate valence compounds were probed and their 4f occupancy and configuration interaction parameters have been quantitatively determined by combining full multiplet calculations with an Anderson Impurity Model (AIM) within a single ligand state approximation [3]. This combination has the advantage that even strong plasmon excitations in the spectra can be corrected for. Results for intermediate valent $CePd_3$ [4], the ferromagnetic and strongly hybridized giant crystal-field system $CeRh_3B_2$ [5], the heavy fermion compounds $CeRu_2Si_2$ [6] and $CeMIn_5$ with M=Co, Rh, and Ir [7] will be shown. We find 4f0 contributions of 22% for $CePd_3$, 14% for $CeRh_3B_2$, 7% for $CeRu_2Si_2$ and of only 3-5% for the three $CeMIn_5$ compounds. In particular the Ce 3d HAXPES data of the latter family suffer from strong plasmons.

3. Institute for Solid State Physics, University of Tokyo, Tokyo, Japan

Stoichometric samarium dihydride (SmH_{2+d}) has been known as an antiferromagnet with T_N=9.7 K from the magnetic susceptibility measurement[1]. T_N was determined to be 9.6 K from the temperature dependence measurement of the resistivity [2]. For superstoichiometric case (d>0), T_N decreases as d increases[2], and is 8 K at d=0.16. Temperature effect on the resistivity at T_N becomes broad. For stoichiometric case (d=0), T_N is determined to be 6.75 K from specific heat measurement [3]. An analysis of the specific heat data suggests that stoichometric samarium dihydride may have the mixed valence with ground state G_7[3]. However a non-negligible value of d is possibly present in their sample[4]. In the previous study, we reported the grand state of the G_7 and the mixed valence of superstoichiometric samarium dihydride(SmH_{2+d}:d=0.16) [5]. However, it was insufficient consideration for Sm^{3+} of Van Vleck term. In the present study, We fully take into account the Van Vleck term and newly analyzed the grand state of the crystal field from the magnetic susceptibility measurement newly performed in the paramagnetic region ($T>T_N$). We have carried out the fitting procedure of the specific heat of paramagnetic region. In follows from the present analysis that in $SmH_{2.16}$, all Sm ion are Sm^{3+} having ground state G_8 and the Sommerfeld coefficient g is 150 mJ/(K^2 mole).

TU.B-P18 - Relation between Heavy Quasi Particles and Crystal Electric Field Multiplet in f2-Configuration Based Systems

T. Hinokihara [1], A. Tsuruta [2], K. Miyake [3]

1. Department of Physics, University of Tokyo, Bunkyo-ku, Japan
2. Department of Materials Engineering Science, Osaka University, Osaka, Japan
3. Toyota Physical and Chemical Research Institute, Nagakute, Japan

Heavy electron systems with f2-configuration basis such as U compounds are known for showing various phases which depend on the crystalline electric field (CEF) multiplet. In order to discuss such various phases, it is significant to analyze quasiparticle states and interaction between quasiparticles in f2-configration based system. We analyzed quasiparticle energy levels and renormalization factors in three orbital (j=5/2) periodic Anderson model with CEF effect. We calculated the system by using slave boson mean field approximation which is introduced auxiliary boson operators up to triple occupied states at each local site. As a result, we clarified the several quasiparticle bands which related to CEF ground state are strongly renormalized. In addition, an enormous flat band which is inconsistent with renormalization factor appears at Fermi energy because of several quasiparticle energy levels tend to degenerate at Fermi energy. This result suggests the direct hopping between f-electrons becomes effectively significant to a shape of Fermi surface at heavy Fermi liquid state in the f2-configuration based system. It is possible to explain the Fermi surface structure and heavy effective mass in UPt3 .

TU.B-P19 - Break-Junction tunneling spectroscopy of Kondo semiconductors semiconductors CeT2Al10 (T = Fe, Os)

4. Liberal Arts and Sciences, Faculty of Engineering, Toyama Prefectural University, Izumi, Japan

The Kondo semiconductor $CeOs_2Al_{10}$ exhibits an antiferromagnetic (AFM) order at T_N = 28.5 K, whose temperature is unexpectedly high for the small ordered moment of 0.3 m_B/Ce [1,2]. On cooling below 60 K, opening of a hybridization gap of 30 meV was observed by polarized optical conductivity [3] and photoemission measurements [4]. At around 38 K ($T > T_N$), openings of a charge gap of 20 meV and a spin gap of 11 meV were observed, respectively, by polarized optical conductivity [3] and inelastic neutron scattering [2] experiments. For better understanding of the relationship between these gap openings and the unusual AFM order, we have performed a tunneling spectroscopic study of single crystals of $CeFe_2Al_{10}$ and $CeOs_2Al_{10}$ by the break-junction technique [5]. For $CeFe_2Al_{10}$ without AFM, we observed two distinct gaps with V_1 = 600 mV and V_2 = 150 mV, where V represents the peak-to-peak voltage difference in the tunneling conductance in the semiconductor - insulator - semiconductor design of the break junction. The former gap appears at $T < 60$ K and the later develops at $T < 30$ K. In $CeOs_2Al_{10,}$ we observed three structures; V_1 = 400 mV appearing at $T < 60$ K is the *c-f* hybridization gap, V_{AF} = 200 mV at $T < T_N$ is attributable to AFM, and the development of V_2 = 100 mV at $T < 16$ K coincides with the semiconducting increase in the resistivity. The magnitude of V_1 and V_2 in $CeFe_2Al_{10}$ are 1.5 times larger than those in $CeOs_2Al_{10,}$ respectively. This result is consistent with the higher T_K in $CeFe_2Al_{10}$ than in $CeOs_2Al_{10}$. For both compounds, no significant anisotropy was observed neither in the gap value nor the opening temperature.

We present an inelastic neutron scattering study of the influence of isoelectronic Tm substitution on the low-energy structure and temperature dependence of the dynamical magnetic response in $Yb_{1-x}Tm_xB_{12}$ (x = 0, 0.08, 0.15, and 0.75) and $Lu_{0.92}Tm_{0.08}B_{12}$ solid solutions [1].
Substantial changes have been observed in the spectral structure and temperature evolution of the Yb contribution to the inelastic response for a rather low content of magnetic Tm ions. The spin-exciton-like resonance mode near 15 meV is steeply suppressed at the lowest measured Tm concentration (x = 0.08). The spin gap is replaced by a pseudogap at concentrations lower than 0.15. These results point to a specific effect of impurities carrying a magnetic moment (Tm, as compared to Lu or Zr) in a Kondo insulator, which is thought to reflect the "under-compensation" of Yb magnetic moments, originally screened in pure YbB_{12}.
A parallel is made with the strong effect of Tm substitution on the temperature dependence of the Seebeck coefficient in $Yb_{1-x}Tm_xB_{12}$, which was reported previously [2].

Using inelastic neutron and x-ray scattering, we looked for signs of incipient symmetry breaking in the lattice and magnetic excitations of URu_2Si_2. The phonons do not show any dramatic temperature dependence. New measurements of the magnetic excitations allow us to estimate the effective moment responsible for the dynamic susceptibility in the hidden order phase. The magnetic excitations resemble the effects of strong electron correlations, whose overall symmetry looks the same above and below the hidden order phase transition.

TU.B-P22 - Magnetic order in USb2 at high pressures

J. Jeffries [1], N. Butch [2], R. Stillwell [1], S. Weir [1]

1. Lawrence Livermore National Laboratory, Livermore, United States
2. NCNR, National Institute of Standards and Technology, Gaithersburg, Maryland

USb_2 is a member of the uranium dipnictide family, and exhibits antiferromagnetism at the relatively high temperature of 203 K. Strong anisotropy in the physical properties has been measured and predicted, including two-dimensional electronic structure. These observations point to strong hybridization of the U 5f states, and suggest that high pressures could substantially perturb the magnetic state and electronic structure of the system. Though the uranium dipnictides have been studied extensively at ambient pressure, few studies have applied significant pressures to these materials. In this presentation, we will report high-pressure electrical transport and structural characterization of USb2 using diamond anvil cell techniques.

CeT_2X_2 compounds, where T = transition d-metal and X = p-metal, crystallizing in centro-symmetric CaBe2Ge2-type tetragonal structure form relatively large family of intermetallics with a variety of interesting electronic properties. The electronic ground state in these compounds strongly depends on the competition between the RKKY and Kondo interaction, but also on the influence of the crystal electric field on the single 4f electron of Ce. The strong interaction between crystal field (CF) excitons and lattice vibrations in $CePd_2Al_2$ leading to the additional peak in energy spectrum (vibron quasi-bound state is formed) [1] is another highly interesting property of CeT_2X_2 compounds. The presented study focuses on $CePd_2Al_{2-x}Ga_x$ compounds, investigated by means of bulk measurements and mainly inelastic neutron scattering experiments. The change of the crystal structure from tetragonal to orthorhombic (for Al rich compounds [1]) or triclinic (for Ga rich compounds [2]) and its influence on the vibron state in these compounds is discussed. The non-magnetic La analogues, undergoing the same structural phase transitions as their cerium counterparts, were investigated as well. The temperature of this structural transition is much higher in the La-counterparts than in Ce-based compounds for $x<0.8$, whereas for $x>1.0$, the opposite trend is observed. The energy spectrum of tetragonal $CePd_2Al_2$ exhibits three CF-like peaks at energies 1.5, 7.4 and 16 meV. First peak is shifted by structural transition (to orthorhombic structure) to 3.7 meV, while the others remain at almost the same energy. Similar behavior is observed also for compound with $x=0.8$, whereas for the rest of the series only two CF peaks were found.

TU.B-P24 - Valence fluctuation mediated quantum criticality in heavy fermions

R.U.H. Wani [1], N. Rao Dasari [2], V. N.S. [3]

1. Jawaharlal Nehru Center for Advanced Scientific Resaerch, Karnataka, India
2. TSU, JNCASR, Bangalore, India
3. TSU, JNCASR, Bangalore, India

Spin fluctuations lead to quantum criticality in heavy fermion systems in which there are many competing interactions like Kondo interaction, RKKY interaction and the effect of lattice coherence. However it is charge/valence degree of freedom rather than spin which is associated with quantum criticality in certain heavy fermion systems. To capture the effect of valence fluctuations in these systems we have investigated extended Periodic Anderson(e-PAM) model within the framework of dynamical mean field theory(DMFT) using continous time quantum Monte Carlo(CT-QMC) as an impurity solver. In the e-PAM there is an additional repulsive interaction Uf c between localized f electrons and conduction electrons. In our preliminary calculations we have found that f level occupancy decreases as we increase the orbital energy of f electrons and this decrease becomes very steep at higher values of Uf c .

TU.B-P25 - Quantum Criticality and Valence Fluctuation Study for Ce- and Yb-based Compounds Probed by 3d-2p Resonant X-ray Emission Spectroscopy

N. Kawamura [1], H. Tonai [2], M. Mizumaki [1], T. Uozumi [2], S. Watanabe [3]

1. Japan Synchrotron Radiation Research Institute (JASRI/SPring-8), Sayo-gun, Japan
2. Osaka Prefecture University, Sakai, Japan
3. Kyushu Institute of Technology, Kitakyushu, Japan

Recently, quantum criticality for Ce- and Yb-based compounds in the heavy fermion (HF) system has been discussed from a viewpoint of valence fluctuation [1]. In this vision, the valence state (f electrons; vf) and d-f intra-atomic interaction (Udf) are important parameters to explain several anomalous phenomena observed near the quantum critical point (QCP). To determine parameters vf and Udf for several Ce and Yb compounds, resonant X-ray emission spectroscopy (RXES) measurement at Ce and Yb L3-edge (2p-4f, 5d excitations) has been performed at BL39XU of SPring-8, and theoretical calculation based on the impurity Anderson model (IAM) combined with a first principle band structure calculation has been used to analyze the experimental results. To verify the applicability of IAM framework, RXES spectra for CeO_2 are analyzed and vf and Udf values are estimated. The RXES spectrum around pre-edge region of X-ray absorption spectroscopy (XAS), which is necessary to determine Udf value, is well reproduced by the calculation. The parameters vf = 0.59 and Udf = 3.0 eV are estimated through the IAM analysis of the spectra. Moreover, the parameters obtained by the calculation well reproduce the experimental results for not only high-resolution XAS spectrum (partial fluorescence yield; PFY) but also X-ray photoemission spectrum and RXES for 3d core [2, 3]. The vf and Udf values for the Ce- and Yb-based HF compounds with $ThCr_2Si_2$-type structure are mainly estimated by analyzing RXES and PFY spectra to discuss the quantum criticality from a viewpoint of valence fluctuation mechanism.

TU.B-P26 - Isotropic magnon dispersion in A-type $CeCu_2Si_2$

Z. Huesges [1], K. Schmalzl [2], C. Geibel [1], F. Steglich [1], O. Stockert [1]

1. MPI Chemical Physics of Solids, Dresden, Germany
2. Institut Laue-Langevin, Grenoble, France

Paramagnons are supposed to provide the pairing glue for unconventional superconductors, not only for the cuprates, but also for heavy-fermion superconductors. For $CeCu_2Si_2$ there is indeed good evidence from inelastic neutron scattering that spin fluctuations drive the superconductivity, which has been studied by comparing the spin susceptibility in the normal and the superconducting state [1,2]. An interesting question is the relation of the paramagnons to the magnons in the antiferromagnetic state. Recently Le Tacon et al. have measured the dispersion of several members of the $YBa_2Cu_3O_{6+x}$ family and found a striking similarity of the magnons in the antiferromagnetic parent compound with paramagnons in samples of varying doping levels [3]. Here, we present the measurement of the magnon dispersion in A-type $CeCu_2Si_2$ by inelastic neutron scattering, and compare it to previous results of S-type crystals [1,2]. We find that the dispersion is almost identical in the antiferromagnetic state, in the paramagnetic state of A-type $CeCu_2Si_2$ (T just above TN) and in the paramagnetic state of S-type $CeCu_2Si_2$ (B above Bc2). The inelastic response only differs in the correlation length and lifetime, which are increased in the ordered state, and the magnitude of the susceptibility, which is enhanced for the A-type crystal due to a weakening of the Kondo effect. In contrast to the cuprates, the magnetism in $CeCu_2Si_2$ is 3-dimensional, evident from the nesting-driven ordering vector of (0.22 0.22 0.52). Thus we have measured the dispersion not only along [110], but also along [001]. We find that the dispersion and the correlation length are very similar for both directions, confirming the 3D-nature of magnetic interactions in $CeCu_2Si_2$.

TU.B-P27 - Magnetic properties of heavy fermion antiferromagnet YbRhGe

S. Nakamura [1], K. Araki [2], K. Katoh [2], T. Nojima [1], A. Ochiai [3]

1. IMR, Tohoku University, Sendai, Japan
2. Dept. Appl. Phys., National Defense Academy, Yokosuka, Japan
3. Dept. Phys., Tohoku University, Sendai, Japan

We investigate magnetic properties and magnetic phase transitions of heavy fermion antiferromagnet (TN=5.9 K) YbRhGe down to 0.5 K and up to 8 T. YbRhGe is the ternary compound having an orthorhombic TiNiSi-type crystal structure which belongs to space group Pnma. The Rh and Ge ions compromise hexagons nearly parallel to the ab-plane and the Yb ions form zigzag chains along the c-axis. YbRhGe is interested as a spin system with characteristic crystal structure where the Kondo effect and the antiferromagnetic RKKY interaction compete with each other. Recently, an additional phase transition was found by specific heat measurements at 1 K. However, details of magnetic properties of YbRhGe at low temperatures have been revealed yet. We have synthesized single crystals of YbRhGe and measured magnetic properties by using SQUID magnetometers and a faraday magnetometer. The magnetic susceptibility for H//a rapidly increases with decreasing temperature below 3 K and becomes to be temperature independent below 1 K. This indicates an antiferromagnetic order at 1 K. Both the spin structure of the local moments and the degrees of magnetic freedom carried by the heavy Fermi liquid may change at this additional phase transition temperature. The magnetization processes of YbRhGe at 0.5 K indicate multi-transitions in the spin structure. Spin flips have been observed not only in the fields directed along the hard axis (c-axis) but also in the fields along the easy axis (a-axis). The complex magnetization processes strongly suggest competitive RKKY interactions in the spin system.

TU.B-P28 - Magnetic properties of a novel $CeCo_{0.715}Si_{2.285}$ compound

J. Moudrik [1], J. Prokleška [1], I. Císarova [2], J. Pospíšil [1], V. Sechovský [1], M. Klicpera [3], B. Ouladdiaf [3]

3. Institut Laue-Langevin, Grenoble, France

We report on the basic physical properties of a novel $CeCo_{0.715}Si_{2.285}$ compound, mainly its rich magnetic phase diagram. Using the Czochralski method (single) crystals have been grown for the first time. The compound crystallizes in the I-42m space group structure with extremely prolongated unit cell (a=4.12A, c=32.84A).
In a zero magnetic field it orders antiferromagnetically at TN=10.5K with another order-to-order transition at 9.5K. Under application of a magnetic field along the c-axis it manifests numerous magnetic phases in small fields (B<500mT), similar to the so-called 'devil's staircase' systems, however, having the high field state stable with respect to field removal. Above 1T the magnetization is almost unchanged up to 14T (maximum magnetic field applied within our study) and quite reduced (0.3muB/Ce) with respect to the free Ce^{3}+ ion. The compound also exhibits strong hysteresis of magnetization in temperature and magnetic field. For fields applied along the a-axis a typical behavior for the antiferromagnetic hard axis is observed.

TU.B-P29 - Magnetic and Electronic properties of RCr$_{2}$Al$_{20}$

T. Namiki [1], S. Tsuchimoto [1], Q. Lei [1], K. Nishimura [1]

1. University of Toyama, Tayoma, Japan

Recently, cage-structured compounds such as filled skutterudites have attracted much attention due to the novel properties such as the heavy fermion behavior and the first observation of unconventional superconductivity in the Pr-based filled skutterudites, and multiple ordering. These novel properties are coming from the low-lying crystal electric field (CEF) due to the crystal structure. Among them, the compounds RT_2Al_{20} (*R*: rare earth, *T*: transition metal) also have the caged and cubic structure. These compounds also show the novel properties. However, only a few compounds (R = Pr, Sm) are studied. To clarify these novel properties, systematic studies are important. Recently, we were succeeded in growing new RCr_2Al_{20} (*R*: Nd, Ho) crystals, and studied magnetic and electronic properties. RCr_2Al_{20} were made by the arc melting method. The obtained samples were measured by the Powder X-ray diffraction analysis. Most of the observed diffraction lines are indexable using $CeCr_2Al_{20}$ type structure and lattice parameters are determined. The obtained values are consistent with previous reports. The temperature dependences of the resistivity ρ for RCr_2Al_{20} show the metallic behaviors down to ~2 K, and no anomaly is observed. The residual resistivity ratio (RRR) becomes ~ 3.

TU.B-P30 - Strong ferromagnetism at the surface of an antiferromagnet EuRh2Si2

Layered compounds are possible candidates for quasi-two dimensional phenomena both in the bulk and particularly at the surface . Here we consider the tetragonal antiferromagnet $EuRh_2Si_2$, which consists of Eu atom arranged on a square lattice, separated by Si-Rh-Si trilayers . The pure spin moments of the Eu-atoms are ferromagnetically ordered in-plane , while neighbouring Eu -planes are coupled antiferromagnetically to each other below an ordering temperature of T_N = 24.5 K. Here we show that large exchange coupling of a Si-derived Shockley surface state to the outermost Eu-layer that is located four atomic layers below the surface of the antiferromagnetic compound $EuRh_2Si_2$. The resulting exchange splitting provides direct information on the temperature dependent magnetism in the discussed Eu layer and at reveals an ordering temperature of 4f moments close to the surface is notably higher than than the bulk T_N .

TU.B-P31 - Relationship between onset of RKKY interaction and Ce element in Ce-based (RE-Gd)Ni; (RE=Ce, Y, Lu) compounds

K. Yano [1], K. Nishimura [2], T. Namiki [3], T. Ohta [4]

The Ce-based (Ce-Gd)Ni compound system, which are composed of a heavy fermion compound CeNi and a ferri-magnet GdNi, shows a peculiar glinearh relationship in M(T) at Gd-poor contents of 0.1…Gd…0.2 and this unusual behavior in M(T) can be found to stem from a collapse-like decrease of RKKY interaction JGd-Gd by using molecular field analysis. Accordingly, the unusual linear behavior does reflect the collapse-like decrease of RKKY interaction between Gd and Gd in the compounds and whether this collapse of RKKY interaction is confined to some characteristics of Ce element or not becomes an interesting and important problem. In order to investigate this problem, the system of (RE-Gd)Ni, where Ce is replaced by non-magnetic RE (Rare Earth) element such as Y and Lu, are suitable. The system of (Y-Gd)Ni, where Ce is substituted by Y, has been preliminary studied and in this system, RKKY interaction seems to revive and does not collapse. Although Y is often classified as RE element, Y has no 4f, 5d and 6s electrons characteristic to RE. In this study, we deal mainly with (Lu-Gd)Ni system in Gd-poor content of 0.10 and 0.15, respectively. In (Lu-Gd)Ni system at Gd-poor content, the M(T) behaves normally curved lines and does not take liner relationship. At present, the collapse-like decrease of RKKY interaction is highly possible to be attributed to some peculiar characteristics of Ce element.

TU.B-P32 - Low temperature anomalies of the magnetic heat capacity of HoxLu1-xB12

A. Khoroshilov [1], N. Sluchanko [2], A. Bogach [2], V. Glushkov [1,2], S. Demishev [1,2], V. Filippov [3], N. Shitsevalova [3], S. Gabani [4], K. Flachbart [4]

Heat capacity C(T,H) measurements have been carried out on high quality single crystals of $Ho_xLu_{1-x}B_{12}$ solid solutions ($x \le 1$) in a wide range of temperatures (0.07 – 300 K) and in external magnetic field up to 90 kOe. For holmium concentrations $x \ge 0.2$ antiferromagnetic phase transition have been detected (Fig 1a) and it was found that Neel temperature $T_N(x)$ changes about lineary in the range of 1-7.4 K. Detailed investigations of the specific heat within the framework of approach developed in [1] allowed us to separate vibration, electron and magnetic contributions to heat capacity. The analysis allows concluding in favor of low temperature magnetic C_m and nuclear C_n components in heat capacity. The first one may be described as a three-level Schottky anomaly attributed to Γ_5 triplet ground state of Ho^{3+} ions [2] with Zeeman splitting in the external magnetic field. The second contribution appears due to hyperfine splitting of holmium nuclear levels, and it can be described very well in terms of a nuclear multi-level Schottky anomaly (see Figs 1b, 1c). The hyperfine field on holmium nuclear is estimated (H_{hf} = 4000-8000 kOe) in combination with effective g-factors of Zeeman splitting of the ground state multiplet of Ho^{3+}-ions (g_1=4.7±0.1 and g_2=10.4±0.1) for all $Ho_xLu_{1-x}B_{12}$ crystals studied. A comparison between the specific heat data and the magnetoresistance results [3] was finally carried out providing with arguments in favor of additional spin-polaron component both in the charge transport and in thermal properties of $Ho_xLu_{1-x}B_{12}$.

7. Institute for Energy Technology, Kjeller, Norway

The Strongly Correlated Electron System YbAl3 alloy has attracted attention due to the fact that it exhibits a variety of cutting-edge physical phenomena [1]. Recently, we have undergone a thorough study of YbAl3 nanoparticles. X-ray absorption measurements supported the decrease of the valence with the reduction of the size of the particles, related to the increase of the Yb2+ contribution [2]. The effect was related to the surface/volume ratio increase due to the downsizing of the particles. We have recently carried out an X-ray diffraction (λ = 0.4126 Å, YbAl3 > 99 %) experiment at ALBA synchrotron facility. A careful crystallographic Rietveld analysis has revealed an intriguing behaviour of the thermal expansion (α) of these YbAl3 nanoparticles at $80 \leq T \leq 300$ K. The lattice parameter variation of the D = 10 nm nanoparticles (milled during 70 h) shows an unexpected change of slope around 180 K. It should be noted that heat capacity did not exhibited any sign of transition at this temperature. It is of paramount significance that the $\alpha = 7.5\ 10{-}6\ K{-}1$ value inferred from the linear variation below 200 K is within the values reported for the bulk alloy, whereas the one (α = 1.5 10-6 K-1) extracted for T > 200 K is anomalously small. The latter α value is approaching those reported for Zero Thermal Expansion (ZTE) compounds [3]. In
consequence, the use of the size as a parameter.

The bulk $YbAl_2$ alloy has been subject of comprehensive studies because it interesting properties associated to the intermediate valence behavior. It was observed that the value of its mean valence increases from 2.15 at low temperatures up to 2.4 at room temperature [1]. In the present work the effects of the mechanical milling on the structural, magnetic, thermal and electronic properties of this alloy are reported. The analysis of the X-ray diffraction data indicates that for 20 h of milling time the particle size reduces down to 47 nm and the lattice strain reaches the value of 0.2 %. Measurements of the magnetic and thermal properties present a similar tendency to that observed in the parent intermediate valence alloy $YbAl_3$ with a reduction of the value of the magnetization and the presence of additional contributions in the specific heat due to the phonon softening [2,3]. In addition, the XANES spectra shows an increase of the Yb^2+ contribution associated to the size reduction, and specifically to the atoms sitting at the surface of the nanoparticles. Interestingly, with the further increase of the milling time up to 70 h and 120 h, a metallurgical transformation to the YbAl3 phase takes place. The results are discussed as the influence of size effects on the above mentioned properties.

UBeGe and ThBeGe crystallize with ZrBeSi type of structure. UBeGe is a ferromagnet with T_C = 157 K and with a large coercive field of 0.55 T. The low field measurements indicate a rather low anisotropy of this ferromagnet. The experimentally determined saturation moment of 2.43 μ_B/U-atom at 7 T agrees well with the theoretically calculated one (LSDA+U) of 2.1 μ_B/U-atom. In the paramagnetic range Curie-Weiss behaviour with μ_{eff} = 3.2 μ_B and ϑ_P = 160 K is observed, in agreement with the strong ferromagnetic interactions. Electrical resistivity and specific heat capacity of UBeGe show strong second-order type anomalies at T_C. All these findings would indicate a well localized character of U 5*f* electrons in studied germanide, which was already expected from the crystal structure. ThBeGe is a simple metallic system with low density of states at the Fermi, which was confirmed by theoretical calculations and measurements of electrical resistivity and specific heat.

TU.B-P38 - Valence state of Tm in YbB_6 and YB_6

8. Institute for Solid State Physics, University of Tokyo

The rare-earth hexaborides RB6 with the CaB6 cubic structure exhibit a wide variety of physical properties depending on the R ion such as an antiferroquadrupole order in CeB6 and valence fluctuation in the narrow-band gap semiconductor SmB6. However, there has been no report for the synthesis of TmB6. The lattice parameters of the solid solutions La1-xTmxB6 and Yb1-xTmxB6 suggested that TmB6 would be a valence fluctuation compound [1]. In this study, we have investigated electronic structure of Yb1-xTmxB6 and Y1-xTmxB6 by means of hard x-ray photoemission spectroscopy (HAXPES) at h*f*Ë = 5.95 keV carried out at BL15XU of SPring-8. The valence states of Tm ions have been directly probed by the Tm 3d HAXPES. We found that the Tm valence state changes depending on the host materials YbB6 and YB6. Only Tm3+ components are detected in the Tm 3d HAXPES spectra of Yb1-xTmxB6 (x=0.1, 0.2), indicating that Tm ion is substituted for Yb as a trivalent state. The Yb valence remains in a divalent state as in YbB6. The Yb2+ 4f7/2 peak at about 1 eV below the Fermi level is shifted to the deeper binding energy side. This shift suggests that the Yb2+ state is stabilized due to the Tm substitution. On the other hand, the Tm 3d spectra of Y1-xTmxB6 (x=0.35) clearly indicate strong fluctuation of Tm valence in Y1-xTmxB6. On cooling, the Tm2+ (Tm3+) component increases (decreases) as often observed in the Yb-based valence fluctuation compounds [2]. In fact, the Tm valence deduced from the Tm 3d spectra decreases from v=2.75 at 300 K to v=2.56 at 20 K.

3. Institute for Materials Research, Tohoku University, Sendai, Japan

UT_2X_{20} (T = Transition Metal, X = Al, Zn) crystallizes in the cubic $CeCr_2Al_{20}$ type structure and shows characteristic behavior. For example, the heavy fermion compound UIr_2Zn_{20} has a large electronic specific heat coefficient of about 400 mJ/mol·K^2 and UMn_2Al_{20} shows a ferromagnetic transition[1,2]. Recently, Burnett et al. found new compounds RNi_2Cd_{20} (R = Rare Earth)[3].

We succeeded in growing single crystals of a new compound UPd_2Cd_{20} by the Cd self-flux method, which is found to be the $CeCr_2Al_{20}$ type structure. The electrical resistivity slightly increases with decreasing temperature, and shows a maximum at 25 K. Below 5 K, the resistivity rapidly decreases and follows the Fermi liquid relation $\rho = \rho_0 + AT^2$ with ρ_0 = 5.4 μΩ·cm and A = 2.4 μΩ·cm/K^2, where ρ_0 is a residual resistivity, and A is a coefficient which relates to effective mass. The observed A value is about 2 times larger than that of heavy fermion compound UIr_2Zn_{20}, implying that UPd_2Cd_{20} forms the heavy fermion state[4]. The temperature dependence of the magnetic susceptibility follows the Curie-Weiss law above 30 K with the effective magnetic moment μ_{eff} = 3.44 μ_B/U. The obtained value of μ_{eff} is close to the value for U^{3+} or for U^{4+} ionic state. The magnetic susceptibility indicates a broad maximum at 6 K and an abrupt decrease at 5 K, suggesting an antiferromagnetic ordering.

Experimental results strongly suggest that UPd_2Cd_{20} is a new heavy fermion antiferromagnet.

TU.B-P40 - Fragile antiferromagnetism in a new Shastry-Sutherland lattice compound $Yb_2Ru_3Ga_{10}$

Y. Muro [1], T. Fukuhara [1], T. Kuwai [2]

1. Faculty of Engineering, Toyama Prefectural University, Tayoma, Japan
2. Graduate School of Science and Engineering, University of Toyama, Tayoma, Japan

Combination between Kondo effect and geometrical frustration attracts much interest on the heavy fermion physics[1]. For ytterbium systems, peculiar magnetic properties due to the above combination were observed in a Shastry-Sutherland lattice (SSL) system Yb_2Pt_2Pb[2]. In this presentation, we report the single-crystal study of a new Yb-based SSL compound $Yb_2Ru_3Ga_{10}$ by measuring the magnetic susceptibility, electrical resistivity, and specific heat. Yb atoms in $Yb_2Ru_3Ga_{10}$, crystallizing in a new tetragonal structure type[3], occupy the 4g site of the space group *P4/mbm* and form the SSL on (001) plane. Single-crystalline samples were grown by a Ga self-flux method. The magnetic susceptibility at B // [100], $c_{[100]}$, shows a Curie-Weiss behavior between 50 K and 300 K while the $c_{[001]}$ shows a small temperature dependence. This anisotropic susceptibility indicates that the Yb 4*f* moments lie in (001) due to the crystal-field effect. The electrical resistivity below 30 K shows a -log$T$ behavior, indicating that $Yb_2Ru_3Ga_{10}$ is a new Kondo-lattice compound. Below 1.4 K, we observed a sharp anomaly accompanying a small hump due to an antiferromagnetic transition with the transition temperature T_N = 1.4 K. This transition disappears at only 0.2 T for B // [100], while T_N survives at 1.4 K for B = 1 T // [001]. The disappearance of antiferromagnetic order at weak magnetic field and anisotropic phase diagram in $Yb_2Ru_3Ga_{10}$ should result from the magnetic frustration arising from the SSL.

TU.B-P41 - Theoretical investigation of the linear and the nonlinear magnetic susceptibility of URu$_{2}$Si$_{2}$ compound

A. Lausmann [1], B. Pedrolo [1], E. Calegari [1], S. Magalhães [2], P Riseborough [3]

1. Universidade Federal de Santa Maria, Santa Maria, Brazil
2. Universidade Federal Fluminense, Niterói, Brazil
3. Temple University, Philadelphia, United States

In the last three decades, the heavy fermion compound URu$_{2}$Si$_{2}$ has attracted much attention mainly due to its unusual behavior. In the absence of an external magnetic field, the specific heat exhibits an anomaly which indicates a phase transition to a unknown ordered state. This phase transition occurs at 17.5 K and the ordered state is known as a Hidden Order phase [1]. Results of magnetic torque experiments on tiny crystals of URu$_{2}$Si$_{2}$ show that, below the ordered temperature T_{HO}, the magnetic susceptibility becomes anisotropic [2]. Moreover, measurements in URu$_{2}$Si$_{2}$ compound show that the nonlinear susceptibility exhibits a strong anomaly at T_{HO} resembling the specific heat anomaly [3]. Recently, a theory based in the underscreened Anderson Lattice Model has been proposed for describe the order parameter of the hidden order phase [4] in URu$_{2}$Si$_{2}. In the present work, this theory is employed to investigate both the linear and the nonlinear magnetic susceptibilities of the model of reference [4]. The magnetic susceptibilities are calculated for two distinct cases: for a magnetic field H$_{z}$ parallel to the axis of quantization and for a magnetic field H$_{x}$ perpendicular to the axis of quantization. The results show that when H$_{z}$ is present, the linear magnetic susceptibility is strongly temperature dependent, whereas for H$_{x}$ the linear magnetic susceptibility is only slightly temperature dependent. For a magnetic field parallel to the axis of quantization the nonlinear magnetic susceptibility presents an anomaly at T_{HO}, which is similarly to the anomaly observed in the specific heat. The present results are in qualitatively agreement with experimental results [2,3] on URu$_{2}$Si$_{2}$.

TU.B-P42 - Thermal Expansion and Magnetostriction Measurements on Heavy-Fermion Compound $YbCu_4Au$

T. Takeuchi [1], Y. Hirose [2], R. Tsunoda [3], F. Honda [4], R. Settai [2]

1. Low Temperature Center, Osaka University, Toyonaka, Osaka, Japan
2. Department of Physics, Niigata University, Niigata, Japan
3. Graduate School of Science and Technology, Niigata University, Niigata, Japan
4. IMR, Tohoku University, Oarai, Ibaraki, Japan

The ternary intermetallic compound $YbCu_4Au$ crystallizes in the AuBe5-type cubic structure and shows a large electronic specific heat coefficient larger than 2 J/K^2mol [1]. The antiferromagnetic order appears below TN ~ 0.8 K with the ordered magnetic moment of 0.85 muB/Yb, which is substantially reduced with respect to that expected for the Gamma7 ground state doublet [2]. It is noted that the temperature-magnetic field (T-H) phase diagram of $YbCu_4Au$ is found to be very similar to that of $YbRh_2Si_2$, which is situated close to the quantum critical point[3,4]. In this study, we measured the specific heat, thermal expansion coefficient, and magnetostriction of polycrystalline samples in the temperature range down to 1.4 K in order to investigate further the T-H phase diagram of $YbCu_4Au$. The temperature dependence of the specific heat under H = 2 T shows a broad peak at T ~ 3 K, and this peak shifts to higher temperatures with increasing magnetic field. This broad peak was interpreted as the Schottky anomaly due to the Zeeman splitting of the Gamma7 doublet [1]. Correspondingly, the thermal expansion coefficient under 2 T shows a broad peak centered at approximately 3 K, and this peak shifts to higher temperatures with further increase in the magnetic field. The magnetostriction up to 9 T indicates anomalous behaviors at temperatures below 15 K. These anomalies in the specific heat, thermal expansion coefficient, and magnetostriction are discussed in relation to the characteristic T-H phase diagram of $YbCu_4Au$ [3,4].

The Eu ions can be either divalent or trivalent in compounds. The trivalent Eu ion doesn't exhibit a magnetism due to the total angular momentum J=0 in the ground state. On the other hand, the divalent Eu ion shows a magnetism with a larger volume compered to that of trivalent ion state. Pressure is expected to change the valence of Eu ions. For example, an antiferromagnet $Eu(Pd_{0.8}Au_{0.2})_2Si_2$ is found to indicate the valence transition above 1.2GPa[1]. In this study, we focused on an antiferromagnet $EuCu_9Sn_4$ and a ferromagnet $EuZn_{13}$ with a similar crystal structure, and measured the temperature dependence of the electrical resistivity under pressure, in order to investigate the pressure effect in different magnetic ordered states. $EuZn_{13}$ crystallizes in the cubic $NaZn_{13}$ type structure[2], which has two types of caged-like structure formed by 12 Zn and 38 Zn atom surrounding Zn atom and Eu atom, respectively. $EuCu_9Sn_4$ crystallizes in the tetragonal $LaFe_9Si_4$ type structure, which forms distorted caged-like structures of $NaZn_{13}$ type[3]. We succeeded in growing single crystals of $EuCu_9Sn_4$ and $EuZn_{13}$ by the Sn and Zn self-flux method, respectively. Recently, we found that $EuCu_9Sn_4$ is an antiferromagnet with the easy plane type anisotropy perpendicular to the [001] direction[4]. The temperature dependence of the electrical resistivity of $EuCu_9Sn_4$ monotonically decreases with decreasing temperature, and indicates a rapid decrease at TN=8.7K. With increasing pressure, TN shows a minimum value of 8.2K at 4GPa. Above 8GPa, the resistivity indicates a hysteresis in the temperature range between 5 and 10K, which could be a sign of the first order valence transition.

Heavy-fermions metals are characterized by a Fermi liquid regime with effective masses reaching hundred to several thousands times that of the free electron mass [1]. Strong electronic interactions can be tuned by pressure, doping, or magnetic field, which leads to magnetic quantum phase transitions where the effective mass is enhanced and exotic phenomena, as non-Fermi liquid and unconventional superconductivity, emerge. Recently, it has been proposed that changes of valence and valence fluctuations might play a significant role in these systems [2]. Valence changes occurring from tuning with high pressure or temperature have been extensively studied on several systems. Heavy fermion systems are also very sensitive to high magnetic fields [3], but the effect of field on the valence state requires magnetic fields higher than those readily available in synchrotron facilities and is still largely unexplored. In this contribution, we present the investigation of valence in Yb-based heavy fermions under fields up to 30 T at temperatures from 4 K to 300 K by x-ray absorption spectroscopy combining the use of a long-duration pulsed magnet developed by the LNCMI-Toulouse and a specially designed helium flow cryostat developed by the ESRF-Grenoble on the Energy-Dispersive-XAS beamline ID24. At low temperature, a small but measurable variation of valence is observed when the field is applied along the easy magnetic axis, while no variation of valence is found when the field is applied along the hard magnetic axis. This anisotropic effect is a signature of the interplay between the magnetic properties and the variation of valence, which is usually understood as a consequence of the Kondo delocalization of the f-electrons.

The tetragonal UT_2Si_2 family (T: transition metals) has been one of the subjects of intense research during last three decades, providing fruitful opportunities for systematic understanding of 5f-electronic properties. Among the numerous studies of UT_2Si_2 compounds, there are only 5 reports about polycrystalline UAu_2Si_2, where it is said to be a heavy-fermion compound with a ferromagnetic ordered state below 20 K. In order to get further insight into the 5f-electronic properties of this compound, we synthesized polycrystalline UAu_2Si_2 and its isostructural nonmagnetic counterpart $ThAu_2Si_2$, and investigated their magnetic, thermal and transport properties by means of magnetization, specific-heat and electrical-resistivity measurements. In addition to these macroscopic measurements, we also performed X-ray-diffraction and 29Si-NMR experiments on powdered sample to obtain microscopic information about the ordered state of UAu_2Si_2. In our detailed bulk measurements, we have found several unusual behaviors that seem to be inconsistent with those expected in normal ferromagnetic compounds as follows: The magnetization shows a distinct cusp anomaly at the transition temperature To = 20 K in high magnetic fields above 5 T. The specific-heat jump at To becomes not broader but more pronounced as the field increases. Moreover, the resistivity shows a Cr-like anomaly below To, which suggests opening of an energy gap at the Fermi surface. These experimental facts strongly suggest that the phase transition at To may not be simply ferromagnetic, as previously reported, but intrinsically antiferromagnetic.
This hypothesis is supported by our preliminary results of the 29Si-NMR experiments.

TU.B-P47 - NMR observation of quadrupole order and multipole fluctuations in PrTi2Al20

T. Taniguchi [1], M. Yoshida [1], H. Takeda [1], M. Takigawa [1], M. Tsujimoto [1], A. Sakai [1], S. Nakatsuji [1]

The intermetallic compound $PrTi_2Al_{20}$ shows a phase transition at 2 K [1,3] associated with the quadrupole moments of Pr ions, for which the ground state of crystal field is non-magnetic doublet [3]. Recent discovery of enhanced superconductivity under high pressure suggests novel mechanism for Cooper paring due to quadrupole fluctuations [4]. Here we report results of Al-NMR in a single crystal PrTi2Al20. When a magnetic field is applied along the 111 direction, certain lines of the NMR spectrum split upon entering into the ordered phase, indicating breaking of the three-fold rotation symmetry due to field-induced magnetic dipole moment perpendicular to the field. This provides microscopic evidence for a symmetry-breaking ferro-quadrupole order of O_{20} (3z2-r2) type. We discuss detailed field- and temperature-dependence of the induced dipole, which is proportional to the quadrupole order parameter. In addition, the nuclear relaxation rate (1/T1) shows strong enhancement below 30 K and a sharp peak near the transition temperature. The possible origin of the nuclear relaxation is the field-induced dipoles associated with quadrupolar fluctuations or octupole moments. We present quantitative analysis of the multipolar fluctuations based on the field and orientation dependence of the nuclear relaxation rates.

Heavy-fermion superconductor URu_2Si_2 has been known to show an enigmatic second-ordered phase transition at 17.5 K, so called 'Hidden Order (HO)', whose order parameter still has remained unsolved. In high magnetic fields for H || [001] at low temperatures, URu_2Si_2 undergoes three meta-magnetic transitions in the range 35 and 39 T with a collapse of the HO phase. While, this compound also exhibits a strong hybridization between conduction electron and 5*f* electrons below T^* ~ 50 K in low-magnetic fields, the *c-f* hybridization is also suppressed in higher magnetic field region above 39 T. Our recent investigation of elastic constant (C_{11}-C_{12})/2 of URu_2Si_2 under pulsed-magnetic fields strongly suggests that the hybridized electronic state possesses an orthorhombic lattice instability with Γ_3 symmetry (x^2-y^2 type). In order to clarify the elastic response of the other symmetry-breaking strains in URu_2Si_2 under high-magnetic fields, we have measured elastic constants of transverse C_{44}, C_{66} ultrasonic modes and also longitudinal C_{11} and C_{33} ultrasonic modes of URu_2Si_2 single crystals by means of high-frequency ultrasonic measurements under pulsed-magnetic fields up to ~62 T for H || [001] in wide temperature range from 1.5 K to ~120 K. Elastic constants C_{33}, C_{44} and C_{66} exhibit successive step-like decreasing through the cascade-like meta-magnetic transition region and keep decreasing above 39 T, while C_{11} and (C_{11}-C_{12})/2, both of which are related to Γ_3-symmetry response, show increasing in higher-magnetic-field region. Such clear contrast in the elastic responses strongly support the idea that the G_3-type orthorhombic lattice instability is related to a symmetry-breaking band instability that arises due to the *c-f* hybridization, and is probably linked to the HO parameter of this compound.

TU.B-P49 - Magnetic, transport, and structural properties of caged compounds ROs_2Zn_{20} (R=La-Nd)

3. Institute for Advanced Materials Research, Hiroshima University, Hiroshima, Japan

Cubic compounds RT_2Zn_{20} (R: rare earth, T: Transition metal) have attracted much attention, because they show various phenomena such as heavy-fermion state, superconductivity, and multipole ordering [1-3]. From the cage-like structure, it is expected that low-energy vibrations of guest ions in the atomic cages may play a role in the physical properties. In fact, the first principles calculation of LaT_2Zn_{20} (T=Ru, Ir) pointed out that the Zn atom at the 16c site in the R_2Zn_{12} cage is vibrating at low frequencies, and the vibration is probably related to the structural transition [3, 4]. In order to perform a systematic study on the magnetic, transport, and structural properties of RT_2Zn_{20}, we have synthesized a series of T=Os compounds with R=La, Ce, Pr, and Nd. We report on the electrical resistivity, magnetization, and specific heat measurements.
All the compounds of $ROs_{2z}n_{20}$ undergo structural transitions, whose temperature decreases with lanthanide contraction. This suggests that the high-temperature structure is stable for smaller lattice volume. The observed relationship between the lattice volume and the transition temperature suggests that the low-energy vibration of the Zn atom at the 16c site plays a role in the structural transitions. The measurements of physical properties of ROs_2Zn_{20} indicate that $LaOs_2Zn_{20}$ without 4f electron is a diamagnet with the electronic specific heat coefficient gamma of 10.4 mJ/K2 mol. $CeOs_2Zn_{20}$ is a valence fluctuating compound whose gamma value is ten times larger than that of $LaOs_2Zn_{20}$. At low temperatures, $PrOs_2Zn_{20}$ displays a van-Vleck paramagnetic behavior, suggesting a non-magnetic ground state. $NdOs_2Zn_{20}$ shows a ferromagnetic transition at 0.6 K. These physical properties of ROs_2Zn_{20} are in parallel with those of the isostructural compounds RRu_2Zn_{20} (R=La-Nd) [2, 3, 5].

TU.B-P50 - High-Frequency Ultrasonic Measurements of $SmOs_4Sb_{12}$ under Hydrostatic Pressure

S. Mombetsu [1], H. Inagaki [1], T. Murazumi [1], T. Yanagisawa [1], H. Hidaka [1], H. Amitsuka [1], P.C. Ho [2], M.B. Maple [3]

1. Department of Physics, Hokkaido University, Sapporo, Japan
2. Department of Physics, California State University, Fresno, United States
3. Department of Physics, University of California, Berkeley, United States

We have carried out ultrasonic measurements on the filled-skutterudite compound $SmOs_4Sb_{12}$ under hydrostatic pressure as high as 1.2 GPa and with frequency up to 250 MHz. This experiment is made possible by installing two semi-rigid coaxial cables into a piston cylinder pressure cell. The elastic constant C_{11} of the present compound shows ultrasonic dispersions (UDs) at ~ 20 K and ~ 60 K at the frequency of ~ 100 MHz under ambient pressure. The UDs are considered to be caused by thermally-activated ionic motions, "Rattling", of the Sm-ion. Thus, the present study provides new information of hydrostatic pressure dependences of the UDs and their relation to the heavy-electron state of this compound. As pressure increases, the UD which appears at higher temperature shifts to lower temperatures, which indicates decreasing of activation energy and/or increasing of relaxation time of the rattling. On the other hand, the UD which appears at lower temperature gradually disappears as pressure increases. We have also found that the elastic response in a low-temperature ordered phase below T_o (~ 2 K at ambient pressure) is dramatically changed by hydrostatic pressure. At 1.2 GPa, C_{11} shows rapid decrease of ~ 3% in the ordered phase in comparison with the change of ~ 0.2% under ambient pressure. The relatively large elastic anomaly implies that a lattice distortion is induced in the ordered phase by hydrostatic pressure. Below 80 K down to T_o, C_{11} also shows Curie-type softening, which is also enhanced with increasing pressure. The present results strongly suggest that 4*f*-electrons of the Sm ion become localized with increasing hydrostatic pressure and the quadrupole degrees of freedom play an important role in the phase transition.

TU.B-P51 - Magnetic and transport properties of mixed-valent europium sulfide $EuPd_3S_4$

S. Michimura [1,2], M. Tanahashi [2], H. Hirabayashi [2], K. Shibata [2], S. Katano [2], M. Kosaka [2]

1. Saitama University, Research And Development Bureau, Saitama, Japan
2. Saitama University, Graduate School of Science & Engineering, Saitama-shi, Japan

We have investigated the magnetic and transport properties of a ternary intermetallic compound $EuPd_3S_4$. The mixed-valent behavior was previously reported from magnetization measurements and ^{151}Eu Mössbauer spectroscopy using polycrystalline samples [1]. $EuPd_3S_4$ undergoes an antiferromagnetic transition at T_N = 3.4 K [2]. The experimental results can be explained by assuming the valence of $Eu^{2.5+}$. In particular, two absorption peaks in Mössbauer spectra, which indicate the divalent and trivalent state, were well defined even at room temperatures. This result may suggest the charge ordered state, the ratio of Eu^{3+} : Eu^{2+} = 1 : 1. On the other hand, the broad maximum around 150 K in the temperature dependence of the thermoelectric power is reminiscent of the behavior observed in the valence fluctuation compounds [3]. Accordingly, the details of the valence state in this compound are still controversial.

In this study, we have succeeded in growing single crystalline samples by using chemical transport method. The saturation magnetization is determined to be 3.3 μ_B at 1.8 K. This is almost the half of the expected value of gJ = 7 μ_B, suggesting that the ratio of Eu valence is estimated to be Eu^{3+} : Eu^{2+} = 1 : 1. The evaluated magnetic entropy also supports this suggestion. Moreover, we have performed measurements of electrical resistivity and powder X-ray diffraction in high temperature regions in order to obtain an anomaly corresponding to a transition to the valence fluctuate state, if the charge ordered state is realized at room temperatures, such as Eu_4As_3 [4]. The resistivity of $EuPd_3S_4$ is linearly proportional to temperature up to 600 K, and lattice constant also increases monotonically with increasing temperature up to 900 K, without any transition. In many valence fluctuation compounds, the deviation from linear temperature dependence is observed on resistivity. We speculate that the charge ordered state is stabilized up to 900 K.

TU.B-P52 - Role of c-f hybridization to the mid-IR peaks in Ce compounds

S.I. Kimura [1], Y.S. Kwon [2], Y. Matsumoto [3], H. Aoki [4], O. Sakai [5]

1. FBS and Physics Department, Osaka University, Osaka, Japan

4. Department of Physics, Tohoku University, Sendai, Japan
5. National Institute for Materials Science, Ibaraki, Japan

Cerium and ytterbium based heavy fermion materials have characteristic peaks in the optical conductivity spectra in the middle infrared region (mid-IR peaks). The mid-IR peaks originate from the hybridization between conduction and 4f electrons, namely c-f hybridization [1]. The peak energies originate from the renormalization of the 4f states due to the electron correlation [2,3], i.e., the mid-IR peaks shift to the lower energy side with approaching to the quantum critical point (QCP) from the heavy fermion region in the Doniach phase diagram. Here, we show the alternative behavior of the mid-IR peaks in the local region of weaker c-f hybridization intensity than QCP.
We measured the optical conductivity spectra of isostructural antiferromagnetic compounds CeM_2Ge_2 (M = Cu, Ru, Rh, Ag) and compared with those of heavy fermions $CeNi_2Ge_2$ and $CeCu_2Si_2$ [4]. As a result, the mid-IR peak energy becomes minimized at slightly local side from QCP and upturn again with decreasing the c-f hybridization intensity. The origin of the behavior can be explained by a weak screening effect of the conduction electron to the 4f states and seems to be strongly related to the quantum criticality.

TU.B-P53 - Anomalous low-energy excitations on LaB_6 investigated by Raman scattering measurements

T. Hasegawa [1], N. Ogita [1], F. Iga [2], M. Udagawa [1,3]

1. Graduate School of Integrated Arts and Sciences, Hiroshima University, Higashi-Hiroshima, Japan
2. College of Science, Ibaraki University, Ibaraki, Japan
3. Institute for Advanced Material Research, Hiroshima University, Hiroshima, Japan

In phonon Raman scattering with different wavelength excitation, its peak energy does not depend on wavenumber of the excitation light, but peak intensity will change due to resonance effect. This invariance of the energy is because of a quite small scattering vector q in a Raman scattering process compared with reciprocal lattice vectors of crystals. However, when we observe excitations with linear dependence on q, e.g. an acoustic phonon or intra-band excitations of electrons, then, peak energy changes due to the wavenumber of excitation light. Intra-band excitation spectrum is broad and the energy of the maximum intensity is expected to be qvF with the Fermi velocity vF. Here, we present the dispersion relations of such electronic excitations in LaB_6, investigated by Raman scattering measurements. We have measured Raman spectra of LaB_6 on (100) and (110) surfaces from 4 K to 300 K. The wavelength of the incident light was varied from 458.0 nm to 632.8 nm. Below 400 cm-1, there is no Raman active phonon mode, while two-phonon excitation due to the flat La vibration bands is found around 200 cm-1. In addition to the two-phonon peak, the anomalous peaks have been clearly observed below 150 K. The peak energies strongly depend on the excitation light energy. In the (x,x) spectra on (100) surface, the peak energy is found at 210 cm-1 for the 514.5 nm line of Ar+ laser. However, with the 632.8 nm line of He-Ne laser, it becomes at 30 cm-1. The dispersion curve of this peak shows that the group velocity is about 1 % of velocity of light. It is typical magnitude of the Fermi velocity. This result suggests that the anomalous excitation is intra-band electronic excitations.

TU.B-P54 - Al-NMR study of single crystal $CeAl_2$ under high pressure

K. Fujiwara [1], T. Umezawa [1], K. Takamiya [1], G. Motoyama [1], K. Miyoshi [1], S. Nishigori [2]

1. Department of Materials Science, Shimane University, Matsue, Japan
2. Interdisciplinary Center for Science Research, Shimane University, Matsue, Japan

$CeAl_2$ is a typical heavy fermion compound (T_N = 3.8 K), that RKKY and the Kondo interaction compete at the low temperature. The electrical resistivity has two peaks owing to the Kondo effect and the crystal-field splitting of 4*f* levels. Two peaks merge around P_C = 2.7 GPa and T_N disappears at P_C. Similar behavior in the resistivity has been also observed in heavy fermion superconductor $CeCu_2Si_2$ around P_C = 4.5 GPa and T_C is quite enhanced at P_C. We have been measured Al-NMR under pressure in order to clarify valence and spin state of Ce ions near P_C. Single crystalline sample (RRR=100, T_N = 3.9 K) was prepared in tetra-arc furnace. In this work, we use the indenter pressure cell and the pressure-transmitting medium was Daphne oil 7373. Since $CeAl_2$ shows a cubic Laves structure, Al site has axial symmetry along (111) direction. Consequently, both Zeeman and nuclear quadrupole interaction (the principal axis: (111) direction) contribute to Al-NMR spectrum. Applying the magnetic field parallel to the (111) direction, energy degeneracy of nuclear spins was resolved, and NMR spectrum shows two inequivalent Al sites. On the other hand, since the (100) direction is 54.7 degrees to a principal axis, and the effect of the nuclear quadrupole interaction becomes zero, only one peak is observed. In this study, we report and discuss temperature and pressure dependence of Knight shift and nuclear relaxation ratio ($1/T_1$) along to (100) and (111) directions.

TU.B-P55 - Electronic structure of $ThRu_2Si_2$ studied by ARPES

S.I. Fujimori [1], M. Kobata [1], Y. Takeda [1], T. Okane [1], Y. Saitoh [1], A. Fujimori [1,2], H. Yamagami [1,3], Y. Matsumoto [4,5], E. Yamamoto [5], Y. Haga [5]

2. Department of Physics, University of Tokyo, Bunkyo-Ku, Japan
3. Department of Physics, Faculty of Science, Kyoto Sangyo University, Kyoto, Japan
4. Graduate School of Engineering, Nagoya Institute of Technology, Aichi, Japan
5. Advanced Science Research Center, Japan Atomic Energy Agency, Ibaraki, Japan

$ThRu_2Si_2$ is an isostructural compound of the heavy fermion superconductor URu_2Si_2 which shows the hidden order transition. Since $ThRu_2Si_2$ does not have 5f electrons, it is a good reference material to understand the contribution of U 5f electrons in the electronic structure of URu_2Si_2. In the present study, we have revealed the band structure and Fermi surface of $ThRu_2Si_2$ by angle resolved photoelectron spectroscopy (ARPES) using soft X-rays (hn=600-800 eV). The experimentally obtained band structure and Fermi surface are compared with those of URu_2Si_2 as well as the result of the band structure calculation. We have found that the states in the vicinity of EF are very different in $ThRu_2Si_2$ and URu_2Si_2, suggesting that U 5f electrons form itinerant bands in URu_2Si_2. The details of the electronic structure of $ThRu_2Si_2$ and the contributions from U 5f electrons in the band structure and Fermi surface of $URu_2Si_2$are discussed.

TU.B-P57 - Novel heavy-fermion antiferromagnet YbRhGe with the TiNiSi-type structure

K. Araki [1], H. Tanaka [1], T. Kohei [1], S. Nakamura [2,4], T. Nojima [2,4], A. Ochiai [3,4], K. Katoh [1]

1. Dept. Appl. Phys., National Defense Academy, Yokosuka-Shi, Japan
2. Inst. For Materials Research, Tohoku Univ, Sendai, Japan
3. Graduate School of Science, Tohoku Univ., Sendai, Japan
4. Univ. Centr. For Low Temp. Sci., Tohoku Univ., Sendai, Japan

YbTGe (T = transition metal) compounds are of much interest because they display a variety of attractive phenomena, such as magnetic ordering, heavy-fermion state, frustration, etc. Recently we have succeeded in growing large single crystals of YbRhGe with the TiNiSi-type orthorhombic structure, which was reported to be antiferromagnet with TN = 7 K *1. In order to investigate low-temperature properties, we have performed specific heat C, electrical resistivity â¤ measurements down to 0.5 K and up to 9 T. These results revealed that YbRhGe undergoes the heavy-fermion state with the electric specific heat coefficient *f*Á 220 mJ/mol K2 and the successive transition at Tm = 1.0 K below magnetic ordering at 6.0 K. The temperature dependence of *f*Ï shows a superzone gap opening along only the c-axis below TN. In magnetic fields applied along the a- and c-axes, the system undergoes a spin-flop state in contrast to no such behavior in the field applied along the b-axis. This suggests that the magnetic moments in the AF phase are lying within the ac-plane.

TU.B-P58 - Possible existence of partially disordered Sm ions in magnetically ordered state of Ising magnet $SmPt_2Si_2$

K. Fushiya [1], Ryuji Higashinaka [1], Tatsuma [1], D Matsuda [1], Yuji Aoki [1]

1. Tokyo Metropolitan University, Tokyo, Japan

RT_2Si_2 (*R* : rare earth; *T* : transition metal) are known to exhibit a variety of strongly correlated electron phenomena. For *R*=Sm, however, only a few reports have been made of systematic physical property investigations using single crystals [1]. Recently, we have succeeded in growing single crystals of $SmPt_2Si_2$ and have studied their magnetic properties [2]. It has been found that there are two magnetically ordered phases; an antiferromagnetically (AFM) ordered phase (I) setting in at T_N=5.1 K and a field induced magnetization plateau phase (II). In phase I, unlike the usual AFM states, a pronounced Curie-Weiss contribution remains in magnetic susceptibility, indicating the existence of "partially disordered" Sm ions. The realization of such inhomogeneous magnetic structures is attributable to geometric frustrations inherent in the crystal structure of RT_2Si_2; note that the axial-next-nearest-neighbor Ising (ANNNI) model accounts for the similar magnetic properties observed in UPd2Si2.
The disordered Sm ions can form a Kondo sublattice through hybridization with conduction electrons [3], resulting in a quasiparticle mass enhancement. This may account for the largely increased electronic specific heat coefficient of 350mJ/K^2 mol observed in phase I. SmPt2Si2 should provide an appropriate system in which one can study the ground-state properties of a "partial Kondo sublattice" immersed in a magnetically ordered phase.

4. Institute of Experimental Physics of SAS, Košice, Slovak Republic

We present the results of complex study of resistivity, magnetoresistance, specific heat and magnetization of solid solutions $R_xLa_{1-x}B_6$ (R=Ce, Ho) in the regime of isolated magnetic impurity (x~1%). In the study it was of special interest to analyze comparatively the charge transport properties, when Kramers (Ce^{3+}) and non-Kramers (Ho^{3+}) ions are introduced in LaB_6 nonmagnetic matrix. The data obtained allow detecting the increase of resistivity with the temperature lowering both in $Ce_{0.01}La_{0.99}B_6$ and $Ho_{0.005}La_{0.995}B_6$ rare earth hexaborides. It was found that instead of logarithmic behavior $\Delta\rho_m(T)$~-lnT, predicted by Kondo model, the magnetic contribution to resistivity obeys the power law $\Delta\rho_m(T)\sim T^{-\alpha}$, which corresponds to the regime of weak localization of charge carriers with the critical exponent values α~0.39 (Ho) and 0.5 (Ce) [1]. Moreover, the analysis of the negative magnetoresistance observed at liquid helium temperatures allows concluding in favor of the formation of many-body states of a spin-polaron type near the magnetic rare-earth ions in the LaB_6 matrix [2, 3]. In accordance with the aforementioned results a new approach to describe the heavy fermion formation in $R_{0.01}La_{0.99}B_6$ (R=Ce, Ho) is proposed.

TU.B-P60 - Intersite electron correlations in quasi-periodic systems

N. Takemori [1], A. Koga [1], H. Hafermann [2]

1. Tokyo Institute of Technology, Tokyo, Japan
2. CNRS, Grenoble, France

Quasicrystal systems have attracted considerable interest since its discovery [1]. An important feature is that the system does not have translational symmetry but rotational symmetry (e.g. 10-fold and 8-fold) which should yield nontrivial electric properties in the metallic quasicrystals. Recently, quantum critical behavior in $Au_{51}Al_{34}Yb_{15}$ has experimentally been realized [2], which stimulates further theoretical and experimental investigations on electron correlations in quasi-periodic systems.
To clarify how electron correlations affect low temperature properties in strongly correlated quasi-periodic systems, we study the repulsive Hubbard model on two-dimensional Penrose lattice. The model Hamiltonian is given as where denotes nearest neighbor site, is the creation (annihilation) operator of a fermion at the ith site with spin , is the hopping integral, and U is the Coulomb interaction. In our previous paper, we have discussed the Mott transition in the model by means of the real-space dynamical mean field theory (RDMFT) [6], which incorporates local electron correlations. However, intersite correlations cannot be taken into account with RDMFT. In the present work, we make use of the real-space dual fermion approach [5], where intersite correlations are taken into account. We then study how magnetic correlations develop at low temperatures.

TU.B-P61 - Influence of the Crystal Field on the Magnetic Properties of $RENi_3Ga_9$ (RE = Gd, Tb, Dy and Ho) single crystals

J. Duque [1], S. Silva [1], G. Mecena [1], T. Meneses [1]

1. Federal University of Sergipe, São Cristóvão, Brazil

In this work, we report on X-ray, heat capacity and magnetization measurements in single crystals of $RENi_3Ga_9$ (RE = Gd, Tb, Dy and Ho) grown from the melt flux-gallium. X-ray analyses confirm that all samples belong to the trigonal (R32) space group. The T-dependence of the magnetic susceptibility reveals that these compounds order antiferromagnetically at low temperature (TN < 20 K) and the evolution of their magnetic properties depends on the crystal-field ground-state configuration. The high-field magnetization measured at 2 K presents field induced transitions which can be related to the spin-flop and/or metamagnetic transitions. In particular case of $DyNi_3Ga_9$, we have observed four successive field induced transitions. Finally, heat capacity data are consistent with the magnetic phase transition observed at low temperature in magnetization measurements.

TU.B-P63 - Charge dynamics of heavy fermions in $CeCu_6$ and $YbRh_2Si_2$ probed by microwave spectroscopy

K. Parkkinen [1,2], D. Hafner [1], M. Thiemann [1], M. Dressel [1], O. Stockert [3], K. Grube [4], H.V. Löhneysen [4,5], C. Krellner [3,6], C. Geibel [3], F. Steglich [3], M. Scheffler [1]

6. Physikalisches Institut, Goethe-Universität Frankfurt, Frankfurt, Germany

$CeCu_6$ and $YbRh_2Si_2$ are two well-known heavy-fermion metals with peculiar behavior related to an antiferromagnetic quantum phase transition. While $CeCu_6$ in the absence of magnetic field is a paramagnet with clear Fermi-liquid behavior at temperatures well below 1 K, $YbRh_2Si_2$ undergoes an antiferromagnetic phase transition at 70 mK (and zero magnetic field) and exhibits pronounced non-Fermi-liquid behavior at higher temperatures. While both materials have been studied in great detail using thermodynamic, magnetic, and transport techniques, there are only few spectroscopic studies that address the physics related to the quantum phase transitions in CeCu6 and $YbRh_2Si_2$. Main challenges here are the involved energy and temperature scales well below 1 K. In the present work, we employ microwave spectroscopy to study the charge dynamics in these two materials at temperatures between 50 mK and 5 K and at frequencies between 2 GHz and 16 GHz.
We have recently developed a new spectroscopic approach, namely superconducting stripline resonators, to study the microwave conductivity of exotic metals and superconductors. While we previously addressed heavy fermions at 4He temperatures, we now implemented the technique into a dilution refrigerator, and we have performed microwave measurements on $CeCu_6$ and $YbRh_2Si_2$ single crystals. For $CeCu_6$ (and in zero magnetic field) we observe a smooth evolution of the microwave surface resistance throughout our complete temperature range, including the Fermi-liquid regime, and we find a substantial anisotropy. For $YbRh_2Si_2$, on the other hand, the temperature dependence of the microwave surface resistance exhibits pronounced anomalies, which we relate to the transitions between antiferromagnetic, Fermi-liquid, and non-Fermi-liquid regimes of the phase diagram for magnetic fields below 80 mT.

TU.B-P64 - trivalent uranium crystal-field states in UGa_2 and UPd_2Al_3 intermetallics

R. Radwanski [1,2], D. Nalecz [1], Z. Ropka [2]

1. Institute of Physics, Pedagogical University, Krakow, Poland
2. Center of Solid State Physics, Krakow, Poland

UPd_2Al_3 exhibits superconductivity coexisting below T_{sc} of 2 K with the antiferromagnetic state (T_N = 14 K) with substantial U magnetic moment. Apart of the surprising superconductivity there was long debate on the role played by *f* electrons, itinerant or localized, and a number of localized *f* electrons. One of the present authors (RJR) has claimed at the very beginning on the existence of the three localized *f* electrons, i.e. of the U^{3+} ion in UPd_2Al_3, in contrary to strong opposition of the "itinerant" community or of "two-localized-f-electrons" community. Much the same debate goes over description of UGa_2. UGa_2 is unique uranium compound being ferromagnet with T_c =125 K. Our U^{3+} description (JMMM 140-144 (95) 1373) was covered by a $5f^2$ claim (Phys. Rev. B 53 (1996) 9658) and later by a dual f-electron model. Recent studies [1] on the single-crystal specimen of UGa_2 have revealed a surprised increase of Tc with pressure but confirmed the strong ferromagnetic properties with a moment of 3.07 uB, 10% larger than the previous value. Magnetization curves have revealed (Ref. 37 in very strong anisotropy with the moments lying along the hexagonal a axis. The ferromagnetic state allows for the evaluation of the macroscopic anisotropy parameters. We have derived a new modified set of crystal-field (CEF) parameters in order to account for the observed larger magnetic moment. We have calculated the splitting of the lowest CEF state in the ferromagnetic state to be 98 K what we claim was seen in the inelastic-neutron scattering experiments and interpreted as a magnon gap of 7-8 meV (Ref. 37 in [1]).
Within the Quantum Atomistic Solid State theory (QUASST), claiming the preservation of the atomic-like states in a solid, we consistently have explained the ground-state properties and thermodynamics, both in the paramagnetic and magnetic state, together with the reproduction of the λ-type peak at the phase transition. In QUASST we look for solutions with an integer number of f electrons in contrary to a 5f-ligand hybridization model.

7. Jülich Centre for Neutron Science at MLZ, Forschungszentrum Jülich GmbH, Garching, Germany

The heavy-fermion compound $CeCu_2Ge_2$ with tetragonal $ThCr_2Si_2$ structure establishes incommensurate antiferromagnetic order below TN = 4.1 K with a propagation vector k = (0.285 0.285 0.550) and Kondo compensated moments of 1.0 μ;B/Ce. The magnetic order was determined to be an amplitude-modulated magnetic structure with moments along the [1-10] direction, i.e., perpendicular to the propagation vector. Similar to the superconducting counterpart $CeCu_2Si_2$, comparable energy scales of the RKKY interaction and the Kondo screening lead to a complex magnetic B-T phase diagram. Crystalline electric field excitations of the Ce3+ moments (J = 5/2) do not play a role here, since the ground-state doublet is well separated from the excited states. Recently Singh et al. (Sci. Rep. 1, 117 (2011)) reported on quantum-critical behavior in the spin dynamics in $CeCu_2Ge_2$ when applying a magnetic field B = 8 T (B || [1-10]). This observation triggered us to study the magnetic order and the spin dynamics of $CeCu_2Si_2$ in more detail at low temperatures (deep in the ordered state and close to TN) and in magnetic fields up to 13.5 T (B || [1-10]). In contrast to Singh et al. the transition at B ~ 7.5…8T is clearly identified as a first-order transition with no appearance of quantum-critical behavior. At higher fields B ~ 13 T the magnetic superstructure peaks vanish and spectral weight of the spin excitations shifts to lower energies. However, quantum-critical behavior there is also not obvious. Additionally, we performed mean-field calculations of the spin-wave spectrum and the magnetic order in $CeCu_2Ge_2$ using McPhase. Given the limitations of the technique the spin-wave dispersions and the magnetic structure are well described. To further improve the theoretical modeling the partially itinerant nature of the 4f Ce magnetism in $CeCu_2Ge_2$ would have to be taken into account.

TU.B-P67 - $Yb_2Ni_{12}Pn_7$ (Pn = P,As): A promising system for studying valence fluctuations and quantum criticality

W. Jiang [1], L. Yang [1], C. Guo [1], J. Chen [2], Z. Hu [3], J. Lee [2], Y. Wang [1], Y. Chen [1], M. Smidman [1], Z. Chen [1]

1. Center for Correlated Matter and Department of Physics, Zhejiang University, Hangzhou, China
2. National Synchrotron Radiation Research Center, Hsinchu, Taiwan
3. Max Planck Institute for Chemical Physics of Solids, Dresden, Germany

We report measurements of the physical properties and electronic structure of the hexagonal compounds $Yb_2Ni_{12}Pn_7$ (Pn = P, As) [1] by measuring the electrical resistivity, magnetization, specific heat, partial fluorescence yield X-ray absorption spectra (PFY-XAS), and resonant X-ray emission spectra (RXES). These demonstrate a crossover upon reducing the unit cell volume, from a mixed valence state in $Yb_2Ni_{12}As_7$ to a heavy-fermion paramagnetic state in $Yb_2Ni_{12}P_7$, where the Yb is nearly trivalent. Upon applying pressure to $Yb_2Ni_{12}P_7$, the temperature at which Fermi liquid behavior is observed (TFL) is suppressed, suggesting the presence of a quantum critical point (QCP) [2] at around 2.8 GPa and there is little change in the Yb valence up to 30 GPa. However, there is a strong increase of the Yb valence for $Yb_2Ni_{12}As_7$ under pressure, before a near constant value is reached. The pressure dependence of the valence and lattice parameters are compared, indicating a correlation between structural and electronic changes. These results indicate that any magnetic QCP in this system is well separated from strong valence fluctuations.

TU.B-P69 - Possible signature of magnetic order inside the superconducting state at low magnetic fields in $CeCoIn_5$

C.F. Miclea [1], M. Niclas [2], A.C. Mota [3], J.D. Thomson [4], R. Movshovich [4]

1. National Institute for Materials Physics, Bucharest-Magurele, Romania
2. Max-Planck-Institute for Chemical Physics of Solids, Dresden, Germany
3. Solid State Laboratory, ETH Zurich, Zurich, Switzerland
4. Los Alamos National Laboratory, Los Alamos, New Mexico, United States

The presence of strong magnetic fluctuations manifested in the heavy fermion compound CeCoIn5 by non Fermi-liquid behavior suggested that this compound is placed in the proximity of a magnetic quantum critical point. However no long range magnetic order has been reported so far. In this study we report on vortex dynamics, dc magnetization and penetration depth measurements in CeCoIn5 down to low temperatures, T=50 mK. While the pinning is rather conventional for a clean limit superconductor which does not break spontaneously any additional symmetries besides the U(1)-gauge, a strong increase in the remnant magnetization, Mrem is observed around T approximately 0.3 K in low magnetic fields just high enough to put the sample in the Bean critical state. Moreover, this anomaly is corroborated by the DC magnetization and the penetration depth measurements at very low fields. We extended the vortex dynamics investigation to Pb irradiated CeCoIn5. While the defects created by irradiation have a clear effect on the relaxation rates, the enhancement of Mrem still takes place at the same temperature. Our findings are consistent with the existence of a magnetically ordered phase, deep inside the superconducting state.

TU.B-P70 - XMCD study of ferromagnetism in $YbCu_2Si_2$ under pressure

F. Wilhelm [1], D. Braithwaite [2], S. M. Ramos [2], E.N. Hering [2], G. Lapertot [2], A. Rogalev [1]

1. European Synchrotron Radiation Facility (ESRF), Grenoble, France
2. SPSMS, UMR-E CEA / UJF-Grenoble 1, INAC, Grenoble, France

In rare-earth intermediate-valence (IV) compounds, the interplay between the magnetic and valence instability represents one of the most studied subjects, with the possibility of tuning the system to a magnetic quantum critical point (QCP), where strong spin and/or valence fluctuations are present. The Ce and Yb Kondo lattices are often considered to be electron/hole equivalents, however Yb compounds also offer a favorable opportunity for studying the role of the valence fluctuations in the quantum criticality, since applying pressure is expected to induce larger changes of the valence. $YbCu_2Si_2$ is an ideal prototype Yb system, obeying Doniach's phase diagram. By applying pressure, the system evolves from a paramagnetic state to an ordered one [1], reached at the critical pressure Pc=7-8GPa. Recent a.c. susceptibility measurements under high pressure strongly suggested that the induced magnetic order is ferromagnetic (FM) [2]. Determining the nature of an ordered phase that occurs only above 8 GPa although, is not trivial. A direct confirmation of ferromagnetism in this compound is highly desirable, especially because systems presenting a FM QCP are quite rare. In this work, we report x-ray magnetic circular dichroism (XMCD) measurements at the L3-edge of Yb in $YbCu_2Si_2$ single crystal at 2K and under pressure up to 15GPa. The amplitude of the XMCD signal is proportional magnetization of the absorbing atom. For pressures higher than 7.5GPa, the field dependence of the XMCD signal shows a typical FM behavior with a tendency to saturate above H=0.5T. Moreover, it was found to be small and almost constant at low pressure, followed by a strong increase above Pc, confirming the FM nature of the ordered phase.

TU.B-P72 - Crystal field in R_2RhIn$_8$ series studied by bulk measurements

P. Čermákm [1], M. Prachařová [2], J Zubáč [2], K. Pajskr [2], P. Javorský [2]

1. Forschungszentrum Jülich, Outstation At MLZ, Jülich, Germany
2. Charles University in Prague, Prague, Czech Republic

The influence of the anisotropy on the magnetic and superconducting properties of heavy fermion compounds has been studied for a long time. Previous studies on R_2RhIn_8 (where *R* is rare earth) showed, that magnetic structures are driven mainly by crystalline electric field (CEF) [1, 2, 3]. We have grown compounds with *R* = Nd, Tb, Ho, Dy, Er and Tm and determined their magnetic structures [2, 3].
In this presentation, we are going to show detailed analysis of specific heat from 1.5 – 300K. Precise Schottky magnetic contribution is determined by subtraction of the electron and phonon specific heat determined from non-magnetic analogues with *R* = La, Lu, Y [4]. Schottky specific heat and susceptibility temperature dependencies are then fitted simultaneously to obtain CEF energy levels. Determined second order B_2^0 CEF parameter is always dominant and its sign determines crystal anisotropy and theoretically calculated exchange constants matches determined crystal structures. The results are discussed in context of CEF and magnetic structures in heavy fermion superconductor Ce_2RhIn_8, where also other effects come into the role.
The new open source software package for simultaneous fitting of specific heat and susceptibility will be introduced.

TU.B-P73 - Neutron scattering and high pressure transport properties in a rare correlated ferromagnet Nd_2PdSi_3

S. Saha [1], R. Wang [1], J. Paglione [1], J. Lynn [2], J. Jeffries [3]

1. Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland, College Park, Maryland, United States
2. NIST Center for Neutron Research, National Institute of Standards and Technology, Gaithersburg, Maryland, United States
3. Condensed Matter and Materials Division, Lawrence Livermore National Laboratory, Livermore, California, United States

The compound Nd_2PdSi_3 belongs to an AlB2-derived ternary family (hexagonal structure, space group P6/mmm) showing many exotic properties [1-3]. This compound attracted recent attention: It is reported to order ferromagnetically below T0~16 K, unlike the other members of this series that order antiferromagnetically. The magnetic ordering temperature T0 is significantly enhanced with respect to the de Gennes-scaled value [3]. Studying polycrystalline sample, the effects of Nd (4f) hybridization on the magnetism is discussed, which is rare in an Nd-based intermetallic compound [3]. We have grown single crystals of Nd_2PdSi_3 using Czochralski method in a tetra arc furnace. We would like to present neutron scattering, magnetic, and transport properties under high pressure on Nd_2PdSi_3 and discuss about Nd (4f) hybridization.

TU.B-P74 - Magnetic and related properties of $Ce_3T_2Sn_7$ (where T = Ti, V, Cr, Co, Ni).

G. Chajewski [1], A. Pikul [1]

1. Institute of Low Temperature And Structure Research, Polish Academy of Sciences, Wroclaw, Poland

Ternary cerium-based intermetallics attract great attention due to variety of intriguing low-temperature physical properties. Although it is commonly believed that their ground state is governed mainly by hybridization of 4f electrons of cerium with conduction band (s, p and d) electrons, there is still little known about the influence of particular groups of electrons on the properties of the f-electron systems. In order to shed more light on that issue we have performed comprehensive investigations of a series of isostructural phases $Ce_3T_2M_7$ (where T is a transition or noble metal and M stands for p-electron element). Here we present preliminary results obtained for a few stanides with Ti, V, Cr, Co and Ni.
Polycrystalline samples of $Ce_3Ti_2Sn_7$, $Ce_3V_2Sn_7$, $Ce_3Cr_2Sn_7$, $Ce_3Co_2Sn_7$ and $Ce_3Ni_2Sn_7$ were prepared by conventional arc melting the stoichiometric amounts of the constituents and studied by means of X-ray powder diffraction, magnetization, electrical transport and specific heat measurements. Rietveld refinement of the experimental powder diffraction patterns confirmed that all the phases studied crystallize in the orthorhombic $La_3Co_2Sn_7$-type structure (space group *Cmmm*, no. 65) with lattice parameters close to those reported for $Ce_3Ni_2Sn_7$ – the only hitherto known compound of this family [1]. Magnetization of the compounds exhibits at elevated temperatures Curie-Weiss-like behavior with the effective magnetic moment close to that expected for a free Ce^{3+} ion. Only in $Ce_3Ni_2Sn_7$ and $Ce_3Co_2Sn_7$ the moments order antiferromagnetically below T_N = 3.8 K and 4.4 K respectively. Specific heat and transport properties of all phases studied show some features characteristic of dense Kondo systems.

TU.B-P75 - Low-temperature properties of the non-centrosymmetric heavy-fermion compound $CeTAl_3$ (T = Cu, Ag, Au, Pd, Pt)

C. Franz [1], R. Schönmann [1], J. Spallek [1], A. Regnat [1], A. Senyshyn [2], P. Cermak [3], P.J. Cabre [1], A. Schneidewind [3], A. Bauer [1], C. Pfleiderer [1]

1. Physik Department E51, Technische Universität München, Garching, Germany
2. Forschungs-Neutronenquelle Heinz Maier-Leibnitz , Garching, Germany
3. Jülich Centre for Neutron Science JCNS, Outstation at MLZ, Garching, Germany

We report a comprehensive study of the series of non-centrosymmetric heavy-fermion compounds CeTAl3 (T = Cu, Ag, Au, Pd, and Pt). Large single crystals have been prepared by means of optical float-zoning. The single-crystal ingots were characterized using Laue x-ray scattering, powder x-ray diffraction, and energy dispersive x-ray spectroscopy. For T = Cu, Au, Pd, and Pt the system crystallizes in the non-centrosymmetric I4mm crystal structure, while we observe a slight orthorombic distortion for T = Ag. Subsequently, the magnetization, specific heat, and electrical resistivity were investigated down to temperatures of 200 mK and in magnetic fields of up to 14 T revealing typical heavy-fermion behavior. At low temperatures, $CeCuAl_3$ and $CeAuAl_3$ order antiferromagnetically, whereas $CeAgAl_3$ is a ferromagnet. Inelastic neutron scattering studies indicate the presence of so-called vibron modes, i.e., coupled modes of phonons and crystal electric field excitations.

TU.B-P76 - Thermal expansion and magnetostriction of heavy fermion $CeRu_2Si_2$ at millikelvin temperatures

D. Inoue [1], D. Kaido [1], Y. Yoshikawa [1], M. Minegishi [1], K. Matsumoto [1], S. Abe [1], S. Murayama [2]

1. Kanazawa University, Kanazawa, Japan
2. Muroran Institute of Technology, Mumoran, Japan

$CeRu_2Si_2$ is well known as a typical heavy fermion compound, which generally exhibits the Landau-Fermi liquid (LFL) state that thermal expansion coefficient and magnetostriction coefficient were proportional to the temperature and magnetic field, respectively, below the Kondo temperature T_K. This compound has a $ThCr_2Si_2$ -type crystal structure that the easy axis (c-axis) and the hard axis (a-axis) of magnetization indicate the metamagnetic behavior for B//c-axis. Here, we have measured linear thermal expansion and magnetostriction of single crystal $CeRu_2Si_2$ along the a-axis (B//a-axis) at temperature down to 12 mK and in magnetic fields up to 9 T. Our dilatometer using the capacitance method composed of the sample and the reference capacitor provides the high precision of $dL/L \sim 10^{-10}$ in millikelvin temperatures. In high-temperature region and high magnetic fields, thermal expansion and magnetostriction exhibited the LFL behavior in contrast to the metamagnetic behavior for B//c-axis and indicated a strong magnetic anisotropy between the direction parallel and perpendicular to the a-axis. Furthermore, we observed non-Fermi liquid behavior that showed the negative contribution about $T < 100$ mK and $B < 1$ T. Thermal expansion and magnetostriction have a close relationship with the partial derivative of entropy and magnetization with respect to pressure. Thus, these properties are apposite to investigate the pressure driven quantum criticali point.

TU.B-P77 - Fermi Surface properties in impurity kondo effect : Quantum oscillation study on $Ce_xLa_{1-x}Ru_2Si_2$ and $U_xTh_{1-x}Ru_2Si_2$

Y. Matsumoto [1], Y. Haga [2], N. Tateiwa [2], N. Kimura [3], H. Aoki [3], E. Yamamoto [2], S. Ohara [1], Z. Fisk [2,4], H. Yamagami [2,5]

5. Kyoto Sangyo University, Kyoto, Japan

In strongly correlated f electron system, many anomalous properties, for example heavy fermion, non-Fermi liquid and unconventional superconductivity, takes place. To understand these properties, it is important to measure the electronic structure. Especially, it is concerned that the relation between Kondo effect and electronic structure is the most important key to reveal the electronic structure because the Kondo effect is likely to be the origin of the delocalized f electron from the de Haas-van Alphen (dHvA) effect measurements study of impurity Kondo state in $Ce_xLa_{1-x}Ru_2Si_2$. We have performed the quantum oscillation study of $Ce_xLa_{1-x}Ru_2Si_2$ alloy and $U_{1-x}Th_xRu_2Si_2$ to reveal the Fermi surface properties of typical heavy fermion compound $CeRu_2Si_2$ and URu_2Si_2. From $LaRu_2Si_2$ with no f electron to $CeRu_2Si_2$ through impurity Kondo state, the Fermi surface continuously changes with Ce concentration. On the other hand, from $ThRu_2Si_2$ with no f electron to x=0.03, Fermi surfaces does not changes. Moreover, we regard $ThRu_2Si_2$ as a reference Ce^{4}+ compound and compared the Fermi surfaces of $ThRu_2Si_2$ and those of $CeRu_2Si_2$. The results indicate that the topology of Fermi surfaces is similar each other.

TU.B-P78 - Single Crystal Growth and physical properties of $R_2Pt_6Ga_{15}$ (R=rare earth)

Y. Matsumoto [1], T. Ueda [1], S. Ohara [1]

1. Nagoya Institute of Technology, Aichi, Japan

We have synthesized the single crystal $R_2Pt_6Ga_{15}$ (R=rare earth) with hexagonal $Sc_{0.67}Fe_2Si_5$ type structure. The magnetic R-ions form a two-dimensional triangle-lattice. The nearest R-R distance is 0.43nm in c-plane. While, the distance between triangle-lattice layers is about 8.7Å along c-axis, which is more than twice as long as the in-plane R-R distance.
We have measured the magnetic properties and specific heat of $R_2Pt_6Ga_{15}$. It is found that the antiferromagnetic order takes place in $R_2Pt_6Ga_{15}$ except R=Ce and Yb.

TU.C-P01 - Quantum criticality of spin liquids in novel insulators and magnets

V. Stephanovich [1], V. Shaginyan [2], E. Kirichenko [1]

1. Opole University, Opole, Poland
2. Petersburg Nuclear Physics Institute, Gatchina, Russia

Strongly correlated Fermi systems are among the most intriguing and fundamental systems in physics, whose realization in some compounds is still under consideration. Quantum spin liquids are promising new phases, where exotic quantum states of matter could be realized. Here we consider a quantum spin liquid (QSL) made of hypothetic particles like chargeless fermionic spinons with spin ½. The QSL can be conveniently realized in geometrically frustrated magnetic insulators like herbertsmithite [1], where important experimental facts have been gathered. We present a theory of the QSL thermodynamic properties. The essence of our theoretical approach is the notion of so-called fermion condensation quantum phase transition [2]. This transition occurs at zero temperature and leads to a quite specific state called fermion condensation. The manifestation of such effect is one more channel of Landau Fermi liquid instability (complimentary to Pomeranchuk criteria), which consists in unlimited increase of the effective mass of Landau quasiparticles which creates flat bands [2]. The application of this formalism permits to reveal the scaling behavior, which strongly resembles that observed in heavy-fermion (HF) metals and two-dimensional 3He. We also describe the dynamic magnetic susceptibility of QSL compounds, which allows us to show that at low temperatures quasiparticles excitations, or spinons, form a continuum, and populate an approximately flat band crossing the Fermi level. Our analysis reveals that the properties of QSL compounds are similar to those of HF metals. Transport properties of the QSL compounds shed light on the QSL nature in them. Analysis of the heat conductivity detects its scaling behavior resembling those of both the spin-lattice relaxation rate and the magnetoresistivity. It reveals a strong magnetic field dependence of the spinons effective mass.

In order to elucidate the dependence of the magnetic ground state on the Ca content (x) in $Sr_{1-x}Ca_xCo_2P_2$ (0<=x<=1, $ThCr_2Si_2$-type structure), we have performed muon-spin rotation and relaxation (\muSR) experiments on $Sr_{1-x}Ca_xCo_2P_2$ powder samples mainly in a zero applied field [1]. The end member compound, $SrCo_2P_2$ is found to be paramagnetic down to 19 mK, which is consistent with recent single crystal [2]. As x increases, such a paramagnetic ground state is observed until x = 0.45 down to 1.8 K. Then, as x increases further, a short-range antiferromagnetic (AF) ordered phase appears at low temperatures for 0.48<=x<=0.75, and finally, a long-range AF ordered phase is stabilized for x>0.75. The internal magnetic field of the other end member compound, $CaCo_2P_2$, is well consistent with that of the A-type AF order state, which was proposed from neutron scattering experiments [3]. The phase diagram determined with \muSR is different from that proposed by macroscopic measurements [4]. The evolution of the magnetic order is connected to the shrinking of the c-axis length as a function of x, which naturally enhances the AF interaction between the two adjacent Co planes.

TU.C-P03 - Quantum criticality of a Kondo quantum dot coupled to helical edge states of 2D interacting topological insulators

C.H. Chung [1,2], S. Silotri [1]

1. Department of Electrophysics, National Chiao-Tung University, HsinChu, Taiwan
2. Physics Division, National Center for Theoretical Sciences, HsinChu, Taiwan

For two decades, the exotic quantum phase transition (QPT) between the one-channel Kondo (1CK) and two-channel Kondo (2CK) ground states has been predicted in a Kondo impurity coupled to two electron-electron interacting 1D Luttinger liquid leads via varying the electron interactions in the lead, defined by the Luttinger parameter 0<K<1. The 1CK-2CK quantum critical point is at Kc=1/2. However, no rigorous theoretical approaches are available so far to access this new quantum critical point due to the divergence of the intra-lead Kondo coupling near 2CK fixed point. We successfully address this long-standing issue of 1CK-2CK QPT in a modern context: in a Kondo quantum dot coupled to two leads made of helical edge states of interacting 2D topological (Quantum Spin Hall) insulators, known as the helical Luttinger liquids. We examine the SU(2) symmetry breaking anisotropic 2-channel Kondo model of our setup via a controlled field-theoretical perturbative renormalization group (RG) approach combined with bosonization and re-fermionization techniques. In the limit of strong electron interactions (K << 1), we find the 2CK phase is favored. However, for sufficiently weak interactions (K close 1), the 2CK state is unstable towards the 1CK fixed point again and the system undergoes a quantum phase transition between 1CK and 2CK quantum ground states as K or Kondo couplings are varied. The quantum critical and crossover behaviors for various thermodynamic quantities near the transition are obtained. Our study serves as the first example of the 1CK-2CK QPT that is accessible by a controlled theoretical approach.

TU.C-P04 - Yb-based quantum critical materials: Single crystal growth and characterization of $YbRh_2Si_2$ and $YbNi_4P_2$

K. Kliemt [1], C. Butzke [1], C. Krellner [1]

1. Goethe-University Frankfurt, Frankfurt, Germany

Heavy fermion systems are model systems to unravel the exciting physics around quantum-phase transitions. Studying these emergent phenomena necessitates the preparation of large and high-quality single crystals. Here, we report on the optimization of the single-crystal growth for two Yb-based quantum critical materials, $YbRh_2Si_2$ and $YbNi_4P_2$.
The prototype heavyfermion system $YbRh_2Si_2$ is situated extremely close to an unconventional antiferromagnetic (AF) quantum critical point (QCP). The AF ordering (TN= 70 mK) can be further lowered by chemically induced negative pressure using Ir-substitution. The QCP is reached for an Ir substitution of x ~ 0.1 in $Yb(Rh_{1-x}Ir_x)_2Si_2$ [1] . Here, we report on the optimization of the crystal growth of the substitution series as well as of the unsubstituted compound from an indium-flux. The latest crystal generation of $YbRh_2Si_2$ grown with that method exhibits a resistivity ratio RR1.8K ~ 33. Furthermore, we report on our experiments to determine the melting point of $YbRh_2Si_2$, which reveal a melting point above 1800°C. In the heavy fermion metal, $YbNi_4P_2$, a ferromagnetic (FM) transition at TC = 0.17K was observed recently [2] and a FM QCP is reached at x ~ 0.1 in $YbNi_4(P1_{-x}Asx)_2$ [3] . We report on the successful crystal growth of $YbNi_4P_2$ by Czochralski method out of a Ni-P self-flux from a levitated melt. Applying this method yields mm^3 sized crystals. The obtained crystals were characterized by Laue X-ray scattering, X-ray powder diffraction, EDX microprobe analysis and resistivity measurements.

TU.C-P05 - Crossover from non-Fermi liquid to Fermi liquid behavior and the superconductivity dome in heavy electron systems

P. Schlottmann [1]

1. Florida State University, Tallahassee, United Sates

nested Fermi surface together with the remaining interaction between the carriers after the heavy particles are formed may give rise to itinerant antiferromagnetism. We consider an electron and a hole pocket, separated by a wave vector Q, and Fermi momenta kF1 and kF2, respectively [1]. The order is gradually suppressed by increasing the mismatch of the two Fermi momenta and a QCP is obtained as TN --> 0. For critical mismatch of the Fermi vectors (tuned QCP) the specific heat over T increases as -ln(T) as T is lowered [1,2] and the linewidth of the quasi-particles is linear in T and |?|. With increasing nesting mismatch and decreasing temperature the specific heat and the linewidth display a crossover from non-Fermi liquid (~ T) to Fermi liquid (~ T2) behavior.
If in addition the vector Q is commensurate with the lattice (Umklapp with Q = G/2), pairs of electrons can be transferred between the pockets. To avoid the QCP this process may lead to superconductivity and a superconducting dome above the quantum critical point. We investigate the conditions under which such a dome arises [2].

TU.C-P06 - Non-linear quantum critical conductance in a dissipative resonant level through a double-barrier

C.H. Chung [1,2], C.Y. Lin [1], H. Baranger [3], G. Finkelstein [3]

1. Department of Electrophysics, National Chiao-Tung University, HsinChu, Taiwan
2. Physics Division, National Center for Theoretical Sciences, HsinChu, Taiwan,
3. Department of Physics, Duke University, Durham, United States

The recent experiment by H.T. Mebrahtu et.al. (Nature Physics 9, 732 (2013)) demonstrated an exotic state of electronic matter obtained by fine-tuning to a quantum critical point (QCP) in a resonant level quantum dot coupled to an Ohmic dissipative nano-wire through a symmetrical double-barrier potential. At low temperatures T and bias voltages V across the dot, the deviation of conductance from perfect transmission shows a universal crossover from a power-law in V/T for V>T (with an exponent related to the dissipation strength) to a constant for V<T, a signature of a non-Fermi liquid quantum critical behavior. However, there is lack of theoretical understanding of it. We theoretically address this issue by investigating the non-linear transport of the system at finite T and V in the resonant tunneling regime. Utilizing combined bosonization and re-fermionization, we map our model onto a voltage-biased spinless resonant level coupled to an effective new Luttinger liquid lead and compute the non-linear conductance via controlled frequency-dependent renormalization group (RG). We address the interplay between decoherence and Luttinger physics. Our results are in excellent agreement with the above-mentioned experiment.

TU.C-P07 - Quantum criticality of an itinerant 5f-electron ferromagnet: Ru doped UCoAl

P. Opletal [1], Jan Prokleška [1], V Sechovský [1]

1. Charles University In Prague, Faculty of Mathematics And Physics, Department of Condensed Matter Physics, Prague, Czech Republic

UCoAl is an itinerant 5f-electron paramagnet appearing on the verge of ferromagnetism. It crystallizes in the hexagonal ZrNiAl-type structure and exhibits strong magnetocrystalline anisotropy with easy axis along the c-axis. At low temperatures it undergoes first-order metamagnetic phase transition (FOMPT) to ferromagnetic state with the critical magnetic field Bc ~ 0.7 T applied along the c-axis and the critical temperature T0 = 11 K where FOMPT changes to crossover behavior. Bc (T0) increases (decreases) with applying hydrostatic pressure. FOMPT disappears at quantum critical point at p = 1.5 GPa and B = 7 T. This is in agreement with the generic H,p,T phase diagram for itinerant quantum ferromagnets. From this phase diagram and pressure experiments on UCoAl, the true ferromagnetic phase would appear in negative pressures $p \leq -0.2$ GPa, which cannot be put into practice. The unusual physics of UCoAl has been attracting researchers for many years. Frequent studies dealt with substituting Co by other d-elements. Depending on d-metal dopant and its amount, ground ferromagnetic or paramagnetic state, where FOMPT completely disappears is realized. It has been shown that as little as 1% of Ru substituted for Co leads to ferromagnetism with TC = 17 K. By lowering nominal Ru content we move closer to the UCoAl ground state. We have grown single crystals of $UCo_{1-x}Ru_xAl$ for x = 0.0025, 0.005 and 0.01 and investigated the corresponding H,p,T magnetic phase diagram by magnetic, electrical resistivity, Hall Effect and thermal expansion measurements. $UCo_{0.9975}Ru_{0.0025}Al$ exhibits paramagnetic ground state and FOMPT with critical magnetic field Bc ~ 0.55 T. In $UCo_{0.995}Ru_{0.005}Al$ ground ferromagnetic state and FOMPT is observed. $UCo_{0.99}Ru_{0.01}Al$ exhibits same ground ferromagnetic state as in previous research. Evolution of magnetism in UCoAl and our single crystals within the generic H,p,T phase diagram of itinerant quantum ferromagnets will be discussed.

TU.C-P09 - Tuning $ZrFe_4Si_2$ by Ge substitution: Confirming the proximity to a magnetic quantum critical point

K. Weber [1,2], N. Mufti [1], T. Goltz [2], T. Woike [3], H.H. Klauss [2], C. Bergmann [1], H. Rosner [1], C. Geibel [1]

1. Max Planck Institute For Chemical Physics of Solids, Dresden, Germany
2. Institute of Solid State Physics, Dresden University of Technology, Dresden, Germany
3. Institute for Structural Physics, Dresden University of Technology, Dresden, Germany

Magnetic systems with reduced dimensionality or frustration are attracting strong interest because these features lead to an increase of quantum fluctuations which often results in unusual, very interesting properties. Our previous studies evidence the AFe4X2 family (A = Y, Lu, Zr and X = Ge, Si) to cover the whole regime from frustrated antiferromagnetic (AFM) order up to the quantum critical point separating the frustrated AFM ground state from the paramagnetic ground state. $ZrFe_4Si_2$ showed evidence for an unusual type of weak magnetic order and was therefore suspected to be near the quantum critical point. In order to get a deeper insight into its ground state, we performed a detailed study of Ge substituted $ZrFe_4Si_2$, where Ge is suspected to stabilize the magnetic state because of a negative chemical pressure effect. We synthesized polycrystalline samples of $ZrFe_4(Si_{1-x}Ge_x)2$ with x = 2 % to 50 % and investigated their magnetic, thermodynamic, structural and transport properties. As expected, with increasing Ge content the magnetic state is stabilized towards a well defined AFM order at high Ge content. This confirms the near-by quantum critical point in $ZrFe_4Si_2$.

TU.C-P10 - Electron doping effect on $AeCo_2As_2$ (Ae = Ca, Sr and Ba)

H. Ohta [1], E. Akabane [1], H. Katori [1]

1. Institute of Engineering, Division of Advanced Applied Physics, Tokyo University of Agriculture And Technology, Koganei, Jpana

We synthesized solid solutions of $Ae(Co_{1-x}Ni_x)_2As_2$ (Ae = Ca, Sr and Ba) for studying electron doping effects on $AeCo_2As_2$. As results of magnetic measurements, we found that $SrCo_2As_2$, which is exchange-enhanced Pauli paramagnet, shows antiferromagnetic ordering with 10% of Ni substitution, despite their uncollapsed tetragonal structure. For the case of $BaCo_2As_2$, Ni substitution does not induce magnetic ordering. However, the Weiss temperature of $Ba(Co_{1-x}Ni_x)_2As_2$ shows maximum at about x = 0.15, where the sample is almost magnetically ordering. These results show that $AeCo_2As_2$ with uncollapsed tetragonal structure have potential to magnetically order. They can not order possibly because their Fermi energy is slightly lower than peak position of density of states.

TU.C-P11 - Perfect Metal Phases of One-Dimensional and Anisotropic Higher-Dimensional Systems

M. Mulligan [1], E. Plamadeala [2], C. Nayak [2,3]

1. Stanford University, Stanford, United States
2. University of California, Santa Barbara, United States
3. Microsoft Research, Station Q, Santa Barbara, United States

We show that a 1D quantum wire with 23 channels of interacting fermions has a perfect metal phase in which all weak perturbations that could destabilize this phase are irrelevant. Consequently, weak disorder does not localize it, a weak periodic potential does not open a gap, and contact with a superconductor also fails to open a gap. Similar phases occur for N>23 channels of fermions, except for N=25, and for 8k channels of interacting bosons, with k>2. Arrays of perfect metallic wires form higher-dimensional fermionic or bosonic perfect metals, albeit highly-anisotropic ones. We will also discuss aspects of transport in such perfect metal wire arrays.

TU.C-P12 - Magneto - crystalline anisotropy and non - Fermi - liquid behaviour in $CeNi_{1-x}Co_xGe_2$

Z. Molčanová [1], M. Mihalik [1], M. Mihalik [1], M. Zentková [1], Viktor Kavečanský [1], J. Briančin [2]

1. Institute of Experimental Physics SAS, Košice, Slovak Republic
2. Institute of Geotechnics SAS, Košice, Slovak Republic

In our contribution we present results of magnetization, AC susceptibility, specific heat and electrical resistivity measurements of $CeNi_{1-x}Co_xGe_2$ heavy fermion system ($0 < x < 1$) which were prepared by arc melting and grown by optical floating zone method in four mirror furnace. The parent compound $CeNiGe_2$ is an antiferromagnetic Kondo system that orders magnetically at T_N = 3.9 K and undergoes a spin structure rearrangement at T_1 = 3.2 K [1] while $CeCoGe_2$ is a nonmagnetic heavy-fermion Kondo compound with j=5/2 ground state and large Kondo temperature T_K > 200 K [2]. Our magnetization and electric resistivity measurements confirmed large magneto - crystalline anisotropy of the system. The susceptibility is strongly anisotropic over the whole temperature range studied but can be fitted with the Curie – Weiss law for all samples. The effective magnetic moments μ_{eff} does not change significantly and has been identified approximately to $2.55\mu_B$ for samples with low concentration of Co, but the paramagnetic Curie temperature changes very much with crystallographic orientation and chemical composition ranging from about – 80 K to small positive values. Heat capacity measurements revealed that characteristic feature of $CeNiGe_2$, the double peak with maxima at T_N =3.6 K and T_1 = 2.9 K, moves to smaller temperature and only single peak appears for sample containing small amount of Co. AC susceptibility results showed that the phase transition from the antiferromagnetic to the paramagnetic state is suppressed to lower temperatures with an increasing concentration of dopant. The maximum detected around 3.8 K for $CeNiGe_2$ decreases to 2.6K for x = 0.05 and the magnetic ordering is suppressed below 0.5 K at about x = 0.3.

TU.C-P13 - Non-fermi liquid behaviors in $PrIr_2Zn_{20}$: Effect of Ga substitution

T. Onimaru [1], K. Uenisi [1], K.T. Matsumoto [1], K. Wakiya [1], K. Umeo [2], T. Takabatake [1,3]

1. Dept. Quantum Matter, AdSM, Hiroshima University, Higashi-Hiroshima, Japan
2. N-BARD, Hiroshima University, Hiroshima, Japan
3. IAMR, Hiroshima University, Higashi-Hiroshima, Japan

Praseodymium-based cubic compounds attract much attention because they show various phenomena arising from nonmagnetic degenerated ground states of 4f2 configuration. In particular, a family of PrT2X20 (X=Al and Zn) show quadrupole order, heavy-fermion superconductivity, and structural transitions.[1-3] The crystalline electric field ground state of most PrT2X20 compounds is a non-Kramers gamma3 doublet that possesses no magnetic dipoles but electric quadrupoles. Among them, PrIr2Zn20 undergoes an antiferroquadupole order at *T*Q=0.11 K and a superconducting transition at *T*c=0.05 K.[1,2] In the temperature range 0.2<*T*<0.8 K, above *T*Q, the magnetic specific heat *C*m and the electrical resistivity rho(T) exhibit non-Fermi liquid (NFL) behavior; *C*m/*T* and rho are proportional to -lnT and rootT, respectively, being characteristic of quadrupole Kondo effect.[4] In the present work, the origin of the NFL behavior have been studied by the measurements of rho, *C*, and the magnetic susceptibility of PrIr2Zn20-*x*Ga*x* for *x*<=1.0.
The lattice parameter for *x*=1.0 decreases by only 0.1 % from that for *x*=0. The values of residual resistivity for *x*=0.5 and 1.0 increase by one-order of magnitude from that for *x*=0. It prevents us from detecting a change of the rootT dependence of rho(*T*) observed for *x*=0. The -lnT dependence of *C*m/*T* varnishes for *x*=0.5 and 1.0, and instead, *C*m/*T* approaches a constant value on cooling below 0.6 K, indicating collapse of the NFL state. As *T* goes down to 2 K, chi(T) continues to increase, although that for *x*=0 remains constant below 5 K. The results indicate the unstable NFL state in PrIr2Zn20. The driving mechanism is likely to be either enhancement of hybridization between the 4f and conduction electrons due to the increase of 4*p* electron density or small splitting of the gamma3 doublet due to the symmetry breaking at the Pr site.

TU.C-P14 - Substitution driven magnetic instabilities of non-Fermi liquid $Ce_3Pd_4Si_4$

E. Bauer [1], N. Robisc [1], K. Sirhan [1], I. Messner [1], R. Kurinjimala [1], B. Raab [1], F. Kneidinger [1], H. Michor [1], J. Sereni [2], A. Gribanov [3]

1. Vienna University of Technology, Vienna, Austria
2. CAB Bariloche, San Carlos de Bariloche, Argentina
3. Moscow State University, Moscow, Russia
4. University of Vienna, Vienna, Austria

An experimental study of ternary $Ce_3Pd_4Si_4$ evidenced non-Fermi liquid properties due to the proximity of this non-magnetic compound to a quantum critical point. The ground state observed for this Ce system appears to be a result of mutual interactions of the crystalline electric field, of the Kondo effect and of RKKY interactions. A subtle change of the balance of these interactions e.g., by pressure or by substitutions is expected to trigger some instability, presumably of magnetic origin. The aim of the present investigation is to reveal the response of the system when certain atoms in $Ce_3Pd_4Si_4$ are exchanged by different other appropriate elements. Here we will show how long range magnetic order in the substituted materials develops on a substitution of Ce/La, of Pd/Ni and of Si/Ge from a study of temperature, pressure and magnetic field dependent transport proper ties, of magnetization and of specific heat.

TU.C-P15 - Theory for anomalous magneto transport of $CeCu_2Si_2$ under the pressure of sharp valence crossover

K. Miyake [1], S. Watanabe [2]

1. Toyota Physical And Chemical Research Institute, Nagakute, Japan
2. Kyushu Institute of Technology, Kitakyushu, Japan

Anomalous and unconventional temperature (T) and pressure (P) dependences of the Hall coefficient of $CeCu_2Si_2$ observed under the pressure [1,2], around which the valence of Ce is known to exhibit sharp crossover from the Kondo to the valence fluctuation regime, are shown to be understood by the effect of critical valence fluctuations (CVF) which explain a series of unconventional behaviors observed in $CeCu_2Si_2$ around P=5GPa, such as enhancements of the superconducting transition temperature and the residual resistivity, and T-linear dependence in the resistivity, and so on [3]. By borrowing the formalism for the superconducting fluctuation effect on the Hall coefficient [4], we calculate the P and T dependence of Hall conductivity and the Hall angle, together with the Nernst coefficient, reproducing the unconventional behaviors observed by a series of experiments [1,2].

TU.C-P16 - Strange Metal Without Magnetic Criticality

T. Tomita [1], K. Kuga [2], Y. Uwatoko [1], S. Nakatsuji [1]

1. Institute For Solid State Physics (ISSP), University of Tokyo, Kashiwa, Japan
2. Center for Advanced High Magnetic Field Science, Graduate School of Science, Osaka University

Recently discovered heavy fermion superconductor ß-$YbAlB_4$ exhibits unconventional quantum criticality despite strong mixed valency. This material is also first Yb-system that exhibits quantum criticality at zero field at ambient pressure. [1-3] Normally, in Yb systems, it is expected that a magnetic order connected to the quantum critical point is driven through application of pressure.
Here, we report our comprehensive study on the pressure vs temperature phase diagram constructed by using the electrical resistivity, magnetization and specific heat measurements of single crystals ß-$YbAl_{1-x}Fe_xB_4$ down to the low temperature of 40 mK under pressure. We observed that non-Fermi liquid observed at ambient pressure is robust with application of pressure up to 0.4 GPa, beyond which a transition from non-Fermi-liquid to Fermi-liquid was observed. In further high pressure regime more than 2.5 GPa, the magnetic order was observed and T_N goes up with pressure, reaching 30 K under 8 GPa, extremely large scale for Yb heavy fermion compound. The same type of behavior is also confirmed in the Fe-doping as a function of chemical pressure. We will discuss the observation of strange metal 'phase' emergent nearby ambient pressure, which is separated from magnetic instability by Fermi liquid phase.[4]

TU.C-P17 - Non-Fermi liquid behavior in disordered Kondo systems $Ce_2Co_{0.8}Si_{3.2}$ and $Ce_2Rh_{0.4}Co_{0.4}Si_{3.2}$

D. Gnida [1], M. Szlawska [1], D. Kaczorowski [1]

1. Institute of Low Temperature And Structure Research, Polish Academy of Sciences, Wroclaw, Poland

The role of nonmagnetic disorder in Kondo lattice systems was investigated in single crystalline samples of $Ce_2Co_{0.8}Si_{3.2}$ and $Ce_2Rh_{0.4}Co_{0.4}Si_{3.2}$ by means of magnetic susceptibility, specific heat and magnetotransport measurements. Both compounds were characterized as Kondo paramagnets. Their low temperature thermodynamic properties are dominated by distinct non-Fermi liquid features, which manifests themselves as a power law divergence of the magnetic susceptibility and the heat capacity over temperature ratio [1, 2]. The temperature dependencies of the electrical resistivity, r(T), are characteristic of Kondo lattice systems. Below the coherence temperature, the resistivity is changing in linear or quasi-linear manner down to 0.4 K or 2 K for $Ce_2Co_{0.8}Si_{3.2}$ and $Ce_2Rh_{0.4}Co_{0.4}Si_{3.2}$, respectively, which is in line with the non-Fermi liquid behaviour observed in the thermodynamic properties. For $Ce_2Rh_{0.4}Co_{0.4}Si_{3.2}$, some shallow minima are observed below 2 K in both components of the resistivity tensor. In the case of $Ce_2Co_{0.8}Si_{3.2}$, similar minima appear in magnetic fields B > 3 T, and their position shift to higher temperatures with increasing field. As both compounds exhibit a high residual resistivity (r0 > 200 uOhmcm) and a small residual resistivity ratio (close to 1) it seems likely that the low-temperature upturns in r(T) occur due to diffusive motion enhanced interactions between conduction electrons. Thus, the anomalous thermodynamic and transport properties of $Ce_2Co_{0.8}Si_{3.2}$ and $Ce_2Rh_{0.4}Co_{0.4}Si_{3.2}$ are mostly governed by the interplay of Kondo effect and RKKY interactions in the presence of sizable atomic disorder, which induces spatial fluctuations in the local density of states and hence smearing off the Kondo and RKKY characteristic energy scales.

TU.C-P18 - High-pressure effect on low-temperature properties of the approximant crystal to magnetic Au-Al-Yb quasicrystal

S. Matsukawa [1], M. Nakayama [1], T. Yamashiya [1], K. Nobe [1], K. Kamiya [1], K. Deguchi [1], K. Imura [1], H. Takakura [2], T. Ishimasa [2], N. Sato [1]

2. Hokkaido University, Sapporo, Japan

Quasicrystals are metallic alloys that possess long-range, quasiperiodic structures with diffraction symmetries forbidden to conventional crystals. The quasiperiodic structure leads us to expect that the electronic state of quasicrystals is different from that of conventional crystals and amorphous materials. More than 100 quasicrystals have been found to date since the discovery of the quasicrystal, but such a novel state had not been reported besides the recent finding of an unconventional quantum criticality in the Au-Al-Yb quasicrystal [1]. In this new type of quasirystal, the magnetic susceptibility and the electronic specific heat coefficient diverge as $T \rightarrow 0$. In contrast, the Au-Al-Yb approximant crystal shows a conventional heavy fermion feature at low temperatures. Therefore, the unconventional quantum criticality of the magnetic quasicrystal may arise from a characteristic state unique to the quasicrystals.
We present here the high-pressure effect on the low-temperature properties of the Au-Al-Yb approximant. At ambient pressure, the inverse magnetic susceptibility of the approximant follows the power low, $1/c \propto T^{0.51}$+const. at low temperatures. The inverse magnetic susceptibility extrapolated to zero temperature, $1/c(0)$, deceases monotonically with increasing pressure. With further increasing pressure, $1/c(0)$ turns to increase, suggesting the presence of a quantum critical point, although it is not clear at present whether the high-pressure state is a long-range ordered state or a glass-like short-range ordered state. This pressure dependence of the low temperature properties is in contrast to that of the magnetic Au-Al-Yb quasicrystal: $1/c(0)$ exhibits the quantum criticality ($1/c \propto T^{0.51}$) at any pressure studied. The comparison between the approximant and the quasicrystal strongly suggests that the unconventional quantum criticality of the magnetic quasicrystal is related to a characteristic state unique to the quasicrystal.

TU.C-P19 - Unconventional quantum critical behavior in nonmetallic $CeOBiS_2$: A mother phase of BiS_2-based superconductor

R. Higashinaka [1], T. Asano [1], T. Nakashima [1], K. Fushiya [1], Y. Mizuguchi [1], O. Miura [1], T. D. Matsuda [1], Y. Aoki [1]

1. Tokyo Metropolitan University, Tokyo, Japan

BiS2-based layered superconductors $LnO_{1-x}F_xBiS_2$ (Ln: rare earth) have been attracting much attention [1]. We have studied the low-temperature properties of $CeOBiS_2$ single crystals by electrical resistivity, magnetization, and specific heat measurements. Ce 4f-electrons are found to be in a well-localized state split by crystalline-electric-field (CEF) effects. The CEF ground state is a pure Jz = ±1/2 doublet, and excited doublets are located above 300 K. At low temperatures in zero field, we observe pronounced - log T divergence in the specific heat, revealing the presence of quantum critical fluctuations of 4f magnetic moments near a quantum critical point (QCP) [2]. Considering that $CeOBiS_2$ is a nonmetal, this phenomenon cannot be attributed to the competition between Kondo and the Ruderman-Kittel-Kasuya-Yosida (RKKY) interactions as in numerous f-electron-based strongly correlated metals. This fact indicates an unconventional mechanism for the QCP in $CeOBiS_2$. Magnetic interactions in a CeO block layer are probably mediated by superexchange interactions. The interactions among Ce ions can be expressed with the spin-1/2 XXZ model. In a 2D quantum spin-1/2 XXZ system along with the J1-J2 frustration, theoretical calculations show that no long-range order (LRO) appears in a certain parameter range called the “quantum paramagnetic phase” [3]. We suggest that $CeOBiS_2$ is the first material found to be located at a QCP among geometrically frustrated nonmetallic magnets.

Close to a quantum critical point, the physical properties of metals may deviate drastically from the predictions of Fermi liquid theory. Compared to static electronic properties, probed by thermodynamic or electronic transport measurements for many quantum critical systems, much less is known about dynamical properties. Investigating the frequency response close to a quantum critical point requires specialized experimental conditions: very low temperatures and techniques that allow investigating very low-energy excitations. The latter can be achieved by using electromagnetic radiation in the microwave range. We apply coplanar waveguide resonators, installed in a dilution refrigerator, to couple the electrons of quantum-critical materials to microwave radiation in the low GHz range. The quality factor and resonance frequency of the transmitted signal are directly related to dynamic properties of the sample: the surface resistance and the surface reactance. For non-resonant experiments in a broad frequency range, high-quality thin films are needed. First perspectives towards this goal, applying molecular beam epitaxy, will also be presented.

TU.C-P21 - Correlation effects in One-Dimensional Quasiperiodic Anderson-Lattice Model

F. Matsuda [1], M. Tezuka [1], N. Kawakami [1]

1. Department of Physics, Kyoto University, Kyoto, Japan

Recently, heavy fermion systems in quasicrystals have attracted much attention after quantum critical phenomena were found in the quasicrystals. In the quasicrystal $Yb_{15}Al_{34}Au_{51}$, quantum criticality of valence fluctuations emerges, which is shown to be quite robust against pressure, while this robustness is not seen in its approximant crystals [1]. The research reported that low-temperature properties of magnetic susceptibility χ, NMR/NQR relaxation rate $(T_1T)^{-1}$, specific-heat coefficient C/T, and resistivity ρ agree very well with the theory of quantum valence criticality. A theoretical research to explain this robustness of quantum criticality has been done by considering a single cluster of $Yb_{15}Al_{34}Au_{51}$ [2].
Can this robustness of quantum criticality be seen in random systems or is it specific to quasiperiodic systems? To answer these questions, we focus on the effects of quasiperiodicity on the quantum criticality of valence fluctuations. We consider the one-dimensional (1D) quasiperiodic Anderson-lattice model, which has quasiperiodically ordered impurities. The sites with an f-orbital are ordered as “Fibonacci word”, which is known as a method to construct 1D quasiperiodic orderings. To treat the correlation effect precisely, we use the density matrix renormalization group (DMRG) method. We find that a valence transition occurs in different ε_f at each site. This is consistent with the previous research, which showed that the robustness of quantum criticality comes from overlap of the critical regimes at each site. Moreover, we discuss the properties which are specific to the 1D quasiperiodic Anderson-lattice model, comparing it against periodic and random-potential models.

Although possible interplay between quadrupole moments and conduction electrons including the non-magnetic Kondo effect has been considered both experimentally[1] and theoretically[2], it remains elusive now. $PrTr_2Zn_{20}$ (Tr = Ir, Rh) have emerged as rare and suitable playgrounds to examine this possibility because 4f-electrons of the Pr ions have the non-Kramers doublet ground state with a quadrupole degree of freedom. In addition, the strong hybridization is expectable due to a high coordination number of the Zn ions surrounding the Pr ion. At low temperatures, both compounds undergo an antiferro-quadrupolar transition below the certain transition temperatures TQ[3, 4]. Here, we present a study of the electric and thermoelectric transport properties of $PrTr_2Zn_{20}$ (Tr = Ir, Rh). Our electric resistivity measurements reveal the non-Fermi liquid behavior with an upward convex curve above TQ, and this characteristic normal-state resistivity is found to satisfy a scaling relation over the wide temperature and field range throughout the compounds. Moreover, on the verge of the quadrupole ordered phase under the magnetic fields, we find a dramatic enhancement of the Seebeck coefficient at low temperatures in both compounds. These features imply a common underlying mechanism presumably dominated by the interplay between quadrupole moments and conduction electrons.

We have investigated single crystals and polycrystals from the series $Nb_{1-y}Fe_{2+y}$, $-0.019 \leq y \leq 0.018$ by muon spin relaxation. With our study utilizing a microscopic experimental tool, we are able to access the full phase diagram previously established by bulk experimental techniques. In addition to the previously studied spin-density-wave phase and the ferromagnetic phase for Fe-rich material, with our data we can now verify the suppression of magnetic order at the quantum critical point at $y \sim 0.015$ on a microscopic level. Further, we establish the reentrance of magnetic order for larger y values, and compare the mSR signature for this supposedly ferromagnetic phase with that from the Fe-rich side of the phase diagram.

TU.C-P24 - Single-ion Kondo physics in the cage compound $CeRh_4Al_{15.37}$

Crystal structures of rare-earth based systems with high aluminium content, such as CeT_2Al_{10} (T=Fe, Ru, Os) [1], produce intermetallic compounds with unusual physical properties that test our understanding of correlated electron phenomena [2]. Aside from the 3-dimensional cage-type structure [2] of CeT_2Al_{10} compounds, a more conspicuous aspect of these crystal structure types is that they have a 2-dimensional layered atomic arrangement [3]. Here we explore the physical properties of the new compound $CeRh_4Al_{15.37}$. It forms in a tetragonal crystal structure [4]. All the atoms are highly coordinated, including Ce with CN=20. Four Al sites have partial occupancy. At a nearest distance of $d_{Ce\text{-}Ce}$ ≈7 Å, the Ce ions are well isolated from each other in the lattice. Above 100 K the full free-ion Ce^{3+} magnetic moment governs the susceptibility. The specific heat $C_p(T)/T$ increases strongly below 6 K, and produces a quasi-logarithmic divergence over more than a decade in temperature. This persists down to 50 mK where $C_p(T)/T$ reaches a very high value of 0.9 J/mol.K^2. Our physical properties data collectively define $CeRh_4Al_{15.37}$ as a Kondo lattice, but with heavy-electron 4f spins remaining in the single-ion Kondo state as $T \rightarrow 0$.

TU.C-P25 - Spin-fluctuation effects near the quantum phase transition of the ising-type itinerant ferromagnet URhAl

Y. Shimizu [1], D. Braithwaite [2], B. Salce [2], T. Combier [2], D. Aoki [2,3], J. Flouquet [2]

3. IMR, Tohoku University, Ibaraki, Japan

It was believed that an itinerant magnetic compound usually has a quantum critical point (QCP), however, in itinerant ferromagnets, $ZrZn_2$, UGe_2, and metamagnet UCoAl, the first-order ferromagnetic wing structures have recently been found at low temperature from hydrostatic pressure experiments. In particular, the tri-critical point in UCoAl is estimated to exist at negative pressure of -0.2 GPa, and we cannot capture the whole picture of its ferromagnetic wing.
In order to gain further understanding of the spin-fluctuation effects as well as the QPT of the itinerant ferromagnetism, we focus on another ferromagnet URhAl, which has the same ZrNiAl crystal structure as UCoAl. Since the atomic radius of Rh is larger than that of Co, URhAl would be a system in which a negative pressure is applied for UCoAl.
By means of resistivity measurements for URhAl under pressure up to 7.5 GPa [1], we found that the critical pressure exists around Pc ~5.2 GPa. The Curie temperature disappears as a first-order phase transition, and the critical behavior of the Fermi-liquid regime cannot be described by a ferromagnetic QCP. However, near Pc, we also observed a large enhancement of the A coefficient of the Fermi-liquid resistivity term, and the resistivity is described rather by a non-Fermi-liquid regime, in which the exponent of resistivity is n~1.6-1.7, close to the expected value for a ferromagnetic QCP. From the magnetic field dependence of resistivity, we observed an anomaly, which is consistent with the presence of a ferromagnetic wing. The nature of the first-order phase transition is probably weak, and the system is dominated by strong spin-fluctuations. An intermediate phase through a Fermi-surface change around the QPT may be possible in URhAl due to the strong spin-fluctuation effect, which persists substantially up to 7.5 GPa.

2. Goethe-Universität Frankfurt, Physikalisches Institut, Frankfurt/Main, Frankfurt, Germany
3. Max-Planck-Institut für Chemische Physik fester Stoffe, Dresden, German

The heavy-fermion material YbRh$_2$Si$_2$ is a model system to investigate strong electron-electron correlations. Weak antiferromagnetic order is observed below 70 mK in the absence of a magnetic field. At zero temperature, this antiferromagnetic order vanishes with an applied magnetic field of 60 mT at a quantum critical point. Electron spin resonance (ESR) is an established spectroscopic tool to study magnetism in solids and to characterize magnetic order. However, conventional ESR studies use frequencies with a corresponding magnetic field of 0.3 T (X-band) and larger and therefore cannot be used to investigate these interesting phases in YbRh$_2$Si$_2$.
With the recent development of coplanar resonators, a wide range of low GHz frequencies are accessible for ESR which lead to corresponding magnetic fields down to 30 mT. In the case of YbRh$_2$Si$_2$ the lower frequencies are of main interest as one can investigate the antiferromagnetic, the non-Fermi-liquid and the Fermi-liquid phase. This work focuses on the antiferromagnetic phase and the transition to the paramagnetic regime. We observe clear signs of the antiferromagnetic transition in the experimental raw data (quality factor of the resonator) as well as in the deduced ESR parameters, namely the \textit{g} factor and the linewidth.
Thus, these results provide opportunities to gain deeper insights in the antiferromagnetic state of YbRh$_2$Si$_2$ and the spin dynamics of the magnetic moments.

TU.C-P27 - Peculiar transport and phase diagram in non-Kramers doublet compounds with quadrupole degree of freedom

K. Izawa [1], T. Yoshida [1], Y. Machida [1], K. Matsumoto [2], T. Onimaru [2], T. Takabatake [2], H. Suzuki [3]

We report unusual transport coefficients of praseodymium compounds $PrPb_3$ and PrT_2Zn_{20} (T=Ir, Rh). These compounds provide unique opportunities to study the nature of novel electronic states inherent in a multipole degree of freedom because they all have a non Kramers doublet ground state with multipole degeneracies. In fact, $PrPb_3$ exhibits an antiferroquadrupolar (AFQ) ordering with incommensurate/modulated structures at transition temperature TQ [1], implying the presence of the RKKY type interaction between quadrupole moments. On the other hand, $PrIr_2Zn_{20}$ and $PrRh_2Zn_{20}$ show an antiferroquadrupolar ordering at TQ followed by superconductivity deep inside the ordered phase [2], implying a close connection between quadrupole and superconductivity. Although these phenomena imply a crucial role of the hybridization between quadrupole moments and conduction electrons, the physics behind them is still far from being clarified. In this study, we carried out measurements of electric and thermoelectric coefficients of these Pr-based compounds to elucidate the nature of the novel electronic states characteristic of multipoles hybridized with conduction electrons. We found a ügunusualüh non Fermi liquid (NFL) behavior of the resistivity with a convex curve above TQ in $PrPb_3$ as well as PrT_2Zn_{20}. Interestingly, such unusual resistivity can be well expressed by a scaling function based on a quadrupolar Kondo lattice model [3] in the wide temperature and field range throughout these materials. Moreover, we also found a strong enhancement of the Seebeck coefficient as well as the coefficient of T2 term of resistivity above the critical field of AFQ ordering at very low temperatures, implying the formation of a non-trivial quantum state due to the quadrupole degree of freedom.

Electronic liquid crystal (ELC) phases are novel phases that have a special symmetry that lies between the Fermi liquid and the Wigner solid, with the symmetry controlled by electron-electron interactions. Hydrostatic pressure is a direct and effective parameter that can change the interactions between electrons and thus is a powerful tool to study the ELC phases. There is an ELC phase induced by the magnetic field in the bi-layer ruthenate $Sr_3Ru_2O_7$, signaled by a pronounced anisotropic peak in the resistivity within a very narrow field range. In our experiment, we studied the anomalous phase by applying hydrostatic pressure to a single crystal of $Sr_3Ru_2O_7$. With the magnetic field near the c-axis, the anisotropy of the ELC phase disappears at very low pressure and the corresponding peak in the resistivity is suppressed below 7.7 kbar. The results suggest that the ELC phase is driven by quantum criticality, which is closely related to the magnetic structure. This is in sharp contrast to the behavior of a second ELC phase, seen with the field aligned in the ab-plane, which is relatively unaffected by hydrostatic pressure [1].

A pressure-induced quantum critical point (QCP) with Kondo destruction was recently suggested to occur in the nickel oxypnictide CeNiAsO at 6.5 kbar [1]. Also partial substitution of As by P in $CeNiAs_{1-x}P_xO$ was shown to drive the system through a QCP, situated somewhere between x = 0.35 and 0.4. Here we present electrical transport measurements on both CeNiAsO and $CeNiAs_{0.65}P_{0.35}O$ in pressures up to 15 kbar and magnetic fields up to 14 T, at temperatures down to 40 mK, an order of magnitude lower than in the previous work [1]. We construct a three-dimensional pressure-magnetic field-temperature phase diagram for both samples and locate quantum critical lines in the T = 0 K plane. Focus is on magnetic field-tuning of samples with fixed pressure near the critical pressure. Both isothermal magnetic field scans and isofield temperature dependencies will be presented.

Extensive high-pressure studies in MnSi revealed an extended parameter range with an unexplained non-Fermi liquid resistivity [1] and partial magnetic order [2] on time scales faster then mu-SR [3]. Detailed measurements of the Hall effect in addition recently identified a topological Hall contribution [4] as a key feature of the non-Fermi liquid regime characteristic of spin fluctuations supporting non-trivial topology akin the skyrmion lattice phase at ambient pressure [5]. However, due to the pressure cell quasi-elastic neutron scattering studies of the slow spin dynamics in the high pressure state of MnSi have not been possible so far. We have therefore revisited the nature of the spin dynamics in MnSi when helimagnetic order is suppressed by substitutional Fe-doping [6]. We explore the nature of the heligmagnetic phase transition in $Mn_{1-x}Fe_xSi$, when helimagnetic order is suppressed under substitutional doping. In our study we combine small-angle neutron scattering and neutron resonance spin echo spectroscopy with measurements of the Hall effect, the ac susceptibility and the specific heat. Tracking the melting transition of long-range helimagnetic order under Fe-doping as combined with recent Hall effect measurements in $Mn_{1-x}Fe_xSi$ [7] we observe microscopic evidence suggesting the formation of a skyrmion liquid.

Tetragonal iron chalcogenides $Fe_{1+x}Ch$ have attracted the attention because of their simple crystal structure, the absence of charge transfer reservoir layer and of arsenic. However, the partial filling of a second interstitial site by iron atoms has crucial effect on the physics of the $Fe_{1+x}Ch$, both on superconducting and magnetic properties of this family of compounds [1]. Recently, several interesting phenomena have been discovered in the non-superconducting parent compound Fe1+xTe as a pressure-induced ferromagnetic transition [2] and a magnetic field induced irreversible transition [3]. In the present work, we will describe some of our recent works on the physical properties of $Fe_{1+x}Te$ under extreme conditions, i. e. under high magnetic fields or under high pressures.
We have recently discovered an irreversible magnetic field induced transition in $Fe_{1+x}Te$ at 53 T for T = 2 K whose critical field decreases strongly with temperature [3]. This transition occurs only for H perpendicular to c and is due to reorientation of the magnetic domains because it is closely related to the magnetic ground state of $Fe_{1+x}Te$. Our X-ray diffraction study of $Fe_{1+x}Te$ under high pressure does not confirm the presence of collapsed phase reported previously [4]. In our transport and thermoelectric experiments under pressure, we have observed anomalies corresponding to the pressure-induced ferromagnetic phase above 1.6 GPa and thermal hysteresis at 1.4 GPa, which coincides with the orthorhombic structural phase [1]. More importantly, for that value of pressure the thermopower coefficient S/T diverges with a ln(1/T) dependence, signaling the existence of critical spin fluctuations at the crossover between the two magnetically ordered phases.

TU.C-P32 - Magnetic field - temperature phase diagrams including modulated magnetic order near the border of ferromagnetism in $NbFe_2$

J. Poulten [1,2], P. Niklowitz [1], M. Hirschberger [3], W. Duncan [1], A. Neubauer [4], K. Seemann [5], C. Peleiderer [4], F. Malte Grosche [6]

6. Cavendish Laboratory, University of Cambridge, Cambrige, UK

Many experimental studies suggest that ferromagnetic quantum critical points (FM QCPs) are hard to approach in real materials, as they are often replaced by a first order quantum phase transition. $Nb_{1+y}Fe_{2-y}$ is a C14 Laves phase system which, in Fe-rich compositions, displays easy-axis ferromagnetism at low temperatures. This ferromagnetic order may be fully suppressed through precise tuning of y [1]. Near the critical composition, bulk measurements have shown Marginal Fermi liquid behaviour, as expected of a FM quantum critical point (QCP) [1]. However, the FM QCP itself appears to be masked by a modulated magnetic order, or spin density wave (SDW) [2], which represents a different route by which a FM QCP can be avoided. In this study we have explored the magnetic field – temperature phase diagrams of Fe-rich $Nb_{1+y}Fe_{2-y}$ through neutron scattering. We have studied high quality single crystal samples of $Nb_{1-y}Fe_{2+y}$, grown in an optical floating zone furnace by performing neutron diffraction at the triple-axis spectrometer MIRA at FRM II in diffraction mode. The phase diagrams including the SDW for both **B**||c and **B**⊥c were obtained. The critical fields of the SDW phase were obtained for both field directions. The critical fields in the B||c case are an order of magnitude smaller than the critical fields in the **B**⊥**c** case. Our results are consistent with phase diagrams from bulk measurements.

TU.C-P33 - Tuning of the modulated magnetic order at the border of ferromagnetism in $NbFe_2$

P.G. Niklowitz [1], M. Gamza [1], M. Hirschberger [2], J. Poulten [1], W. Duncan [1], A. Neubauer [3], P. Cermak [4], A. Schneidewind [4], K. Seemann [4], E. Faulhaber [4]

5. Cavendish Laboratory, University of Cambridge, CB3 0HE, U.K.

The border of ferromagnetism in the C14 Laves phase $NbFe_2$ is characterised by unusual low-temperature properties: signatures of marginal Fermi liquid behaviour are observed, consistent with ferromagnetic quantum criticality [1], but the ferromagnetic quantum critical point appears to be masked by an ordered state of different origin [2]. Recently we have directly observed the ordering wavevector q1 of this state by neutron diffraction, showing that the ferromagnetic quantum critical point is masked by modulated magnetic order. Here we report on comprehensive B, T and y tuning of the modulated magnetic order. We have observed the evolution of the modulated magnetic order using neutron scattering studies on several single-crystalline Nb1-yFe2+y samples ranging from Fe-rich to nearly stoichiometric composition. Our data reveals a significant dependence of q1 on the different tuning parameters, which indicates to which extent the modulated magnetic order can be understood as emerging from ferromagnetic quantum criticality. We also report on pressure tuning of the modulated magnetic order. Electrical transport measurements on single crystals reveal that the modulated magnetic order can be fully suppressed by pressure. The region around the critical pressure is characterized by non-Fermi liquid behaviour, which suggests that the modulated order itself is a source of quantum criticality.

TU.D-P01 - Magnetization jumps in [Mn((R/S)-pn)]2[Mn((R/S)-pn)2(H2O)][Cr(CN)6]2 molecular magnets

M. Kirman [1], A. Talantsev [1], R. Morgunov [1]

1. Institute of Problems of Chemical Physics of Russian Academy of Sciences

Recently, the authors [1] presented a theoretical calculation discontinuity of magnetization caused by a commensurate-to-incommensurate magnetic phase transition. Our purposes are experimental observing and identification of magnetization jumps in $[Mn((R/S)\text{-}pn)]_2[Mn((R/S)\text{-}pn)_2(H_2O)][Cr(CN)_6]_2$ chiral magnets described in [2,3]. We used SQUID magnetometer to obtain magnetic hysteresis loops of the sample at T = 2- 50 K. The static magnetic field was stepwise swiped with the step dH = 2 – 0.2 Oe in the 0 - 50 kOe range.
Series of the magnetization jumps was observed. These jumps appeared in magnetic field close to coercive field. The starting field of magnetic jumps decreases as sample was heated. Observed jumps caused by quantized energy of spin soliton lattices of different periods. Transitions between these states was observed as steps on the field dependence of the magnetization.
Magnetization jumps caused by spin soliton formations were experimental observed in $[Mn((R/S)\text{-}pn)]_2[Mn((R/S)\text{-}pn)_2(H_2O)][Cr(CN)_6]_2$ molecular magnets.
The work was supported by the RFBR grant 14-02-31022, 15-02-05149.

TU.D-P02 - Single-ion magnet behavior of Co(II) in cyclodextrine-based multinuclear sandwich-type complexes

N. Nedelko [1], P. Aleshkevych [1], A. Kornowicz [2], J. Lewinski [2], A. Krzyzewski [1], S. Lewinska [1], A. Slawska-Waniewska [1]

1. Institute of Physics, Polish Academy of Sciences
2. Warsaw University of Technology

In recent years, a novel group of materials known as mononuclear Single-Molecule Magnets (or Single-Ion Magnets (SIMs)) expands rapidly. Many interesting properties are revealed but not all of them are well described and understood, including the origin of the field-induced slow magnetic relaxations in SIMs containing 3d Kramers ions with an easy-plane magnetic anisotropy. We report the magnetic studies of the two Cyclodextrine-templated sandwich-type complexes $[(\gamma\text{-CD})_2Co_4Li_8(H_2O)_{12}]$ (1) and $[(\alpha\text{-CD})_2Co_3Li_6(H_2O)_9]$ (2) which contain the heterometallic rings {Co, Li, Li}$_4$ and {Co, Li, Li}$_3$, respectively. Each Co(II) center adopts distorted trigonal bipyramidal geometry with the CoO_5 environment. Variable temperature *ac*/*dc* magnetic measurements and X-band EPR spectrometry studies have shown that both in 1 and 2 the individual Co(II) ions (in high spin state, S = 3/2) endowed with positive value of zero-field splitting parameter *D* exhibit field-induced slow magnetic relaxations consistent with the SIMs behavior. Interestingly, the slow magnetization dynamics in 1 shows the nearly single relaxation process, whereas in 2 - two relaxation processes are evident. A comparison of the spin-relaxation pathways of Co(II) ions in 1 and 2 and their dependences on the applied static magnetic fields has been performed.

The research was partially performed in the laboratories founded by POIG.02.02.00-00-025/09.

TU.D-P03 - Magnetism of Mn(dppm)2(OAc): Field induced slow magnetic relaxation of single five-coordinated Mn(III) ion

N. Nedelko [1], P. Aleshkevych [1], A. Kornowicz [2], J. Lewinski [2], A. Krzyzewski [1], S. Lewinska [1], A. Slawska-Waniewska [1]

1. Institute of Physics, Polish Academy of Sciences
2. Warsaw University of Technology

The novel crystalline Mn(dppm)2(OAc) compound (where OAc = acetate and dppm = (S)-diphenylpyrrolidinmethanolate) has been studied with variable temperature static and dynamic magnetic susceptibility measurements as well as X-band EPR spectrometry. The experimental data were analyzed within the spin-Hamiltonian formalism. The results obtained show that Mn(dppm)2(OAc) incorporates Mn(III) centres in a high-spin state (S = 2). The compound studied exhibits paramagnetic behaviour in the temperature range 2 - 300 K with the influence of a ground state zero-field splitting effect (D ~ -2 cm-1) at the lowest temperatures. ac magnetic susceptibility measurements in the presence of dc magnetic field reveal a slow magnetization dynamics of mononuclear five-coordinated Mn(III) ions that is unexpected considering the assigned very small single ion anisotropy of Mn. The detailed investigations of the spin-relaxation processes and their dependences on the applied dc field have been performed to establish the origin of slowing of the relaxation dynamics and the nature of this Single-Ion Magnet like behaviour. Additionally, detailed EPR studies performed on a single crystal allowed to reveal the presence of Mn(II) impurity ions (below 1 %) built-in a regular crystalline structure. The super-hyperfine structure related to interaction of these ions with nucleus of two 14N ligands was observed.
The research was partially performed in the laboratories founded by POIG.02.02.00-00-025/09.

TU.D-P04 - Magnetostructural correlations in anion-radical salts M(bipy)3(TCNQ)4, where M=Co, Ni, Zn

A. Feher [1], D. Šoltésová [1], Erik Èižmár [1], G. Vasylets [2], V. Starodub [3]

3. Institute of Chemistry, Jan Kochanowski University of Humanities and Sciences, 25-406 Kielce, Poland

Materials based on anion-radical salts of 7,7',8,8'-tetracyanoquinodimethane (TCNQ) and containing transition-metal complex cations are very interesting for the study of their physical properties because of thetendency to form low-dimensional magnets. Three novel anion-radical saltsZn(bipy)$_3$(TCNQ)$_4$·H_2O, Co(bipy)$_3$(TCNQ)$_4$·H_2O and Ni(bipy)$_3$(TCNQ)$_4$·$(CH_3)_2CO$ were synthesized and structurally characterized [1]. The lattice contains$[M^{II}(bipy)_3]^{2+}$cations(where M= Zn, Co and Ni, bipy = 2,2'-bipyridine) and two types ofcrystallographically independent $TCNQ^{\cdot-}$stacks. We present experimental results of the magnetic susceptibility (1.8 K –300 K) and magnetization measurementsup to 7 T.All compoundsexhibit structural tetramerization of anion-radical stacks leading to the creationof antiferromagnetic dimers with singlet ground state.While behaviour of compound containing Co ion can be described at low-temperatures by the presence of single-ion anisotropy,an indication of ferromagnetic coupling in the system containing Ni ion was observed.The experimental results were analysed by own algorithm employing EasySpin simulation package [2].
This work was supported by the Slovak Research and Development Agency under contract No. APVV-0132-11 and VEGA 1/0145/13.

Paramagnetic Ionic Liquids (MILs) are promising new smart materials that allow adding further features to the typical properties of ionic liquids such as magnetic, photophysical or electrochromic behaviour which are due to the incorporated metal ions [1].
Here we present the thermal, structural and magnetic studies of two novel MILs, comprised of 1-ethyl-2,3-dimethylimidazolium (Edimim) cation and tetrahaloferrate(III) (FeX_4) (X = Cl and Br) anion. Their crystal structure is formed by layers of cations (in non-planar configuration) and anions stacked upon one another in a 3D manner with several non-bonding interactions: hydrogen bond, anion-π, and halide-halide. The field-cooled molar susceptibility (c_m) measured under 1 kOe of both compounds increases and reaches a maximum at approximately 2.9 K and 9 K for Edimim[$FeCl_4$] and Edimim[$FeBr_4$] respectively, indicating the existence of a long-range magnetic ordering, also observed in other compounds with the 1-ethyl-3-methylimidazolium (Emim) and 1,3-dimethylimidazolium (Dimim) cations [2-4]. At low temperatures, the heat capacity data of these MILs shows a l-type anomaly characteristic of a three-dimensional magnetic ordering. This anomaly becomes rounder and smaller in height as the applied magnetic field increases, shifting to lower temperatures, as expected for an antiferromagnetic ordering. The magneto-structural correlations give the evidence that the 3D magnetic ordering takes place via Fe-X---X-Fe interactions, displaying a higher superexchange magnetic interaction between the planes.

5. School of Chemistry, University of Manchester, United Kingdom

The comparison of the magnetic properties of the closed molecular antiferromagnetic ring Cr_8 with the open ring Cr_8Zn shows that, while the nearest-neighbor exchange constant JCr-Cr changes only from ~ 16.9 K [1] in the closed ring to ~ 15.3 K [2] in the open one, the different spin topology has dramatic effects on the level spacing between the S=0 ground state and the excited magnetic states [3]. The aim of the present work is to explore the effect of spin topology on the spin dynamics by means of proton nuclear magnetic resonance and relaxation. The proton NMR measurements were performed in Cr_8 and Cr_8Zn in the temperature range $1.65 < T < 300$ K at different external magnetic fields. The temperature dependence of 1/T1 was found to be similar in both open and closed rings with a magnetic field dependent peak centered at a temperature of the order of the corresponding exchange constant JCr-Cr. No detectable effects due to changes in the low temperature energy levels separation, which were instead revealed in the magnetization measurements and related to the spin topology, were observed. The peak of 1/T1(T) could be fitted with a single correlation frequency as in most molecular magnets [4]. A new feature, not previously observed, consisting in a well resolved smaller peak below 4 K and possibly related to a second correlation frequency of the magnetization [5], was also singled out.

TU.D-P08 - Raman scattering study of a chiral two-dimensional molecule-based magnet

N. Ogita [1], T. Hasegawa [1], M. Udagawa [1], L. Li [2], K. Inoue [2]

1. Graduate School of Integrated Arts and Sci., Hiroshima University
2. Department of Chemistry and Institute for Advanced Materials Research, Hiroshima University

Green needle-shaped crystals, [{Cr(CN)6}{Mn(R/S)-pnH(H2O)}](H2O); ((R/S)-pn=(R/S)-1,2-diaminopropane), is known as the two-dimensional chiral ferrimagnet of Cr^{3+} and Mn^{2+} below Tc=38K [1]. The crystal structure is an orthorhombic (P212121 space group). The two-dimensional chiral network is constructed of [Cr(CN)6] and Mn ion to form a bimetallic square, which is arranged almost perpendicular to the c-axis. One chiral (R/S)-pn ligand and two water molecules separate the Mn-Cr sheets, and (R/S)-pn coordinates to a Mn^{2+} ion in the sheets. Although the magnetic moment of Mn and Cr ions does not locate at chiral positions, the chiral structure of a molecule might give an unusual spin structure [2]. Therefore, to elucidate the lattice dynamics and the spin-lattice coupling, polarization and temperature dependence of the Raman spectra have been measured.
Among a lots of peaks in observed spectra, some peaks show the intensity difference between cross polarization spectra of (x,y) and (y,x). (a,b) denotes the polarization directions of incident(a) and scattered(b) light, respectively. This asymmetry of the Raman tensor can be regarded these peaks as the vibration of the magnetic moment or chiral atoms. In the temperature dependence of the stretching vibrations of cyanide, the energy decrease has been found at around Tc. This result denotes that the atomic vibration is affected by the spin structure. On the other hand, drastic spectral change, such as peak split and appearance, is observed at around 250K with decreasing temperature. This anomaly suggests the drastic change of the lattice, such as the structural transition, might occur at around 250K.

TU.D-P09 - Correlation between dielectric and magnetic properties on fullerene-based magnets

T. Kambe [1], K. Oshima [1]

1. Okayama University

The orbital degeneracy plays an essential role in fullerene superconductors. The cooperative ordering of the ligand ions or molecules removes the orbital degeneracy of the C_{60} and, then, leads to the spatial arrangement of the C_{60}'s orbitals. This should produce a coherent magnetic interaction among localized spins on C_{60}.

The α-phase of Tetra-*kis*-(dimetylamino)-etylene C_{60} (abbreviated as α-TDAE-C_{60}) is known as the first fullerene magnet, of which the ferromagnetic transition temperature, *T*c, is as high as 16 K. Other α-TDAE-C_{60} polymorph has different arrangement of orbitals and undergoes an antiferromagnetic transition around 7 K. We recently discovered the existence of permanent dielectric moments around C_{60} in these magnets, and implied that the two polymorphs exhibit clear differences in their dielectric responses at room temperature [1]. In this presentation, we summarize the different character of dielectric properties for these polymorphs and discuss possibility of magneto-electric couplings.

TU.D-P10 - Magnetic properties of FePc on In/Si(111) surface studied with ab initio calculations

J.M. Hyun [1], H. Kim [1]

1. Department of Physics, Sookmyung Women's University,

Metal-organic systems have attracted much attention for potential applications in future electronic devices. Among these systems, metal phthalocyanine (MPc) represents one of the most promising classes because of its thermal and chemical stability. In recent years, there has been a variety of work performed on MPc systems such as FePc, CoPc, NiPc, and CuPc on graphene/Ni(111) [1-2] as well as on metallic surface [3-5]. However, it is scarcely known about them on nanostructured metal-semiconductor hybrid substrates. Theoretical analysis is highly required to understand issues such as the MPc-substrate interaction, which may affect the molecular adsorption mechanism and the magnetic properties on the metal/semiconductor hybrid surfaces. In this presentation, we report density functional theory (DFT) calculations on the FePc on Si(111)In-4×1. We have examined various adsorption sites on In chain, Si Seiwatz chian, and boundary area. The magnetic moment of an isolated FePc molecule is calculated to be 2 μ_B. Upon adsorption, the magnetic moment of FePc is reduced to about 1 μ_B and 0 μ_B on Si and In chains, respectively. The stable adsorption sites and electronic structure will be discussed.

TU.D-P11 - A ferrimagnetic dodecnuclear Fe(III) complex exhibiting single-molecule magnet behavior

J.P. Tong [1], X.J. Xu [1], D.J. Yang [1], Jun Tao [1]

1. Xiangyang Noncommissioned Officers School, Xiamen University, Fujian, China

Single- molecule magnets (SMMs) have attracted considerable attention these decades. The discovery of SMMs has immensely prompted the investigation of polynuclear magnetic clusters with high blocking temperature and slow magnetization relaxation. Commonly, metal ions with anisotropy (Mn^{3+}, Co^{2+}, Tb^{3+}, Dy^{3+}, etc.) are mostly introduced. And a molecule containing all high spin Fe(III) ions with anisotropy is rare.
Herein, we report a novel dodecnuclear Fe(III) cluster with ferrimagnetic magnetic property. Magnetic studies have revealed the ferromagnetic interactions within the $[Fe_4(OH)_4]$ core and among the eight peripheral Fe(III) ions as well as antiferromagnetic interactions between the $[Fe_4(OH)_4]$ core and the peripheral Fe(III) ions, thus resulting a ferrimagnetic cluster with ground state ST = 10. Molecular anisotropy mainly caused by the symmetry of the structure. The molecule has a S4 symmetry, which indicates the presence of uniaxial with c axis. The ac susceptibilities show slightly frequency-dependent behavior at temperature range of 1.8-7K. And the out-of-phase susceptibilities slightly moved to higher temperature range when dc field increased, indicating the potential of the molecule as a SMM and not a spin glass state.

Exchange coupling of spin-bearing metallo-organic complexes to ferromagnetic (FM) substrates leads to an exchange induced magnetic moment in the molecules [1,2]. Recent studies on square-planar 3d metal-porphyrins and -phthalocyanines adsorbed on bare magnetic substrates and oxygen covered magnetic substrates show FM and AFM alignment of molecular spins, respectively. Such magnetic ordering is mostly attributed to direct or indirect exchange coupling in the case of FM alignment of the Chromium spins versus the spins contained in the substrate atoms [2,3] and to superexchange coupling in the case of their AFM alignment [4]. In this contribution, a combined experimental and theoretical study on CrTPP molecules adsorbed on ferromagnetic substrates reveals an unexpected antiferromagnetic (AFM) exchange coupling of these molecules to bare cobalt substrates [5]. The experimentally observed AFM interaction is first confirmed by DFT+U calculations and alternatively described within the framework of Goodenough-Kanamori-Anderson (GKA) rules. According to the GKA model, the electrons from the less than half-filled 3d shell of the Chromium ion interact with those from the out-of-plane orbitals of the cobalt atoms via an indirect 90 degree exchange coupling mechanism mediated by the porphyrin's nitrogen atoms.

The factorised state in 1D Antiferromagnetic chains with a transverse field has been known for a long time[Kurmann]. Recently this state has been linked to the Entanglement Transition[Marty]. When quantifying entanglement it is common to use local measures such as Quantum Discord[Campbell] and concurrence[Amico2008]. In contrast, many experimental probes such as neutron scattering rely on global measurements. Here we demonstrate theoretically, through exact diagonalisation, that the Entanglement Transition can be realised experimentally in molecular magnets above zero temperature. We predict a remarkable change in the finite-temperature neutron scattering cross section as the applied field passes through the Entanglement Transition.

TU.D-P14 - Slow magnetic relaxation of Co-NIT ferrimagnetic chains

M. Novak [1], R. Allão Cassaro [2], M. Vaz [3], P. Lahti [4]

1. Instituto de Física, Universidade Federal do Rio ee Janeiro, Brazil

Isolated highly anisotropic ferrimagnetic chains, known in the molecular magnetism community as Single Chain Magnets (SCM) present magnetic bistability due to slow magnetic relaxation similar to single molecule magnets (SMM). SCMs appear to have some advantage in reaching higher blocking temperatures, whose main ingredients are strong intrachain magnetic interactions and uniaxial anisotropy plus as weak as possible interchain interactions.
We have developed recently a new family of one-dimensional ferrimagnetic chain compounds containing nitronilnytroxide radicals with large polycyclic aromatic ring pendants. We have found an extremely large antiferromagnetic exchange interactions for a ferrimagnetic manganese(II) chain[1] and record blocking temperature for the isostructural cobalt(II) chain[2]. In these cobalt(II) chains, the large local anisotropy and strong metal-radical antiferromagnetic interaction are responsible for slow magnetic relaxations at low temperatures, with record blocking temperatures ($T_b \approx 14$ K) and among the highest coercive fields for molecular magnets ($H_c \approx 50$ kOe at 8 K). These promising improvements in Tb are attributed to strong intrachain exchange interaction, nearly parallel local anisotropy axis and high isolation of individual chains. The large distance between chains insured a vanishing interchain interaction and no magnetic ordering, allowing the full observation of the chains' magnetic switching dynamics. The Glauber-like relaxation shows two distinct Arrhenius relaxation processes attributed to finite size long and short chains. The low temperature hysteresis loops are consistent with the presence of two sets of chains, which unblocks at different fields. These chains do not fall in the Ising limit, and so is well suited to motivate further theoretical models and simulation developments.

TU.D-P15 - A stochastic model for magnetic dynamics in single-molecule magnets

R. López-Ruiz [1], P. Todero de Almeida [1], M.G.F. Vaz [2], M.A. Novak [3], F. Béron [1], K. Roberto Pirota [1]

1. Unicamp
2. Universidade Federal Fluminense
3. Universidade Federal do Rio de Janeiro

The work simulates the magnetization dynamics in superparamagnets with tunneling reversal possibility using a simple stochastic model which takes into account: (i) the thermal activation described by the occupation of levels according to the Boltzmann distribution and (ii) the possibility of tunnel effect described by the Landau-Zenner model.
Both hysteresis and relaxation simulation curves were compared experimentally using the Mn12 single-molecule magnet as a model system. The simulations are experimentally scalable allowing to quantify the time of the simulation stage. Despite being a simple simulation model, the simulations are consistent with a thermally-activated tunneling magnetization reversal phenomenology in which blocking temperature displaces with the variation of the physical parameters involved in the simulation. The relaxation curves present an exponential decay and its field-dependent characteristic relaxation time values give a robust interpretation of hysteresis loops. In terms of inversion mechanism competition, we can separate the quantum and the classical contributions to the characteristic relaxation time.

TU.E-P01 - Full-potential KKR calculations for electronic and magnetic properties of transition metal monosilicide MSi (M=Cr-Co) and mixtures of FeSi and CoSi, based on the generalized-gradient approximation

M. Asato [1], C. Liu [2], N. Fujima [3], T. Hoshino [3]

1. National Institute of Technology, Niihama College
2. Graduate School of Science and Technology, Shizuoka University
3. Graduate School of Engineering, Shizuoka University

The cubic B20 structure transition metal monosilicides MSi (M=Cr-Co, 8 atoms per unit cell) are an interesting because they exhibit a wide variety of magnetic and transport behavior which reflects the importance of the details of the band structure near the Fermi surface [1]. Recently the mixtures (Fe(1-c)Co(c)Si) of FeSi and CoSi are expected as a new magnetic material exhibiting giant magnetoresistance [2]. The purpose of the present work is to clarify systematically the electronic and magnetic properties of MSi (M=Cr-Co) and Fe(1-c)Co(c)Si, by ab-initio calculations based on the generalized-gradient approximation in density functional formalism and the full-potential Korringa-Kohn-Rostoker Greenüfs function method [3]. The calculated results are summarized as follows: (1) The experimental results for the lattice parameters of MSi are reproduced within the error of 1% of the measured values; (2) The fundamental features of the experimental results such as nonmagnetic (NM) semiconductor of FeSi, NM semimetal of CoSi, and ferromagnetic (FM) metal of MnSi are understood by using the calculated DOS of NM state. The experimental results for FM or NM states of MSi are understood by the simple Stoner condition [4]; (3) The fundamental features of electronic and magnetic properties of Fe(1-c)Co(c)Si are understood by the virtual binary alloy (MSi) model where the nuclear charge of M is the concentration average of nuclear charges of Fe and Co.

4. CEMS RIKEN
5. University of Michigan

We study theoretically the electronic properties of AA-stacked bilayer graphene in a transverse electric field. The AA-BLG consists of two graphene layers, up and down. Each carbon atom of the upper layer is located above the corresponding atom of the lower layer. The strong on-site Coulomb repulsion stabilizes the antiferromagnetic order in such a system. The antiferromagnetic order is suppressed by the transverse bias voltage, at least partially. The interplane Coulomb repulsion and nonzero voltage stabilize an exciton order parameter. The exciton order parameter coexists with the antiferromagnetism and can be as large as several tens of meV for realistic values of the bias voltage and interaction constants. The application of a transverse bias voltage can be used to control the transport properties of the bilayer.

TU.E-P03 - Magnetic properties of $Ce_{n+1}Co_{3n+5}B_{2n}$ (n = 0, 1, 2, 3) compounds investigated by ^{59}Co NMR

K. Shimizu [1], K. Kakiuchi [1], T. Ito [2], H. Ido [2]

1. Department Of Physics, Faculty Of Science, University Of Toyama, Toyama, Japan
2. Department Of Electronic Engineering, Tohoku Gakuin University, Sendai, Japan

The compounds $Ce_{n+1}Co_{3n+5}B_{2n}$ (n = 0, 1, 2, 3 and ∞) have been known to show various interesting magnetic properties which depend on *n.* The complex magnetic properties of the compounds, however, have not been fully clarified. We present the ^{59}Co spin-echo NMR results on the compounds (n = 0, 1, 2, 3). In addition to the zero-field spectra, the field-swept spectra from non-magnetic Co are also observed for $Ce_3Co_{11}B_4$ and $Ce_2Co_7B_3$. These spectra arise from 3g-Co in $Ce_3Co_{11}B_4$ and $6i_2$-Co in $Ce_2Co_7B_3$. In order to estimate the spin and orbital moments, m_{spin} and m_{orb}, for respective Co-sites in $Ce_{n+1}Co_{3n+5}B_{2n}$ we use the equation $H_{hf} = am_{spin} + bm_{orb}$ with the hyperfine coupling constants a of -110 kG/m_B and b of 600 kG/μ_B, which are estimated by the above equation with the experimental values of H_{hf} and theoretical values of spin and orbital moments for 2c- and 3g-Co atoms in $CeCo_5$[1,2]. The magnitude of m_{spin} for 2c-Co is estimated to be ~1.2 m_B for $Ce_{n+1}Co_{3n+5}B_{2n}$ (n = 0, 1, 2, 3), and for $6i_1$-Co in $Ce_3Co_{11}B_4$ and $Ce_2Co_7B_3$ the m_{spin} to be about 0.4 m_B, while m_{orb} of 2c-Co varies from ~0.3 in $CeCo_5$ to ~0.1 m_B in $Ce_2Co_7B_3$, and m_{orb} for the other sites are of the order of 0.08 to 0.01 m_B. These results are discussed together with energy band calculations[1] and magnetization measurements on $Ce_{n+1}Co_{3n+5}B_{2n}$ [3-5].

TU.E-P04 - Optical investigation on the electronic structure of FeGe thin film

Y. Lee [1], S. Cho [2]

1. Soongsil University, Seoul, South Korea
2. Ulsan University, Ulsan, South Korea

We investigated the electronic structures of the FeGe expitaxial films by using optical spectroscopy. The films were grown on an epi-ready semiconducting GaAs(100) substrate by molecular beam epitaxy. Electric and magnetic measurements revealed that our films show ferromagnetic-metallic behavior, and interestingly a complex M-H curve could be related ot the skyrmion. In spectroscopic ellipsometry, we compared the optical conductivity spectra with the theoretical calculation. Infrared spectroscopy identified the formation of the low energy resonance mode. We discuss the low energy electrodynamics of our films in relation to their unusaul magnetic properties.

TU.E-P05 - Effect of annealing on magnetic and structural properties of half-metallic Co_2MnAl Heusler ribbons

T. Ryba [1], L. Galdun [1], Z. Vargova [2], M. Obaida [3], K. Saksl [4], M. Durisin [4], V. Haskova [1], P. Szabo [4], C. Garcia [5], R. Varga [1]

The Heusler alloys are materials for many applications as spintronics, magnetocaloric cooling, sensors etc. [1]. Particularly, the applications in spintronics are significantly influenced by high value of magnetic moment, high spin polarization, high Curie temperature and small Gilbert damping. Half-metallic composition as Co_2MnAl is a typical example of full Heusler (L21 - structure) alloy with high calculated (100%) value of spin polarization [1-2]. This alloy is typically produced by arc-melting of pure elements and subsequent long-term annealing. On the other hand, rapid quenching (melt-spinnig) is a rapid method for preparation of large amount of homogeneous ribbons of Heusler alloy without necessity of further annealing. In the given contribution, we offer the comparison of structural and magnetic properties of annealed (48 hours at 990 K) and as-cast half-metallic rapidly quenched Co_2MnAl alloy. As-cast sample of Co_2MnAl exhibit B2 structure while annealed sample shows L21 structure. Hysteresis loops and temperature dependence of magnetization shows direction of easy magnetization in parallel direction and Curie temperature is above 700 K, chemical composition and orientation of grains were determined by SEM/EDX. Spin polarization of the sample was measured by point contact method, giving values of 76 % for as-cast sample and 72 % for annealed one. Value of spin polarization was not affected by annealing of sample. This results is in good agreement with the theory of Y-Z disorder [3].

TU.E-P06 - Dilute ferromagnetic InMnP

S. Zhou [1], M. Khalid [1], E. Weschke [2], W. Skorupa [1], M. Helm [1]

1. Helmholtz-Zentrum Dresden, Rossendorf, Germany
2. Helmholtz-Zentrum Berlin for Materials and Energy, Berlin, Germany

We have synthesized a new magnetic semiconductor, InMnP, by Mn ion implantation and pulsed laser annealing [1, 2]. Clear ferromagnetic hysteresis loops and a perpendicular magnetic anisotropy are observed up to a Curie temperature of 42 K. Large values of negative magnetoresistance and magnetic circular dichroism as well as anomalous Hall effect are further evidences of a ferromagnetic order in InMnP. An effort is made to understand the transport mechanism in InMnP using the theoretical models. We find that the valence band of InP does not merge with the impurity band of the heavily doped InMnP (8 %). Our results suggest that impurity band conduction is a characteristic of Mn-doped InP and GaP which have deep Mn-acceptor levels.

TU.E-P07 - First-principles study of spin-wave dispersion in FeCo alloy system with tetragonal distortion

Y. Kota [1], A. Sakuma [2]

1. Fukushima National College of Technology, Fukushima, Japan
2. Tohoku University, Sendai, Japan

Tetragonally distorted FeCo alloys are a strong candidate as novel hard-magnetic material without rare-earth elements. After the giant magnetocrystalline anisotropy of tetragonal FeCo alloys was predicted theoretically, many experimental trials have been performed to realize such a property. In previous studies, however, the Curie temperature of tetragonal FeCo alloys (especially in the disordered phase) was not investigated, though the Curie temperature is an essential property of ferromagnetic materials. Moreover, the stability of the ferromagnetic state in tetragonal FeCo alloys is unclear, whereas the ferromagnetic state in pure-Fe system tends to become unstable by tetragonal distortion. To verify these points, analyzing FeCo system deviated from the ferromagnetic ground state is an important topic. In this work, we study the spin-wave dispersion of tetragonal FeCo alloys to clarify the stability of the ferromagnetic state and the exchange stiffness constant. The electronic structure calculations of tetragonal FeCo alloys with the spin spiral structures are performed by using the tight-binding linear muffin-tin orbital method under the local spin-density approximation. Also the coherent potential approximation is adopted to deal with the substitutional disorder between Fe and Co atoms. The obtained results reveal that the ferromagnetic state is stable in tetragonal FeCo alloys, and that the exchange stiffness constant is about 70% compared with the stiffness constant of cubic FeCo. When the degree of the tetragonal distortion from the bcc structure is increased, the exchange stiffness constant decreases monotonically. Even so the Curie temperature estimated from the stiffness constant of tetragonal FeCo alloys is sufficiently higher than room temperature, and the tetragonal FeCo is utilizable as a hard-magnetic material.

TU.E-P08 - Investigating the metallic and insulating behaviors in $NiCo_2O_4$ thin films by X-ray absorption spectroscopy

Y.Y. Chin [1], Y. Bitla [2], J.C. Lin [3], N. Chien [2], R.R. Liu [4], Y.M. Zhu [4], H.J. Liu [2], Q. Zhan [4], H.J. Lin [1], C.T. Chen [1]

1. National Synchrotron Radiation Research Center, Hsinchu, Taiwan
2. Department of Materials Science and Engineering, National Chiao Tung University, Hsinchu, Taiwan
3. Institute of Physics, Academia Sinica, Taipei, Taiwan
4. Department of Material Physics and Chemistry, University of Science and Technology Beijing, Beijing, China
5. Department of Physics, Durham University, Durham, United Kingdom

In the present work, we investigate distinct transport behaviors of $NiCo_2O_4$ thin films under different growth conditions by use of X-ray absorption spectroscopy and magnetic circular dichroism. Comparing the experimental spectra with the theoretical calculations, the valence and spin states of Co and Ni are determined. We found that the metallic and insulating behaviors in $NiCo_2O_4$ thin films could be understood by the percolation threshold. Besides, the increase of the resistivity at low temperature in the metallic phase may be linked to the change of the magnetization.

TU.E-P09 - Magnetic and resistivity properties in half-metallic glass-coated Co_2FeSi Heusler microwires

L. Galdun [1], T. Ryba [1], V. Prida [2], V. Zhukova [3], A. Zhukov [3], Z. Vargova [1], R. Varga [1]

1. Inst. Phys., Fac. Sci., UPJS, Kosice, Slovakia
2. Dpto. De Física, Universidad de Oviedo, Oviedo, Spain
3. Dpto. Fisica de Materiales, Fac. Quimicas, UPV/EHU, San Sebastian, Spain

Co_2-based Full Heusler alloys are one of the most promising materials predicted to exhibit 100% spin polarization at the Fermi energy level (E_F), which renders these alloys suitable candidates for spintronics applications. However the theoretical values of spin polarization for the half-metal Co_2FeSi with the highest Curie temperature (T_C 1100 K) and magnetic moment per unit cell ($m = 6m_B$/f.u.) are much higher as the values determined with point contact Andreev reflection (PCAR) spectroscopy. This phenomenon could be explained through the sensitivity of atomic order in $L2_1$ phase, which is crucial for obtaining the spin-polarized material. [1].
One of the few disadvantages of Heusler alloy is their complex production process that usually consists of Arc melting of pure elements followed by long term annealing at high temperature. This process can be reduced by rapid quenching of master alloy that brings more homogeneous sample and no post treatment is necessary [2].
In the given contribution, we present the application of another type of rapid quenching production method using Taylor-Ulitovski technique to produce glass-coated microwire [3]. This method increases the quenching rate by one order (comparing to melt-spinning) and allows production of up to kilometres of the wire from 1g of master alloy. Basic structural and magnetic characterizations are provided. It is shown that due to a high quenching rate it is possible to achieve microwires, with polycrystalline $L2_1$ structure and well defined magnetic anisotropy that are especially suitable for spintronics applications.

TU.E-P10 - Half-metallic ferromagnetism in Sn-doped perovskite ruthenates: A first-principles study

J. Yu [1], N. Kim [1], R. Kim [1]

1. Seoul National University, Seoul, South Korea

The half-metallic ferromagnets are unusual materials which show metallic property in one spin channel and insulating property in the other spin channel. There have been many attempts in searching of new half-metallic materials after the pioneering work on the Mn-based Heusler alloys. Among them, perovskite oxides has attracted some attention as a promising class of materials for half metallic ferromagnets. Here we propose Sn-doped perovskite ruthenates as a new breed of perovskite oxides which can pose a range of properties from ferromagnetic metal to a large gap semiconductor, where a mixture of B-site ions, Ru and Sn, can generate possibly an emerging physical property like half-metallicity for some range of x, where x represents the ratio of Sn substituting Ru. To investigate the electronic and magnetic properties of Sn-doped perovskite ruthenium oxides, we carried out first-principles electronic structure calculations. From the calculation results, we demonstrate that the Sn-doped ruthenium oxides transforms from a ferromagnetic metal for $x<0.5$ to a ferromagnetic half-metal for $0.5<x<0.7$ to an insulator for $x>0.7$. The formation of half-metallic state in Sn-doped ruthenates evidently originates from the reduced hopping of Ru 4d electrons due to the presence of the substituted Sn elements between Ru atoms. The effect of tilting and rotation of RuO_6 octahedron is still present. But the angle of the octahedron is unchanged with increasing Sn doping and no further noticeable lattice distortion is observed in the fully relaxed lattice structures. We suggest that the realization of half-metallic ferromagnetic state in a perovskite oxide contribute to its possible memory and spintronic device applications.

TU.E-P11 - Effect of hydrogen on magnetic properties of ε-Fe_2O_3

D. Hirai [1,2], S. Tsuneyuki [1,2,3], Y. Gonda [1,2,4]

1. Department of Physics, The University of Tokyo, Tokyo, Japan
2. Elements Strategy Initiative Center For Magnetic Materials, Tsukuba, Japan
3. Institute For Solid State Physics, The University of Tokyo, Tokyo, Japan
4. Department of Materials Science and Engineering, Tokyo Institute of Technology, Tokyo, Japan

ε-Fe_2O_3 has attracted attention for next-generation high-density magnetic recording media and high-frequency electromagnetic wave absorbers, due to its large coercivity [1]. However, this origin remains unelucidated.

In this study, we performed first-principles calculation to understand the magnetic properties. Our calculation is based on density functional theory. First, we show that the pristine ε-Fe_2O_3 exhibits zero magnetization in contrast to experiments showing a finite one [1]. To obtain a finite magnetization, we considered the influence of hydrogen on the magnetic properties. It is shown that hydrogen can be naturally included in ε-Fe_2O_3 from the discussion of formation energy. As a result of the introduction of hydrogen in the unit cell, we observed the finite spin magnetic moment of 1 μ_B. In addition, we found that the enhancement of magnetocrystalline anisotropy energy (MAE) compared to that of the pristine case. Based on the second-order perturbation scheme on the spin-orbit interaction [2,3], we clarified that this enhancement is originated from only a specific Fe site, which is nearest Fe site from the oxygen site bonding hydrogen. Further, we found that the spin-orbit coupling between occupied $dx^2\text{-}y^2\downarrow$ and unoccupied $dxy\downarrow$ of this Fe site is the most important for the MAE enhancement. Our study suggests that the existence of hydrogen plays a significant role on the magnetic properties.

TU.E-P12 - X-ray and visible magnetic circular dichroism spectroscopy of $Pr_{1-x}Sr_xMnO_3$ thin films: Comparative study

A. Rogalev [4], Y. Samoshkina [1], I. Edelman [1], A. Sokolov [1], K. Ollefs [2], N. Andreev [3], V. Chichkov [3]

1. Kirensky Institute Of Physics, Krasnoyarsk, Russia
2. European Synchrotron Radiation Facility (ESRF), Grenoble, France
3. National University of Science and Technology 'MISIS', Moscow, Russia
4. European Synchrotron Radiation Facility (ESRF), Grenoble , France

$Pr_{1-x}Sr_xMnO_3$ polycrystalline films with x = 0.2 and 0.4 were prepared with the dc magnetron sputtering and investigated by x-ray magnetic circular dichroism (XMCD) at Mn K- and Pr L-edges and also by visible magnetic circular dichroism (MCD). The XANES (x-ray absorption near-edge structure) spectra were measured additionally. General shape of XMCD and XANES spectra at the Mn K-edge for the $Pr_{1-x}Sr_xMnO_3$ films is very similar to that for manganites of other composition presented in literature, in particular for the $La_{1-y}Ca_yMnO_3$. However, in the studied samples an evolution of XANES spectra is not observed when the doping element concentration increases, namely, there is no systematic energy shift and the enhancement of the pre-edge structure intensity at E ~ 6557 eV what were characteristic for the above-mentioned manganites. XMCD spectra at Mn K-edge also coincide for the both $Pr_{1-x}Sr_xMnO_3$ films but show the enhancement of dichroic signal with x increasing. Similar behavior is observed for XMCD and XANES spectra at the Pr L-edges. In the case of MCD in visible range, for the films with x = 0.2 and 0.4 we have traced the correlation of the MCD peculiarities in different spectral interval not only with the x value but with the conductivity type of samples. Thus, MCD spectroscopy seems to be sensitive method to study the electronic and magnetic structure of $Pr_{1-x}Sr_xMnO_3$. The observed MCD features were associated with the different ratios Mn^{3+}/Mn^{4+} in the films and also with the presence of free charge carriers in the samples and explained in terms of electronic transitions. The behavior of XMCD and XANES spectra for $Pr_{1-x}Sr_xMnO_3$ films needs additional research.

TU.E-P13 - Electronic structure and magnetic properties of $(LaMnO_3)m/(SrTiO_3)n$ Superlattices

A. Aezami [1], M. Reza Abolhassani [2], M. Elahi [2], M. Niayfar [1]

1. Department of physics, Science and Research Branch, Islamic Azad university, Ahwaz, Iran
2. Department of physics, Science and Research Branch, Islamic Azad University, Tehran, Iran

We study the magnetic structure and Curie temperature of the $(LaMnO_3)m/(SrTiO_3)n$ superlattices (SLm-n) with m=1, 2, 3 and n=1, 2, 3, 8 based on density functional calculations using Quantum-Espresso open source code. We find that the electronic and magnetic structure changes with the thickness of the layer, which is in agreement with experimental results. The leakage of the Mn eg electrons from the $LaMnO_3$ side to the $SrTiO_3$ side show different magnetic structures. This in turn affects the interfacial magnetism via the superexchange interaction. Using Stoner model for all of these superlattices before and after adding U term on the Ti atoms, we have found that magnetic order of interfacial atoms of these superlattices changes to ferromagnetic by implying U=5 eV on the Ti atoms. The inclusion of electron-electron correlation with U=5 eV on the Ti atoms for all of the superlattices makes the 2DEG formed at the interface half-metallic. We found that the values of Curie temperature obtained (by mean field approximation) with U=5 eV on the Ti atoms are in good agreement with the experimental results.

TU.E-P14 - Quantum interference of surface-induced friedel oscillations enhanced by fermi-surface nesting in layered manganites

R. Yamamura [1], T. Hotta [1]

1. Department Of Physics, Tokyo Metropolitan University, Hachioji, Japan

In recent decades, some manganites have been focused as important materials for the cathodes in Li-ion batteries and catalysts in photosynthesis. Manganites work as cathodes and catalysts by the valence change mainly from Mn^($^{4+}$) to Mn^($^{3+}$) in the process of chemical reaction. Since such a reaction occurs on the surface of manganites, to achieve high efficiency as these materials, it is desirable to obtain the situation with Mn^($^{4+}$) ions on the surface and Mn^($^{3+}$) in the bulk. We can naively expect to realize this situation in metallic materials, but it is still unclear what microscopic mechanisms cause such valence imbalance of manganese ions between surface and balk. To clarify this point, we have investigated imbalance of Mn^($^{3+}$) and Mn^($^{4+}$) ions between surface and bulk in layered manganites on the basis of an orbital degenerate double-exchange model with surfaces for several types of t_2g spin structures. First we confirm that the number of Mn^($^{4+}$) ions on the surface is larger than that in the bulk, explained by the surface-induced Friedel oscillation. The wavevector of Friedel oscillation is closely related with nesting vector along the direction of oscillation. Thus, when two Fermi-surface curves exist, we observe two Friedel oscillations with the wavevectors equal to the nesting vectors. In particular, when two nesting vectors possess similar values, quantum beat phenomena appear due to the interference between two Friedel oscillations and the number of Mn^($^{4+}$) ions is actually increased on the surface. Furthermore, we report the appearance of the arrangement of x^2-y^2 orbital on the surface in the three-dimensional ferromagnetic state.
A part of this presentation will be submitted as an original paper to Journal of the Physical Society of Japan and will be also presented at the meetings of the Physical Society of Japan.

TU.E-P15 - First-principles study for the chiral magnet $Cr(NbS_2)_3$

T. Shishidou [1]

1. ADSM, Hiroshima University, Hiroshima-shi, Japan

In the layered intercalated compound $Cr(NbS_2)_3$, Cr atoms order in the sqrt 3 x sqrt 3 superlattice and the arrangement of S atoms, octahedrally coordinating to Cr's, takes on chirality along c axis. In accord with the chiral crystal structure, Cr local moments (S=3/2) show long-period chiral magnetic structure (L=48nm). Furthermore, it is theoretically predicted that the chiral spin soliton lattice would emerge by applying a small magnetic field perpendicular to the c axis, and is actually proved experimentally. An anomaly in electrical conductivity is also observed, which shows clear dependency on the magnetic soliton density and makes this material attractive. It is widely believed that the neighboring spin interaction is ferromagnetic and competes with the Dzyaloshinsky-Moriya interaction, leading to the chiral magnetic order. However there has been no ab initio study, which discusses the electronic structure in detail and estimates the various magnetic interactions. In this study, aiming at discussing the crystal structure, the fundamental electronic structure, and the magneto crystalline anisotropy (MCA) of $Cr(NbS_2)_3$, we carry out density-functional theory calculations based on the all-electron FLAPW method. Since the magnetic chiral period is very long, we can approximately use a collinear ferromagnetic alignment for the present purpose. After the full structural relaxation, the S atoms exhibit the chiral arrangement accounting for the experiment. The Cr t2g majority-spin states are believed to be well localized to form S=3/2. However, our study shows that the a1g orbital of the t2g manifold hybridizes strongly with Nb 4d states and bears an itinerant character. This orbital is considered to have some role on the Cr-Cr magnetic interaction and also to couple magnetically with conducting states. MCA is evaluated to be easy-plane type, being in agreement with experiment.

TU.E-P16 - Anomalous oxidation state of iron in two-leg ladder compound $Ba_6Fe_8S_{15}$

H. Aruga Katori [1], T. Adachi [1], H. Ohta [1], S. Nakamura [2,3], A. Fuwa [4]

1. Institute Of Engineering, Tokyo University Of Agriculture And Technology, Tokyo, Japan
2. Department of Science and Engineering, Teikyo University, Itabashi, Japan
3. Advanced Research Institute of Science and Engineering, Waseda University, Tokyo, Japan
4. Faculty of Science and Engineering, Waseda University, Tokyo, Japan

$Ba_6Fe_8S_{15}$ shows a tetragonal structure (space group I4/m), in which FeS_4 tetrahedra construct Fe_4S_{10} clusters. Infinite columns of the tetrahedrally coordinated irons in this cluster can be viewed as one-dimensional twisted two-leg ladders. There is only one crystallographic iron site in $Ba_6Fe_8S_{15}$, suggesting that the charge is delocalized and iron ion has an average valence of +2.25.
To clarify the oxidation state of iron and magnetism, we synthesized $Ba_6Fe_8S_{15}$ and performed the magnetization and Mössbauer spectroscopy measurements. Magnetization measurements were carried out using a vibrating sample magnetometer in the temperature range between 1.5 K and 300 K in fields up to 12 T. 57Fe Mössbauer spectra were measured in conventional transmission geometry in the temperature range between 4.2 K and 300 K. The temperature dependence of magnetization observed in high temperature region shows a similar behavior to that of one-dimensional antiferromagnetic chain system. The Mössbauer spectra above 120 K indicate the existence of only a single quadrupole doublet, which is consistent with the evidence of one crystallographic Fe site. Below 110 K, however, we observed the spectra characterized by two kinds of magnetic hyperfine patterns, indicating an existence of complicated magnetic order. These spectra cannot be explained if the mixed valence state of Fe^{2+} and Fe^{3+} is realized. By analyzing Mössbauer spectra in detail, we discuss the oxidation state of iron including possibility of a structural phase transition and an electric charge ordering.

TU.E-P17 - Metal-Insulator Transition driven by all-in/all-out magnetic ordering in $Cd_2Os_2O_7$

C.H. Sohn [1], H.G. Jeong [1], H.S. Jin [1], J. Yamaura [2], S.Y. Kim [1], L.J. Sandilands [1], H.J. Park [1], K.W. Kim [3], S.J. Moon [4], D.Y. Cho [5]

5. Department of Physics, Chonbuk National University, Jeonju, Korea
6. ISSP, University of Tokyo, Kashiwa, Japan

We investigate the metal-insulator transition driven by all-in/all-out (AIO antiferromagnetic ordering in 5d pyrochlores $Cd_2Os_2O_7$ using optical spectrsocopy and first-principle calculations. The temperature dependence in band gap and free carrier density clearly reveals hidden sequential phase transitions, from paramagnetic metal to AIO metal to AIO insulator. The accompanied spectral weight transfer and first-principle calculations further show that the origin of such phase transitions is Lifshitz transition induced by AIO ordering. Our result clearly demonstrates how AIO ordering leads the metal-insulator transition in 5d pyrochlores and lays a groundwork for searching exotic phenomena including Weyl semimetal and quantum critical behaviors.

TU.E-P18 - Fabrication of epitaxial Mn_2CoAl films for spintronic applications using spin-gapless semiconductors

K. Ueda [1], S. Hirose [1], M. Nishiwaki [1], T. Hajiri [1], H. Asano [1]

1. Nagoya University, Nagoya, Japan

Spin-gapless semiconductors (SGS) are magnetic semiconductors with zero-gap and half-metallic characters simultaneously due to their special band structures, and they have high potential for fabricating novel spintronic devices. An inverse Heusler compound, Mn2CoAl, is one of promising candidates for SGS because SGS-like transport properties (temperature-independent conductivity, linear MR, etc.) have already been reported for bulk Mn2CoAl. Preparation of SGS in film form is necessary to fabricate devices. However, there are only several reports on the growth of Mn2CoAl films, which have room for improvement. In this study, we have tried fabricating high-quality Mn2CoAl films for spintronic applications using SGS.
Mn2CoAl films were formed by ion-beam assisted sputtering (IBAS), which is effective to obtain Heusler films at lower growth temperature [1]. XRD measurements revealed epitaxial Mn2CoAl films (Mn2CoAl (001)[110]// MgAl2O4 (001)[100]) can be formed on MgAl2O4 substrates at the growth temperature (Tg) of 300~600°C. These films showed ferromagnetic hysteresis at room temperature. The c-axis lattice constant and saturation magnetization (Ms) increased as Tg decreased and they became 0.5792 nm and ~240 emu/cc with Hc of ~70 Oe for Tg= 300°C, which are comparable to those for bulk Mn2CoAl (c= 0.5798 nm; Ms: ~350 emu/cc, Hc: ~100 Oe). One of possible reasons for smaller c-axis and Ms is interfacial reaction/diffusion between Mn2CoAl and MgAl2O4 at higher Tg. The films showed semiconducting behaviors with very small activation energy of ~3 meV and relatively small resistivity of ~700 μΩcm for semiconductors, which agree well with zero band-gap features of SGS. The electron concentration and mobility deduced from Hall resistivity measurements (ρxy) is ~7*1020 cm-3 and ~12 cm2/Vs at 4 K, which were comparable to reported values for Mn2CoAl films. These results indicate high-quality Mn2CoAl films can be obtained on MgAl2O4 by IBAS.

TU.E-P19 - Semiconducting behaviour of $Ce_3Cu_3Sb_4$ revisited

L. Kalinowski [1], P. Witas [1], M. Fijałkowski [1], J. Goraus [1], A. Œlebarski [1]

1. Institute of Physics, University Of Silesia, Katowice, Poland

The recent complex investigations have shown $Ce_3Cu_3Sb_4$ as a ferromagnetic semiconductor [1,2] and a good material for thermoelectric applications [3,4]. The semiconducting properties of $Ce_3Cu_3Sb_4$ were, however, questioned [5] and activated behavior in resistivity was attributed to magnetic polaron effect. Our ab-initio calculations predict for this compound a broad energy gap located near the Fermi energy EF, which prefers the semimetallic character of $Ce_3Cu_3Sb_4$ and strong gradient of the density of states (DOS) at EF. The presence of the pseudogap near the Fermi level is fully supported by the resistivity vs. temperature experiment, which exhibits the activated behavior, while the gradient in DOS can enhance the thermoelectric properties of this material. Basing on the fully relativistic FPLO calculations we also investigated the band structure of the $Ce_3Cu_{3-x}Ni_xSb_4$ alloys which did not show the significant change of the energy gap with alloying. However, thermopower of the $Ce_3Cu_{3-x}Ni_xSb_4$ is strongly reduced. We interpret this effect as result of the change of DOS at the Fermi level. To evidence the effect, we also investigated the magnetic, electric transport, thermoelectric properties and Hall effect for $Ce_3Cu_{3-x}Ni_xSb_4$.

7. Faculty of Science, University of the Ryukyus, Nishihara, Japan, Japan

We grew high-quality single crystals of $LaCo_2P_2$ with the $ThCr_2Si_2$-type tetragonal structure by the Sn-flux method, and measured the electrical resistivity, specific heat, magnetic susceptibility, magnetization, and de Haas-van Alphen (dHvA) effect for a ferromagnet $LaCo_2P_2$, together with related compounds $SrCo_2P_2$ and $EuCo_2P_2$. An as-grown sample of $LaCo_2P_2$ is of a thin plate with the tetragonal (001) plane. The typical size is 2×2×0.5 mm^3. The residual resistivity r_0 and residual resistivity ratio RRR are r_0=1.17 mWcm and RRR=69, respectively, indicating a high-quality sample. From the results of magnetic susceptibility and magnetization measurements, $LaCo_2P_2$ is a ferromagnet with a Curie temperature T_C=130 K and a saturated moment of 0.4 m_B/Co. Note that a magnetic easy-axis corresponds to the [100] direction. When the magnetic field is applied along a hard-axis of the tetragonal [001] direction, magnetization reaches the saturated moment in magnetic fields larger than 50 kOe. These experimental results are consistent with the previous report [1]. We thus carried out the dHvA experiment in magnetic fields ranging from 50 to 150 kOe. Main dHvA branches possess the dHvA frequencies F=(2-7)×10^7 Oe, where the dHvA frequency F (=$c\hbar S_F/2pe$) is proportional to the maximum or minimum cross-sectional area of the Fermi surface S_F, which is shown as a unit of magnetic field. The corresponding cyclotron effective masses are (2-3) m_0 (m_0: rest mass of an electron). The present relatively large cyclotron masses are due to the magnetic correlation of Co-3d electron, which are compared with much larger cyclotron masses of (3-7) m_0 for a nearly ferromagnet $SrCo_2P_2$ [2]. The strong correlation is realized in $SrCo_2P_2$.

TU.E-P21 - Spin stiffness constant of half-metallic ferrimagnet in Mn-based Heusler alloys

R. Umetsu [1,2], T. Kanomata [3]

1. Tohoku University, Sendai, Japan
2. JST-PRESTO, Tokyo, Japan
3. Tohoku Gakuin University, Sendai, Japan

Mn-based Heusler alloys with half-metallic electronic structure have a potential candidate for the spintronics devices. Recently, many kinds of Mn-based Heusler alloys have been predicted as showing half-metallic electronic states from the first principle calculations [1,2]. In our experimental studies, some Mn-based Heusler alloys with high phase stability were suggested and their physical properties have been investigated. The spin stiffness constant, D, indicates thermal stability of the exchange interaction and such the excitation of the spin will relate to the performance of the devices. In the present study, we evaluated the value of D for Mn-based Heusler alloys and discuss the obtained values comparing with that for various Co-based Heusler alloys [3]. Polycrystalline specimens of Mn_2VAl and Mn_2CoGa were prepared by arc-melting or induction melting. After the identifications of the composition, microstructure and crystal structure, magnetic measurements were performed with a SQUID magnetometer up to 5 T and a vibrating sample magnetometer. The spontaneous magnetization was confirmed from the Arrott plot at each measured temperature. The Curie temperature, TC, of Mn_2VAl, $Mn_{50}V_{20}Al_{30}$ and Mn_2CoGa were 768, 754 and 741 K, respectively. The value of D was evaluated from the temperature, T, dependence of the spontaneous magnetization in each specimen below 150 K, where linear dependence of T3/2 was observed. The D values for these materials were obtained to be'5.2 - 5.4' meV-(nm)2 and significantly larger than that for Co-based Heusler alloys (Co_2FeAl; 4.7, Co_2MnSi; 3.5, Co_2MnGa; 2.4 meV-(nm)2) [3]. The strong exchange interaction would be the reason that the Mn-based Heusler alloys indicate high TC even though they have not so large total magnetic moment.

TU.E-P22 - Magnetic properties of the kondo insulator $CeRu_4Sn_6$

A. Sidorenko [1], H. Winkler [1], A. Prokofiev [1], S. Paschen [1]

1. Institute of Solid State Physics, Vienna University of Technology, Austria

Kondo insulators (KIs) continue to attract attention as less explored relatives of the heavy fermion metals. $CeRu_4Sn_6$ is one of the rare examples of a KI with tetragonal crystal structure. Indications for a narrow gap formation somewhat below 100 K have been provided early on by electrical resistivity measurements on polycrystalline samples [1]. Electrical resistivity [2] and optical conductivity measurements [3] on a single crystals revealed a strong anisotropy, indicating the development of an anisotropic energy pseudogap. Here we present our magnetic property investigation of single crystalline $CeRu_4Sn_6$. The magnetic susceptibility as well as magnetic isotherms were studied in wide ranges of temperature (300 mK - 1000 K) and magnetic field applied along the principle crystollographic axes. It is discussed to which extent the results can be understood within the framework of a simple crystal electric field approach.

TU.E-P23 - Curie temperature within the electronic correlation formalism in double perovskites systems

O. Navarro [1], F. Estrada [1], M. Avignon [2]

1. Instituto de Investigaciones en Materiales, UNAM, Mexico D.F., Mexico
2. Institut Néel, CNRS and Université Joseph Fourier, Grenoble, France

The half-metallic ferromagnetic double perovskite Fe-Mo based compound is considered as an important material in view of its potential spintronic applications due to its high Curie temperature TC=420K, complete spin polarization and substantial low-field magnetoresistance at room temperature [1]. So, It is fundamental to understand the role of electronic parameters controlling the half-metallic ground state and high Curie temperature in this system. In this work we present an electronic approach to study the Curie temperature behavior in double perovskites systems, this approach is based on a correlated electron picture with localized Fe-spins and conduction Mo-electrons interacting with the local spins via a double-exchange-type mechanism [2]. The Curie temperature behavior shows an enhancement with the on-site Hubbard electronic interaction.

TU.E-P24 - Half-metallic properties of (001) surfaces of quaternary Heusler alloys CoFeCrZ (Z=Al and Ga): A first-principles study

J.I. Lee [1], B. Bialek [1], D.C. KIm [2]

1. Inha University, Incheon, South Korea
2. Halla University, Wonju-si, South Korea

Half-metallic ferromagnets, which are characterized by complete spin polarization at the Fermi level, are perfect candidates for spintronic applications as sources of spin-polarized charge injection. Since the NiMnSb with half-Heusler structure was predicted to be a half-metal [1], various kinds of half metallic materials, such as ferrite, chromium oxide, manganese, transition metal pnictides, and chalcogenides were found. Heusler and half-Heusler structured half-metals have attracted much attention for the spintronics application, since their structures are compatible with the usual, zinc-blende structured, semiconductors. Recently, a first-principles study led to a prediction that quaternary Heusler compounds, CoFeCrZ (Z=Al, Ga) are excellent half-metallic ferromagnets [2]. In this study, we investigate the electronic and the magnetic properties at the (001) surfaces of CoFeCrAl and CoFeCrGa by means of the full-potential linearized augmented plane wave (FLAPW) method [3] within general gradient approximation [4]. We considered two types of surface termination: CoFe-terminated and CrZ-terminated surfaces, Z being either Al or Si. From the calculated total magnetic moments and the local density of states, we found that half-metallicity is preserved only the CrAl-terminated surface of the CoFeCrAl. The CrSi- and CoFe-terminated surfaces are almost half-metallic. The magnetic moment of the Cr atom at the CrAl(001) surface of CoFeCrAl is 2.98 bohr magneton, almost twice the bulk value. The magnetic moment of Co atom at the FeCo-terminated surface of CrFeCoAl is increased compared to the bulk value, while the magnetic moment of the Fe atom decreases to nearly zero from reported 1.63 bohr magneton bulk-like value [2].

TU.E-P25 - Magnetic exchange interaction between A'-site transition-metal ions in A-site-ordered perovskites

M. Toyoda [1,2], K. Yamauchi [1], T. Oguchi [1,2]

1. Institute Of Science And Industrial Research, Osaka University, Osaka, Japan
2. Japan Science and Technology Agency

The magnetic exchange interaction has been studied in the A-site-ordered perovskite-structure oxides $AA'3B_4O_{12}$ by using ab initio electronic structure calculations. These oxides are of special interest because they can contain magnetic transition-metal ions at a part of the A sites as well as at the B sites. In general, the A sites in perovskite-related structures are occupied by cations with larger ionic radii such as strontium and lanthanum. However, in this particular structure, octahedral rotation and tilting around B sites change the local oxygen coordination around 3/4 of the A sites (called A' sites r) to an almost square-planar coordination. The spins at the A' sites interact with each other in a different manner than the B-site spins. In order to understand the magnetic exchange interaction between the A'-site spins, Heisenberg-type exchange coupling constants J are calculated for several compounds, such as $CaCu_3Ge_4O_{12}$, $CaCu_3Sn_4O_{12}$, $CaCu_3Ti_4O_{12}$, $YMn_3Al_4O_{12}$, and $LaMn_3V_4O_{12}$. It is found that the magnetic exchange interaction is comprehensively explained by super-exchange mechanism, the sign of which depends on the electronic configuration of the A'-site transition-metal ions.

TU.E-P26 - Spin gapless ferrimagnetism induced by triangular frustration in (111)-oriented FeX/GaX (X = N, P, and As) superlattices

M. Nakao [1]

1. Department Of Precision Engineering, Tokai University, Toyko, Japan

We investigate the electronic and magnetic properties of iron pnictide monolayers in tetrahedrally coordinated FeX/GaX (X = N, P, and As) superlattices with (111) orientation to explore for spin gapless semiconductors, in which both electrons and holes can be fully spin polarized. Using density functional calculations, we find that the quasi-two-dimensional FeX monolayers embedded in compound semiconductors are always geometrically frustrated antiferromagnets regardless of their stacking sequence and separation. Here we treat the exchange-correlation functional within the spin-polarized generalized gradient approximation plus Hubbard U method to account for electron correlation; turning on an appropriate on-site Coulomb repulsion U leads the system to a spin gapless semiconducting state. There is a narrow gap between the conduction and valence bands for both the majority and minority spins, while there is no gap between the majority spin state in the valence band top and the minority spin state in the conduction band bottom. Among possible collinear spin arrangements, the magnetic ground state is a four-sublattice structure with an up-up-down-down (UUDD) configuration. Competing ferrimagnetic UUD three-sublattice and UUUDD five-sublattice structures lie close in energy. Upon either electron doping or applying a magnetic field, the quasi-2D FX monolayers will exhibit spin gapless ferrimagnetism. We suggest that artificially synthesized frustrated systems are favorable candidates for a new class of spintronic materials.

TU.E-P27 - Electronic structure and magnetic properties of $(LaMnO_3)m/(SrTiO_3)n$ superlattices

A. Aezami [1], M. Reza Abolhassani [2], M. Elahi [2], M. Niyaifar [1]

1. Science And Research Branch, Islamic Azad University, Ahwaz, Iran
2. Department of physics, Science and Research Branch, Islamic Azad University, Tehran, Iran

We study the magnetic structure and Curie temperature of the $(LaMnO_3)m/(SrTiO_3)n$ superlattices (SLm-n) with m=1, 2, 3 and n=1, 2, 3, 8 based on density functional calculations using Quantum-Espresso open source code. We find that the electronic and magnetic structure changes with the thickness of the layer, which is in agreement with experimental results. The leakage of the Mn eg electrons from the $LaMnO_3$ side to the $SrTiO_3$ side show different magnetic structures. This in turn affects the interfacial magnetism via the superexchange interaction. Using Stoner model for all of these superlattices before and after adding U term on the Ti atoms, we have found that magnetic order of interfacial atoms of these superlattices changes to ferromagnetic by implying U=5 eV on the Ti atoms. The inclusion of electron-electron correlation with U=5 eV on the Ti atoms for all of the superlattices makes the 2DEG formed at the interface half-metallic. We found that the values of Curie temperature obtained (by mean field approximation) with U=5 eV on the Ti atoms are in good agreement with the experimental results.

TU.E-P28 - Chemical disorder and enhanced curie temperature of $Co_{2-x}Fe_{1+x}Si$ heusler alloys

J. Karel [1], J. Fischer [1], P. Adler [1], L. Wollmann [1], S. Fabbrici [2], G. Fecher [1], F. Albertini [2], C. Felser [1]

1. Max Planck Institutue For Chemical Physics Of Solids, Dresden Germany
2. Institute of Materials for Electronics and Magnetism, Parma, Italy

Co_2-based Heusler compounds are one of the most promising classes of materials for high performance spintronic devices, owning in part to their very high spin polarization; many of these compounds are theoretically predicted to be half-metallic ferromagnets, which exhibit 100% spin polarization at the Fermi energy. In this work, the magnetic and structural properties including the Curie temperature (TC) were investigated for a series of bulk $Co_{2-x}Fe_{1+x}Si$ ($0<x<1$) Heusler alloys. Co_2FeSi has the highest TC reported for a Heusler alloy, but we found an enhanced TC (14K greater than Co_2FeSi) for the middle composition ($x=0.4$) of the series. We will show that this increase seems to be connected to the local atomic Fe environments, which were probed using Mössbauer spectrometry. Namely, we find two different magnetic hyperfine fields corresponding to Fe in two different positions in the lattice. An occupancy change (Fe-Co disorder) on one of these positions leads to an enhanced hyperfine field for Fe in the other position, which scales with TC. Moreover, a very small change in lattice constants also follows the same trend in TC.
The valence electron concentration (Nv) is varied across this series; as Nv increases (x decreases), the local magnetic moment carried by Co also increases. These findings are supported by theoretical calculations of the local atomic moments and the exchange parameter.

TU.E-P29 - Magnetic structure of $Hf_{0.825}Ta_{0.175}Fe_2$ itinerant-electron system as probed by neutron diffraction under high pressure

L.V.B. Diop [1,2], O. Isnard [1,2]

1. Univ. Grenoble Alpes, Inst. Néel, Grenoble, France
2. CNRS, Inst. Néel, Grenoble, France

Laves phase compounds of $Hf_{1-x}Ta_xFe_2$ are known as itinerant-electron magnets and have attracted a lot of attention due to their unusual magnetic and electronic properties and their potential applications in giant magnetoresistance and magnetic refrigeration. The pseudobinary system $Hf_{1-x}Ta_xFe_2$ crystallizes in the hexagonal $MgZn_2$-type structure (space group P63/mmc) in which the Fe atoms are located on two inequivalent crystal sites (2a and 6h) with the Hf/Ta atoms occupying the 4f site. Despite the enormous current interest in the $Hf_{1-x}Ta_xFe_2$ compounds, there appear to have been no direct measurements of the magnetic structure in this series of compounds. The magnetic structures of these intriguing compounds remain unknown. We report here a detailed neutron powder diffraction study for a chosen composition $Hf_{0.825}Ta_{0.175}Fe_2$ as a function of both temperature and pressure. As main results, $Hf_{0.825}Ta_{0.175}Fe_2$ exhibits a temperature-induced first-order transition at 200 K from the ferromagnetic (FM) to the antiferromagnetic (AFM) state upon heating. In the FM state at 1.5 K the Fe-6h atoms have a magnetic moment of 1.48 µB and those Fe-2a a magnetic moment slightly lower 1.41 µB. On the other hand in the AFM state, the antiferromagnetic arrangement is only due to the Fe-6h atoms which carry a moment of 0.51 µB: they are ferromagnetically coupled within a given (001) layer and antiferromagnetically between successive layers along the c-axis, while the Fe-2a atoms do not carry any ordered magnetic moment. A remarkable spontaneous volume magnetostriction of deltaV/V = 0.88% is observed at the FM-AFM transition. The application of hydrostatic pressure suppresses the low temperature FM ground state. It completely vanishes under pressures higher than 7.5 kbar, that corresponds to the decrease of volume of only 0.43%. The ferromagnetic order gets substituted by a new antiferromagnetic order under pressure.

TU.E-P30 - Spectral signatures of thermal spin disorder and excess Mn in half-metallic NiMnSb

K. Belashchenko [1], J. Weerasinghe [1], S. Mu [1], B. Pujari [1]

1. University of Nebraska-Lincoln, Lincoln, Nebraska, United States

Effects of thermal spin disorder and excess Mn on the electronic spectrum of half-metallic NiMnSb are studied using first-principles calculations [1]. Temperature-dependent spin disorder, introduced within the vector disordered local moment model, causes the valence band at the Γ point to broaden and shift upwards, crossing the Fermi level and thereby closing the half-metallic gap above room temperature. The spectroscopic signatures of excess Mn on the Ni, Sb, and empty sites (Mn_{Ni}, Mn_{Sb}, and Mn_E) are analyzed. Mn_{Ni} is spectroscopically invisible. The relatively weak coupling of Mn_{Sb} and Mn_E spins to the host strongly deviates from the Heisenberg model, and the spin of Mn_E is canted in the ground state. While the half-metallic gap is preserved in the collinear ground state of Mn_{Sb}, thermal spin disorder of the weakly coupled Mn_{Sb} spins destroys it at low temperatures. This property of Mn_{Sb} may be the source of the observed low-temperature transport anomalies in NiMnSb.

TU.E-P31 - ESR study of heavily Na-doped low-silica X zeolite near the insulator-to-metal transition

T. Nakano [1], K. Mukai [1], S. Hayashi [1], Y. Nozue [1]

1. Department of Physics, Osaka University, Osaka, Japan

In low-silica X (LSX) zeolite, b-cages with an inner diameter of 0.7 nm and supercages (cavities) with that of 1.3 nm are arrayed in a double diamond structure. The chemical formula of Na-form LSX is given by $Na_{12}Al_{12}Si_{12}O_{48}$ per supercage (or b-cage). Cationic Na clusters can be generated in both cages by the loading of guest Na atoms. Non-magnetic insulating states have been observed up to high loading density of $n \sim 11$, where n indicates the number of guest Na atoms (or s-electrons) per supercage [1,2]. It has been proposed that the strong electron-phonon coupling of Na atoms stabilizes small multiple bipolarons, and the insulating state is realized in spite of such a heavy doping [2]. However, a sudden metallic transition occurs at $n >$ 12, which is explained by a formation of mobile large polarons [2,3]. In the present work, we performed ESR experiments in order to examine the spin susceptibility c_{spin} near the insulator-to-metal transition. We precisely evaluated the absolute values of c_{spin} by analyzing the ESR intensity as well as the DC magnetization. In a metallic sample with the highest loading density, n = 16.7, a temperature-independent component is clearly observed. From the obtained value, ~3 x 10^{-7} emu/cm^3, the number of carriers can be estimated to be ~5 electrons per supercage if we assume the component originates from Pauli paramagnetism of free electrons. The sample at n = 11.3 shows an insulating behavior in the electrical resistivity. However, c_{spin} is found to contain the temperature-independent component with ~1 x 10^{-7} emu/cm^3, indicating a finite density of state at the Fermi level. These results indicate that it is necessary to take into account not only the polaron effect but also the weak localization in order to understand the mechanism of insulator-to-metal transition in this system.

TU.E-P33 - Pressure induced insulator to metal transition in neutral radical FBBO

D. Tian [1], S. Julian [1], S. Winter [2], A. Mailman [2], R. Oakley [2]

1. Department of Physics, University Of Toronto, Toronto, Ontario, Canada
2. Department of Chemistry, University of Waterloo, Waterloo, Ontario, Canada

Though first proposed by Haddon more than 40 years ago[1], a metallic half-filled neutral organic radical has yet to be realized, primarily due to the difficulties to overcome the large Coulomb barrier and narrow electronic bandwidth inherent in this kind of compound. The layered fluoro-substituted oxobenzene-bridged bisdithiazolyl, or FBBO, recently showed to exhibit a number of encouraging properties and has been identified as a promising candidate [2]. Though its conductivity remains activated under ambient conditions, FBBO was found to have a small Mott-Hubbard gap that can be closed at 3GPa [2], according to previous room temperature infrared absorption and transport experiments. In this report, we present further investigations of the conductive behaviors of FBBO under various pressures at low temperatures, by the means of four probe transport experiments in a diamond anvil cell. At 6.2GPa the sample exhibited a positive resistance/temperature profile and a room temperature resistance three orders of magnitude smaller than the first pressure at 2.6GPa, indicative of the transition to a metallic state. Hysteresis loops emerged below 1.4K in magneto-resistance measurements, suggesting a magnetic ground state in qualitative agreement with the weak canted AFM order found at ambient pressure [2,3].

TU.E-P34 - Spectral features of angle-resolved photoemission in a magnetic-polaron system

H.D. Kim [1]

1. Center For Correlated Electron Systems, Seoul, Korea

EuB_6 is a well-known semimetal that has a ferromagnetic (FM) ground state with Tc = 15.5 K. It has attracted much attention because of a resistivity upturn just before the FM transition, which was ascribed to magnetic-polaron formation. Angle-resolved photoemission (ARPES) spectra in the FM phase show two clear exchange-split B 2p bands, which may originate from an antiferromagnetic Kondo coupling between B 2p and Eu 4f electrons. At high-enough temperature, where there is no resistivity anomaly, two bands completely merge together. But, at slightly higher temperature than Tc, there is a vestige of exchange-split band near the Fermi level (EF), while well below the EF, the two bands has already merged. In order to clarify this behavior, we simulated ARPES spectra with a Kondo lattice model. By treating a local moment as an Ising spin, the model was solved for a 40 x 40 lattice by the Monte Carlo method with the Metropolis algorithm. In order to probe enough k points for resolving a Fermi surface for a semimetallic system, we employed open boundary conditions. Calculated ARPES spectra show that two exchage-split bands in the FM phase merge at first well below the EF, while there are still split bands near the EF. At high-enough temperature, they become a single band. All these results explain quite well the observed ARPES spectra.

TU.E-P35 - Magnetic properties of Cr-based ternary compound CrAlGe

S. Yoshinaga [1], Y. Mitsui [1], R. Umetsu [2], K. Koyama [1]

1. Faculty of Science, Kagoshima University, Kagoshima, Japan
2. Institute for Materials Research, Tohoku University, Sendai, Japan

Mn-based compound MnAlGe with a tetragonal Cu_2Sb-type structure is ferromagnetic at the temperature below Curie temperature T_C of 518 K [1]. The compound has a large magnetic moment of 3.25 m_B and a magnetic anisotropy associated with the anisotropic crystal structure. Therefore, this compound has been considered to be one of the candidates for memory and spintronic devices. Cr substitution for Mn in the compound enhanced the saturation magnetization M_S and T_C [2]. According to the report of ternary phase diagram of Cr-Al-Ge, fully substituted compound CrAlGe exists as a stable phase. However, the structural and magnetic properties of CrAlGe are not characterized yet in details. In this study, we have performed X-ray diffraction (XRD) and magnetization measurements for CrAlGe in order to clarify the fundamental properties.

Polycrystalline CrAlGe was prepared by induction melting process of a mixture made of appropriate amounts of pure elements. The obtained ingots were annealed at 1073 K for 1 day and then quenched into water. XRD measurements were carried out at room temperature. Magnetization measurements were performed for $5 \leq T \leq 390$ K and magnetic fields B up to 5 T.

Our XRD analysis showed clearly that the crystal structure of CrAlGe is not the tetragonal Cu_2Sb-type but the orthorhombic $TiSi_2$-type with lattice parameters of a = 0.4744 nm, b = 0.8229 nm and c = 0.8705 nm. From detailed analysis, Cr atom occupied the 8a-site and both atoms of Al and Ge are at the 16f-site of the $TiSi_2$-type structure. CrAlGe is ferromagnetic and has M_S = 0.2 m_B at 5 K and T_C = 83 K, suggesting that CrAlGe is a weak itinerant ferromagnet.

4. Department of Physics, The University of Tokyo, Tokyo, Japan

Impurity hydrogen (H) affects the electronic and magnetic properties of semiconductors with three charge states (H^0, H^+, H^-).
We estimate H states in semiconductors (SiO_2, TiO_2, CdS, GaN, ZnO, and so on) by using first-principles calculation based on density functional theory (DFT). Total electron number in a supercell is changed to study the charge state of H (H^0, H^+, H^-) and the magnetic moment. The charge states are determined by Bader analysis after the optimization of semiconductors with a H atom. The calculation results show different H states for each semiconductor. SiO_2 takes three charge states (H^0, H^+, H^-), TiO_2 takes H^+ only, and the others take H^+ and H^- in the above semiconductors. In the example of SiO_2, a neutral H atom is localized in interstice. When H is in H^+ state, the H atom is located near the O atom. The distance between H and O atoms is about 1.03Å, which is almost the same as the O-H bond length in H_2O of 0.96Å. Similarly, when H is in H^-, the H atom forms a Si-H bond of 1.33Å. The magnetic moment of H^0 is $1\mu_B$, and that of the H^+ and H^- is 0. We show the stable charge state by evaluating the detect-formation energy and discuss the cause of the H states by calculating the dielectric constant and the effective mass of the semiconductors in this poster.
We also understand H behavior by calculating the isotropic and anisotropic hyperfine coupling constants. Because muonium in crystals behaves similarly to H, muon spin rotation (μSR) has played an important role in identification of hydrogenlike states in semiconductors. We evaluate the accuracy of DFT calculation for H in semiconductors by the comparison with hyperfine parametes of μSR.

TU.E-P37 - Magnetism and insulator-to-metal transition of strongly correlated polarons in alkali-metal loaded zeolites

T. Nakano [1], G. Prasad Hettiarachchi [1], L.M. Kien [1], T. Goto [1], Y. Nozue [1]

1. Department Of Physics, Graduate School Of Science, Osaka University, Osaka, Japan

Guest alkali-metals of Na, K and Rb can be loaded into regular nanospaces of host porous crystals of zeolites X, sodalite and P without changing their framework structures (cages and cavities). Magnetisms, such as ferromagnetism, antiferromagnetism and ferrimagnetism, have been observed depending on the framework structures of zeolites, kinds of alkali metals and the loading densities. An insulator-to-metal (IM) transition is observed with the increase in the loading density. These s-electrons have an interaction with the displacement of alkali-metal cations in nanospaces as well as the mutual interaction between them, which leads to the electron-phonon interaction (EP) and the electron correlation simultaneously. Hence, we will explain these electronic properties by the concept of strongly correlated polarons. Small polarons with magnetic moments, which are the self-trapped quantum states stabilized by the EP interaction, are formed as clusters in the regular nanospace. An insulating state is observed up to some amounts of loading density of alkali-metals. Large polarons, which are the extended states being mobile as free carriers, are generated with the increase in the loading density, and an IM transition occurs. The interactions between small polarons and between large and small polarons play an important role in magnetisms. When the EP interaction is large enough to combine two small polarons against a Coulomb repulsion, small bipolarons without magnetic moment are generated preferentially. These behaviors are generally understandable in the scheme of the electron transfer energy (t), the electron Coulomb repulsion energy (U), the EP interaction energy (S) and the s-electron density (n).

TU.E-P38 - 77Se NMR study on the possible excitonic insulator Ta_2NiSe_5

S. Li [1], Y. Kobayashi [1], Masayuki Itoh [1]

1. Department of Physics, Graduate School of Science, Nagoya University, Furo-cho, Chikusa-ku, Nagoya, Japan

The excitonic insulator is an exotic electronic state ascribed to the BCS or Bose-Einstein condensation of electron-hole pairs formed by the strong Coulomb interaction, if the binding energy is much higher than the energy gap between valence and conduction bands. Recently, Ta_2NiSe_5 was proposed as a candidate of the excitonic insulator on the basis of a Ta_5d conducting band and a flat Ni_3d-Se_4p valance band observed by the ARPES experiment. Ta_2NiSe_5 is crystallized into the monoclinic structure. $NiSe_4$ tetrahedra form one chain along the a axis, whereas $TaSe_6$ octahedra form two chains beside the $NiSe_4$ chain. These chains form a layer along the c axis and the layers are weakly coupled via the Van der Waals interaction. Magnetic susceptibility shows a drop accompanied by the structural transition at Tc=328 K. Although intensive experimental and theoretical studies have been made after the ARPES study, it remains uncovered whether Ta_2NiSe_5 is an excitonic insulator or not below Tc. In this study, we have performed 77Se NMR measurements on both powder and single crystal samples to study the local electronic and magnetic properties of Ta_2NiSe_5. We observed powder NMR spectra coming from the three Se sites, Se1 with neighboring one Ni and two Ta atoms, Se_2 with three Ta, and Se_3 with two Ni and two Ta. Each Se powder spectrum was found to have a so-called powder pattern governed by the isotropic and anisotropic Knight shifts. The observed Knight shifts, which decrease with lowering temperature below Tc, clearly show a nonmagnetic ground state. The nuclear spin-lattice relaxation rate was also found to show the activated temperature dependence below Tc.

TU.E-P39 - NMR/NQR studies on the phase transition in A-site-ordered perovskites $ACu_3Cr_4O_{12}$ (A= La and Bi)

Y. Kobayashi [1], M. Iguchi [1], M. Itoh [1], M. Isobe [2], H. Takagi [2], H. Sakurai [3], H. Takagi [2]

1. Department of Physics, Graduate School of Science, Nagoya University, Japan
2. Max Planck Institute For Solid State Research, Stuttgart, Germany
3. National Institute for Materials Science, Tsukuba, Japan

Chromium oxides with a high-valance Cr ion exhibit anomalous physical properties owing to hybridization between Cr and O orbitals. One of such systems, the A-site-ordered perovskite AAüf3Cr4O12 with a mixed-valence Cr ion, is expected to have the inter-site charge transfer and the charge disproportionation as discussed in the iron oxides. In $ACu_3Cr_4O_{12}$ (A= La and Bi) which were recently synthesized, a phase transition was reported to take place with a structural change at Ts ~220 and 170 K for La and Bi, respectively. In this study, we have performed 63,65Cu-NMR/NQR and 53Cr-NMR measurements on powder samples to examine the valence states of the Cu and Cr ions at Ts in $ACu_3Cr_4O_{12}$ (A= La and Bi). In $LaCu_3Cr_4O_{12}$, the change observed at Ts in the 63,65Cu-NQR spectra show that the Cu valence change takes place, whereas the Cu Knight shift and the nuclear spin-lattice relaxation rate indicate that the Cu ion changes from a paramagnetic to non-magnetic state below Tc. This result means that the Cu valence may change from high-temperature Cu^{2+} (3d9) to low-temperature Cu^{3+} (3d8) or $Cu^{2+}L$ (3d9L), where L denotes a hole in the O2p orbital, owing to the inter-site charge transfer between the Cu and Cr ions. On the other hands, in $BiCu_3Cr_4O_{12}$, the 63,65Cu-NMR/NQR spectra show that the Cu ion is preserved to be in a divalent state through Ts.

TU.E-P40 - Electric field dependence of the induced magnetic moment of pd thin film

M. Kim [1], T. Quang [1], J.M. Hyun [1], H. Kim [1]

1. Sookmyung Women's University, Seoul, South Korea

Electric field dependence of the magnetic properties in a Pd thin film on MgO (001) substrate is theoretically investigated within the density functional theory framework. The result reveals that the Pd, which is paramagnetic in bulk, prefers a ferromagnetic phase with the induced Pd spin magnetic moment of 0.31 ~ 0.34 μ_B when it is grown expitaxially on the MgO (001) substrate due to the in-plane lattice expansion by 6.7%. Under the external electric filed (EF) perpendicular to film surface, the induced Pd magnetic moments are modulated in different ways for each Pd layer. The modulation of the surface Pd moment emerges for the EF above a critical value, E_c = 1.3 V/A, showing a non-linear variation with EF which can be explained by the linearized Stoner model, whereas the change of interface Pd moment exhibits a linear increase up to E_c and a non-linear variation above E_c. With the reversed EF, a similar EF-dependence was obtained for both the surface and the interface Pd moments, but with the different critical field of E_c = - 0.5 V/A. From the analysis of the site-projected and orbital-decomposed density of states, we found a strong correlation between the modulation of induced Pd moments and the Pd(d) states. This intriguing EF-induced variation of Pd magnetic moments was confirm to be of purely electronic origin, and not related with ionic displacements.

TU.E-P41 - Tailoring of electronic and magnetic properties of bcc Fe- based high entropy alloys

K. Perzynska [1], K. Szymanski [1], A. Matwiejczyk [1], M. Biernacka [1], D. Oleszak [2], L. Hawelek [3], J. Waliszewski [1], M. Gutowska [4], T. Zajarniuk [4], A. Szewczyk [4]

1. Faculty of Physics, University of Bialystok, Bialystok, Poland
2. Faculty of Materials Science and Engineering, Warsaw University of Technology, Warszawa, Poland
3. Institute of Non Ferrous Metals in Gliwice, Gliwice, Poland
4. Institute of Physics, Polish Academy of Sciences, Warszawa, Poland

Structural, electrical and magnetic properties of *bcc* $Fe_{1-x}A_x$ alloys are presented, where the A corresponds to various compositions of the elements: A = (Co, Ga, Cr, V, Al, Ni, Ge, Si). The system is closely related to the known family of the High Entropy Alloys (HEA). The samples were synthesized by melt spinning technique and exhibit *bcc* type of structure. Systematic changes in the residual resistivity, magnetic moments, specific-heat and electronic structure with the A content are observed.
The change from metallic to the semiconductor-like behaviour of temperature dependence of the electrical resistivity $\rho(T)$ with an increase of dopants (x) has been observed. One possible explanation of this behaviour is a low density of electronic states at the Fermi level in samples. This behaviour was verified by measurement of the low-temperature specific-heat. Properties of the $Fe_{1-x}A_x$ system with *bcc* structure for small x are generally similar to those of pure iron. So, at first step of data interpretation the constant magnetic contribution was subtracted from all samples. Despite the small magnetic contribution to specific-heat, this procedure apparently improves the linearity of C/T vs. T^2 at low temperature. The Debye temperatures and the electronic specific heat coefficients were determined from a linear plot of C/T vs. T^2. The results show a linear decrease of the Debye temperature with concentration x. The electronic specific-heat parameter, γ, reaches a minimum at x=0.4. At this concentration change of sign of the temperature coefficient of resistivity was observed. The experimental results are compared to the results of electronic structure calculations.

TU.E-P42 - Thickness dependent dynamic study of ion-beam sputtered Co_2FeAl thin films

S. Akansel [1], A. Kumar [1], S. Husain [2], S. Chaudhary [2], P. Svedlindh [1]

1. Engineering sciences, Uppsala university, Uppsala, Sweden
2. Department of Physics, Indian Institute of Technology Delhi, Delhi, India

The Co based Heusler alloy Co_2FeAl (CFA) is a promising material for spintronics due to its half-metallicity, high Curie temperature and low Gilbert damping constant (α), which are key requirements for spin devices. However, to obtain high quality CFA thin films is still a challenge and it has been found that the CFA thin film quality varies with the growth process and post deposition annealing treatment. Moreover, there are rarely any reports on the ion-beam sputter deposition of CFA thin films.
In the present work CFA thin films were deposited from a 99.5% pure Co_2FeAl target by reactive ion beam sputtering on HF-treated Si (100) substrates at the optimized deposition temperature of 300°C. A series of different thicknesses, 1.8, 3.3, 5.0, 6.6, 8.8, 12.4, 16.5 nm have been prepared and all samples were capped with a 5 nm Ta layer. The XRD measurements show that the films exhibit the disordered B2 crystallographic structure. The thickness dependent static and dynamic properties of the films were studied by SQUID magnetometry and out-of-plane VNA-FMR measurements in field-sweep mode. The saturation magnetization and coercivity of the samples varied with film thickness in the range of 459 to 766 emu/cc and 3 to 8 Oe, respectively. The thickness and frequency dependent variation of the line-width and resonance field were obtained and the results evidence an extrinsic contribution to the linewidth originating from the inhomogeneous and local variation of the effective demagnetization field contributions. The effective magnetization $4\pi M_{eff}$ and intrinsic α values were found to be in the range of 9 to 11.4 kG and 1.8×10^{-2} to 2×10^{-3}, respectively. The lowest value of $\alpha = 2\times10^{-3}$ is comparable to the smallest values observed for epitaxial CFA films.

TU.E-P43 - Moessbauer spectroscopy study of collapse-like decrease of Fe magnetic moment in amorphous (Fe-Cr)-B and Fe(Cr-Cu)-B alloys

K. Yano [1], H. Tange [2], S. Lee [3], E. Kita [3]

1. Nihon University, Japan, Chiyoda, Tokyo, Japan
2. Ehime University, Matsuyama, Japan
3. University of Tsukuba, Tsukuba, Japan
4. University of Tsukuba, Tsukuba, Japan

There remains to be some unsolved problems and hard nuts to crack in magnetism for amorphous (a-) transition metal (TM)-metalloid alloys. One of them is a rapid decrease, that is, a collapse-like decrease of magnetic moment of TM such as Fe and Co substituted by Cr, V and so on in the so-called Slater-Pauling curve. This phenomenon has been found by Mizoguchi et al. in 1974 and thereafter there seems to have been no decisive improvements in this problem. In this study, the electronic states of Fe in a-$(Fe\text{-}Cr)_{80}B_{20}$ and a-$\{Fe(Cr\text{-}Cu)\}_{80}B_{20}$ alloys have been investigated by employing the Moessbauer spectroscopy. The hyper-fine field (the peak value of the distribution) decreases rapidly to 1.2 uB at Cr=0.15 (15 at %) in a-$(Fe\text{-}Cr)_{80}B_{20}$ alloys at 4.2 K and this result nearly correspond to the value obtained by magnetization measurement. However, the Moessbauer spectroscopy shows a characteristic profile at Cr=0.15 and it suggests that the substitution of Cr by non-magnetic TM element such as Cu can give some useful informations. Regarding this, the result is to be discussed at the Conference. Furthermore, at Cr=0.05 (5 at %), the Moessbauer spectroscopy reveals that the magnetization unexpectedly orients perpendicular to the film surface from 77 K to 4.2 K.

TU.E-P44 - Studies of 27Al NMR in $SrAl_4$

H. Niki [1], N. Higa [1], H. Kuroshima [1], T. Toji [1], M. Morishima [1], M. Minei [1], M. Yogi [1], A. Nakamura [1], M. Hedo [1], T. Nakama [1]

1. Department of Physics, Faculty of Science, University of The Ryukyus, Nishihara, Japan
2. Faculty of Science, Kobe University, Hyogo, Japan

A charge density wave (CDW) transition at TCDW = 243 K and a structural phase (SP) transition at approximately 100 K occur in $SrAl_4$ with the $BaAl_4$-type body center tetragonal structure, which is the non-4f-divalent-Sr reference compound of EuAl4 [1]. To understand the behaviors of the CDW and SP transitions, the 27Al NMR measurements in $SrAl_4$ have been carried out. Al atoms have two crystallographically inequivalent sites, denoted Al(I) and Al(II), respectively. High-quality single crystal of $SrAl_4$ was grown by the Al-self flux method. NMR measurements using the powder sample and single crystal of $SrAl_4$ have been done applying in the external magnetic field of approximately 6.5 T. The 27Al NMR spectra corresponding to the sites I and II are obtained. The temperature dependence of Knight shifts of the 27Al(I) and 27Al(II) shows the different behaviors. The value of 27Al(I) Knight shift is almost constant above TCDW, decreases monotonously below TCDW, has a step-like anomaly around at 100 K because of the structural transition, keeps constant until 50 K, and decreases below 50 K. However, the value of 27Al(II) Knight shift keeps almost constant from room temperature to 4.2 K. The shift to the negative side of the Knight shift at the Al(I) site below TCDW is attributable to the core polarization of the d-electrons. The line width below TCDW is modulated by an electrical quadruple interaction between 27Al nucleus and CDW charge modulation. The value of the 1/T1T of 27Al(I) takes an almost constant value above TCDW, decreases monotonously below TCDW, and keeps constant below 60 K. However, the value of the 1/T1T of 27Al(II) takes a constant value between 4.2 and 300 K. The density of state at the Fermi level below 60 K would be about 0.9 times less than that above TCDW.

TU.E-P45 - Influence of structural disorder on electronic structure and magnetic properties of YCo_2-based compounds

Z. Sniadecki [1], M. Werwinski [2]

1. Institute of Molecular Physics, Polish Academy of Sciences, Poznan, Poland
2. Department of Physics and Astronomy, Uppsala University, Uppsala, Sweden

The studied intermetallic compounds based on YCo_2 Pauli paramagnet [1] with Nb and Ti substitutions crystallize in C15 Laves phase structure. Samples obtained by melt-spinning process exhibit magnetic ordering induced by chemical and topological disorder. Experimentally observed ferrimagnetic ground states for YCo_2 systems with Y atoms substituted by Ti and Nb [2] find theoretical explanation on the basis of the electronic band structure calculations. FP-LAPW method (Full Potential--Linearized Augmented Plane Wave) implemented in the WIEN2k code was utilized to determine the site preference energies for the Nb and Ti substitutions in YCo_2, by systematic study of YCo_2 structures with point defects. The considered defects are vacancies and Nb and Ti substitutions on Y or Co sites. Calculations show that the Ti and Nb impurities strongly prefer to occupy the Y sites. Moreover, the considered point defects in place of Y stabilize the ferrimagnetic ground state stronger than the point defects on Co sites. The calculated magnetic moments on Co atoms are close to 1 μ_B and opposite to smaller (0.1 μ_B – 0.66 μ_B) moments localized on Y and dopants. Substitutions that enhance the lattice parameter induce magnetic ordering. The results of calculations are in good agreement with our measurements. The intermetallics with Nb and Ti content higher than 10 at.% tend to form multiphase systems.

The central part of the Cu-Mn-As ternary system has become attractive after a recent rediscovery of CuMnAs, a material promising for applications in antiferromagnetic spintronics [1, 2]. CuMnAs crystallizes in an orthorhombic structure. It orders antiferromagnetically below the Néel temperature of 400 K and shows semi-metallic character. Experiments on thin films have shown that the orthorhombic CuMnAs compound can be epitaxially grown on GaAs substrate while tuned to tetragonal Cu_2Sb-type structure and enhanced Néel temperature TN=475 K [1]. Single crystals of CuMnAs, $Cu_{1.1}Mn_{0.9}As$, $CuMn_3As_2$, and a new compound $Cu_2Mn_4As_3$ were prepared from bismuth and lead flux. The samples were characterized by microprobe analysis and single crystal x-ray diffraction. It was confirmed that the stoichiometric CuMnAs crystallizes in orthorhombic structure with lattice parameters a = 0.6577 nm, b = 0.3854nm, c = 0.73096 nm. While the Mn-rich samples $CuMn_3As_2$ and $Cu_2Mn_4As_3$have orthorhombic structure with twice as large unit cell prolonged along the a-direction. The Cu-rich $Cu_{1.1}Mn_{0.9}$Ascrystallizes in the Cu_2Sb-type tetragonal structure. Magnetization measurements have shown that the stoichiometric CuMnAs order antiferromagnetically with the Néel temperature between 340 K and 400 K, while the Néel temperature of the Cu-rich samples was well above 400 K, in agreement with study on thin films [1]. The new compound $Cu_2Mn_4As_3$ orders magnetically below 315 K. The type of the order is most likely antiferromagnetic, however,considering the type of crystals structure which has 3 independent Mn-sites, more complex magnetic structure can be expected. The magnetic anisotropy was found to be rather weak in all studied compounds.

Transition metal magnets are characterized by having moments strongly linked to their local environment. This leads to a rich interplay between d-electron magnetism and nearest-neighbor interactions.[1] Topological non-trivial arrangement, like skyrmions in MnSi, have been trust important for developing new devices, however the Mn-Si family have been not extensively studied. In particular, previous neutron scattering in polycrystalline or powder samples of Mn_5Si_3 show several magnetic phases, with two magnetic transitions T_N^1 = 60 K and T_N^2 = 90 K. Below T_N^1, spins are arranged in a non-collinear structure, showing local chirality. This phase is destroyed by a magnetic field of several Tesla, favoring the high temperature antiferromagnetic arrangement.[2]
In this work, a study of the phase diagram of the Mn_5Si_3 system is presented. Crystals of Mn_5Si_3 were grown out of Cu flux. Needles with typically 6 mm in length and a non-regular octagonal cross section of about 1 mm^2 were obtained. Magnetization measurements up to 7 T and down to 2 K were performed on individual needles along their main axis. Known magnetic transitions T_N^1 and T_N^2 were observed in combination with a new additional transition T_N^1* at 45 K. T_N^1 was observed magnetic field independent, whereas T_N^1* strongly decreases with the magnetic field. In addition, several transition were observed for the phase down T_N^1* when increasing field at a fixed temperature. Our measurements suggest that the low temperature magnetic non-collinear structure unwinds with the magnetic field through metamagnetic transitions. There is an additional intermediate magnetic phase between 45 K and 60 K, which is probably also non-collinear. The role of sample synthesis on the magnetic structure is briefly discussed.

3. Institut Laue-Langevin, Grenoble, France
4. University of Warwick, Coventry, United Kingdom

We study high-quality Heusler ($Co_2FeSiAl$) /Si heterointerfaces for silicon (Si)-based spintronic applications. Heusler alloys are predicted halfmetals (i.e 100% spin polarised materials at the Fermi level). Recent reports have shown that the integration of spin functionality into existing Si large-scale-integrated circuits technologies for next-generation semiconductor devices with ultra low power consumption [1]. To utilize Co 2FeSi Al as source and drain electrodes in Si-based spin transistors, the magnetic and structural properties at the interface should be explored since the Si atoms may diffuse at $Co_2FeSiAl$/Si interfaces.
A 25 nm $Co_2FeAlSi$ film was deposited on Si(111) substrate by molecular beam epitaxy at room temperature [2]. Using polarized neutron reflectivity on the sample, we observed a magnetic dead layer at the $Co_2FeAiSi$/Si(111) heterointerface. Structural analysis with atomic resolution has been performed on this heterointerface to understand the origin of the magnetically dead layer. Based on the cross-sectional transmission electron microscopy images we construct atomistic models of this interface and explained possible causes of magnetic properties of the $Co_2FeAlSi$/S interface. Finally, we propose plausible atomic interface structures that would preserve halfmetalicity of the $Co_2FeAlSi$ up to the very interface based on first principle electronic calculations.

TU.E-P49 - The effect of post annealing conditions on the iron oxides thin films grown on MgO(100)

B. Kuerbanjiang [1], D. Pingstone [1], C. Chirnside [1], L. Lari [1], S. Tear [1], V. Lazarov [1]

1. University Of York, Heslington, York, United Kingdom

Growth defects, domain structures and off-stoichiometric compositional deviation are the cause of anomalous magnetic and transport properties of magnetite (Fe_3O_4) thin films. Post-annealing at high temperature of Fe_3O_4 films in a CO/CO_2 atmosphere results in a significant improvement of magnetic and magnetotransport properties [1,2] compared to bulk specimens. In this work, we present atomistic study on the oxidation of Fe thin films as well as FeO_x with aim to understand the correlation between the structure and functional properties of iron oxide films. Control of the oxidation, and structure was achieved by in-situ O-plasma annealing followed by ex-situ postannealing in CO/CO_2 gas mixture. By optimizing post-annealing conditions, we show the influence of annealing temperature and flux of CO/CO_2 gas mixture on the structure of the Fe oxide films by means of x-ray photo electron spectroscopy, magnetoresistance, alternating-gradient force magnetometer and transmission electron microscopy techniques.

TU.E-P51 - Transport properties of a metallic two-dimensional triangular antiferromagnet Ag_2CrO_2

T. Kida [1], A. Okutani [1], H. Yoshida [2], M. Hagiwara [1]

1. Osaka University, Osaka, Japan
2. Hokkaido University, Sapporo, Japan

Geometrically frustrated conducting magnets exhibit unconventional anomalous Hall effects (AHE) that could be used to realize materials required for the emerging field of spintronics [1]. Ag_2CrO_2 is one of the suitable materials for investigating the relationship between geometrical frustration and the AHE. Ag_2CrO_2 consists of triangular lattice planes of CrO_2, which are well separated by the metallic Ag_2 layers [2]. This compound is an S=3/2 (Cr^{3+} ion) frustrated triangular lattice antiferromagnet (TN = 24 K) without orbital degrees of freedom. Recently, Matsuda et al. [3] have reported that a partially disordered state with 5 sublattices abruptly appears at TN, accompanied by a structural distortion, and found anomalous magnetic excitations, which cannot be explained simply by linear spin-wave theory. In this study, we have investigated the transport properties of Ag_2CrO_2 and discussed the coupling with the magnetism in this compound. Polycrystalline samples of Ag_2CrO_2 were synthesized using a high-pressure technique [2]. The transport measurements were performed by using a conventional dc four-probe technique in a 16 T superconducting magnet. The resistivity of this compound displayed metallic behavior and an abrupt decrease at TN. Below TN, almost linear positive magnetoresistance was observed. On the other hand, just above TN (T = 25 K), a large negative magnetoresistance of 38% at 8 T was observed. The absolute value of the negative magnetoresistance decreases with increasing temperature. The Hall resistance showed a non-linear behavior as a function of the magnetic field below TN. These results suggest the transport properties of Ag_2CrO_2 are closely related to its unusual antiferromagnetic spin-structure.

TU.E-P53 - The ground-state phase diagram of the XXZ spin-s kagome antiferromagnet

J. Richter [1], O. Goetze [1]

1. Institute for Theoretical Physics, University Magdeburg, Magdeburg, Germany

We use the coupled cluster method at high orders of approximation in order to calculate the ground-state phase diagram of the XXZ spin-s kagome antiferromagnet with easy-plane anisotropy, i.e., the anisotropy parameter Δ varies between Δ=1 (isotropic Heisenberg model) and Δ=0 (XY model) [1,2]. Anisotropy as well as larger spin quantum numbers s>1/2 have relevance for the experimental research. Moreover, anisotropic spin models are of great interest with respect to engineering models of quantum magnetism on optical lattices. The interplay of frustration, quantum fluctuations and anisotropy leads to a rich ground-state phase diagram. We find that for the extreme quantum case, s=1/2, the ground state is magnetically disordered in the entire region $0 \leq \Delta \leq 1$. For s=1 the ground state is disordered for $0.818 < \Delta \leq 1$, it exhibits √3x√3 magnetic long-range order for $0.281 < \Delta < 0.818$, and q=0 magnetic long-range order for $0 \leq \Delta < 0.281$. We confirm the recent unexpected result of Chernyshev and Zhitomirsky [3] that the selection of the ground state by quantum fluctuations is different for small Δ (XY limit) and for Δ close to one (Heisenberg limit), i.e., q=0 magnetic order is favored over √3x√3 order for $0 \leq \Delta < \Delta c$ and vice versa for $\Delta c < \Delta \leq 1$.
We calculate the critical Δc as a function of the spin quantum number s.

TU.F-P03 - Preparation and characterization of poly-alpha-olefin-based ferrofluids

J.H. Kim [1], K. Park [1]

1. Research Center For Advanced Magnetic Materials, Chungnam National University, Daejeon, South Korea

Magnetite of fine particles was synthesized by adding an excess ammonium hydroxide to a solution of iron (II) and (III) chlorides. Surfactants of oleic acid and span 80 were in turn applied to the magnetic particles as a combined stabilizer, and poly-alpha-olefin (PAO) 30 and 60 were used as liquid bases for low viscosity and for high viscosity, respectively. The ferrofluids were prepared with the concentrations of 200, 300, 400 and 500 mg/mL, which were characterized by density, dispersion, magnetization and viscosity. The fluid density varied from 0.98 g/mL to 1.27 g/mL in the PAO 30 base and from 1.01 g/mL to 1.30 g/mL in the PAO 60 base with increasing concentrations, depending on the density difference between two types of bases, and the dispersion percent of the stabilized fluids indicated about 80% at the lowest concentration for both bases. The saturation magnetization of the ferrofluids depended on the content of bare particles corresponding to the fluid concentration, exhibiting the values of 16 to 41 mT in proportion to the concentration from 200 mg/mL to 500 mg/mL. The viscosity variation with temperature was least at the 400 mg/mL PAO-30-based ferrofluid and the 300 mg/mL PAO-60-based ferrofluid. Considering the magnetic applications of ferrofluid, the highest possible concentration is more desirable.

TU.F-P04 - Magnetic and magnetoelectric properties of Fe_3O_4 nanocrystal self-assembly

S. Kohiki [1], Y. Nakamura [1], K. Akiyama-Hasegawa [2], M. Mitome [2], D. Tsuya [2]

1. Kyushu Institute of Technology, Kitakyushu, Japan
2. National Institute for Materials Science, Tsukuba, Japan

The red brick wall of traditional semiconductor electronics boosts development of a spin-polarized current switching device using negative magnetoresistance (MR) of Fe_3O_4 nanocrystal (NC) arrays. MR is defined as MR = $(R_H - R_0)/R_0$, where R_H and R_0 are the differential resistance in non-zero and zero magnetic fields, respectively. Enhancement of magnetic coupling between adjacent NCs leads larger MR. Here, we report ferromagnetism for Fe_3O_4 NC, the spin-glass state and MR larger than −50% for Fe_3O_4 NC arrays at 300 K. Fe_3O_4 is known to have fully spin-polarized (P = 1) carriers up to 840 K, while P = 1 at 300 K is still controversial. Fe_3O_4 NCs with the crystallite size of 38 nm were synthesized by refluxing a mixture of Iron(III) acetylacetonate, dibenzylether and oleic acid. A self-assembly of Fe_3O_4 NCs was fabricated via drop casting of colloidal particles on an insulator substrate. In three-dimensional systems of Fe_3O_4 NCs isolated by oleic acid thin layers, MR is connected to P and the relative magnetization of the system (m) by MR ≡ $P^2m^2/(1 + P^2m^2)$. Here, m relates to the angle (ϑ) between the magnetic moment of adjacent NCs as $m^2 = \langle\cos\vartheta\rangle$. Both P = 1 and m = 1 conditions give rise to MR = −50%. Fe_3O_4 NCs exhibited ferromagnetic hysteresis loop at 300 K with spontaneous magnetization of 1 μ_B/Fe. The NCs demonstrated cooling history-dependence indicating the superparamagnetic state for each NC below 300 K. Temperature-dependent AC susceptibility revealed the frustrated magnetic state above 300 K for the self-assembly of Fe_3O_4 NCs. Larger R_0 than R_H resulted in MR of −56%, which proves P = 1 for Fe_3O_4 NC even at 300 K. Thus, Fe_3O_4 NC is promising for a normally-OFF spin-dependent current switch device application.

TU.F-P05 - Effect of dextran coated superparamagnetic iron oxide nanoparticles during in vivo observation of the rats

5. ISTO, UMR 7327 CNRS, Université d'Orléans, Orléans Cedex 2, France

The superparamagnetic iron oxide nanoparticles have attracted a lot of interest due to their widespread biomedical and diagnostic applications.In this study, we report the synthesis of dextran coated iron oxide magnetic nanoparticles (D-IONPs) with spherical shape uniform size distribution. The average grain size of the monodisperse D-IONPs deduced from the Transmission Electron Microscopy (TEM) is 7.5 (± 0.5) nm. The hydrodynamic diameter of D-IONPs determined by dynamic light scattering (DLS) was equal to 30 nm, approximately. The clear lattice fringe in the HR-TEM image demonstrates the well crystalline nature of resultant nanoparticles. The adsorption of dextran on surface of iron oxide was evidenced by Attenuated Total Reflectance Fourier transform Infrared (ATR-FTIR) spectroscopy. The magnetic hysteresis measurement of dextran coated maghemite nanoparticles showed a superparamegnetic comportment at room temperature. The tolerability of the D-IONPs was demonstrated by in vivo observation of rats during one month after intraperitoneal injection. The histological investigations were performed every 14 days. The hematology analysis data in rats after intraperitoneal injection of D-IONPs are presented. The results obtained after the 28 days from histological investigations and hematology analysis data in rats are comparable to those obtained for rats in the control group.Keywords: dextran, maghemite, superparamagnetic, in vivo, histological investigations

TU.F-P06 - Synthesis, self-organization and magnetism of iron oxide and Au-iron oxide core/shell nanocomposite particles

D. Muraca [1], S. Sharma [1], M. Knobel [1], P. Mendoza Zelis [2]

1. Instituto de Física Gleb Wataghin (IFGW), Universidade Estadual De Campinas (Unicamp), Campinas, SP, Brazil
2. Instituto de Fisica La Plata CONICET, La Plata, Argentina

This work reports a simple chemical synthesis of Au-iron oxide nanocomposites using Au nanoparticles seeds and their systematic oxidation in the presence of dry air atmosphere at various temperatures (125-250 C). It has been observed that the oxidation not only facilitate the self-organization of iron oxide nanoparticles, but also to switch these nanocomposites into core-shell Au-iron oxide structures. We have observed a systematic improvement in the core and shell shape through controlling the reaction time as well as the oxidation temperature. Spherical and spherical-triangle shaped core-shell structures have been synthesized at an optimum oxidation temperature of 125 C and 150 C for 30 minutes, whereas with the further increase in the temperature as well as oxidation time, there is a full amendment in the core-shell structures. The nanoparticle samples have been thoroughly characterized using X-ray diffraction (XRD), high-resolution transmission electron microscopy (HR-TEM), Mossbauer spectroscopy and superconducting quantum interference device (SQUID) magnetometer.

TU.F-P07 - Magnetic properties and crystal structure of $DyMn_2O_5$ nanoparticles embedded in mesoporous silica

T. Tajiri [1], Y. Ando [2], H. Deguchi [2], M. Mito [2], A. Kohno [1]

1. Faculty of Science, Fukuoka University, Fukuoka, Japan
2. Faculty of Engineering, Kyushu Institute of Technology, Kitakyushu, Japan

Magnetic properties and Crystal structure of nanoparticles differ from those of the bulk crystal owing to surface and finite size effects. In a rough approximation, the energy states of the magnetization vector of the particles can be modeled as a double well potential separated by barriers whose characteristics depend on the particle size and magnetic anisotropy. Recently, multiferroic materials have been widely studied because of the interesting physics such as magneto–electric effect. Multiferroic compound $DyMn_2O_5$ shows antiferromagnetic ordering of Mn moments at $T_N \approx 40$ K and commensurate–incommensurate magnetic transition at $T_N' \approx 27$ K. In addition, the Dy magnetic moments order below 8 K. $DyMn_2O_5$ undergoes a transition to a ferroelectric phase below T_N. We attempted to synthesize $DyMn_2O_5$ nanoparticles with few nanometers and investigated their magnetic properties and crystal structure. The $DyMn_2O_5$ nanoparticles were synthesized in pores of mesoporous silica. Powder X-ray diffraction (XRD) patterns for the $DyMn_2O_5$ nanoparticles exhibited some broad Bragg peaks, which were attributed to the crystal structure of bulk $DyMn_2O_5$. The XRD experimental results indicated that successful synthesis of the $DyMn_2O_5$ nanoparticles with average particle size of 7-20 nm. The lattice constant *b* of the nanoparticles increased monotonically with decreasing particle size, which suggested that the crystallographic structure distorted with decreasing particle size. We measured the temperature dependence dc magnetic susceptibility and magnetization curves for the nanoparticles. These results exhibited superparamagnetic behaviors. The evaluated Weiss temperature for the nanoparticles changed in sign and magnitude which decreased linearly with increasing particle size. These results suggested that the decrease in particle size induces the distortion of crystallographic structure and the changes in magnetic exchange interactions.

TU.F-P09 - Proton relaxometry and magnetic hyperthermia evaluation of gadolinium doped nickel ferrite nanoparticles

T. Yadavalli [1], S. Ramaswamy [2], G. Chandrasekharan [1], H. Annal Therese [1], R. Chennakesavulu [3]

1. Nanotechnology Research Centre, SRM University, Kattankulathur, Tamilnadu, India
2. Accendere Knowledge Management, Annanagar, Chennai, Tamilnadu, India
3.Department of Pharmacy Practice, SRM University, Kattankulathur, Tamilnadu, India

Based on our previous paper, a low temperature ferrous sulfate method was used for the synthesis of gadolinium doped nickel ferrites. However, post several unsuccessful attempts, doping experiments using hydrothermal synthesis method formed nanoscale nickel ferrites with a maximum doping concentration of 20%. The results were confirmed by X-ray diffraction studies with no phase separation at 20% dopant concentration. Samples with higher gadolinium concentration demonstrated the formation of multiple phases in addition to nickel. Low temperature and room temperature magnetic studies conducted on the samples, concluded that the samples NGFO-10 and NGFO-20 were potential candidates for relaxometry and magnetic hyperthermia studies due to their single phase property and high magnetic saturation values. Further, relaxometry studies established that nickel ferrite nanoparticles with 20% gadolinium dopant concentration had a high relaxation rate of 6.63 s-1 at a concentration of 0.1 mg/mL. Further, four different concentrations of the same were subjected to magnetic hyperthermia based nanoparticle heating studies as a function of time. At a concentration of 1 mg/mL, samples attained a temperature of 68ºC under 250 seconds concluding that gadolinium doped nickel ferrite nanoparticles are ideal candidates for magnetic theragnostic system

TU.F-P10 - Synthesis of Co doped $AgFeO_2$ delafossite nanoparticles

T. Yamazaki [1], K. Mori [1], M. Hachisu [1], S. Morimoto [1], K. Hyodo [1], Y. Ichiyanagi [1]

1. Graduate School Of Yokohama National University, Yokohama, Japan

It is known that $AgFeO_2$ bulk crystal exhibits semiconductive material with two Néel temperatures of T_{N1} = 15 K and T_{N2} = 9 K, with ferroelectricity below 9 K. Cobalt doped delafossite nanoparticles $AgFe_{1-x}Co_xO_2$ ($0 \le x \le 0.3$) with an average diameter of approximately 10 nm were synthesized by co-precipitation method from silver nitrate and iron (III) nitrate, cobalt (II) nitrate and sodium hydroxide. Obtained samples were examined by X-ray powder diffraction (XRD), X-ray fluorescence (XRF), a TEM imaging and X-ray absorption fine structure (XAFS) measurement. The c axis of the lattice constants was shortened in accordance with increase Co-ion doping. XAFS analysis provided that Fe ions mainly exist in the valence of Fe^{3+} and Co ions also mainly exist in the valence of $Co^{3+.}$ The magnetic properties and the optical properties of the samples were measured by SQUID magnetometer and spectrophotometer. From the behavior of *M-T* curves of $AgFe_{1-x}Co_xO_2$ ($0 \le x \le 0.3$) nanoparticles, the magnetic transition temperature T_{N2} shifted higher than $AgFeO_2$ bulk crystal. While the T_{N2} shifted lower temperature as the Co–ion doping increased. Co doped $AgFeO_2$ nanoparticles were newly prepared, and magnetic and optical properties of these particles were clarified. TU.F-P11 - Evolution of complex magnetoresistance and perpendicular magnetic anisotropy in cobalt nanoparticles in silver matrix

D. Kumar [1], S. Chaudhary [1], D.K. Pandya [1]

1. Thin Film Laboratory, Physics Department, Indian Institute of Technology Delhi, New Delhi, India

We report on the evolution of the perpendicular magnetic anisotropy and unusual complex magnetotransport behavior observed in cobalt nanoparticles embedded in a silver matrix. Thin silver films containing cobalt nanoparticles were deposited by co-sputtering technique with cobalt concentration varied from 11.8 to 45.1 at.%. These samples have been analyzed by temperature dependent magnetoresistance and magnetization, atomic force microscopy (AFM) and magnetic force microscopy (MFM) studies. Here we present our interesting finding of a transition from normal to complex magnetoresistance (MR) behavior, in conjunction with MFM evidence of the existence of a magnetic microstructure perpendicular to the film plane for 32.6% film that shows the complex behavior at 20 K. The dc-magnetization studies provide additional support to the presence of perpendicular magnetic anisotropy for this film. The perpendicular magnetic anisotropy gets reduced with the increase of cobalt concentration. The complex *MR* behavior also decreases with the increase of cobalt concentration. The room temperature *MR*, coercivity behavior and remanence to saturation magnetization ratio indicate the presence of direct ferromagnetic interactions due to the presence of ferromagnetic particles for $x \geq 32.6$films. The observed complex *MR* behavior and perpendicular magnetic anisotropy are interpreted in terms of manifestation of the transition of interparticle magnetic interaction nature from dipolar to direct ferromagnetic ones.

TU.F-P12 - Excluded volume causes integer and fractional plateaus in magnetic colloidal ratchet currents

P. Tierno [1], T. Johansen [2], T. Fischer [3]

1. University Of Barcelona, Barcelona, Spain
2. University of Oslo, Oslo, Norway
3. University of Bayreuth, Bayreuth, Germany

We study the collective transport of paramagnetic colloids driven above a magnetic bubble lattice by an external rotating magnetic field. We measure a direct ratchet current which rises in integer and fractional steps with the field amplitude. The stepwise increase is caused by excluded volume interactions between the particles, which form composite clusters above the bubbles with mobile and immobile occupation sites. Transient energy minima located at the interstitials between the bubbles cause the colloids to hop from one composite cluster to the next with synchronous and period doubled modes of transport. The magnetic colloidal current may be polarized to make selective use of type up or type down interstitials.

TU.F-P13 - Depinning and collective dynamics of magnetically driven colloidal monolayers

P. Tierno [1]

1. University Of Barcelona, Barcelona, Spain

We study the collective dynamics of interacting paramagnetic colloids transported via a magnetic ratchet effect above a modulated periodic potential. Upon increasing the modulation frequency, the particles undergo a series of dynamic transitions, from a continuous smectic flow to a disorder flow, and later enter into a two phase flow regime, ending in a complete pinned state. In the disordered phase, the system organizes into density waves due to traffic jams, as in granular systems, while the two phase flow regime shows strong similarities with plastic flow in vortex matter. Finally, it is shown that induced attractive interactions between the moving colloids lead to enhancement of the particle current due to formation of condensed chains traveling along the modulated landscape

TU.F-P14 - Enhanced room temperature ferromagnetism of Sol-Gel synthesized $LaMnO_3$ nanoparticles

C. Liu [1], B. Lee [1], P. Tola [1], D.H. Kim [1]

1. Hankuk University Of Foreign Studies, Seoul, South Korea

Lanthanum-based perovskite-type oxides ($LaMO_3$) containing transition metals are well known as functional inorganic materials having wide applications such as electrodes for fuel cells, gas sensors, ion sensors, catalysts, and various biomedical materials. $LaMO_3$ has been reported to show interesting magnetic properties and broad electric properties induced by oxygen vacancies. In this work we investigated the effect of polyvinyl alcohol (PVA) on the magnetic properties of $LaMO_3$ nanoparticles synthesized by the sol-gel method. The precursor chemicals of La and Mn elements were first dissolved in a mixed solvent of acetic acid and methanol to get a clear precursor solution, then 6 wt% PVA of different volume (0, 5, 10, and 15 ml) was added. The final product was obtained by annealing the reaction precipitates at 700oC for 2 h. Although PVA did not seem to cause obvious effect on the crystallinity and composition of the $LaMO_3$ nanoparticles, the morphology and magnetic properties showed noticeable dependence on the amount of PVA added during the sol-gel process. The $LaMO_3$ nanoparticles became more porous when PVA solution was added, and the $LaMO_3$ nanoparticles prepared with 10 ml PVA showed much improved room temperature ferromagnetism despite the fact that bulk $LaMO_3$ shows antiferromagnetism with a Neel temperature of 140 K. X-ray photoelectron spectroscopy measurement revealed that the addition of PVA adjusted the amount of cation vacancies in the $LaMO_3$ nanoparticles. The amount of Mn^{4+} ions in $LaMO_3$ nanoparticles was increased with the addition of PVA solution, which directly affected the magnetic properties. Our results provide a simple approach to prepare $LaMO_3$ nanoparticles with enhanced room temperature ferromagnetism.

TU.F-P15 - Stability of patrons inscribed on arrays of magnetic nanowires

E. Vogel [1], J. Faundez[1], E. Cisternas[1]

1. Universidad De La Frontera, Temuco, Chile

Magnetic nanowires trapped in the membranes used to produce them can be used to store information in the form of patterns representing shapes, symbols, or barcodes. In the present paper we calculate the repulsive interacting energy among the ferromagnetically oriented wires in the pattern contrasting with a random background. The starting point is the interaction between a pair of wires; an algorithm is designed to calculate all the interactions within the pattern without truncations due to distance between elements. Then two lines of thought are followed to test stability: A) The inscription of an opposite ferromagnetic band within the pattern of variable width w; B) The detection of weak points within the pattern which are more lenient to reversion which could lead to loss of the stored information. Results are reported both by means of functional plots (i.e. dependence of the total repulsive energy per wire with respect to relevant parameters) and graphically (color coded maps showing particularly weak and strong points within the pattern with respect to possible magnetization reversals). Several letters in the Arial font are used as actual examples for previous analysis. Some of the main conclusions are: i) for w between 0.35 to 0.40 in units of the actual width of the pattern the best conditions for stability are reached; ii) wires in the periphery of the patterns are the most stable; iii) wires at the center of the pattern are the less stable under possible spontaneous reversal than can trigger a cascade of reversals leading to the fading away of the stored ferromagnetic domain. Several stabilization mechanisms are proposed. Acknowledgements: Fondecyt under contract 1150019 and Center for the Delopment of Nanoscience and Nanotechnology (CEDENNA) under contract FB0807.

TU.F-P16 - Magnetic anisotropy of maghemite nanoparticles probed by RF transverse susceptibility

A.I. Figueroa [1,2], J. Bartolomé [1], L.M. García [1], F. Bartolomé [1], A. Millán [1], F. Palacio [1]

1. Instituto de Ciencia de Materiales de Aragón, CSIC-Universidad de Zaragoza. Departamento de Física de la Materia Condensada, Zaragoza, Spain.
2. Magnetic Spectroscopy Group, Diamond Light Source, Didcot, United Kingdom

The radio frequency (RF) magnetic transverse susceptibility (TS) technique has been used over the years with great success to study the magnetic anisotropy of different magnetic nanostructured systems [N.A. Frey. Surface and Interface Magnetism in Nanostructures and Thin Films. PhD thesis (University of South Florida, Tampa, 2008); A. I. Figueroa. Magnetic Nanoparticles. A Study by Synchrotron Radiation and RF Transverse Susceptibility. Springer International Publishing (2015)]. It is a powerful and sensitive technique to directly extract the magnetic anisotropy constant K_{eff} of nanoparticles systems and to study their interparticle interactions. Understanding these parameters in nanoparticle systems is of paramount importance to evaluate their potential applications in diverse fields like biomedicine. In this work, TS measurements on γ-Fe_2O_3 (maghemite) nanoparticles, with sizes between 5 and 13 nm in diameter, allow us to estimate their K_{eff} and examine its variation as a function of the particle size. The resulting K_{eff} values range from 4 to 8 $\times 10^4$ erg/cm^3, being on the order of the magnetocrystalline anisotropy in bulk maghemite. K_{eff} values increase as the particle diameter increases, which is consistent with an anisotropy enlargement with bigger core volume of the particles. Evidences of anisotropy field distribution given by the size distribution in the samples, and interparticle interactions that increase as the particle size increases are also observed in the TS measurements. Thus, the effects of interparticle interactions in this maghemite system overcome those of thermal fluctuations, in contrast with TS results obtained for other iron oxide particles such as SiO_2 – coated magnetite [A. I. Figueroa et. al., Nanotechnology 24, 155705 (2013)].

TU.F-P17 - Universal behaviour for magnetic entropy change in Ba-doped $La_{0.7}Ca_{0.3}MnO_3$ nanoparticles

T.D. Thanh [1,2], D.C. Linh [2], T.A. Ho [1], T.L. Phan [3], S.K. Oh [1] N, S.C. Yu [1]

1. Chungbuk National University, Cheongju, South Korea
2. Vietnam Academy of Science and Technology, Hanoi, Vietnam
3. Hankuk University of Foreign Studies, Yongin, South Korea

$La_{0.7}Ca_{0.3-x}Ba_xMnO_3$ (x = 0, 0.025, and 0.05) nanoparticles with the crystallite size of d_C = 39-45 nm were synthesized by utilizing the solid-state reaction and mechanical ball milling methods. We have used the Banerjee's criteria, the mean-field, and the thermodynamic theories, and isothermal magnetization, $M(H)$, data around Curie temperature (T_C) to investigate the magnetic phase transformation and the temperature (T) and magnetic field (H) dependences of magnetic entropy change, $\Delta S_m(T, H)$, for nanoparticles. These exhibit the samples undergoing a second-order magnetic phase transition with an existence of the ferromagnetic short-range order in the samples. Under an applied magnetic field change H = 30 kOe, the maximum value of ΔS_m (denoted as $|\Delta S_{max}|$) are obtained about 4.4 $J \cdot kg^{-1} \cdot K^{-1}$ corresponding to a refrigerant capacity (RC) value about 140 $J \cdot kg^{-1}$. Field dependences of $|\Delta S_{max}|$ and RC can be expressed by the power laws, $|\Delta S_{max}| = a \cdot H^n$ and RC = $b \cdot H^N$, where a and b are coefficients, n and N are the field exponents, respectively. Interestingly, all the $\Delta S_m(T, H)$ curves measured at different applied fields are collapsed onto a universal curve, $\Delta S_m(T, H)/\Delta S_{max}$ versus $\vartheta = (T - T_C)/(T_r - T_C)$, where T_r is the reference temperature.

TU.F-P18 - Core-shell Ag@Fe_3O_4 brick-like nanoparticles for magnetic hyperthermia

M.E. Fortes Brollo [1], C. Sato [2], D. Muraca [1], R. López-Ruiz [1], K. Pirota [1], M. Knobel [1]

1. Instituto de Física Gleb Wataghin, Unicamp, Campinas - Brazil
2. Brazilian Synchrotron Light Laboratory (LNLS) / Brazilian Center of Energy and Materials (CNPEM), Campinas - Brazil

Research on the heating efficiency of magnetic nanoparticles (NPs), under an alternating magnetic field for tumor treatment via hyperthermia has attracted a great interest in the last few years. Magnetite nanoparticles (Fe_3O_4) have shown excellent properties for this therapy, given their high values of energy dissipation. Coupled with an optical active noble metal such as Ag or Au, they could give rise to a wide variety of interesting phenomena, with potential application as markers for biological molecules, for example. Here we investigate the heating efficiency of multifunctional Ag (core)-magnetite (shell) nanoparticles. These NPs were synthesized by a rather simple synthetic route, resulting in compact, brick-like nanostructures (size) with interesting magnetic properties [1].
Magneto-hyperthermia was evaluated by means of the specific absorption rate (SAR) parameter, usually employed to evaluate the heat emission of a magnetic material when a resonant alternating magnetic field (frequency of 313 kHz) is applied. The results of our novel NPs were compared with pure magnetite and dimer (Ag-Fe_3O_4) NPs. The results indicate that these unique, compact core-shell NPs display SAR values similar to recent reported results of colloidal suspensions of plain magnetite with similar diameter, which are considered one of the best choices for in vivo applications.

TU.F-P19 - Tailoring magnetic size-dependent properties of Co-ferrite nanoparticles for permanent magnet applications

A. López-Ortega [1], E. Lottini [1], C.d.J. Fernandez [2], C. Sangregorio [3]

1. INSTM And Dipartimento Di Chimica, Firenze, Italy
2. INSTM and CNR-IMEM, Parma, Italy
3. INSTM and CNR-ICCOM, Sesto Fiorentino (Firenze), Italy

Magnetic nanoparticles (NPs) have attracted a great interest in the last decades thanks to their novel fundamental properties emerging from their extremely reduced size. Special attention has been devoted to cobalt ferrite ($Co_xFe_{3-x}O_4$) NPs due to their cheap manufacturing and high magnetic anisotropy. In particular, the application of cobalt ferrite in the realization of permanent magnet has attracted a renewed interest as an alternative to rare-earth base materials. Many works have been focused on the correlation between magnetic properties and stoichiometry, particle size and structural defects, demonstrating cobalt ferrite NPs are a promising candidate for permanent magnet application, although a global picture of the effect of each parameter on the final properties is still missing. Indeed, all these investigations have been limited to a short range of particle sizes and to confined temperatures. Therefore, a deeper understanding in structural, size-dependent and morphological effects on final physical properties appears necessary. Herein, we present the synthesis and investigation of a series of cobalt ferrite NPs with average size covering a broad range (from 4 to 60 nm), with narrow size distributions and controlled shape and stoichiometry. Structural, morphological and magnetic characterizations were carried out using several techniques, including transmission electron and helium ion microscopy, X-ray diffraction analysis and magnetometric measurements. The evolution of the magnetic properties was studied as a function of particle size and shape. In addition, we evaluated the (BH)max product, the figure of merit of permanent magnets, obtaining the maximum values ever reported in the literature for cobalt ferrite NPs (i.e., 2.1 MGOe (18 MJm-3) for 40 nm NPs) (see Fig. 1(i)). Finally, this study allowed us to settle the limits of cobalt ferrites for permanent magnet applications in base of the definition of the (BH)max product. (This research was supported by EU-FP7 NANOPYME Project (No. 310516)).

TU.F-P20 - Magnetic properties of mechanically alloyed bcc Fe-Pd influenced by hydrogen

Y. Jiraskova [1], J. Bursik [1], I. Turek [1], J. Cizek [2], O. Zivotsky [3]

3. Department of Physics and RMTVC, VèB-Technical University of Ostrava, Ostrava, Czech Republic

Metastable Fe-Pd powder samples of nominal composition $Fe_{95}Pd_5$ were synthesized by mechanical alloying using a high-energy ball mill. Their fundamental properties, i.e., chemical and phase composition, lattice parameters, microstructure, morphology, grain size, macro- and micro-magnetic properties were monitored during milling procedure and discussed from the viewpoint of the milling atmosphere used. For these purposes the X-ray diffraction, Mössbauer spectrometry, high resolution scanning and transmission microscopy and magnetic measurements at room and elevated temperatures were applied. Two samples were prepared: the A sample was a mixture of Fe powder and of Pd powder pre-charged with hydrogen, the B sample was a mixture of Fe and Pd powders. The input Fe powder for both samples was annealed to remove oxides. Two objectives were followed: (i) the alloying of Fe and Pd(H) in A sample during milling under Ar atmosphere and (ii) the alloying of Fe and Pd in B sample during milling under hydrogen atmosphere. The A sample yields after 5 h of milling a slight decrease in saturation magnetization as compared to pure Fe, supported by a similar tendency of the hyperfine induction, but no highly defected interfacial phase has been observed. This phase appeared after further milling. On the contrary, the highly defected phase was detected after the same milling time (5 h under hydrogen) in sample B yielding a similar decreasing trend of magnetic behavior in the next steps and surprisingly a higher sensitivity to oxidation. The analyzed Henkel graphs point to negative magnetic interactions among the particles.

TU.F-P21 - On the interplay of dipolar interactions and surface spin disorder in colloidal maghemite nanocrystal clusters

Understanding the enhanced or collective magnetic properties of nanoscale systems made of multiple subunits is a key in their exploitation in various application fields extending from photocatalysis and magnetic storage to biomedicine. This study illustrates the controlled assembly of single-crystal, colloidal maghemite nanoparticles (NPs) via a high-temperature polyol-based pathway. The outcome is hydrophilic, size-tunable (50-90 nm) colloidal nanoclusters (CNCs), composed of crystallographically oriented maghemite NPs (10 nm). [1] Bulk ac/dc susceptibility of frozen aqueous dispersions and local-probe Mossbauer spectroscopy of such nanocolloids are complemented by Monte Carlo simulations. We discuss the impact on the microscopic interaction effects of the nanoparticle assembly process as this is dictated by the increasing volume fraction, ϕ, of the inorganic magnetic phase (i.e. from individual NPs to larger cluster-like nanoparticle assemblies). In addition to room-temperature ferrimagnetism, the study of the magnetic dynamics recognizes two different spin-dynamical regimes. Scaling-law analysis and Monte Carlo calculations suggest that a spin-glass state (T_f <70 K) arises (i) in the individual NPs, from strong dipolar interactions and their impact on the surface spin disordering, whereas (ii) in the assembly of such NPs in clusters (with increased ϕ), from the interplay of dipolar interactions with an additional spin disorder due to the defected nanoparticle surface coordination environment. In this second case, the former interaction mechanism is responsible for the observed memory effects at the high-temperature superspin glass transition (T_B <200 K). We suggest that the clarification of magneto-structural characteristics and coupling effects that influence the magnetization of a colloidal assembly of nanocrystals is essential in engineering functional nanoarchitectures for magnetically-driven technologies (e.g. MRI, magnetic hyperthermia etc).

TU.F-P22 - Influence of annealing process on the structure and magnetic behavior of $Ba_{0.5}Co_{0.5}Fe_2O_4$ nanoparticles

N. Osman [1], T. Moyo [1]

1. University Of KwaZulu-Natal, Durban, South Africa

The structure and magnetic properties of Ba0.5Co0.5Fe2O4 nanoparticles were investigated for the as-synthesized and sample annealed at different temperatures of 300 ºC, 400 ºC, 500 ºC and 600 ºC. The phase structure was studied by means of X-ray powder diffraction (XRD). The XRD result revealed that the annealing process up to 500 ºC decreases the sample microstrain and increases the crystallinity of the sample. The iron distribution and hyperfine interaction on the tetrahedral site and octahedral site for the as-prepared and sample annealed at different temperatures were studied using room temperature Mössbauer spectroscopy. The hyperfine field increases as the annealing temperature (TA) increases. The values of isomer shift show only the existence +3Fe. Investigation of the magnetic behavior for the as-prepared and the annealed samples was carried out using a mini-cryogen free VTI system in temperature range from 300 K to 4 K in the external magnetic fields of up to 5 T. The saturation magnetization decreases dramatically as the TA increases whereas the coercivity increases. The hysteresis loops as a function of measuring temperature show the effect of spin freezing. The values of the remanence (Mr) at 4 K decreases as the TA increases, whilst at 300 K, Mr increases with increasing TA. The measurement of reduced remanence shows cubic anisotropy for as-prepared and the samples annealed at different temperature.

TU.F-P23 - Dimensionality effects on the dynamics of dipolar interacting ferromagnetic fine particles: A monte carlo investigation

D. Brinis [1,2], D. Ledue [2], R. Patte [2], A. Laggoun [1]

1. Unité de Recherche MPE- Université de Boumerdes, Boumerdes , Algérie
2. Groupe de Physique des Matériaux, UMR 6634 CNRS - Université de Rouen, Saint-Etienne-du-Rouvray, France

The magnetization dynamics of one- or two-dimensional self-organized assemblies of interacting nanoclusters [1] which are potential candidates for ultra-high density magnetic recording media was investigated using Monte Carlo simulations [2]. The study was focused on the temperature variation of the ac-susceptibility as well as the decay over time of the magnetization of cobalt nanoparticleshaving the same anisotropy axis. Evidence was found of significant dipolar interaction effects on the peak position of the imaginary part of the ac-susceptibility and on the relaxation time due to the common easy axis and the low-dimensionality of the assemblies even for low concentration (less than 10%). With increasing the strength of the dipolar interactions, the peak of the out-of-phase component shifts towards higher or lower temperatures depending on whether the magnetic moments are oriented in the plane assembly or perpendicular to it [3]. A peak shift towards higher (lower) temperatures is clearly linked to an increase (decrease) of the relaxation time. The relaxation time in the presence of dipolar interactions still follows an Arrhenius law [4] with an effective energy barrier which is either larger or smaller than the anisotropy energy barrier. It is also shown that random positions slightly strengthen the influence of dipolar interactions.

TU.F-P24 - Effect of Zn concentration on photonic crystals band structure of $Co_{1-x}Zn_xFe_2O_4$ nanoparticules under an external perpendicular magnetic field

G. Zambrano [1], N. Porras-Montenegro [2], M.E. Gomez [1], J. Alonso Lopez [1,3], L.E. González [2]

1. Thin Films Group, Universidad del Valle, , Cali, Colombia
2. Grupo de Física Teórica del Estado Sólido, Universidad del Valle, Cali, Colombia

Ferrofluids based on $Co_{1-x}Zn_xFe_2O_4$ magnetic nanoparticles are colloidal systems composed of a single domain of magnetic nanoparticles dispersed in a polar or a nonpolar carrier liquid. These kinds of systems are considered soft magnetic materials with interesting technological applications in nanotechnology, when the ferrofluids are placed in an external magnetic field. Morphological characterization of the $Co_{1-x}Zn_xFe_2O_4$ magnetic nanoparticles was obtained through high-resolution transmission electron microscopy studies. In addition, we observed self-assemblies of $Co_{1-x}Zn_xFe_2O_4$ magnetic nanoparticle aggregates forming columns in a hexagonal 2D photonic crystal, when the ferrofluid was encapsulated in a cell glass under the action of a tunable magnetic field applied perpendicular to the film. The dependence of the ferrofluid effective refractive index with the applied magnetic field strength was determined by laser interferometry measurements by using a Mach–Zehnder interferometer. To determine the optical response of 2D magneto-controllable photonic crystals based on ferrofluids under the action of a DC external magnetic field, the Maxwell-Garnett theory, the experimentally calculated effective refractive index, and the plane wave expansion method were used. The photonic band structure of 2-D photonic crystals for these ferrofluids were simulated, finding that the optical response of photonic crystal depends on the ferrofluid effective refractive index, the area ratio, the permittivity of magnetic columns, and on the composition of $Co_{1-x}Zn_xFe_2O_4$ ferrofluids. The results showed that the photonic band structure of the ferrofluid with the least Zn concentration (x = 0.25) presented a complete band gap in the IR range ($\lambda \cong 10.6$ μm) at low perpendicular applied magnetic field. Finally, the procedure used in this work may be considered an alternative method to characterize the optical response of nanostructured ferrofluids in the presence of external magnetic fields. These results can be taken into account for technological applications of ferrofluids as magneto-controllable photonic crystals.

TU.F-P26 - Crystal Field Effects Of Er^{3+} In Cubic $NaY_{1-x}Er_xF_4$ Nanoparticles

A.F. Garcia-Flores [1], G. Lesseux [2], T. Caldonazo [2], D. Garcia [3], R. Urbano [2], C. Rettori [1,2]

1. Universidade Federal do ABC, CCNH, Santo André-SP, Brazil
2. Instituto de Física Gleb Wataghin, UNICAMP, Campinas-SP, Brazil
3. Centro Atómico Bariloche, S.C. de Bariloche, Río Negro, Argentina

In this work we report on the synthesis and the magnetic properties of $NaY_{1-x}Er_xF_4$ nanoparticles (NPs) doped with Er^{3+} ions (nominal concentration x = 0.01). The NPs were synthesized by thermal decomposition of trifluoroacetate precursors in a solution of octadecene and oleic acid at 300 ˚C. X-ray Diffraction (XRD) confirms their cubic crystallographic structure, *Fm-3m*. Transmission Electron Microscopy (TEM) images display that the synthesized NPs are nanopolyhedral and particle sizes vary from about 15 to 50 nm. The powder-like magnetic susceptibility data of the $NaY_{1-x}Er_xF_4$ NPs was fitted using a crystal field (CF) Hamiltonian appropriated for a J = 15/2 multiplet corresponding to Er^{3+} ions sited in cubic symmetry with $\mu_{eff} = 9.58\mu_B$ and x = 0.008(1). The obtained 4th order CF parameter B_{40} = 0.0096 K ($B_{60} << B_{40}$) predicts an overall CF splitting of 318 K and a Γ_8 quadruplet ground state. By X-Band Electron Spin Resonance (ESR) experiments a Γ_7 doublet excited state with g = 7.0(4) was detected, in agreement with the scheme of energy levels resulting from the magnetic susceptibility analysis.

TU.F-P29 - Structural changes in ferronematic liquid crystals studied by surface acoustic waves

Peter Bury [1], Štefan Hardoň [1], Jozef Kúdelčík [1], Peter Kopčanský [2], Milan Timko [2]
1. Department Of Physics, Žilina University, Žilina, Slovakia
2. Institute of Experimental Physics, Slovak Academy of Science, Košice, Slovakia

The response in attenuation of surface acoustic wave (SAW) of frequency 30 MHz propagating along ferronematic liquid crystals (6CHBT) to both electric and low magnetic field (up to 1.0 T) has been studied experimentally. Three low volume concentrations (Φ_1=1×10^{-5}, Φ_2=5×10^{-5} and Φ_3=1×10$^{-4)}$ of spherical magnetic nanoparticles were added to liquid crystal during its isotropic phase. In contrast to undoped 6CHTB the distinctive SAW attenuation responses induced by both electric and magnetic fields in ferronematic liquid crystals below Fréedericksz transition have been observed suggesting structural changes. The geometrical re-ranking of magnetic nanoparticles was registered for some orientations of magnetic field, too. Observed results confirmed the significant influence of the presence of magnetic nanoparticles and their concentration on the structural properties of 6CHTB.

TU.F-P30 - Interactions in densely packed nanoparticle systems

M. Svante Andersson [1], R. Mathieu [1], P.S. Normile [2], S.S. Lee [3], G. Singh [4], P. Nordblad [2], J.A. De Toro [1]

1. Department of Engineering Sciences, Uppsala University, Uppsala, Sweden
2. Instituto Regional de Investigacíon Científica Aplicada (IRICA) and Departamento de Física Aplicada, Universidad de Castilla-La Mancha, Ciudad Real, Spain
3. Institute of Bioengineering and Nanotechnology, Singapore, Singapore
4. Ugelstad Laboratory, Department of Materials Science and Engineering, Norwegian University of Science and Technology (NTNU), Trondheim, Norway

Spherical y-Fe_2O_3 nanoparticles having a very narrow size distribution were packed using a hydraulic press which resulted in a filling fraction close to random close packing (64%). Three samples were made from 8, 9 and 11.5 nm particles. Reference samples were made by pressing the same particles coated with a thick silica shell. The references were used to determine the properties of the individual magnetic particles which are only very weakly interacting. From SQUID magnetometry it was found that all of the samples are superspin glasses exhibiting dynamic properties; aging, memory, rejuvenation and critical slowing down qualitatively similar to atomic spin glasses. The dependence of the freezing temperature as a function of particle size suggests that dipolar interactions dominate in these systems in spite of the direct contact between the particles.

TU.F-P31 - Autoresonant switching of the magnetization in single-domain nanoparticles

G. Klughertz [1], L. Friedland [2], G. Manfredi [1], P.A. Hervieux [1]

1. Institut de Physique et Chimie des Materiaux de Strasbourg, CNRS and Universite de Strasbourg, Strasbourg, France
2. Racah Institute of Physics, Hebrew Univesrity of Jerusalem, Jerusalem, Israel

The ability to control the magnetization switching in nanoscale devices is a crucial step for the development of fast and reliable techniques to store and process information. Also, the quest for higher density in magnetic data storage implies future use of smaller nanoparticles with high magnetic anisotropy to overcome the superparamagnetic limit. But an increased anisotropy requires larger fields to reverse the magnetization of the nanoparticle, which is experimentally difficult experimentally. To elude this limitation, a microwave field can be combined with the static field [1], and it has been shown that the optimal microwave field should be modulated both in frequency and magnitude [2].
We investigate the magnetization reversal of single-domain Co nanoparticles with uniaxial anisotropy under the macrospin approximation. We show that the switching dynamics can be controlled efficiently by combining a static magnetic field with a microwave field with time-dependent frequency (autoresonance) [3]. According to the autoresonance theory, a nonlinear oscillator can be strongly excited by using a weak chirped frequency drive [4]. If the drive strength exceeds a threshold, the oscillator will stay phase-locked to the drive and excited to high amplitudes without any feedback.
We provide a full theoretical framework for the autoresonant switching technique, by exploiting the analogy between the magnetization state of a nanoparticle and a two-level quantum system [5], whereby the switching process can be interpreted as a population transfer. We derive the threshold amplitude of the microwave field and consider the effects of damping and thermal fluctuations. Finally, using a mean field approach, we show that dipolar interactions in a chain of nanoparticles tend to cancel out the effect of the temperature on the threshold.

TU.F-P32 - Magnetooptical study of ferritin with different iron content

M. Koralewski [1], L. Melnikova [2], M. Pochylski [1], Z. Mitroova [2], P. Kopcansky[2]

1. Faculty of Physics, Adam Mickiewicz University, Poznań, Poland
2. Institute Of Experimental Physics SAS, Košice, Slovakia

Ferritin is the iron-storage protein of living organisms. It consists of ferrihydrite-like mineral core surrounded by the apoferritin hollow sphere with diameter of about 12 nm, capable of accommodating up to 4500 iron atoms according to the specific requirements of the metabolism [1, 2]. Understanding the precise mechanisms of iron ions incorporation and release in ferritin in vivo is very important in relationship with many various diseases (cancer, neurodegenerative, cardiovascular) that could be caused by iron ions accumulation and overloading of ferritin biomacromolecules followed by the disruption of the normal storage function of this protein. In generally, chemical composition of the ferritin core significantly differs between physiological and pathological occurrence [3]. Magnetooptical measurements of ferritins could be useful for qualitative and quantitative distinguishing of various mineral core structures [4].
Our work presents experimental investigation of magnetooptical properties of reconstructed and reduced horse spleen ferritin (HSF) core modified by the chemical process. Iron reduction of ferritin was done by partial core reduction of HSF followed by iron(II) chelation. Ferritin reconstruction was realized using the apoferritin shell, oxidant and iron(II) solution in anaerobic conditions. Magnetically induced optical birefringence (Δn) and Faraday rotation was measured at room temperature for aqueous suspensions of modified ferritins with different iron contents. It was shown that magnetic birefringence and Cotton-Mouton constant of studied aqueous suspensions provides evidence that the ferritin core behaves as a non-Euclidian solids and uptake and release process is not symmetrical. Both magnetooptical phenomena suggest that iron mineral with high magnetization do not appear in the synthetic core of ferritins.

TU.F-P33 - High performance core-shell structured magnetic nanoparticles: Fabrication, characterization, and application

L. Wang [1], Y. Jin [1], J. Wang [1], A. Ferrie [1], Y. Chen [1]

1. Corning Incorporated, Corning, United States of America

Heterostructured magnetic nanoparticles, such as core-shell structured magnetic nanoparticles (Mag@shell), are emerging as next generation materials due to their synergistically enhanced magnetism and multi-functionalities for various fields including high density magnetic storage, chemical catalysis, magnetic resonance imaging (MRI), and biomedical separation and diagnostics. In this presentation, we will review some of our recent work on the design and fabrication of core-shell structured magnetic nanoparticles with high performance capabilities. The core-shell structured magnetic nanoparticle examples in this presentation will include either inorganic shell or organic shell or both, e.g. Mag@gold, Mag@silver, and Mag@polymers. The core-shell structures were characterized and confirmed by a series of instruments and analysis methods including HRTEM, EDX hypermap element maps, XRD, XPS, and surface reactivity. The magnetic properties of Mag@shell were studied by a SQUID instrument, which showed differences between magnetic nanoparticles with shell and without shell in terms of blocking temperature, magnetization, and coercivities. These core-shelled magnetic nanoparticles have demonstrated feasibility and capability for different applications. The internal evaluation results showed some of our core-shell structures had comparable or better performance in biomedical separation and diagnostic applications than similar products currently in the market.

TU.F-P34 - Magnetostatic interactions in dense clusters of magnetic nanoparticles

N. Usov [1], O. Serebryakova [1]

1. Pushkov Institute Of Terrestrial Magnetism, Ionosphere And Radio Wave Propagation RAS

A detailed numerical simulation of quasistatic hysteresis loops of dense quasispherical clusters of interacting magnetic nanoparticles is carried out. Both the clusters of magnetically soft and magnetically hard nanoparticles are considered. The clusters are characterized by an average particle diameter D, the cluster radius Rc, the particle saturation magnetization Ms, and the uniaxial anisotropy constant K. The number of particles in the cluster varies between N = 30 - 120. The particle centers are randomly distributed within the cluster, their easy anisotropy axes being randomly oriented. It is shown that a rare assembly of identical random clusters of nanoparticles can be characterized by two dimensionless parameters: 1) the intensity of mutual magnetostatic interaction, K/Ms^2, and the average particle concentration within the cluster, g = VN/Vc. Here V is the nanoparticle volume, and Vc is the volume of the cluster, respectively. For magnetically soft nanoparticles, K/Ms^2 << 1, the universal hysteresis loops of the assembly are constructed. In the variables (M/Ms, H/Ms) these hysteresis loops depend only on the particle filling factor g, which varies in the range 0 <g <0.5. The hysteresis loops of magnetically hard nanoparticles in the variables (M/Ms, H/Ha), where Ha = 2K/Ms is the anisotropy field, are close to the standard Stoner-Wohlfarth hysteresis loop.

TU.F-P35 - Preparation of ε-Fe_2O_3 nanoparticles by crystal structural transformation of iron oxide nanoparticles

R. Nishida [1], A. Muramatsu [1], M. Nakaya [1]

1. Tohoku University, Sendai, Japan

Introduction : ε-Fe_2O_3 nanoparticles have received much attention from the industrial point of view due to their large coercivity at room temperature. However, it is very difficult to obtain single-phase ε-Fe_2O_3 nanoparticles, because ε-Fe_2O_3 phase is an intermediate phase on the transformation from γ-Fe_2O_3 phase to α-Fe_2O_3 phase. To prepare ε-Fe_2O_3 phase selectively, focusing on the formation energy of ε-Fe_2O_3 phase is important. In this study, the effects of treatment temperature and particle size on the formation of ε-Fe_2O_3 phase were investigated.
Experimental : FeO nanoparticles with the size of 24, 40 and 60 nm were synthesized by our previous method (*Chem. Lett*. 42, 863 (2013)). As-obtained nanoparticles were coated with SiO_2 shell to prevent their tremendous aggregation during heat treatment (*J. Chem. Chem. Eng*. 7, 1050 (2013)). The resulting SiO_2 coated FeO nanoparticles were treated at 1000 - 1200 °C in the air.
Results and Discussion : When 40 nm FeO nanoparticles with ca. 15 nm SiO_2 shell were treated, significant aggregation and increase in particle size were observed at every treatment temperatures. As-prepared nanoparticles were found the mixture of γ-Fe_2O_3, ε-Fe_2O_3 and α-Fe_2O_3 phases. When 40 nm FeO nanoparticles were treated to cover with ca. 40 nm SiO_2 shell, the particle aggregation was completely inhibited. The crystal structure was found to transform from γ-Fe_2O_3 phase to α-Fe_2O_3 phase via ε-Fe_2O_3 phase as the treatment temperature increased. The ε-Fe_2O_3 nanoparticles formed at 1100 °C showed large coercivity of 20.8 kOe at 300 K. As a result, the control in change in the crystal structure with temperature, under the complete inhibition against aggregation nor the growth in size, is the most important so that ε-Fe_2O_3 is selectively formed as a desired product. TU.F-P36 - Spin diffusion in nonlocal spin valves operated by spin pumping

L. Feiler [1], N. Kuhlmann [1], G. Meier [1,2,3]

1. Institut für Nanostruktur- und Festkörperphysik, ehem. Institut für Angewandte Physik und Zentrum für Mikrostrukturforschung, Universität Hamburg, Hamburg, Germany
2. The Hamburg Centre for Ultrafast Imaging, Hamburg, Germany
3. Max-Planck Institute for the Structure and Dynamics of Matter, Hamburg, Germany

In the past years, high frequency properties of magnetic nanostructures became of great interest since they offer fundamental understanding of spin dynamics as well as new potential technological applications. We study lateral spin valves in nonlocal geometry [1], using the spin-pumping effect as injection mechanism [2]. A pure spin current that arises from a ferromagnetic nanostructure driven at ferromagnetic resonance (FMR) is injected into the adjacent normal metal. In addition a second ferromagnetic electrode enables to detect and quantify the pure spin current. We simultaneously measure the broadband FMR transmission and the nonlocal voltage, in order to be able to comprehensively interpret the data.
To calculate the spin diffusion length, in the experiments the power of high-frequency excitation is varied. The resulting power dependence of the non-local voltage is fitted to a model that includes the spin-current injection by spin pumping, its diffusive decay in the normal metal, and the heating of the device. The latter could cause a Seebeck contribution. For devices with a copper normal metal strip we estimate from the experimental data a spin-diffusion length of 174 nm at room temperature. The presented method allows to determine the spin-diffusion length within one sample and in a short measurement time in comparison to standard methods [3].
Financial support of the Deutsche Forschungsgemeinschaft via SFB 668, GK 1286 and the excellence cluster CUI is gratefully acknowledged.

TU.F-P37 - Effects of milling conditions on nano-scale MnFe(P,Si) particles by surfactant-assisted high-energy ball milling

T. Nguyen [1], E.H. Bruck [1], N.H. van Dijk [1]

1. FAME, RST, TU Delft

The effects of milling parameters on nano-scale MnFe(P,Si) particles obtained by surfactant-assisted high-energy ball milling have been investigated. The presence of surfactant oleic acid prevents the re-welding of crushed particles and enhances the dispersion of nanoparticles in the solvent during the ball milling. This is supported by the fact that without the surfactant, the heptane remained clear after milling while it changed color from transparent to brown when the surfactant was added to the milling process. The XRD peak intensity decreases and the peaks broaden with increasing milling time, indicating a decrease in grain size. With increasing the milling time, spontaneous magnetization becomes lower and thermal hysteresis becomes smaller. This may be due to a larger contribution of the surface states as a result of either a decrease in particle size or surface contamination. The surfactant concentration does not have a strong impact on the magnetic properties of the obtained nanoparticles which is consistent with the X-ray diffraction data showing the same patterns at different surfactant concentration.

TU.F-P38 - Effects of milling conditions on nano-scale MnFe(P,Si) particles by surfactant-assisted high-energy ball milling

TU.F-P39 - Synthesis of iron-oxide nanoparticles. Size and shape effect on magnetic properties

J.M. Orozco [1], D. Muraca [1], S. Sharma [1], M. Knobel [1]

1. Universidade Estadual De Campinas, Campinas, Brazil

Iron-Oxide nanoparticles with sizes between 5-18nm obtained by means of thermal decomposition and their static magnetic properties are reported. Sizes and shapes were tuned making small changes in the synthesis process (concentration of some of its reactives were varied). Furthermore, in one case, the final step of the synthesis was modified allowing the reaction to have contact with room atmosphere obtaining an increment on the average size of the nanoparticles and different geometries. Structural characterization, X-ray diffraction and TEM images was performed in different samples and related with magnetic measurements. Zero Field Cooled and Field Cooled (ZFC/FC) magnetization at several applied fields as well as hysteresis loops at different temperatures were measured. From these data it was possible to infer blocking temperatures, coercive field, saturation magnetization and log-normal size distribution of the nanoparticles (based on conventional superparamagnetism modelling). Values of anisotropies from ~2.8x104J/m3 to ~7.9x104J/m3) and saturation magnetization at room temperature (from ~37A.m2/kg to ~78A.m2/kg), were obtained, indicating a strong dependence on interactions, size and shape of the nanoparticles.

TU.F-P41 - Soft magnetic $Zn_xMn_{1-x}Fe_2O_4$ spinels

M. Schmidt [1], M. Christensen [1]

1. Center for Materials Crystallography, Department of Chemistry and iNANO, Aarhus University, Aarhus, Denmark

Soft magnetic nanoparticles with spinel structure has attracted significant attention due to potential applications in bio imaging and for permanent magnets.[1] By reducing the size below 10 nm it has been shown that superparamagnetic nanoparticles with very high magnetic saturation (175 emu/g) can be obtained.[2] The magnetic properties of the spinel structures are related to the position of the transition metals. The general formula of the spinel structure can be written as [AII+]tet[BIII+]oct,2O4, where A is the tetrahedral site normally preferred by the $^{2+}$ ion, while B is the octahedral site preferred by the $^{3+}$ ion. Ideally all the Zn^{2+} should be allocated on the tetrahedral site, however conventional powder X-ray diffraction cannot establish this and more advanced characterization techniques like EXAFS or neutron powder diffraction must be employed. We have prepared a series of spinel structures (Fd-3m, a= 8.44 ┼) with formula $Zn_{1\ x}Mn_xFe_2O_4$ (x=0, 0.2, 0.4, 0.5, 0.6, 0.8, and 1) using hydrothermal synthesis from chloride precursors, which were precipitated using ammonia hydroxide. The magnetic properties of the compositions range were determined using vibrational sample magnometry. In our studies we are not capable of reaching the high saturation magnetization values reported in the literature. In fact the pure Zn sample appears to be antiferromagnetic corroborate with Zn^{2+} occupying the A site. While for the Mixed Mn and Zn structures our findings suggests that Zn^{2+}, Mn^{2+} and Fe^{3+} is randomly distributed over the two A and B site in the spinel structure.

3. Laboratoire de Physique des Lasers, Atomes et Molécules (UMR 8523), Université Lille 1 Sciences et Technologies, Villeneuve d'Ascq, France

Magnetic nanoparticles are extensively studied for applications which include flexible electronics, MRI imaging and drug delivery, multiple state memory elements, highly transparent magneto-optic materials, magnetic field sensors etc. The combination of cobalt ferrite polymer materials can account for significant advances in different technological areas. The study of polymer coated cobalt ferrite nanoparticles for cancer therapy applications is sustained by the interesting properties of both components (e.g. biocompatibility, magnetic response).
Our work was focused on studying both the influence of laser wavelength and fluence and solution type on the particle dimension, chemical and magnetic properties of the laser ablated nanoparticles. The cobalt ferrite target was obtained by conventional ceramic technique using commercially available pure oxides (Fe_2O_3 and Co_3O_4) as starting materials. The milled powders were pressed into disks at 250 MPa and sintered in air at 1250 oC for 5 hours with a 100 oC/h heating rate followed by a natural cooling to room temperature. The target was immersed in different solutions of distilled water, ethanol and PEG (Mw=4000 and 6000) in different concentrations. The nanoparticles were obtained using the first (1064 nm) and second harmonic (532 nm) of an Nd-YAG laser with a 10 nm pulse duration and 10Hz repetition rate. The laser radiation was focused on the single phase cobalt ferrite pellet by a 7 mm focal length lens and the fluence was varied from 4 to 12J/cm2. The solutions were dried at 100 oC and the material was collected for further investigations. The structural and chemical properties of the obtained nanoparticles were studied by X-ray diffraction, scanning electron microscopy/energy dispersive X-Ray spectroscopy, transmission electron microscopy and dynamic light scattering. The magnetic response was investigated using a vibrating sample magnetometer. The obtained nanoparticles presented a spinel structure with particle dimensions and magnetization values depending on the laser fluence.

TU.F-P43 - Dopant effect on the magnetic and structural properties in $Sn_{1-x}TM_xOy$ nanoparticles (TM = Co, Fe and Mn)

C. Meneses [1], T. Cunha [2], I. Costa [2], J. Duque [1], R. Lima [3]

1. Universidade Federal De Sergipe, Departamento de Física, Campus de Itabaiana, Itabaiana, Brazil
2. Universidade Federal De Sergipe,Departamento de Física, Campus São Cristóvão, São Cristóvão, Brazil
3. Universidade Fedeal de Campina Grande - Unidade Acadêmica de Física, Campina Grande, Brazil

In this work we have investigated the magnetic and structural properties in TM-doped SnOy nanoparticles (TM = Fe, Co and Mn; y = 1 and 2) obtained using different chemical methods. The results of X-ray diffraction allied to the Rietveld refinment revealed that the samples present an average particlea size from 4 to 60 nm. These results were confirmed by transmission and scanning electron microscopy. The optical band gap was estimated by UV-Vis and your values are close to 4 eV for both tin oxides. Fittings of magnetization curves as a function of temperature show only 1% and 20% of the ions are in a paramagnetic state for SnO_2 and SnO doped samples, respectively. The magnetization as a function of field curves show that all Fe-doped SnOy samples present a ferromagnetic ordering at room temperature. We have observed also an increasing in the magnetization and a decreasing in your coercive field with increasing of the dopant concentration. Such ordering can be attributed to interaction between the diluted Fe ions, provided by possible defects in the crystal structure. The EPR results obtained at room temperature show two lines presenting g's close to 4,3 and 2, corresponding to the values of the ordered and paramagnetic components, respectively.

TU.F-P44 - Fe,Mn-dilution effect on the magnetic properties in Zn_{1-x}(Fe,Mn)O nanoparticles

C. Meneses [1], I. Costa [2], T. Cunha [2], J. Almeida [1], J. Duque [1]

1. Universidade Federal De Sergipe, Departamento de Física, Campus de Itabaiana, Itabaiana, Brazil

2. Universidade Federal De Sergipe,Departamento de Física, Campus São Cristóvão, São Cristóvão, Brazil

In this work we have studied the magnetic, optical and structural properties of ZnO nanoparticles pure and doped with different concentrations of Fe and Mn synthesized by three different synthesis methods; co-precipitation (CP), hydrothermal (SH) and thermal decomposition (DT). The samples were characterized by measurements of X-ray diffraction (XRD) and analyzed allied to Rietveld refinement method, absorption in the UV-Vis region, scanning and transmission electron microscopy (SEM and TEM), and magnetization measurements as a function of field and temperature (MvsT, MvsH). Through XRD analysis we have observed a dependence of the size with increasing temperature for both CP and SH methods well as a change in morphology with temperature for the samples system synthesized by SH. XRD analysis through the Williamson-Hall plot associated with the TEM images show that particles obtained by SH and CP methods present an anisotropic growth, different of the particles obtained by DT method, that they present a spherical-like shape. The XRD results for Zn_{1-x}FexO systems obtained by the CP and SH present only one phase but from point of view magnetic properties we have observed that these samples present transition at low temperature (T = 10K) similar to an antiferromagnetic ordering. However, the Zn_{1-x}FexO samples obtained by DT synthesis we have observed a paramagnetic behavior evidenced by MvsT curves. Therefore, at room temperature the MvsH curves indicated a ferromagnetic behavior. All Zn_{1-x}MnxO (x=0,01, 0,5 e 0,10) present a paramagnetic behavior. The UV-Vis results show for all systems a slow increase in gap band with increases of dopant concentration.

TU.F-P45 - Behavior of the magnetic hyperfine field in Fe_3O_4 nanoparticles doped with hafnium

I. Matos [1], G. Cabrera-Pasca [1], R. Vianden [2], R. Saxena [1], A. Carbonari [1], J.A. Souza [3]

1. Ipen-Usp, São Paulo, Brazil
2. HISKP, Bonn University, Bonn, Germany
3. Universidade Federal Do ABC, Santo André, SP, Brazil

Fe_3O_4 magnetic nanoparticles (MNPs) have been intensively investigated because their non-toxic and biocompatibility characteristics and due to its ability to become magnetized when exposed to a magnetic field, which is enhanced by the presence of superparamagnetism. These features make them good candidates for new biomedical applications, which include drug delivery, imaging, labeling and tracking cells. Fe_3O_4 has a cubic inverse spinel structure with two different A and B sites, with tetrahedral and octahedral coordination of oxygen, respectively. A-sites are occupied by Fe^{3+} ions whereas B-sites carry Fe^{2+} and Fe^{3+} ions in equal proportions. Doping Fe_3O_4 nanoparticles with other elements can tune its magnetic behavior and an investigation of the local effects of this doping within an atomic scale is necessary. In this work, we have investigated the local magnetic properties of Hf-doped Fe_3O_4 (5%) by perturbed γ-γ angular correlation (PAC) spectroscopy using $^{181}Hf(^{181}Ta)$ and $^{111}In(^{111}Cd)$ as probe nuclei. $^{181}Hf(^{181}Ta)$ probe nuclei were obtained by irradiating of Hf-doped Fe_3O_4 with thermal neutrons in the IEA-R1 research reactor of IPEN. Doped Fe_3O_4 samples were prepared by co-precipitation method. The structure of compounds were characterized by X-ray diffraction (XRD) and their morphology by transmission electron microscopy (TEM). XRD Results show that the samples crystallize in the expected structure with single phase. Magnetization measurements were also carried out and show an expected magnetic behavior with a blocking temperature around 100 K. PAC results for the measured temperatures with both compounds showed a pure time-dependent magnetic dipole interaction below 300 K, which is ascribed to the time dependence of the superparamagnetic behavior of the nanoparticles.

TU.F-P46 - Tuning the size of magnetic $CoFe_2O_4$ nanocrystallites - An in situ powder X-ray diffraction study

H. Lyder Andersen [1], M. Christensen [1]

1. Center for Materials Crystallography, Department of Chemistry and iNANO, Aarhus University, Aarhus, Denmark

Magnetic spinel ferrites, MFe_2O_4 (M = Co^{2+}, Cu^{2+}, Ni^{2+}, etc.), are very important magnetic materials with many modern technological applications.[1] Notably, $CoFe_2O_4$ has a large magnetic anisotropy, high abundance and excellent chemical stability as well as a good saturation magnetization, mechanical hardness and relatively high Curie temperature (~793 K).[2] This makes $CoFe_2O_4$ an important magnetic material with a wide range of uses in e.g. magnetic recording media, ferrofluids and biomedicine.[3] In this study, the evolution of size and size distribution during hydrothermal synthesis of nanocrystalline $CoFe_2O_4$ has been investigated by in situ synchrotron powder X-ray diffraction (PXRD). Controlling the size and size distribution during $CoFe_2O_4$ nanocrystallite synthesis is a key issue as the electrical, optical and magnetic properties are highly dependent on the crystallite size.[4] Varying synthesis temperature or [OH] concentration in the precursor proves to have no significant effect on the final volume-weighted nanocrystallite sizes (~12 nm) of $CoFe_2O_4$. However, analysis by whole powder pattern modeling of the [OH] concentration series reveals a substantial difference in the number-weighted size distributions when varying the amount of base used. Furthermore, changing the metal ion concentration prior to NaOH addition in the precursor preparation gives a handle to control the nanoparticle sizes (~5-15 nm). The in situ experiments show almost instantaneous formation of the $CoFe_2O_4$ nanocrystallites, without significant growth or broadening of the size distribution after 60 s. Magnetic hysteresis curve measurements illustrate, how this facilitates the tailoring of materials with specific magnetic properties, as larger particles (~15 nm) exhibit hard magnetic properties while the smaller particles (~6-7 nm) are superparamagnetic. More information can be found in a recently published paper.[5]

TU.F-P47 - Coexixtance of superparamagnetic and spin glass behaviors in $Co_{30}Cu_{70}$ granular alloy and room temperature memory effect

S. Dhara [1], R. Roy Chowdhury [1], B. Bandyopadhyay [1]

1. Saha Institute Of Nuclear Physics, Kolkata, India

Granular binary alloys display interesting magnetic and magneto-transport properties. We have studied the magnetic properties of $Co_{30}Cu_{70}$ alloy prepared by borohydride reduction of $CoCl_2$ and $CuCl_2$ solutions with CTAB as the capping agent. XRD studies shows diffraction peaks coming only from fcc Cu phase confirming alloy formation. From XRD line width and TEM micrographs average particle size is calculated as 15 nm. ICPOES studies confirms elemental compositions of the sample as Co-31.26% and Cu-68.74%.The temperature dependencies of magnetization in ZFC-FC protocols of $Co_{30}Cu_{70}$ shows branching which indicates superparamagnetism. Blocking temperature from ZFC-FC magnetization is 367K. The peak in the ZFC curve at 7K is coming for spin glass like short range magnetic interaction that is suppressed at high external magnetic field like 1 Tesla. We have study the memory effect $Co_{30}Cu_{70}$ sample. The difference between this ZFC magnetization with intermittent stop and the normal ZFC magnetization as a function of temperature shows a dip at the stopping temperature if there exist a spin glass like ordering. First we have chosen TS as 10 K but at this temperature MZFC-MZFC(ref) shows no dip. But when TS is 4 K, i.e., below the glassy temperature 7 K there is a dip in the difference. In the superparamagnetic region intermediate changes in condition, either by decreasing temperature or by switching field to zero, do not affect the relaxation mechanism. Rather, it repeats the previous history which is a signature of memory effect. At the room temperature the sample is in blocked state, it shows memory effect in room temperature. This room temperature memory is very important in technological application which causes by distribution of particle sizes of non-interacting superparamagnetic system. At the end, we conclude that the sample is superparamagnetic with a small glassy contribution in low temperatures and the sample shows room temperature memory effect.

TU.F-P48 - Characterization of biocompatible magnetic nanoparticles modified by PEG

M. Kubovcikova [1], I. Antal [1], M. Koneracka [1], V. Zavisova [1], J. Kovac [1], P. Kopcansky [1]

1. Institute Of Experimental Physics, Slovak Academy Of Sciences Bratislava, Slovak

Magnetic fluids (MF) are stable colloidal suspensions of magnetic nanoparticles (around 10 nm in diameter) in a liquid carrier. To meet biomedical requirements they have to be superparamagnetic, and non-toxic. Due to their small size and superparamagnetic behaviour, MFs offer a variety of uses in the field of biomedicine. This paper deals with preparing magnetite nanoparticles sterically stabilized by sodium oleate and modified with polyethylene glycol (PEG, average molecular weight of 6 kDa) to produce biocompatible magnetic fluid (MFPEG). Characterization of prepared magnetic nanoparticles in terms of size distribution, thermal and colloidal stability and magnetic properties was carried out. Different methods such as dynamic light scattering (DLS), differential centrifugal sedimentation (DCS) and magnetic measurements were used to determine particle size distribution. The magnetic measurements confirmed superparamagnetic behaviour of samples at room temperature. Thermal stability of both MF and MFPEG was observed using DLS and via application of AC magnetic field, where changes in the temperature dependence of AC susceptibility were monitored. The out-of-phase component of the complex susceptibility as a function of applied field frequency was used for hydrodynamic diameter determination of modified magnetic nanoparticles. From the peak observed at 997 Hz we determined a Brownian relaxation time 1,6.10-4 s and consequently a hydrodynamic diameter of approx. 76 nm. This value correlates with the values obtained from DLS and DCS measurements with the output of 51.72 nm and 47.2 nm respectively for unmodified sample and 65.56 nm and 685 nm for MFPEG, respectively. Finally, the magnetic core diameter calculated from magnetic measurements was estimated to be 6.85 nm. The exact characterization of the prepared magnetic nanoparticles allows the further MF modification with specific biocompatible material (PEG), which offers good prospects of biomedical application.

For practical purpose of liquid crystals, the mixtures of substances are used. The transition from crystalline to liquid phase is more complex and proceeds through several intermediate phases. The controlled nematic to isotropic phase transition is usually exploited in liquid crystal based displays.
The binary mixture of bent-core (10DClPBBC) and rod-shaped (6OO8) liquid crystals (with the weight ratio of 1:1) was chosen as a model substance combining the properties of both types of the liquid crystals. The mixture was doped with the spherical and the rodlike magnetic nanoparticles with the concentrations of 7,5 x 10-4 and 8,5 x 10-4, respectively. DSC experiments were performed for the pure as well as the doped mixture at different heating rates ranging from 1 to 16 ^{o}C/min. The kinetics of nematic to isotropic phase transition was evaluated in the framework of the differential isoconversional method. The addition of the magnetic nanoparticles lowered the phase transition temperature. This effect is more intensive in the case of the rodlike magnetic nanoparticles. Measured enthalpy change decreased from the value of 2 J/g for the pure mixture to the value of about 1,5 J/g for the liquid crystal mixture modified by the magnetic nanoparticles. The calculated apparent activation energy showed non-monotonous behaviour and the sensitivity on the shape of added magnetic nanoparticles.
This work was supported by the projects Nos. 26220120021 and 26110230097 provided in the frame of Structural funds of the European Union.

TU.F-P50 - Influence of magnetic nanoparticles on phase transition temperatures in bent-core and rod-shaped liquid crystal mixture

A. Juríková [1], K. Csach [1], J. Miskuf [1], N. Tomasovicová [1], Z. Mitróová [1], V. Závisová [1], M. Koneracká [1], P. Kopcanský [1], N. Éber [2], K Fodor-Csorba [2]

1. Institute Of Experimental Physics, Slovak Academy Of Sciences, Kosice, Slovakia
2. Institute for Solid State Physics and Optics, Wigner Research Centre for Physics, Hungarian Academy of Sciences, Budapest, Hungary

Binary mixtures of bent-core and rod-shaped liquid crystals (LCs) are the subject of intensive research due to their potential applications. Whereas pure bent-core compounds have LC phases above room temperature, which limits their utility for many applications, mixtures of bent-core and rod-shaped molecules can extend the mesophase temperature range to near room temperature. We studied phase transitions of the binary mixture of bent-core and rod-shaped LCs with the weight ratio of 50:50 wt% using differential scanning calorimetry. Isotropic to nematic transition at the temperature above 90°C was followed by nematic to smectic transition below the temperature 40°C and by crystallization at sub-ambient temperature. The same transitions were observed for the mixture doped with two types of magnetic nanoparticles, spherical and rodlike. The influence of the nanoparticle shape on the transition temperatures in the bent-core and rod-shaped LC mixture was studied. The phase transition temperatures varried with cooling rates (2-10°C/min). The activation energies of the phase transitions in the LC mixtures were evaluated from linear fits of Kissinger plots. Doping the LC mixture with the magnetic nanoparticles caused the shift the transition temperatures at continuous cooling from the isotropic state. The isotropic to nematic phase transition temperature was shifted to lower temperatures by rodlike nanoparticles more than by spherical ones. Nematic to smectic and smectic to crystalline phase transition temperatures were lowered by doping the liquid crystal mixture with rodlike nanoparticles, whereas the spherical nanoparticles caused the shift towards the higher temperatures. The highest shift of the phase transition temperature (up to several °C) was observed for crystallization of the mixture doped by the rodlike nanoparticles. It was found that among the studied transitions the crystallization was the phase transition with the lowest apparent activation energy.

Assemblies of nanoparticles are widely studied in many research fields such as spintronics ,medicine or catalysisà Their properties will depend on the size, shape, crystallographic structure and chemical composition of the nano-particles. In addition, assemblies of nanoparticles often show wide size distributions making the interpretation of their properties even more complicated. Indeed the structure and the chemical order of the particles might change with the size of the particles within the particles size distributions. In this work we show that Ferromagnetic Nuclear Resonance (FNR, i.e. Nuclear Magnetic Resonance for ferromagnets) [1] allows mapping the structure and the chemical order of assemblies of nanoparticles within their size distributions. In this study we have investigated two types of assemblies of nanoparticles with wide size distributions. The first type of nanoparticles consists in Cobalt nanoparticles used in catalysis for producing synthetic fuel. We have shown that the smallest particles in the size distributions have mostly an hcp crystallographic structure while the largest ones have mostly an fcc structure [2]. This information provides a unique insight into the morphology of such distributions of nanoparticles. The results are correlated to the catalytic activity of the samples. In a second example we study the chemical composition in-homogeneities within the size distribution of CoFe nanoparticles.

TU.F-P52 - Exchange-bias and collective magnetic behavior of random binary compacts of maghemite nanoparticles

J.A. De Toro [1], M. Svante Andersson [2], S.S. Lee [3], P.S. Normile [1], P. Muñiz [1], G. Singh [4], J.M. Colino [1], R. Mathieu [2], P. Nordblad [2]

4. Department of Chemical Engineering, Norwegian University of Science and Technology

The narrow size distribution achieved in the synthesis of maghemite nanoparticles [1] has allowed the accurate control of the bimodal size distribution resulting from the mixture of two types of almost monodispersed particles (9.0 and 11.5 nm in diameter). The mixing was performed in liquid solution to ensure a random distribution of the two populations. The solutions were then dried and the resulting powders compressed to form close-packed discs with different proportions of small (volume V) and big (volume 2V) nanoparticles. Superspin glass behavior with a single transition temperature (which increases linearly with the proportion of big particles) is observed across all the series, but the effective broadening of the size distribution smears out the transition peak observed in AC and DC magnetic susceptibility curves and affects the dynamical critical exponent. The temperature and frequency dependence of the magnetic susceptibility at and below the freezing temperature is discussed in detail. The end members of the series (pure small/big particles) exhibit different values of the exchange bias field, indicating the presence of a similarly thick magnetically disordered shell in the particles of each volume (a result confirmed from the difference between the 'Langevin magnetic size' and the TEM size). Furthermore, the strong dipolar interactions present in these random-close-packed systems [1] do not significantly affect the exchange bias of the individual particles, as concluded from the linear variation of this parameter across the concentration series. This result is discussed in the light of recent Montecarlo simulations on core/shell interacting particles [2].

TU.F-P53 - Interactions and surface effects in bimagnetic CoO_core/$Co_{0.5}Ni_{0.5}Fe_2O_4$_shell nanoparticles

G. Lavorato [1], E.Winkler [1], E. Lima Jr [1], D. Peddis [2], H. Troiani [1], E. Agostinelli [2], D. Fiorani [2], A. Ghirri [3], D. Rinaldi [3], R. Zysler [1]

1. Centro Atómico Bariloche, S.C. de Bariloche, RN, Argentina
2. Istituto di Struttura della materia-CNR, Monterotondo (Rome),Italy
3. Università Politecnica delle Marche, Ancona, Italy

With the aim to investigate the surface effects on bimagnetic core/shell nanoparticles we have fabricated antiferromagnetic CoO nanoparticles encapsulated within a ferrimagnetic $Co_{0.5}Ni_{0.5}Fe_2O_4$ shell. The material was synthesized by seed-mediated growth high-temperature decomposition method, which leads to nanoparticles composed by ~ 2.4 nm CoO cores surrounded by a ~2 nm thick $Co_{0.5}Ni_{0.5}Fe_2O_4$ shell. We have analyzed the magnetic properties of two samples by ac and dc-magnetization measurements: the as-synthesized (A-sample) and the annealed in air at 573 K nanoparticles (B-sample). From the ac-susceptibility we have observed that the B-sample presents a single peak centered in the 150-200 K range, following a Vogel-Fulcher phenomenological law. On the contrary, the A-sample presents two peaks, one located in the 100-150 K range, which also follows the Vogel-Fulcher law and a low temperature maximum located at 2-5 K, which is weakly frequency sensitive. The Vogel-Fulcher dependence can be related to the progressive blocking of interacting magnetic supermoments and the fitting parameter indicates that the interactions are weaker in the as-synthesized sample. The ZFC-FC measurements confirm the superparamagnetic-blocked behavior, where the mean blocking temperatures are <TB>~64 K and <TB>~104 K for the A and B samples, respectively. Instead, the frequency dependence of the low temperature peak of the as-synthesized sample follows a Power Law compatible with spin-glass transition. Finally, it is important to mention that the annealed sample presents an enhanced coercivity (HC) with an exchange bias field (HEB), i.e. HC~13kOe and HEB~1.5 kOe at 50 K, compared to the as-synthesized sample. These results indicate that the annealed bimagnetic nanoparticles behave as an exchange coupled system while the as-synthesized system presents weaker intraparticle interactions with a lower TB. In addition, the surface of the $Co_{0.5}Ni_{0.5}Fe_2O_4$ shell remains magnetically disordered and thermally fluctuates and freezes into a spin-glass- like state at a much lower temperature.

TU.F-P54 - Coffee ring effect analyzed by eddy current sensing in drying magnetite solution droplets

J.C. Martínez-García [1], A. Rascón [1], D. Lago-Cachón [1], M. Rivas [1], J.A. García [1]

1. Departamento de Física & IUTA, Universidad de Oviedo. Edificio Departamental Este, Gijón, Spain

When a drop of particle dispersion is evaporated on a surface, the solid phase creates non-homogenous ring-shaped patterns, commonly known as coffee rings [1]. Different characteristics of the particles (size, covering, electrostatic charge and magnetic properties) or the liquid (pH and viscosity) influence the formation of these patterns [1]. Therefore, creating homogenous depositions of particles is not a simple task. In this work magnetic nanoparticles (MNP) have been dried onto glass slides and blotting paper strips and the resulting concentration pattern has been analyzed using an electromagnetic impedance-based sensor. The sensing principle has been recently identified by the authors [2] and is based on the eddy-current effects produced by the superparamagnetic character of the nanosized particles [2]. In this work the method is tested for 2D-scanning of the droplets. For room temperature-evaporated droplets more than 90% of the particles are located on the outer ring, occupying 30% of the surface. With the aim of achieving homogenous samples for sensing purposes, different temperature-controlled deposition protocols have been carried out and tested by means of the eddy-current sensor.

TU.F-P55 - Bottom-up Structuring of Magnetic $SrFe_{12}O_{19}$ Nanoplatelets

M. Saura-Múzquiz [1], C. Granados-Miralles [1], M. Christensen [1]

1. Center for Materials Crystallography, Department of Chemistry and iNANO, Aarhus University, Denmark

Hard magnetic materials are of key importance in a large variety of scientific and technological applications.[1, 2] The discovery of high performance rare-earth magnets directed the attention away from conventional magnets. However, recent geopolitical problems have sparked the need for new and cheaper rare-earth reduced/free magnetic materials consisting of more abundant elements.[3]
Nano-structuring of conventional magnetic ferrites has the potential to significantly improve their magnetic performance making them a viable alternative for certain applications.[4] An excellent candidate is the hexaferrite $SrFe_{12}O_{19}$ due to its pronounced magnetocrystalline anisotropy. Here, $SrFe_{12}O_{19}$ nanoparticles of various sizes have been synthesized using the Supercritical Hydrothermal Flow method. Control over the particle size has been achieved by varying synthesis parameters, such as pH, temperature and the metal concentration upon addition of the base. Results, obtained from Rietveld refinement of powder X-ray diffraction data, TEM and AFM, reveal a platelet-like shape of the nanoparticles, thin along the crystallographic *c*-axis (~3-8 nm), and large in the *ab*-plane (~20-60 nm). The aspect ratio of the nanoplatelets (*ab/c*) is variable, and highly dependent on particle size. Compaction of the tailored nanoplatelets into bulk magnets has been carried out through Spark Plasma Sintering, obtaining highly aligned nanocrystals. This leads to large enhancement of the magnetic properties, reaching a maximum of 25.11 kJ/m^3.

Only recently was it possible for the first time to measure the x-ray magnetic circular dichroism (XMCD) of free, size selected clusters. This achievement opens up new possibilities to better understand how spin coupling and orbital magnetic moment in 3d transition metals develop from the isolated atom to the bulk material. With this in mind, we have now measured the XMCD of free 3d transition metal molecules consisting of two and three atoms, i.e. dimers and trimers. We have studied cationic homonuclear molecules of chromium, manganese, iron, and cobalt. The high complexity of the electronic structure of these smallest molecules is evidenced by the numerous attempts in the literature to theoretically describe their electronic ground states. For chromium and manganese, it turns out that the experimentally obtained x-ray absorption spectra and the XMCD show a very good agreement with simulated atomic spectra, indicating that the 3d orbitals remain atomically localized in the molecules and their ferromagnetic ground state arise from the dominating double-exchange contribution. In the case of iron and cobalt dimers, the application of the XMCD sum rules allows the resolution of spin and orbital contributions to the total magnetic moment in these molecules and to therefore determine their electronic ground state. The comparison with theoretical studies in the literature show that in the case of iron the calculations systematically underestimate the orbital magnetic moment.

TU.F-P57 - Spatially-resolved EELS analysis of antibody distribution on biofunctionalized magnetic nanoparticles

6. Departamento de Física de la Materia Condensada; Universidad de Zaragoza, Zaragoza, Spain

We have made use of Spatially Resolved Electron Energy Loss Spectroscopy (SR-EELS) using Scanning Transmission Electron Microscopy (STEM) for the identification and determination of the spatial distribution of the components/elements of immuno-functionalized core-shell superparamagnetic nanoparticles at subnanometer scale [1].
Core-shell magnetic nanoparticles are commonly used in biomedical applications, as supports for macromolecules of biological interest. The shell, either organic or inorganic, allows in principle the use of different functionalization protocols to link a large variety of biological moieties, depending on the final purpose. The functionalization of nanoparticles with antibodies makes possible the use of the nanoparticles in applications based on immuno-recognition processes, in which the particles act, for example, as carriers for targeted drug delivery, as labels for immuno-assays etc. An adequate immobilization strategy is critical to guarantee not only the stability of the antibody binding on the nanoparticle surface, but also its correct orientation. Therefore, detailed knowledge of the functionalized nanoparticle surface is crucial when working with nanoparticle-antibody conjugates. Some information can be obtained by means of biochemical techniques but there is still a need for characterization at microscopic level. The results obtained in our work have shown, for the first time to our knowledge, how SR-EELS measurements allow the study and direct identification of the biological moieties (protein G and anti-Horse Radish Peroxidase antibody, which were used in our model system) on the nanoparticle. Our findings provide information on their spatial localization/distribution on the nanoparticle surface. We conclude that the data obtained in this study, together with those gathered by conventional biochemistry techniques, provide insight into the efficiency and potential applications of these nanoparticles in biomedicine and related fields.

Structural and magnetic properties of co-deposited (x at.% Fe)Yb (x = 0.3 - 5.0) films have been investigated by X-ray absorption spectroscopy, Mössbauer spectroscopy and magnetization measurements. EXAFS analysis indicates a short-range order for Fe atoms, which is consistent with nano-sized Fe clusters. Room temperature Mössbauer spectra reveal three paramagnetic components that order magnetically at 4.2 K. Specifically, low temperature Mössbauer spectra show a broad magnetic hyperfine field distribution, which can be attributed to inhomogeneous inter-cluster interactions; compatible with susceptibility data that suggest spin-freezing behavior with weakly interacting clusters at temperatures below ca. 20 K. Our data indicate that the Fe clusters are in nanometer scale and for this reason, the gyromagnetic ratios, determined by ferromagnetic resonance experiments that is dependent on Fe concentration, display values smaller than that found for the metallic Fe-bulk.

TU.F-P59 - Pressure-dependence of the magnetic irreversibility in the disordered phase of Superantiferromagnetic $TbCu_2$ nanoparticles

M. De La Fuente Rodríguez [1], C. Echevarria-Bonet [1,5], D.P. Rojas [2], I. de Pedro [1]N, J. Rodríguez Fernández [1], J.A. Blanco [3], P. Gorria [3], M.L Fdez-Gubieda [4], L. Fernández Barquín [1]

3. Universidad de Oviedo, Oviedo, Spain
4. Universidad del País Vasco/EHU, Leioa, Spain
5. Institut for Energy Technology

Recent investigations on metallic nanoparticles of $TbCu_2$ produced by inert-gas high-energy milling have revealed the existence of a superantiferromagnetic state with a Néel temperature $T_N \approx 47$ K. On top of that ordered state, there is an evidence for a spin freezing $T_f \approx 9$ K due to the presence of surface of randomized moments [1]. The frozen moments interface provokes the existence of magnetic anisotropy giving rise to exchange bias [2]. The role of the magnetically disordered phase depends on the size of the nanoparticles and it is clearly affected by the magnetic field affecting the irreversibility [1]. However the dependence of the irreversible state with the pressure (P) is not so well analyzed. In this contribution we will show the effect in the Neel and freezing temperatures. The nanoparticle alloys have been obtained after different milling times ($0.5\ h \leq t \leq 15\ h$) with a reduction of the size ($D \leq 25$ nm) and increase of microstrain ($\eta \leq 0.7$ %), as revealed by X-ray diffraction. DC-magnetization ZFC-FC curves were obtained for $P \leq 11$ kbar at different cooling fields $H \leq 1$ T. The results indicate that there is not a significant modification of the T_N values as expected. By contrast, The T_f values are reduced with increasing P indicating that magnetic moments become stiffer. As an indication, the variation of $T_f(P)$ with pressure is around 10% which is much smaller than $T_f(H) \approx 70$ % in the $t = 2$ h nanoalloy. The relative importance of the variation of T_f with pressure and field will be discussed. In this sense, in superparamagnetic core/shell nanoparticles the blocking temperature is also modified by pressure [3] and occurs in spin glasses of LaGdAu in which the T_f-decrease reaches $\Delta T_f/\Delta P = -14$ mK kbar^{-1} [4].

TU.F-P60 - Co and Ni doping in iron oxide nanoparticles: A systematic study

T. Orlando [1], M. Albino [2], C. Innocenti [2], C. Sangregorio [2], M. Corti [1], A. Lascialfari [3]

1. Department of Physics and INSTM, University Of Pavia, Pavia, Italy
2. Department of Chemistry 'U. Schiff' and INSTM, University of Florence, Florence, Italy
3. Department of Physics and INSTM, Università degli Studi di Milano, Milan, Italy

The role of the magnetic material is crucial in determining the physical properties at the nanoscale. Several iron oxide nanostructures doped with cobalt, zinc or gadolinium have been already investigated, but a complete and systematic study on the effect of doping is still missing. In order to address this issue, five cobalt and nickel substituted ferrite ($Co_xNi_yFe_{3-x-y}O_4$) nanoparticles were ad hoc synthesized, having a fixed size (7 nm) and a step-by-step doping, going from “pure” Co-ferrite to “pure” Ni-ferrite. This allowed us to explore the influence of the doping avoiding any contribution coming from the size-effect or from the different synthesis procedure. A complete set of DC and AC susceptibility measurements were performed, allowing us to study both static and dynamic properties. The evolution of the magnetization, the blocking temperature and the parameters governing the magnetization reversal were explored as a function of doping. A deeper study about the magnetic anisotropy, directly connected with the lattice structure and the ions arrangements, was then performed. Using two distinct approaches, the effective anisotropy constant K_{eff} was estimated. The first relies on the direct estimation of the energy barrier from fit of the ZFC curve; the second allows the evaluation of K_{eff} from the value of the coercive field. Comparing the obtained data with the ones of undoped iron oxide nanoparticles having similar size, a clear trend connected to the amount and the kind of doping material was found. Specifically, the “pure” cobalt ferrite exhibits a very high anisotropy compared to all the other nanoparticles and, in general, the more is the cobalt doping, the higher is the anisotropy barrier. On the contrary, the anisotropy barrier of “pure” Ni-ferrite turns out to be even lower than the one of undoped maghemite particles, although the nickel ion is magnetic.

TU.F-P61 - Synthesis strategies of single-core magnetic nanoparticles

H. Gavilán [1], S. Veitemillas- Verdaguer [1], L. Gutiérrez [1], M. Puerto Morales [1]

1. Institute Of Material Science (ICMM-CSIC) Cantoblanco, Madrid, Spain

Among other functional nanomaterials, magnetic iron oxide nanoparticles (MNPs) are especially promising as contrast enhancement agents for magnetic resonance imaging (MRI), drug carriers for disease treatment and heat mediators for cancer treatment by magnetic hyperthermia. Each of these biomedical applications requires MNPs with specific properties, and therefore it is of great importance to be able to control the shape, size and magnetic interaction of MNPs. Nowadays, just a few synthesis strategies and coating methods allow the production of single core nanoparticles, by preventing aggregation and minimizing the inter-particle interactions [1]. However not all the size ranges and varieties of shapes are covered by the synthesis of direct magnetic cores. We present a three-step aqueous approach to obtain Fe_3O_4 single-core particles based on the synthesis of antiferromagnetic nanoparticles, its coating and subsequent transformation to magnetite. This method has the advantage of the low inter-particle interactions of as-synthesized nanoparticles that allows the coating of the particles independently. In addition, it covers different size ranges and allows obtaining different morphologies that antiferromagnetic materials exhibit. This opens up new possibilities and interesting magnetic behaviours. Regarding hyperthermia for cancer treatment, different geometric shape leads to distinct shape anisotropy, resulting in significant difference in hysteresis loss and Specific Absorption Rates (SAR) values [2]. Recently, Serantes et al. found that the chain-like arrangement biomimicking magnetotactic bacteria could exhibit better heating performance than the randomly distributed system, implying the crucial role of shape anisotropy [3].

The careful control of the coating process of the antiferromagnetic particles allows the obtention of single-core antiferromagnetic nanoparticles that will remain as single core entities once their crystalline structures is transformed into magnetite. By fine-tuning the initial particles sizes and morphologies, we have produced a library of single core MNPs that may have very interesting properties for different biomedical applications.

TU.F-P62 - Mössbauer Study of Co-Ti ferrite nanoparticles for magnetic hyperthermia treatment

Y. Ichiyanagi [2], A. Kamzin [1], K.E. Romachevsky [1], K. Mori [2]

1. Yokohama National University, Yokohama, Japan
2. A. F. Ioffe Physico-Technical Institute of RAS, St Petersburg, Russia

Study of magnetic hyperthermia treatment attracted attention recent years. Magnetic nanoparticles (MNPs) are sufficiently small to be introduced into cells, and some particles such as magnetite (Fe_3O_4) particles are known to be biocompatible with the human body.
In this study, functionalized MNPs, SiO_2-shelled $Co_{1+x}TixFe_{2-2x}O_4$, ($0.2 \leq x \leq 0.5$) ferrite nanoparticles with average diameters ranging from 6 to 12 nm were produced by a wet chemical method. The use of these nanoparticles in hyperthermia treatments has been discussed on the basis of measurements of their AC magnetic susceptibilities.
Fig. 1 shows the X-ray diffraction patterns and Mössbauer spectra for the $Co_{1+x}TixFe_{2-2x}O_4$ (x = 0.2, 0.3, 0.4, and 0.5) samples. Single-phase spinel structure was confirmed in all the different samples. The broad peak observed around 25◦ on X-ray diffraction patterns corresponds to amorphous SiO_2.
The imaginary part of the AC magnetic susceptibility χ" was measured for samples placed in a 1-Oe, 100-Hz AC magnetic field at room temperature. The optimum concentration of Ti ions was found to be that corresponding to x = 0.3 with diameter of 12 nm. This result was confirmed by the Mössbauer spectra, indicating that the Co-Ti ferrite at x = 0.3 was in a superparamagnetic state and this was determined from the AC magnetic susceptibility measurements. A temperature increase of about 10 K was observed in a 300-Oe, 10-kHz field. The determined values of T/dt ranged from 0.001 to 0.008 K/s, depending on the frequency and composition when a field with a fixed strength of 50 Oe was applied; when the frequency was fixed at 10 kHz, the determined values of $\Delta T/dt$ ranged from 0.05 to 0.9 K/s. These samples are expected to be used as thermal agents in magnetic hyperthermia treatment. In vitro experiment supported the drastic hyperthermia effect.

TU.F-P63 - Coherency of reversible magnetization changes in Ni nanorods

C. Schopphoven [1], A. Tschöpe [1], C. Dennis [2], R. Shull [2]

1. Universität des Saarlandes, Campus D2.2, Saarbrücken, Germany
2. National Institute of Standards and Technology, Gaithersburg, United States of America

Magnetic particles allow the contactless application of forces or torques through external magnetic fields, which enables the use of such particles as microrheological probes or as active components in soft magnetic actuators. Detailed characterization of the magnetic properties of the particles is of vital importance to correctly analyze microrheometric measurements or predict and optimize the system behavior of magnetically functionalized soft composites. The objective of this study was the characterization of reversible magnetization changes of cylindrical ferromagnetic nanoparticles in transverse homogeneous magnetic fields and the related magnetic torque acting on the particles.
We investigated uniaxial ferromagnetic nickel nanorods with a mean diameter of ~20 nm and a mean length of ~320 nm. The nanorods were synthesized by current-pulsed electrodeposition of Ni into porous alumina (AAO) templates. The particles were then released by dissolving the alumina layer and embedded in a mechanically stiff 10 wt % gelatin hydrogel matrix. Application of a homogeneous field during gelation resulted in a uniaxial texture of the sample. The field-dependent magnetization components parallel and perpendicular to the applied field in an angular range of 0^o- 90^o with respect to the sample texture axis were measured using a vector vibrating sample magnetometer (VVSM). The resulting angles and values of the average magnetization vectors were then compared with the predictions of the Stoner-Wohlfarth model for coherent rotation.
At lower angles of the texture axis (0^o - 70^o) the magnetization rotation was largely coherent over the entire field range of 0 - 1500 mT as indicated by a nearly constant total magnetization. At larger angles, the deviation from coherency was negligible for small field strength up to 100 mT. However, a significant drop of the total magnetization was observed in the case of high field strength and angles approaching 90^o, indicating incoherent rotation. These results provide the range of parameters in which the Stoner-Wohlfarth model with an experimentally determined effective anisotropy constant can be applied to describe the magnetic torque acting on the cylindrical ferromagnetic nanoparticles.
We acknowledge financial support by the German National Science Foundation (DFG Priority Program SPP 1681).

TU.F-P64 - Iron oxide-based magnetic nanostructures for enhanced theranostic applications

E. Fantechi [1,2], A. Roca [1], J. Nogués [1,3], C. Innocenti [2], M. Albino [2], C. Sangregorio [4]

3. Istitució Catalana de Recerca i Estudis Avanþats (ICREA), Barcelona, Spain
4. Consiglio Nazionale delle Ricerche - Istituto di Chimica dei Composti Organometallici (CNR-ICCOM), Firenze, Italy

Magnetic nanoparticles (MNPs) are excellent building-blocks for the development of innovative biomedical nanodevices with multi-fold therapeutic and diagnostic activities. Among the different applications of MNPs, one of the most promising is their use as heat mediators for Magnetic Fluid Hyperthermia (MFH), a thermal treatment of cancer that relies on the highest sensitivity of tumoral cells to temperature with respect to healthy ones. There is an increasing interest in improving the hyperthermia efficiency of MNPs for MFH, with the aim to reduce the dose required and improve the efficiency of the treatment. Up to now, the most investigated materials for MFH are the iron oxides magnetite and maghemite. In this contribution, we present two promising strategies for the enhancement of hyperthermic efficiency of these materials. In the first one, the magnetic and hyperthermic properties of the material are tuned through the partial or total substitution of Fe(II) with other bivalent cations, like Co(II) and Zn(II). Here we focus on highly monodisperse Co-doped [1,2] and Co/Zn-doped iron oxide-based MNPs, investigating the dependence of the hyperthermic efficacy on the magnetic and structural properties, and considering the role of magnetic anisotropy and saturation magnetization in increasing the heat release capability. A second promising strategy is the realization of magnetic-plasmonic nanosystems able to combine MFH with another hyperthermic therapy, i.e., Plasmonic Absorption Hyperthermia (PAH), in which plasmonic NPs generate heat when irradiated with laser light. In this contribution we focus on complex hetero-dimer magnetic-plasmonic nanostructures, based on iron oxide and gold. The results show that hetero-dimer nanoparticles exhibit plasmonic and magnetic properties similar to the ones of the different counterparts.

Disorder among surface spins largely dominates the magnetic response of ultrafine magnetic particle systems. In this work, we examine time-dependent magnetization in high-quality, monodisperse hollow maghemite nanoparticles with a 15 nm outer diameter and enhanced surface-to-volume ratio. The nanoparticle ensemble exhibits spin-glass-like signatures in dc magnetic aging and memory protocols and ac magnetic susceptibility. The dynamics of the system slows near 50 K, and becomes frozen on experimental time scales below 20 K. Remanence curves indicate the development of magnetic irreversibility concurrent with the freezing of the spin dynamics. A strong exchange-bias effect and its training behavior point to highly frustrated surface spins that rearrange much more slowly than interior spins with bulk coordination. Monte Carlo simulations of a hollow particle reproducing the experimental morphology corroborated strongly disordered surface layers with complex energy landscapes that underlie both glass-like dynamics and magnetic irreversibility. Calculated hysteresis loops reveal that magnetic behavior is not identical at the inner and outer surfaces, with spins at the outer surface layer of the 15 nm hollow particles exhibiting a higher degree of frustration. Our study sheds light on the origin of spin-glass-like phenomena and the role of surface spins in magnetic hollow nanostructures.

TU.F-P66 - Dielectric and magnetic properties of a-Fe_2O_3 nanoparticles

J.W. Chen [1], Y.H. Huang [1], N. Rao G [1]

1. Department Of Physics, National Taiwan University, Taipei, Taiwan

We have investigated the dielectric and magnetic properties of the a-Fe_2O_3 nanoparticles prepared by the co-precipitation method. Iron nitrite was used as a precursor material. X-ray diffraction reveals the obtained nanoparticles are of the rhombohedral structure with space group $R\bar{3}c$. The particles sizes were determined from the XRD peak width using the Sherrer relation. The size of the particles was found between 45 nm and 100 nm, depending on the annealing temperature T_A.

The magnetization of the samples were taken using a commercial SQUID in a field of 5 KOe between 2 K and 300 K. The results show a monotonic decrease of the Morin temperature T_M from 260 K to 254 K as the particle size reduces from 100 nm to 45 nm. Below T_M, features in the $M(T)$ curves were observed at ~ 110 K and ~ 20 K, respectively.

The real part dielectric constant e'(T) curves of the samples exhibit distinct behaviors in different temperature regions. Below 110 K, e' is almost independent of temperature and test frequency, and approaches to a constant value e_s (e_s < 20, depending on the particle size). For T > 110 K, e'(T) increases with increasing T and decreases as the test frequency increases. The loss tangent tand exhibit a peak at the temperature near the inflection temperature observed in the e'(T) curves.

Our results indicate that core-shell structure in the samples studied. The observed features in the $M(T)$ and e'(T) curves at T ~ 110 K can be attributed to the Verwey transition due to existence of g-Fe_3O_4 in the shell of the nanoparticles.

TU.F-P67 - Beyond the effect of particle size: Influence of $CoFe_2O_4$ nanoparticle arrangements on magnetic properties

D. Peddis [1], C. Cannas [2], A. Musinu [2], A. Ardu [2], F. Orrù[2], D. Fiorani [1], S. Laureti [1], D. Rinaldi [1,4,5], G. Muscas [1,3], G. Concas [3]

4. Dipartimento di Fisica e Ingegneria dei Materiali e del Territorio, Università Politecnica delle Marche, Ancona, Italy
5. Consorzio Nazionale Interuniversitario per le Scienze Fisiche della Materia (CNISM)

This paper focus on assemblies of $CoFe_2O_4$ nanoparticles, analyzing the influence of the synthesis method on nanoparticles arrangement and magnetic proprieties. Using synthesis procedures based on direct micelle (DM) and high thermal decomposition (HTD) of metalorganic precursors, are been prepared three samples of $CoFe_2O_4$ nanoparticles with the same average particles size of about 5 nm. HTD method allows to obtain high crystalline nanoparticle coated by oleic acid and self-assembled in hexagonal close packing (H-$CoFe_{HTD}$) [1]. The DM method results appropriate to prepare either individual irregular arrangement of $CoFe_2O_4$ nanoparticles (I-$CoFe_{DM}$) or secondary spherical iso-oriented nanoporous assemblies with a high surface area (S-$CoFe_{DM}$) [1]
Despite the same particle size, magnetization measurements of the HTD sample show tendency towards cubic anisotropy ($M_R/M_S \sim 0.7$), while in DM samples a uniaxial anisotropy ($M_R/M_S \sim 0.4$) is observed. The comparison between I-$CoFe_{DM}$ and S-$CoFe_{DM}$ samples indicates that the ordering of nanocrystals at the mesoscopic scale induces an increase of the coercive field ($\mu_0 Hc$ = ~1.17 T → ~ 1.45 T) and of the reduced remanent magnetization (M_R/M_S: ~ 0.4→ ~ 0.5). The reason for these differences is discussed. In particular, a detailed study on interparticle interactions is carried out, highlighting the influence of the molecular coating and of the formation of spherical iso-oriented assemblies [2].

5. Consorzio Nazionale Interuniversitario per le Scienze Fisiche della Materia (CNISM)

Among nanostructured magnetic materials, nanoparticles are unique complex physical objects. In fact, at the nanoscale magnetic single-domain particles are formed, leading to new supermagnetic behaviors, depending on nature and strength of interparticle interactions [1]. In addition, the physics of nanoparticles is influenced by the modification of the structural and electronic properties at the particle surface [2].
Nanoparticles of spinel ferrites are of great interest, not only for their technological applications but also from the point of view of fundamental science. In particular, magnetite (Fe_3O_4) has been one of the most widely studied and utilized magnetic materials in the life of humankind. It is characterized by high Curie temperature (T_C = 850 K in bulk magnetite) and nearly full spin polarization at room temperature, which make it a potential material for spintronics. [3].
This paper focuses on the study of the magnetic properties of 9 nm magnetite nanocrystals. XRD and TEM measurements indicate the presence of crystalline particles, with a fraction of them only partially crystallized or highly defective. The analysis of the temperature dependence of the zero-field-cooled/field-cooled magnetization and of the thermoremanent magnetization provides evidence of the existence of three magnetic regimes [4]: 1) a high temperature superparamagnetic (SPM) regime (300−100 K), centered at a broad maximum due to the blocking process of particles moments; 2) an intermediate regime (100−30 K), centered at a maximum at the Verwey transition; 3) a low temperature regime (below 30 K) centered at a peak identifying a collective super-spin-glass type transition of particles moments.

TU.F-P69 - Magnetic properties of transition metal co-doped TiO_2 nanoparticles and local structure analysis by XAFS measurements

M. Hachisu [1], K. Mori [1], K. Hyodo [1], S. Morimoto [1], T. Yamazaki [1], Y. Ichiyanagi [1]

1. Yokohama National University, Yokohama, Japan

$Ti_{0.97-x}Co_{0.03}MxO_2$ (M = Fe, Mn, Nb x = 0, 0.02, 0.04) nanoparticles encapsulated with amorphous SiO2 were synthesized by our novel preparation method. An anatase TiO2 single-phase structure was confirmed using X-ray diffraction. The particle size could be controlled to be about 5 nm. The composition of these nanoparticles was investigated by X-ray fluorescence analysis. The magnetization curves for the nanoparticles indicated ferromagnetic behavior at room temperature. The dependence of the electrical conductivity on the frequency was measured by an LCR meter, and the carrier concentration was determined. X-ray absorption fine structure spectra (XAFS) showed that the Ti^{4+}, Fe^{3+}, Mn2+:3+=1:2, and Co^{2+} states were dominant in our prepared samples. A reduction in the coordination number was also confirmed. Magnetization value was drastically improved where M = Fe, x = 0.02 sample. We concluded that the ferromagnetism interaction originated in oxygen vacancies around the transition metal ions and exchange ferromagnetic or antiferromagnetic interaction occurred between transition metal ions.

TU.F-P70 - AC magnetic susceptibility and hyperthermia effect in vitro experiment of cozn-ferrite nanoparticles

Y. Ichiyanagi [1], T. Yamazaki [1], S. Morimoto [1], K. Hyodo [1], K. Mori [1], M. Hachisu [1]

1. Yokohama National University, Yokohama, Japan

CoZn-ferrite ($Co_{0.8}Zn_{0.2}Fe_2O_4$) nanoparticles (NPs) were prepared by the novel wet chemical method. Single phase spinel structure in amorphous SiO_2 was confirmed by X-ray diffraction patterns. Particle sizes were estimated between 5 and 17 nm. These magnetic particles were further functionalized for biomedical applications and cancer cell selective NPs were developed by conjugating with folic acid.

AC magnetic susceptibilities were measured by SQUID magnetometer. Temperature dependence of imaginary part of magnetic susceptibility χ" for various particle sizes of Co-Zn ferrites suggested that the particle system followed Néel relaxation theory. The peaks corresponding to freezing temperature T_f shifted towards higher temperature side as the particle size increased. χ" has a peak around 8 nm at 300 K, and this phenomenon indicated the most effective condition for heat dissipation upon an application of the external field. An AC field was found to cause an increase in temperature, with the 8 nm particles exhibiting the highest temperature increase as expected. In addition, *in vitro* experiments to study the hyperthermia effects of CoZn-ferrite particles on human cancer cells were carried out. Remarkable effect of magnetic hyperthermia was observed.

TU.F-P71 - Energy losses in bacterial magnetosomes

Magnetic losses in liquid suspension of magnetosomes can be investigated by analysis of minor hysteresis loops and specific absorption loss power determined calorimetrically. Hysteresis losses may be determined in a well-known manner by integrating the area of hysteresis loops, a measure of energy dissipated per cycle of magnetization reversal. It depends strongly on the field amplitude as well as the magnetic prehistory.
In our contribution we present the calculation of the energy contribution from hysteresis losses as a function of applied magnetic field. Losses were calculated from the minor hysteresis loops of magnetosomes extracted from Magnetotacticum Spirillum-AMB1. Samples of magnetosomes were divergent in length i.e. chains of magnetosomes have been modified due to mechanical effects during sonication. Specific absorption rate (SAR) values were 356 W/gmagnetite and 178 W/gmagnetite for samples IM (isolates magnetosomes) and SM (sonicated magnetosomes), respectively. These values were compared with results obtained from calorimetric measurements estimated at 10 kA/m and 508 kHz which were 963 W/gmagnetite and 463 W/gmagnetite for IM and SM samples, respectively. We can see that the obtained values for quasistatic experiments are lower comparing to the calorimetric measurement what largely reflecting higher relaxation during static measurements and thus a lower value of magnetic losses converted into heat.

TU.F-P72 - Arsenic adsorption in a magnetic stabilized bed made of magnetic aggregates based on hydrated iron oxides

A.M. Estevez [1], J.M Rodriguez [1], A. Alvaro [1], P. Augusto [1], C. Torrente [1], T. Castelo-Grande [2]

1. APLICAMA - Dep. Chem Engineering - Fac Chem Sciences - Univ Salamanca, Salamanca, Spain
2. LEPABE, Departamento de Engenharia Química, Faculdade de Engenharia da Universidade do Porto, Porto, Portugal

Arsenic contamination of waters represents a world-wide problem, and regions of Spain, North of Europe, Argentina, Bangladesh or India, are among the most problematic sites. Technologies have been investigated to handle this problem (e.g. precipitation, reverse osmosis). However all these technologies have been facing practical difficulties, which, together with the severity of the problem, implies the need to search for new methods for a more effective and economical elimination of arsenic in groundwater and surface water streams. Iron oxides have shown a high and effective capacity of water-contained arsenic adsorption. In the present work we have prepared magnetic aggregates based on hydrated iron oxide FeOOH - which high-adsorption capability was previously determined -, on magnetite and sodium alginate. These magnetic aggregates were then introduced in a magnetic stabilized bed (see Figure 1), through which arsenic contaminated water was driven.
Figure 1. Experimental Setup used: 1.- Deposit (Water and arsenic); 2.- Pumps; 3.- Valves; 4.- Flowmeter ; 5.- Thermometer; 6.- Manometers; 7.- Distributor; 8.- Solenoid; 9.- Adsorbent Bed of Particles. 10.- CC Power Source; 11.- Electrical Network; 12.-Sample Collection, 13.- Regenerator Deposit.
Results obtained show a good level of arsenic removal (26 mgAs/gFeOOH),. Using higher magnetic field intensities leads to an improvement in the water flowrate that we are able to treat. A first-order adsorption kinetic has been proven to exist by the kinetic study done. Adsorption constants were also determined, as well as the influence of the main variables on their experimental values, and they increase at high arsenic concentrations, as well as when water flowrate increases. A hydrodynamic study was performed, as well as the determination of the pressure drops and the interstitial velocities, as well as the minimum fluidization and elutriation velocities.

TU.F-P73 - Nanomagnetic particles synthesis: Comparision of methods and applications

P. Augusto [1], C. Torrente [1], A.M Estevez [1], T. Castelo-Grande [2], D. Barbosa [2], M. Gonzalez [1], M. Diego [1], E. Martin [1], B. Rodriguez [1], A. Sanchez [1]

1. APLICAMA - Dep. Chem Engineering - Fac Chem Sciences - Univ Salamanca, Salamanca, Spain
2. LEPABE, Departamento de Engenharia Química, Faculdade de Engenharia da Universidade do Porto, Porto, Portugal

Synthesis of nanomagnetic particles has experienced a boom in the last decade. However for practical reasons, and in the moment of choosing a manufacturing method, it is important to have a strong basis for a correct choice. Integrated Science, where in the same Research Project or Plan, the research is planned and followed from the initial production until the final applications, is amongst the most important driven goals set by the European Commission in the H2020 Programme. Therefore, in this work, we have investigated three of the mostly used magnetic particle synthesis methods - co-precipitation, microemulsion and pirolisis - and compared the final particles. We have produced magnetite particles in the micron size and found out that differences of pH of the magnitude of 1 do not influence the results. Then we have compared the different nanomagnetic particles produced by the three methods and concluded among others that: the co-precipitation method provides a cheat and simple way of manufacture, but there is an inherent heterogeneous distribution of sizes and, also, aggregates are hard to avoid; the microemulsion method provides a more homogenous distribution of sizes and avoids almost the formation of aggregates, but there are difficulties in getting the surfactant out of the particles, and it does not seem proper for larger-scale; in laser pirolisis the particles obtained show highly homogenity and may even achieve high rates of magnetization, however it has problems when larger nanosized particles are in order. We then made a literature review of several applications: environmental applications (ex.: heavy metal removal), magnetic hyperthermia, enzyme immobilization and biotechnical applications, and by comparison with the characteristics of the particles obtained in the three different methods, arrived to the conclusion that each application has its own needs and that dependent on the final application a determined synthesis method is mostly appropriated.

TU.F-P76 - Novel structures and spin correlations in nanomagnets

Spin-polarized nanoparticles or clusters have attracted much interest due to novel magnetic properties and potential applications in nanoscale spintronics, ultra-high density magnetic recording, and permanent magnetism. Furthermore, the nonequilibrium fabrication process used for clusters and particles can also stabilize metastable structures and often leads to new crystal and spin structures. In this talk, we discuss our recent work on Co-Si and Mn-Si nanoclusters, which exhibit magnetic properties significantly different from the corresponding bulk alloys. This includes highly anisotropic Co_3Si and Mn_5Si_3, Co_2Si nanoclusters exhibiting very weak itinerant ferromagnetism, and MnSi and CoSi nanoclusters with B20-type crystal structures. The unique nanocluster properties will be explained using DFT first-principle calculations. This research is supported by US-DOE and NSF-DMREF.

2. Swiss Light Source, Paul Scherrer Institut, Villigen-PSI, Switzerland

Iron oxide-based nanoparticles (NP) have outstanding magnetic properties and promising applications for spin-filter devices, biomedicine, and catalysis. In addition to finite-size effects, a key issue for research is how the intrinsic magnetic properties of the individual particles are modified by their own electronic structure, chemistry, surface termination and crystallinity.
By combining synchrotron X-ray absorption spectra (XAS) with photoemission electron microscopy (PEEM), we analyze the electronic structure and chemical bonding of individual, $Fe_{3-x}O_4$ and $Co_xFe_{3-x}O_4$ NP in the size range of 8 to 24 nm, synthesized by thermal decomposition of organometallic precursors [1], and deposited onto Si substrates. All the NP display high crystalline quality and macroscopic bulk-like magnetic properties [2,3]. However, the spectra from individual NP show that the variation of some synthesis parameters significantly alter the cationic distribution and the uniformity of magnetic phases [5]. In particular, In particular, 13-nm NP synthesized using oleic acid as a surfactant and iron oleate (III) as a metallic precursor are very homogeneous in stoichiometry, compatible with an Fe_3O_4 core surrounded by a thin γ-Fe_2O_3 shell. In contrast, 24-nm NP, synthesized with the same precursors but with a different solvent and no stabilizer, are inhomogeneous, composed of either a thick FeO or metallic Fe core surrounded by a thin Fe_3O_4 shell or an Fe_3O_4 core surrounded by a thin γ-Fe_2O_3 shell.
Furthermore, spatially-integrated X-ray magnetic circular dichroism (XMCD) spectra and element-specific hysteresis loops of mono-disperse assemblies of the $Co_xFe_{3-x}O_4$ NP using both electron and fluorescence yields have enabled the deconvolution of the electronic and magnetic contributions of the NP surface from those of the inner core regions.
This work was supported by MINECO (MAT2012-33037), DURSI (2009SGR856 and 2014SGR220), and European Union FEDER funds (Una manera de hacer Europa). A.F.R. acknowledges support from the MICIIN “Ramón y Cajal” Programme.

Co-ferrite nanoparticles (NPs) are especially suitable for potential applications in biomedicine and in technology because of their high values of the magnetocrystalline anisotropy, saturation magnetization and the magneto-optical coefficients. However, Co-ferrite NPs in literature show magnetic properties with high variability depending on the preparation method, what limits the standardization of those procedures for large scale applications. Consequently, the choice of a suitable synthesis method, where one can get control of the size, shape, stoichiometry and the crystallinity of the particles, is of key importance to make progress in the fundamental understanding of the properties of nanoparticulate Co-ferrite systems as compared to those of bulk-counterparts. Within this framework , we report on the effect of the 1,2-hexadecanediol content on the structural and magnetic properties of $CoFe_2O_4$ nanoparticles synthesized by thermal decomposition of metal-organic precursors in 1-octadecene. Although pseudo-spherical particles having an average size of about 8 nm and similar stoichiometry have been observed in all studied samples, a high level of variability of the crystal quality and, in turn, of the magnetic properties has been found as a function of the amount of 1,2-hexadecanediol added to the reaction mixture. The magnetic study reveals that samples progress from glassy magnetic behavior to bulk-like, ferrimagnetic order as the crystal quality improves. The analysis of the reaction mixtures by Fourier transform infrared spectroscopy at various stages of the reaction shows the key role of the 1,2-hexadecanediol on favoring the decomposition of the metal-organic precursor, formation of an intermediate $Co^{2+}Fe^{3+}$-oleate complex and, finally, the nucleation of nanoparticles at lower temperatures. This work was supported by Spanish MINECO (MAT2011-23641, MAT2012-33037, MAT2013-48054-C2), Catalan DURSI (2014SGR220) and European Union FEDER funds (Una manera de hacer Europa). C. Moya acknowledges Spanish MINECO for a Ph.D. contract (BES-2010-038075) and a three months stay at the ICMM-CSIC (Madrid).

TU.F-P81 - Designing new manganite/ferrite nanocomposites with tunable magnetic and electrical properties

G. Muscas [1,2,3], R. Mathieu [3], A. Puri Kumar [3], G. Concas [2], G. Varvaro [1], D. Peddis [1]

Entering the nanometer scale regime, the magnetic behavior changes dramatically with respect to the bulk state and new phenomena appear, such as Supermagnetism [1]. Nanostructured strongly electron correlated magnetic oxides represent a very interesting class of materials due to their electronic and magnetic properties and for their important technological applications (magnetic recording, biomedicine, ferrofluid technology, catalysis, etc.).In order to synthesize new or improved such transition metal oxide systems, we have developed new nanocomposites of Colossal Magneto-Resistance (CMR) manganites (i.e., $La_{1-x}Ca_xMnO_3$, LCMO) with a hard magnetic material as ferrites (i.e., $CoFe_2O_4$, CFO). This class of composites has already attracted a great interest for the Tunnel Magneto-Resistance effect (TMR) [2], employed in actual hard drives. We propose a new approach to synthesize nanocomposites $CoFe_2O_4/La_{0.67}Ca_{0.33}MnO_3$, in order to maximize interphase interactions. A comparison between such nanocomposites (NC) and a mechanical mixing (N-MIX) of the same two phases in nanoparticle phase is carried out by a complete structural and morphological characterization, together with detailed magnetometry studies. All the results suggest that a strong coupling only occurs for the NC sample, whose magnetic behavior resembles that of an exchange-spring system [3] as clearly indicated by both the M(H) curve (figure 1) and the associated switching field distribution.

We have investigated the structural and magnetic properties of the heavy-fermion $YbNi_2$ [1] crystalline alloy when submitted to high-energy ball milling. The sample was characterized by means of DC magnetic susceptibility and electron spin resonance (ESR) of the intrinsic Yb^{3+}. The analysis of the x-ray diffraction data shows a reduction of the particle size down to 12 nm for 20 h of milling time. The ferromagnetic (FM) contribution practically dissapears and a new magnetic phase arises at lower temperatures, below T_C, as observed in other rare earth FM alloys under mechanical milling [2]. In the vicinity of T_C = 10.5 K, the ESR parameters (linewidth and g-factor) show distinct anomalies, which can be associated with a presence of strong magnetic fluctuations at an onset of FM ordering. The Orbach-Aminov spin-lattice relaxation processes with the involvement of the first excited crystalline electric field level of Yb^{3+} at $\Delta \approx$ 75 K dominate the electron spin dynamics of $YbNi_2$ in the paramagnetic phase [3]. The Yb^{3+} ions in bulk $YbNi_2$ are primarily located in almost perfect cubic crystal field. Data of ESR measurements demonstrate different types of distortions observed in the core and the surface regions of the nanocrystallites.

Curved surfaces of nanoobjects result in the effective anisotropy-like effects and Dzyaloshinskii-like terms in the exchange energy [1]. Geometry of the Moebius ring allows combining of curvature-induced [1] and topological effects [2]. They influence the magnetic ground state as well as the magnetization dynamics. We study numerically and analytically the impact of curvature on the magnetic domain walls in Moebius ring of different sizes and easy-normal anisotropy [3]. Moebius ring topology leads to appearance of either longitudinal or transversal domain walls in the ground state. While the former wall type is favorable for the system with strong anisotropy (large quality factor, the ratio between the anisotropy and magnetostatic energies), the latter one appears when the quality factor is close to one. A vortex state is observed when the quality factor is small.
Furthermore, we show that the geometry induced Dzyaloshinskii interaction influences on the structure of the domain walls and determines their location in the Moebius ring. Namely, we found the presence of the coupling between the geometrical chirality of the Moebius ring and the direction of the magnetization rotation (magnetic chirality) of the walls: (i) The transversal domain wall always has the magnetic chirality opposite to the chirality of the Moebius ring and has a favorable position on the ring. (ii) The longitudinal domain wall is placed along the central line of the Moebius ring and has the same magnetic chirality as the sample.
The developed analytical approach can be readily applied to investigate a variety of geometries with vector fields defined on them. As an example, peculiarities of the magnetic domain wall structures will be discussed for the uniformly twisted strips.

Magnetic nanoparticles exhibit unique properties in comparison with their corresponding bulk analogues, originating from the size and surface effects of the nanostructured materials. The chemically synthesized FePt nanoparticles are of special interest. It was shown recently that thermal treatment of chemically synthesized materials can induce the phase transformation from the disordered *A*1 phase, with low anisotropy, to the ordered $L1_0$ phase creating the nanomaterials with high magnetocrystalline anisotropy. In our work we have prepared and studied the FePt core-shell nanoparticles with Pt shell. The particles were synthesized by a reverse micelle method based on the process of the self-assembly of surfactants (CTAB). The method allowed us to control the spherical shape of the particles as well as their size by tuning the molar composition of the reactants. The structural characterization of the nanoparticles was made by powder X-ray diffraction, XANES (X-ray Near Edge Spectroscopy) measurements at absorption edges of Fe K (7112eV) and Pt L3 (11564eV), ASAXS (Anomalous Small Angle X-ray Scattering) and HRTEM measurements. The measurements confirm the spherical, core-shell morphology of the prepared FePt particles, with the average diameter about 5 nm. The DC magnetic susceptibility, measured in ZFC and FC regimes using SQUID based magnetometer in temperature range of 2-300 K, shows on the unconventional behaviour of the sample with two blocking/freezing temperatures T_{B1}~ 5 K and T_{B2}~ 25 K, as determined from the two discrete maxima on the ZFC curve. The magnetization curves measured at different temperatures in the fields up to 5T confirm the existence of exchange bias. From the *M* (*H*) at 300 K the magnetic moment mP ~250 μB was calculated for as-prepared FePt nanoparticles. The magnetic relaxation study by AC susceptibilities (χ' and χ'') suggests the existence of strong dipolar interaction between nanoparticles. The characteristic relaxation time τ0 ~ 2 x 10-15 s, the measure of effective energy barrier T_0 = 10 K and effective anisotropy constant K_{eff} = 2.6 x10^6 J/m^3 were estimated from the magnetic relaxation studies.

TU.F-P85 - Nanocomposite magnetic materials obtained by synthesis of Fe nanoparticles in presence of $SrFe_{12}O_{19}$ nanoparticles

V. Nachbaur [1], N. Maât [1], E. Folcke [1], M. Jean [1], J.M. Le Breton [1]

Rare earth magnetic materials are ubiquitous in our current way of life, and more particularly when they are used as permanent magnets. Due to supplying troubles, toxicity and high cost of these compounds, their replacement by more available and affordable materials is a very current topic. Designing nanocomposites with high magnetic coupling is currently the subject of numerous investigations, and appears as a very promising way to obtain new permanent magnet materials. With this aim, we have synthesized and investigated strontium hexaferrite - iron nanocomposites. Synthesis of strontium hexaferrite, with the stoichiometry $SrFe_{12}O_{19}$, has been achieved with a solvothermal process followed by ceramic treatment. By modifying experimental conditions, various shapes and sizes (micronic, sub-micronic and nanometric) are obtained. Iron nanocrystallites were obtained by reduction of $FeCl_3$ iron chloride with $NaBH_4$ sodium borohydride as reducing agent. Iron crystallites appear as filaments linked by one common crystallographic direction, with a dimension of few nanometers. To obtain $SrFe_{12}O_{19}$/Fe nanocomposites, iron nanocrystallites were synthesized in presence of hexaferrite nanoparticles. Nanocomposites have been characterized by X-ray diffraction, electron microscopy (SEM and TEM), and magnetic measurements (VSM and SQUID). The influence of nanostructure on magnetic properties is identified and interpreted. The properties of the nanocomposites are intermediate between those of $SrFe_{12}O_{19}$ and Fe phases. The occurrence of magnetic coupling between iron and strontium hexaferrite particles is discussed. Financial support of the French “Agence Nationale de la Recherche” (ANR), through the program “Investissement d’avenir” (ANR-10-LABX-00-01) LabExEMC3 is gratefully acknowledged.

TU.F-P86 - Chemical synthesis of $SrFe_{12}O_{19}$ nanoparticles: influence of processing parameters on structural and magnetic properties

N. Maât [1], J.M. Le Breton [1], E. Folcke [1], A. Rossigny [1], V. Nachbaur [1], M. Jean [1], R. Lardé [1]

1. Groupe de Physique des Matériaux - UMR 6634 CNRS, Université et INSA de Rouen, France

Increasing the magnetic properties of $SrFe_{12}O_{19}$ hexaferrites by nanostructuration is one way to obtain rare-earth free new permanent magnet materials. We prepared $SrFe_{12}O_{19}$ nanostructured powders by hydrothermal processing of strontium and ferric nitrates in a Teflon lined bomb for temperature between 110 and 215°C and time between 5 and 90h. The influence of Fe/Sr ratio, synthesis temperature and synthesis time, on both structural and magnetic properties of the as-synthesized powders, was investigated. The powders were characterized by X-ray diffraction, transmission electron microscopy, scanning electron microscopy and VSM measurements. The first stages of formation of $SrFe_{12}O_{19}$ particles were investigated as well. The nanoparticles form in a crystalline state, grow first in the (a,b) plane of the hexagonal structure, and then in the c-direction. The results show that the best magnetic properties are obtained for a Fe/Sr ratio of 3, and synthesis at 170°C for 20h. These synthesis conditions correspond to the formation of single phase $SrFe_{12}O_{19}$ well-crystallized particles, about 200 nm large and about 30 nm thick. For a Fe/Sr ratio of 3, the powder is single phase, while for a higher ratio, Fe_2O_3 hematite is formed. For lower temperature and lower processing time, $SrFe_{12}O_{19}$ nanoparticles and secondary $Sr_3Fe_2(OH)_{12}$ phase coexist. For higher temperature and longer processing time, micrometric $SrFe_{12}O_{19}$ particles and Fe_2O_3 hematite phase coexist. Financial support of the French “Agence Nationale de la Recherche” (ANR), through the program “Investissement d’avenir” (ANR-10-LABX-00-01) LabExEMC3 is gratefully acknowledged.

The proposed use of exchange bias to overcome the superparamagnetic limit [1] triggered a renewed interest in bi-magnetic magnetic core/shell nanoparticles [2]. However, most of the studies are being carried out in ferromagnetic (FM) transition metal core and the corresponding antiferromagnetic (AFM) shell, (FM/AFM systems)[2]. In this work we present the study of the structural and magnetic properties of 'inverted' antiferromagnetic/ferrimagnetic (AFM/FiM) core/shell nanoparticles as opposed to the typical FM/AFM. The AFM/FiM nanoparticles were prepared by thermal decomposition of iron organic compounds leading to the AFM-core (FeO), which is passivated under air resulting in a FiM-shell (Fe_3O_4). Two extreme sizes of the AFM/FiM nanoparticles, small (9 nm) and large (45 nm), are investigated. The results show that while both systems exhibit some similar features, like exchange bias, there are also important differences [3]. The detailed characterization by neutron diffraction, Mössbauer, and electron spin resonance evidences that while the core in the large particles is antiferromagnetic and has a more bulk-like behavior, in the smaller ones the core is highly non-stoichiometric and strained, displaying no significant antiferromagnetism. Namely, while the large particles exhibit clear a transition at the Néel temperature, (TN) of the core (with an enhanced TN = 250 K) and a clear Verwey transition of the shell (despite its reduced thickness), the core in the small ones seems to be non-magnetic and the shell does not exhibit any Verwey transition. The results evidence that the spread of magnetic results in the literature for FeO/Fe_3O_4 nanoparticles stem from the strong size effects exhibited by this system and highlight the importance of ample characterization to fully understand the properties of nanostructured metal oxides.

3. Siberian Federal University, Krasnoyarsk, Russia

The work is devoted to the study of the morphology and magnetic properties of $Cu_{1-x}Fe_xCr_2Se_4$ nanoparticles synthesized via thermal decomposition of metal nitrate or chloride salts and selenium powder with different ratios of the raw material components in the high-temperature organic solvent. Correlations between technological conditions and nanoparticles morphology, on one hand, and between the morphology and magnetic properties of nanoparticles, on the other hand, are obtained. According to the high-resolution transmission electron microscopy data (JEOL JEM-2100), nanoparticles of two types coexist for all raw material compositions: thin hexagon plates and thin belts (for nitrate salts) or rods (for chloride salts). Moreover, all the types of the nanoparticles are single crystalline ones with the $CuCr_2Se_4$ structure, besides the particles with x=0.4 demonstrate a more complicated structure. For some compositions, the belts gather into large conglomerates forming hierarchical particles. The magnetization temperature dependences of the nanoparticles demonstrate different shapes for FC and ZFC modes characteristic for heterogeneous systems such as super paramagnetic particles. However, contrary to usual situations, the magnetization maximum is observed not only in ZFC but also in the FC curve. The maxima positions and widths depend on the nanoparticle morphology. The Curie temperature for all the samples with x=0 is about 410 K; it decreases with the x value increase. Magnetic circular dichroism (MCD) in the region 1.2-3.5 eV demonstrates several extremes of different signs, which are close to the maxima positions, observed in the spectrum of the imaginary part of the off-diagonal component of the optical conductivity tensor for the $CuCr_2Se_4$ single crystal [1]. The similarity of the MCD spectra for all the samples evidences the same nanoparticle electronic structure independent of their morphology.

TU.F-P89 - Magnetic and EPR studies of electron-hole asymmetry in bulk and nanoparticles of $Bi_{1-x}Ca_xMnO_3$ (x = 0.4, 0.6): A comparison

G. Singh [1], S.V. Bhat [2]

1. Department of Pjhysics, Indian Institute Of Science, Bangalore, India And National Physical Laboratory, New Delhi, India
2. Department of Pjhysics, Indian Institute Of Science, Bangalore, India

Electron-hole asymmetry, which refers to the asymmetry in the phase diagram across x = 0.5 in doped rare earth manganites such as $Re_{1-x}A_xMnO_3$ (Re is a trivalent rare-earth ion such as La, Bi, Nd, Pr, Sm and A is a divalent alkaline earth ion such as Ca, Sr, Ba, Pb) is known to vanish on reducing the size of the particles to a few nanometers. Bismuth based manganites provide an interesting model system for comparison: e.g. though the doped rare earth manganites show disappearance of charge order (CO) on size reduction to nanoscale, CO in Bi manganites is found to be more robust. Here we study the effect of size reduction on magnetic properties and EPR parameters of electron (x = 0. 6, BCE) and hole (x = 0.4, BCH) doped $Bi_{1-x}Ca_xMnO_3$ (BCMO). Nearly spherical nanoparticles (D ~ 30 nm) of BCMO were prepared by sol-gel synthesis and the bulk samples using the solid state reaction route. Magnetic and X-band EPR measurements were carried out on all the samples. Lineshape fitting was carried out using the double Lorentzian function accounting for clockwise and counterclockwise rotating components of the microwave field. It is found that the electron-hole asymmetry in the nanoparticles of electron doped (x = 0.6) and hole doped (x = 0.4) $Bi_{1-x}Ca_xMnO_3$ samples still persists. The values of the extracted EPR 'g' parameter for the bulk and the nano samples indicate that the electron-hole asymmetry has reduced but has not completely vanished in the BCMO samples.

TU.F-P90 - Preparation and magnetic properties of interaction-free magnetite nanoparticles

J. Balachandran [1], M. Fukunaga [1], I. Furukawa [1], J. Cuya [1], H. Mamiya [2], H. Miyamura [1]

1. The University Of Shiga Prefecture, Hikone, Japan
2. National Institute of Materials Science, Tsukuba, Japan

Synthesis routes for magnetic oxide, metal and alloy nanoparticles (NPs) have witnessed unprecedented growth since the year 2000. Especially, the main focus has been on monodispersity, controllability of size, stability and composition of the NPs. However, despite the fact that considerable progress has been made in the size and size distribution control, the true magnetic characteristics of NPs is yet to be revealed due to interaction between particles. As a consequence, the application-oriented design of magnetic particles has become difficult. Thus in this study, we have attempted the preparation of interaction-free magnetite nanoparticle (MNPs) system, intending their application in the field of magnetic fluid hyperthermia, by coating the same with silica-shell of different thicknesses and measured their temperature dependence of magnetization and First Order Reversal Curve (FORC) analysis to evaluate the magnetic interaction qualitatively and quantitatively. First, magnetite particles with average diameter of 7.8 nm were synthesized by reducing goethite in 1-octadecene. Then, these magnetite particles were coated with silica shell thicknesses of 6.5, 13.7 and 20.8 nm. When zero-field cooled and field cooled temperature-dependent magnetization of these samples were measured, the peak of the normalized magnetization as a function of temperature shifted to lower temperature for increasing silica-shell thicknesses. And also, the low temperature increase in the field-cooled magnetization became pronounced as the silica-shell thickness became larger. These results indicated the decrease in magnetic interaction with the increase in inter particle distance caused by thicker silica-shell qualitatively. To measure the magnetic interaction between particles quantitatively, FORC analysis was performed on dry uncoated and silica-coated MNPs. The results suggested that the interaction field decreases with increasing silica-shell thickness of 6.5 and 14 nm, compared to uncoated magnetite particles. Furthermore, the preparation of an interaction-free sample was confirmed when the magnetite particles were coated with a silica shell thickness of 20.8 nm.

TU.F-P91 - Acoustic investigation of biocompatible magnetic fluid under magnetic field

P. Bury [1], J. Kúdelčík [1], S. Hardon [1], M. Kubovcikova [2], M. Timko [2], P. Kopčanský [2]

1. Department Of Physics, Žilina University
2. Institute of Experimental Physics, Slovak Academy of Science, Bratislava, Slovakia

The study of structural properties of biocompatible magnetic fluid (BCMF) is very important in view of their biomedical applications as magnetic drug targeting (MDT), magnetic resonance imaging (MRI), hyperthermia effect and so on. The behavior of BCMF in an external magnetic field was studied by acoustic spectroscopy. The linear increase, decrease and jump change of the external magnetic field up to 300 mT was applied and corresponding changes of acoustic attenuation were studied. The strong dependence of acoustic attenuation on magnetic field intensity, magnetic field sweep rate and time of exposure were observed. These effects are connected with the structural changes of magnetic nanoparticles in the water-based magnetic fluid when an external magnetic field is applied. The interaction between the magnetic field and the magnetic moments of the nanoparticles leads to the aggregation of magnetic nanoparticles and following clusters formation. Measurements were made also for several temperatures from the range of 15-30 ^{o}C to know the influence of thermal motion to cluster creation. The significant influence on the change of acoustic attenuation was observed, too. The obtained results are very important for MDT for example, for the using of optimal concentration of MNPs as it is impossible to use very concentrated BCMF due to the strong aggregation of MNP.

TU.F-P93 - Cobalt ferrite nanoparticles: A two phases behavior at low temperature

M. Saidani [1], W Belkacem [1], A. Bezergheanu [2], N. Mliki [1], C. Bazil Cizmas [2]

1. Laboratoire Matériaux, Organisation et Propriétés, Faculté des Sciences de Tunis, Université de Tunis El Manar, Tunis, Tunisia
2. Transilvania University of Brasov, Dept. Electrical Engineering & Applied Physics, Brasov, Romania

Studies of the $Co_xFe_{3-x}O_4$ (x = 0, 0.4, 0.8 and 1) ferrite nanoparticles prepared by a solvothermal chemical route are herein presented. The microstructure has been studied by X-ray diffraction (XRD) and by transmission electron microscopy (TEM) and. The XRD patterns were mainly indexed with a cubic spinel structure. The TEM analysis shows a decrease of the mean size when x increases and HRTEM analysis for x = 1.8 exhibits a very irregular shape that can exert strains on the magnetic results. The magnetic dynamics behavior is investigated by measurements of magnetic hysteretic properties and zero field cooling (ZFC) susceptibility. These measurements were performed by VSM method in temperature range of 5K-700K and magnetic field up to 7T. The dependence of the irreversibility field, inversely proportional to the particle size, clearly indicates that the magnetic anisotropy of our particles finds its origin on the surface layer. The behavior of the magnetization at low temperature is interpreted in terms of surface interparticle interactions effects by means of the power Bloch law and the Kneller law. When increasing x from 1 to 1.4, no noticeable variations in the coercivity at 10 K has been detected whereas a decrease of the saturation magnetization has been found. This could be related to the effect of the value of the Co^{2+} magnetic moment which it is less than that of Fe^{3+}. The other samples exhibit a different behavior. Fitting the saturation magnetization dependence vs the temperature using the power T3/2 Bloch law has confirmed the existence of the frustration of the surface moments. Also, for x = 0, we have identified the presence of the hematite with a ratio of 42 % while we didn't identify any additional phase (like maghemite or magnetite) for the other contents.

TU.F-P94 - Small angle neutron scattering and superspin glass behavior in compacts of as-received and 350 ^{o}C-annealed maghemite nanoparticles

P. Normile [1], D. Alba Venero [2], R. Fan [3], S. King [2], G. Singh [4], S.S. Lee [5], D. Marques [1], P. Muñiz [1], J.A De Toro [1]

5. Institute of Bioengineering and Nanotechnology, 31 Biopolis Way, The Nanos, Singapore, Singapore

A compact of highly monodisperse, essentially bare maghemite nanoparticles (NPs) was recently reported to exhibit model superspin glass (SSG) behavior [1]. Here, a similar compact together with a second compact of NPs from the same (washed) powder batch but annealed at 350 ^{o}C in air (prior to compaction) are studied by small angle neutron scattering (SANS). The purpose of the annealing is to boil off any small residue of the oleic acid surfactant (still coating the particles after washing) and thus provide “truly” bare maghemite particles. Transmission electron microscopy, however, suggests the annealing also yields an initial stage of particle coalescence. The second compact shows very similar scaling of the magnetic relaxation time in AC susceptibility to the first, but its SSG freezing transition (in DC magnetization) is 202 K compared to 165 K in the as-received NP compact. A structural correlation peak indicative of a random close packing (RCP) of spherical particles is clearly observed in the SANS from the first compact but is absent in that from the second, where a significantly wider particle size distribution (but just a 5 % larger mean diameter) is found. By recording the difference between SANS registered with and without a saturating magnetic field applied to the sample, a magnetic contribution to the scattering is identified in both compacts. Field is found to drive the majority of magnetic correlations to length scales beyond the capability of the experimental setup (Qmin = 0.1 nm^-1) in both, however, differences in the temperature and field dependence of the magnetic scattering exist. For example, in the first compact, depending on its magnetic history, field also induces magnetic correlations at the position of the RCP correlation peak.

4. EMAT, University of Antwerp, Antwerp, Belgium
5. CNR-ICCOM, Sesto Fiorentino, Firenze, Italy

The exchange bias effect, first reported by Meiklejohn and Bean in Co|Co ferromagnetic(FM)|antiferromagnetic(AFM) core-shell (CS) nanoparticles [1], manifests as a horizontal hysteresis loop shift and a coercivity increase due to interface coupling between AFM and FM or ferrimagnetic (FiM) phases. Interestingly, being an interface effect, exchange bias is only observed at the nanoscale. In the last decades main efforts were devoted to study exchange bias in thin films. However, with the increased capability of synthesizing CS nanoparticles with controlled features, the interest extended to these kinds of structures as well. Here, an investigation on inverted AFM|FiM CS noparticles of formula $Co_xFe_{1-x}O$ | $Co_xFe_{3-x}O_4$, is presented. Narrowly size distributed CS nanoparticles with mean diameter from 7 to 20 nm were synthesized by thermal decomposition of mixed iron and cobalt metal-oleate, leading to the formation of an AFM-core ($Co_xFe_{1-x}O$) which is passivated under air yielding the corresponding FiM-shell ($Co_xFe_{3-x}O_4$). The presence of a $Co_xFe_{1-x}O$ | $Co_xFe_{3-x}O_4$ CS structure was confirmed by X-ray Diffraction and Electron Energy Loss Spectroscopy analyses: all the samples are characterized by the presence of a constant FiM shell thickness (tShell=2 nm) and a variable AFM core diameter (dCore=7,11,16 nm). Low temperature hysteresis loops revealed the presence of exchange bias and increased coercivity as indeed expected for a good exchange coupling between core and shell phases. Since the exchange bias effect is affected in an entangled way by the core and shell size [2], the synthesized NPs were used to systematically address the effect of the size of AFM counterpart which has been less studied than the FM size dependent properties. (Research supported by EU-FP7 NANOPYME Project (No. 310516) [www.nanopyme-project.eu] and EU-FP7 ESTEEM2 Project (No. 312483)).

TU.F-P96 - Mössbauer and magnetic study of $Co(Ti,Sn)_xFe_{2-x}O_4$ nanoferrites

J.Z. Msomi [1], N. Ngema [1], T. Moyo [1]

1. School of Chemistry and Physics, University of KwaZulu-Natal, Durban, South Africa

Sn or Ti-substituted $CoFe_2O4$ ferrite, $Co(Ti,Sn)_xFe_{2-x}O_4$ (0=x=1.0, in steps of 0.1), fine powders with particle size of about 10 nm were synthesized by high energy ball milling. The compounds were also prepared by hydrothermal process to study the relationship between the preparation processes and the magnetic processes. TEM analysis shows formation of spherical nanoparticles with spherical nanoparticles. Our work indicates that the various synthesis routes can determine the properties of the magnetic nanoparticles. The properties of the nanosized specimen produced are compared to those of bulk samples reported in previously [1]. The Mössbauer spectra indicate ordered magnetic spin state in all the compounds. The evolution of the magnetic properties as a function of particle size is also presented.

TU.F-P98 - Structural and magnetic properties of $CoFe_2O_4$ nanoparticles diluted in SiO_2 amorphous matrix

J. Duque [1], H. C. Costa [1], J. S. Lima [2], A. Coelho [3], T. Meneses [1]

1. NPGFI, Federal University of Sergipe, São Cristóvão, Brazil
2. Unidade Académica de Física, Universidade Federal de Campina Grande, Campina Grande, Brazil
3. Instituto de Física 'Gleb Wataghin' – UNICAMP, Campinas, Brazil

In this work, we carried out a systematic study of the structural and magnetic $CoFe_2O_4$ nanoparticles embedded inside a SiO_2 amorphous matrix. In order to control the mean distance between particles we have prepared via sol-gel method different samples changing the amount of Fe and Co salts and the tetraetilortossilicato (TEOS). X-ray, transmission electron microcopy and magnetization analysis allow us to estimate the particle mean size. Besides, all analyzed samples present single crystalline phase belonging to the spatial group Fd3m. The T-dependence of the magnetization shows typical behaviors of a classical magnetic nanoparticle system, that is, a maximum in the ZFC curve and a thermal hysteresis in the low temperature region. It was observed a displacement of the maximum into high temperatures for increasing the $CoFe_2O_4$ nanoparticles in the SiO_2 matrix. The coercive data were fitted for using a generalized model which take account the particle size distribution of the system. Finally, we have attributed the change in maximum of ZFC curve and the decreasing in the effective anisotropy constant to the possible interparticle interactions.

TU.F-P100 - Ultrafast hyperthermia using Fe_3O_4 nanoparticles

V. Tzitzios [1], G. Basina [2], C. Hadjipanayis [3], G. Hadjipanayis [4]

1. Institute of Materials Science, Demokritos, Athens, Greece
2. Department of Chemistry, University of Crete, Voutes, Heraklion, Greece
3. Department of Neurosurgery, Emory University School of Medicine, Winship Cancer Institute of Emory University,GA, United States
4. Department of Physics and Astronomy, University of Delaware, Newark, DE, United States

In the past few years, much work has been published on Fe_3O_4 nanoparticles especially on synthetic protocols to control their size, shape and surface functionality.[1] For optimal magnetic hyperthermia, the maximum Specific Loss Power (SLP) for isolated Fe_3O_4 nanoparticles was reported in the 10-15 nm size range.[2] More recently, it was reported that nano-assemblies of Fe_3O4 nanoparticles can lead to significantly increased SLP values.[1, 2,3].
In this study, we report an alternative synthesis of Fe_3O_4 nano-assemblies based on a modified polyol method that uses Fe lactate as the iron source in the presence of poly-vinyl-pyrrolidone (PVP) as the morphogenetic and capping agent. The as-made PVP coated Fe_3O_4 nano-assemblies, were further functionalized by citrate ions in order to increase their water solubility. The nano-assemblies have a flower-like morphology with 30-40 nm mean diameter and consist of 6-8 nm mean diameter isolated Fe_3O_4 nanoparticles. The temperature profiles, obtained from hyperthermia measurements in water solution, showed an increase in temperature from 293 to 338 K (ΔT=45 K) after only 79 sec of field exposure with a very high heating rate of 0.57 ^{o}C/sec in the case of citrate functionalized nanoparticles. Future in vitro hyperthermia studies on therapy-resistant human brain cancer (glioblastoma) cells will also be performed with the Fe_3O_4 nano-assemblies. In addition, distribution and in vivo hyperthermia studies will be performed by MRI in an intracranial rodent glioma model.

Cubic-shaped Fe_3O_4 nanoparticles (NPs) with a size of approximately 40 nm were synthesized by the reduction of $Fe(acac)_3$ as a precursor; benzyl ether and squalane as the solvent; and decanoic acid as the stabilizing ligand. We have investigated the influence of the oxidation on the magnetic properties of the NPs. The morphology, structure and magnetic properties of the NPs were investigated using analytical tools such as transmission electron microscopy, X-ray diffraction (XRD), thermogravimetric analyses, ferromagnetic resonance (FMR), micro-Raman spectroscopy and vibrating sample magnetometry. XRD analysis showed peaks characteristics of the Fe_3O_4 phase for the sample. The NPs exhibit ferrimagnetic properties with a relatively high saturation magnetization of 80 emu/mg at room temperature. In the zero-field-cooled and field-cooled magnetization curves a sharp Verwey transition at 120 K was observed for stoichiometric magnetite NPs. The Verwey transition was also observed in temperature dependent FMR measurements. The NPs oxidized in air at room temperature for a time period of a few months. In the oxidized NPs, the Verwey transition is broadened and shifted to lower temperatures due to a maghemite shell surrounding the NPs. Structural investigations by micro-Raman spectroscopy also revealed magnetite NPs with a partial surface oxidation to maghemite.

TU.F-P102 - SANS, Mössbauer and magnetic characterization of interacting iron oxide nanoparticles

The magnetic properties of an ensemble of iron oxide nanoparticles (IO-NPs) primarily depend on the structural properties of the individual particles, but also on interparticle interactions, which has significant implications e.g. in biomedical applications such as hyperthermia. To standardize the magnetic parameters driving those applications is a need for the near future. In the present study two samples of IO-NPs with nearly identical average core diameters (10-11 nm), but with different interparticle distances, were characterized by Small Angle Neutron Scattering (SANS), Mössbauer and magnetization measurement. In the first sample, the particles were coated with an organic surfactant (DMSA) and aggregated to clusters consisting of several dozens individual particles. In contrast, the particles of the second sample were surrounded by a rigid silica shell with a thickness of abour 30 nm, increasing the interparticle distance to at least 60 nm and as result significantly decreasing the amount of dipolar interactions. According to Mössbauer measurements the IO-NPs in both samples were predominantly composed of maghemite and exhibited low polydispersity < 6%, as verified by SANS. Hence, the two particle systems can be regarded as model systems to investigate the influence of dipolar interactions on the magnetization behavior of aggregated and nearly monodisperse IO-NPs. In this work the Zero-Field-Cooled and the Field-Cooled curves of both samples were adjusted by global fitting routines [1], which were modified e.g. to incorporate the influence of dipolar interactions. This work is part within a 18-institution consortium to standardize IO-NPs and is supported by EC FP7 NMP project NanoMag Project (grant no. 604448).

TU.F-P103 - The effect of pH on the structural and magnetic properties of $MnFe_2O_4$ nanoparticles synthesized via proteic sol-gel process

N. Ferreira [1], S. Farias [1], M. Macêdo [2]

1. Departamento de Física, Universidade Federal do Amazonas, Manaos, Brazil
2. Departamento de Física, Universidade Federal de Sergipe, São Cristóvão, Brazil

During the past few decades, the design, preparation and characterization of spinel ferrite nanoparticles have been the subject of intense research not only for their fundamental scientific interest but also for their high potential for application in high-density magnetic recording, ferrofluids technology, magnetic resonance imaging, and biomedical drug delivery. In this work, we report the structural, microstructural, and magnetic properties of $MnFe_2O_4$ nanoparticles synthesized via proteic sol-gel method at different pondus hydrogenii (pH) value. Five solutions were prepared by adding 5g of $Fe(NO_3)_3{\cdot}9H_2O$ and 1g of $C_4H_6MnO_4$ to 25 mL of *in natura* coconut water. 1M NaOH solution slowly dropped in each one of the 5 solutions to change the pH values to 2, 4, 7, 10 and, 12. Then, the mixtures were polymerized to form the gels at 100°C for 24h and, after that, calcinated at 400°C for 1h to produce the nanoparticles. According to XRD and TEM studies, all $MnFe_2O_4$ samples were cubic spinel single phase with space group Fd-3m. The crystal lattice constant was decreased gradually from 0.8526 to 0.8464nm with pH increasing from 2 to 12. In addition, the average crystallite size, which is determined from Scherrer formula, was about 14-35nm. The magnetization results showed small hysteresis loops. The saturation magnetization increased from 51 emu/g to 65 emu/g with pH increasing from 2 to 12, which is among the best values reported so far. Meanwhile, the coercive force increased drastically from 6.7 to 73Oe. This behavior suggests that the variation of the cationic distribution between octahedral and tetrahedral sites contribute to the unique magnetic behavior of the samples at room temperature. Our results indicate that adjusting in pH *enhances* systematically the structural and magnetic properties of the $MnFe_2O_4$ nanoparticles synthesized via proteic sol-gel process.

TU.F-P104 - XRD, Mössbauer and magneticstudy of $Mn_xMg_{0.5-x}Zn_{0.5}Fe_2O_4$ nanoparticles

W.B. Dlamini [1], J. Msomi [1], T. Moyo [1]

1. University Of KwaZulu-Natal, Durban, South Africa

We report Mn substitution in Zn-Mg ferrite nanoparticles. Single phase nanoferrite powders bearing the chemical formula $Mn_xMg_{0.5-x}Zn_{0.5}Fe_2O_4$ ($0 \leq x \leq 0.5$ in steps of 0.1) were produced by co-precipitation technique. The compounds were characterized by X-ray diffraction, Mössbauer and VSM measurements. The particle size varies between 9 nm and 15 nm. Changes in the saturation magnetization and coercive fields with increasing Mn content have been observed. Mössbauer spectra reveal transformation from ordered to disordered magnetic spin state with increasing *x*. The variation of the magnetic parameters such as coercive fields and saturation magnetization as a function of temperature is also presented.

TU.F-P105 - Magnetic properties of $Mg_{0.5}Co_{0.5}Fe_2O_4$ and $Mg_{0.8}Co_{0.2}Fe_2O_4$: The effect of milling

W.B. Dlamini [1], J. Msomi [1], T. Moyo [1]

1. University Of KwaZulu-Natal, Durban, South Africa

In the present work, $Mg_{0.5}Co_{0.5}Fe_2O_4$ and $Mg_{0.8}Co_{0.2}Fe_2O_4$ nanoparticles with particle diameters of about 15 nm were synthesized by glycol-thermal reaction. To further reduce the particle size and to study the effect of milling, the as prepared specimens were then milled for up to 40 hours. The properties of the as-prepared, milled and bulk compounds are compared. The phase purity and morphology of the compounds are investigated by X-ray diffraction, transmission electron microscopy and Fourier Transform infrared spectroscopy. The 57Fe Mössbauer effect spectra show ordered magnetic spin state in both $Mg_{0.5}Co_{0.5}Fe_2O_4$ and $Mg_{0.8}Co_{0.2}Fe_2O_4$ nanosized compounds. The M-H loops of the compounds have been traced using the Vibrating Sample Magnetometer (VSM). The magnetization data show an increase in coercive fields to a maximum value and then a reduction with further milling. This is explained on the basis of domain transformation from multi- to single-domain behaviour. The variation of magnetization as a function of temperature (FC and ZFC) is also presented.

TU.F-P106 - Modulation of interacting phenomena in iron oxide nanoparticle colloids

D. Cabrera [1], D. Ortega [1,2,3], G. Salas [1,2], F.J. Teran [1,2]

1. Imdea Nanociencia, Madrid, Spain
2. Unidad Asociada de Nanobiotecnologia, CNB-CSIC ---IMDEA, Madrid, Spain
3. Institute of Biomedical Engineering, University College London, London, United Kingdom

Iron oxide nanoparticles (IONP) have attracted much attention due to their capabilities acting as magnetic nanocarriers, hyperthermia mediators and/or contrast agents. Their applications in biomedicine mainly relies on their magnetic response, which can be significantly altered by magnetic dipolar interactions. Hence, controlling the latter is of great importance towards the clinical use of IONP as reliable actuators.
Here, we report on the influence of particle size, media viscosity as well as field amplitude (H) and frequency (f) conditions on interacting phenomena. We assess the specific absorption rate (SAR) and AC hysteresis loops of IONP colloids. Recently, a theoretical model was proposed[1] for describing magnetic dipolar interactions and their implications on tuning the dynamical magnetic response of IONP colloids when varying particle concentration. Our results indicate that SAR concentration dependence is tightly related to particle size. While large sizes (19 nm) show a non-monotonic behaviour with a relative SAR maximum within a given concentration range, small sizes (12 nm) show a progressive SAR decay until reaching a minimum which remains constant in the studied concentration range. The variation of H and f gives rise to a rich variety of behaviours resulting in a progressive SAR decay (at low-f) towards non-monotonic behaviour (at high-f). Relative SAR maxima occurring at given concentrations which tightly depend on H. Considering that SAR = A*f, where A is the area of hysteresis loop, we have proven how magnetic parameters involved in the A determination (i.e. coercitivity and remanence) differently change with IONP concentration. We also show the role of colloidal viscosity in shaping hysteresis loops with smaller squareness with respect to water dispersions, and consequently reducing the heating efficiency. Finally, we discuss the departure of our data from the currently available physical models (i.e. LRT or Stoner-Wohlfarth based models).

TU.F-P107 - Effects of vanadium doping on the magnetism of FeCo and FeCo/SiO_2 Core/Shell nanoparticles

R. Desautels [1,2], J. Freeland [3], M. Rowe [2], J. van Lierop [1]

1. University Of Manitoba, Winnipeg, Manitoba, Canada
2. Toyota Research Institute of North America, United States
3. Argonne National Laboratory, Lemont, United States

The breadth of magnetically soft alloys accessible through traditional top-down metallurgical techniques is far narrower in nanoparticle form. Additionally, in magnetic nanoparticle systems, complex core/shell structures have been shown to exhibit unique and useful magnetism from interfacial effects. Core/shell nanoparticles are the ideal ingredient for todayíªs high quality devices and other nanoscale technological applications, however, a detailed understanding of their magnetism is lacking. Furthermore, physical properties such as ductility are of significant importance for the fabrication of devices. Historically, vanadium has been added to increase the ductility of the ingredients used. Here, we report on the effects that vanadium doping of FeCo and FeCo/SiO_2 nanoparticles has had on their structure, composition and magnetism. X-ray powder diffraction experiments and transmission electron microscopy images have indicated that these nanoparticle (doped and not doped) were amorphous, and for the core/shell systems the silica coating encompassed the nanoparticles completely. X-ray absorption spectroscopy (XAS) and magnetic circular dichroism (XMCD) experiments indicated that these amorphous nanoparticles, free of oxygen contamination, formed complex strained systems. XAS spectra presented mixed metallic and non-metallic-like features, however, XMCD spectra were purely metallic-like. A marked increase of the nanoparticles coercivity as well as a decreased saturation magnetization occurred with V-doping in both FeCo nanoparticles and FeCo/SiO_2 core/shell nanoparticles, despite similar blocking temperatures. In addition, only V-doped FeCo/SiO_2 nanoparticles exhibited an exchange bias loop shift of 0.141(1) T at 5 K, likely from the formation of a V-oxide (identified by XAS spectra) interfacial region in-between the FeCo core and SiO_2 shell. Magnetic anisotropies were calculated from χAC susceptibility experiments and were an order-of-magnitude larger in comparison to the bulk counterparts of the nanoparticles, consistent with these high surface area systems.

TU.F-P108 - Iron/silicon/ silica nanoparticles synthesized via laser pyrolysis technique and thermal treatment

A multitude of iron based nanoparticles, such as iron oxides, metallic iron embedded in polymer or amorphous carbon matrix, iron carbides or iron nitrides are found in many bio-medical, pharmaceutical, and industrial processes or products due to their magnetic properties. On the other hands, SiO_2 nanoparticles possess a low to an inert toxicity and no proved toxicological change in drug delivery applications. Therefore, composite nanoparticles with iron based core and silica shell should provide benefit properties: high magnetic susceptibility and low toxicity. Laser pyrolysis was used to synthesize almost spherical Fe@Si nanoparticles with superparamagnetic properties, high saturation magnetization (more than 50 emu/g), 8-12 nm mean size diameter and narrow size distribution. TEM, SAED, XRD, EDX and VSM (virgin curve and hysteresis loop) measurements were used for structural and magnetic characterization of as synthesized and thermal treated powders. In optimal conditions nanopowder with iron based core with silica shell were obtain. The both proposed nanomaterials, as synthesized and thermal treated, possess good water compatibility. Stable dispersions with 40 to 100 nm hydrodynamic diameter were realized using L-3,4-dihydroxyphenylalanine (L-Dopa) or sodium carboxymethylcellulose (CMC-Na) as stabilizers. Some suspensions with a high degree of nanoparticle concentrations (5, 10 or 20 g/l) have high saturation magnetization values, up to 5 Gs.

TU.F-P111 - Magnetic and structural characterization of the cobalt ferrite nanoparticles

We present a systematic study on the structural and magnetic properties of $Co_xFe_{3-x}O_4$ magnetic nanoparticles (MNPs) with sizes between 5 to 25 nm, prepared by thermal decomposition of Fe(acac)3 and Co(acac)2. The correlation between magnetic parameters and size, morphology and stoichiometry of the MNPs are analyzed. All samples were indexed within the Fd_3m space group as expected for cubic spinel crystal structure. A systematic deviation of the atomic Co:Fe ratio from the stoichiometric 1:2 value is present in all samples, and this composition is demonstrated to be present and homogeneous both at macroscopic and single-particle scale. Magnetization M (T,H) data reflected the large crystalline magnetic anisotropy of the MNPs through high blocking temperatures (TB) and large coercive fields (HC ≈ 1.6 MA/m for T = 5 K). For the smallest particles (<d>=5 nm), surface spin disorder the M(H) curves do not saturate up to H = 11.2 MA/m (14 T), suggesting the existence of a magnetically hard surface. The large magnetic anisotropy allowed seeing that the temperature dependence of HC (T) deviates from the usual T 1/2 law expected for thermally-driven magnetic (Neel) relaxation of single domain MNPs.

TU.F-P113 - Room temperature ferromagnetism in (Fe,Cr)-doped $CeO_{2-\delta}$ nanoparticles synthesized by proteic sol-gel process

N. Ferreira [1]

1. Departamento de Física, Universidade Federal do Amazonas, Manaus, Brazi

Room-temperature ferromagnetic semiconductors have generated extraordinary research interest due to their potential applications in spintronic devices. More recently, theoretical studies have predicted room-temperature ferromagnetism mediated by doping with qualified transition metal in several inorganic oxides. Among these, cerium oxide (CeO_2) has been extensively studied because its electronic configuration and structural properties are similar to silicon. In the present study, Cr and Fe co-doped $O_{2-\delta}$ nanoparticles were synthesized successfully via proteic sol-gel process. The CeO_2, $Ce_{0.95}Fe_{0.05}O_{2-\delta}$ and $Ce_{0.93}Fe_{0.05}Cr_{0.02}O_{2-\delta}$ samples were prepared by dissolving $Fe(NO_3)_3{\cdot}9H_2O$, $Cr(NO_3)_2{\cdot}9H_2O$ and $Ce(NO_3)_3{\cdot}6H_2O$ with suitable stoichiometries in coconut water (*Cocos Nucifera*). Then, the mixture was polymerized to form the gel at 100°C for 24h and, after that, calcinated at 400 °C for 1h to produce the nanoparticles. X-ray diffraction reveals that the CeO_2, $Ce_{0.95}Fe_{0.05}O_{2-\delta}$ as well as $Ce_{0.93}Fe_{0.05}Cr_{0.02}O_{2-\delta}$ nanoparticles were cubic in structure (fluorite phase) and no other secondary phase was found in all the samples indicating that Cr and Fe cations are substituted at the Ce sites. Transmission electron microscopy measurements show that the average size of these nanoparticles is in the range 10-20 nm. It was observed that all samples showed the Raman vibrational frequency around 468 cm^{-1}, which is the expected value for the vibrational mode of the Ce-O_8. CeO_2 nanoparticles exhibit diamagnetism while $Ce_{0.95}Fe_{0.05}O_{2-\delta}$ exhibit saturated hysteresis loop at room temperature indicating ferromagnetic behavior (M_s~0.13 emu/g). Moreover, the M-H curves at room temperature for the $Ce_{0.93}Fe_{0.05}Cr_{0.02}O_{2-\delta}$ nanoparticles indicated enhancement in ferromagnetism (M_s~0.34 emu/g). Our results demonstrate that proteic sol-gel process can be used to synthesize Fe and Cr doped CeO_2 nanoparticles with potential for spintronics applications.

TU.F-P114 - Synthesis, structural and magnetic properties of mixed Zinc-Cobalt ferrite nanoparticles

P. Copolla [1], G. Siqueira Gomide [3], F. Gomes da Silva [2], F.L. de Oliveira Paula [3], R. Aquino [2], J. Depeyrot [3], F. Augusto Tourinho [1]

3. Grupo de Fluidos Complexos, Instituto de Física, Universidade de Brasília, Brasília, Brazil

Magnetic ferrite nanoparticles (NPs) have attracted considerable attention because of their electrical, structural, optical and magnetic properties that lead to novel technological and biological applications. We currently elaborate ferrite based NPs in order to disperse them in water [1]. In this context, we have synthesized several samples of $Co_{(1-x)}Zn_{(x)}Fe_{(2)}O_{(4)}$ mixed ferrite NPs, each one with a different stoichiometric parameter x varying from 0.1 to 0.9. Our NPs, obtained by hydrothermal coprecipitation in alkaline medium, have their chemical composition checked by using atomic absorption spectroscopy and their structure by X-Ray Diffraction (XRD) experiments realized on powder samples. In addition, Transmission Electron Microscopy (TEM) pictures show their morphology and allow a mean size determination. It clearly indicates a mixture of nanospheres and nanocubes of similar sizes. This is described by an averaged size, which well matches the one deduced from XRD analysis, performed by Rietveld refinement. The diffractograms reveal for all samples a pure spinel structure, with zinc ions mostly located at tetrahedral sites and cobalt ions mainly distributed among octahedral sites. This is in agreement with a magnetization decrease with zinc content. Hysteresis loops measurements were performed at 300K and at 5K using a PPMS magnetometer. At 300K, we observed non-zero remanence and coercivity for higher cobalt content. At low temperature, coercivity and remanence also increase with increasing Co content. Furthermore, a sudden drop in the magnetization is observed close to remanence, being more pronounced for samples with higher cobalt content. This behavior is associated to both NPs with uniaxial and cubic anisotropies.

TU.F-P115 - Towards ideal biotechnologically applicable magnetic particles with highly tunable perpendicularly magnetized synthetic anti-ferromagnets

T. Vemulkar [1], R. Mansell [1], D. Petit [1], R.P. Cowburn [1]

1. Cavendish Laboratory, University of Cambridge, Cambridge, United Kingdom

The use of ferrofluids in biological applications has become an important area of technological innovation. We demonstrate the fabrication of zero remanence, low susceptibility and high moment ferrofluids for biotechnological applications via the lift off of lithographically patterned multilayer thin films. Perpendicularly magnetized CoFeB/Pt thin film bilayers that are antiferromagnetically coupled via RKKY interactions across a Pt/Ru/Pt spacer form the basic building block of this work. This bilayer system demonstrates sharp switching to saturation magnetization at a specific applied field. The RKKY coupling gives a zero remanence state with a low susceptibility, a necessity to prevent particle agglomeration in the ferrofluid. We then repeatedly stack this bilayer system 12 times to increase the moment of the magnetic stack independently of the other system parameters. This 12 times repeated bilayer system is sputtered on pre-patterned resist, and lifted off into solution to create a ferrofluid of particles that are 2 μm across. We demonstrate that the magnetic properties of the thin film are transferred to the particles in the solution. Polar magneto-optical Kerr effect hysteresis loops of individual particles recondensed on a substrate are compared to vibrating sample magnetometer hysteresis loops of both the thin film, and an aliquot of the ferrofluid. Interestingly, we see that the ferrofluid shows a slightly higher RKKY coupling strength as compared to the thin film, as well as zero remanence and very small low field susceptibility, less than half that of the thin film hard axis. We also demonstrate the ability to tune the magnetic anisotropy through the CoFeB thicknesses, the switching field via the RKKY coupling strength, and the total magnetic moment through the number of repeats of the bilayer building block. We use this work to outline a parameter space for the fabrication of these highly tunable synthetic ferrofluids for biotechnological applications.

Tu.F-P122 - Ferronematics in low magnetic fields

P. Kopcansky [1], N. Tomasovicova [1], V. Gdovinova [1], M. Timko [1], V. Zavisova [1], N. Eber [2], T. Toth-Katona [2], F. Royer [3], D. Jamon [3], C.K. Hu [4]

The orientational order of liquid crystals (LCs) can be controlled by magnetic or electric fields due to the anisotropy of dielectric permittivity or diamagnetic susceptibility. Very small anisotropy of the diamagnetic susceptibility of liquid crystals causes that liquid crystals are rather control by electric field in practise than by magnetic field. In order to increase the magnetic susceptibility of liquid crystals Brochard and de Gennes´ introduce the great idea of doping them with fine magnetic particles so called ferronematics [1]. A linear magnetodielectric response has been detected in planarly oriented ferronematics samples far below the threshold of the magnetic Freedericksz transition in the presence of a weak orienting bias magnetic field (2mT) [2]. In our study, magneto-optical and dielectric properties of magnetic nanoparticle doped nematic LCs has been investigated by means of applying different orienting bias magnetic fields B_{bias} as well as electric fields E_{bias}. The liquid crystals 4-n-hexyl-4´-cyanobiphenyl (6CB) and 4-(trans-4´-n-hexylcyclohexyl)-isothiocyanatobenzene (6CHBT) were doped with spherical magnetite nanoparticles of 10nm in diameter. The obtained results ie linear magnetic field dependence of magnetoptical and magnetodielectric effects in low magnetic field region showed that bias fields allow controlling these effects of ferronematic samples. This can be used as liquid sensors for the mapping of magnetic field similar to mapping spacial distribution of temperature by liquid crystals for example.

The understanding of magnetism at the ultimate length scale is one of the current frontiers in solid state physics. Some metals whose bulk material do not fulfill Stoner criterium to support ferromagnetic ordering, like Pd, may undergo a crossover to magnetic behavior by several ways: a neighboring magnetic material may polarize it, or more interestingly, a perturbation of the Pd coordination may cause the Pd to interact magnetically producing magnetic particles. We have prepared Pd13 particles, supported in NaY and KL (iron-free) zeolites, in two chemical states: Pd13 particles in the bare neutral cluster, and Pd13 with absorbed H. The surface effects attributable to the loss of local symmetry are maximized in this clusters. These Pd13 samples are model systems for this study on nano-magnetism as they are are virtually monodisperse and the Pd loading of the zeolite is ≈ 6% in weight, and therefore, the interaction between particles can be neglected. We have also prepared a series of high quality Pd nanoparticles by cosputtering, embedded in amorphous ZrO2 within a wide size range (from 2 to 25 nm) and a very narrow size distribution. Particles are well isolated, with sharp particle-matrix interfaces due to immiscibility between the two phases. In-house characterization includes SEM and HR-TEM, EDX, EPS, and SQUID magnetometry. All the foregoing suggests that this is a clean system to study the spontaneous magnetic moment in Pd nanoparticles larger than 1.5 nm in diameter. The magnetization of the Pd13 and larger Pd nanoparticles at T = 1.8K shows a dominant diamagnetic signal, clearly accompanied by a paramagnetic curve. The data collection coalesces obeying a corresponding-states law which can be properly fitted to a 2 µB Langevin function. For the larger particles, a decreasing magnetic moment with increasing particle size is evidenced from experiments.

TU.G-P01 - [Co/Pt] multilayers structural, magnetic and electronic properties: role of the Pt thickness

K. Dumesnil [1], M. Bersweiler [1], D. Lacour [1], S. Robert [1], M. Hehn [1]

1. Institut Jean Lamour, Université de Lorraine and CNRS, Nancy, France

[Co/Pt] multilayers constitute archetypes of perpendicularly magnetized systems and have been widely used for almost two decades in close connexion with the development of spintronic devices: magnetic tunnel junctions (MTJs), magnetic recording media, devices where the magnetization is manipulated by spin-transfer torqueà Most attention has been focused on the origin and optimization of the strong perpendicular anisotropy, mainly exploring the role of Co thickness and interface morphology. This study aims in exploring more particularly the role of the Pt thickness and of oxide buffer layers as MgO and Al_2O_3, commonly used as insulating barriers in MTJs. Using [Co/Pt] multilayers as electrodes in MTJs may namely require their growth on such oxides, which could affect the interface morphology and consequently the magnetic and transport properties. Accurate structural, magnetic and transport investigations have been performed to correlate various properties of [Co(0.58nm)/Pt]4 stackings (effective anisotropy, saturation magnetization, effective tunnel polarisation) to the interface morphology when varying the Pt thickness and the nature of the oxide buffer layer.

The results first highlight the prominent role played by the Pt thickness: increasing the Pt thickness tends to smooth the interfaces and then to improve the Perpendicular Magnetic Anisotropy (PMA). The roughness is however significantly increased when using an oxide buffer instead of Pt, especially for Al_2O_3, which leads to a reduced PMA. Simultaneously, rough interfaces (small Pt thickness and/or oxide buffers) obviously drive a large enhancement of the saturation magnetization via the polarization of Pt atoms in direct contact with Co.

Interestingly, the Pt thickness also appears to play an important role in the effective tunnel polarization, determined from Tunnel Magneto Resistance values in [Co/Pt]-based MTJs. A decrease of the low temperature effective spin polarization is observed versus Pt thickness, consistently with the exponential decay expected for the induced magnetic moment in the Pt layers.

TU.G-P02 - Perpendicular magnetic anisotropy and Gilbert damping study in amorphous FeTaC film

Spin transfer torque (STT) has grater credibility towards ultrafast spin dynamics in ferromagnets by switching the magnetization of spin valves and magnetic tunnel junctions. In STT devices, the low spin polarized current density which manipulates the magnetization reversal requires low the Gilbert damping constant (α) and high perpendicular magnetic anisotropy (PMA).[1] These material specification parameters 'α' and PMA were explored in soft ferromagnetic thin film $Fe_{80}Ta_{20}C_{12}$ based alloy of thickness 200 nm by using micro-strip ferromagnetic resonance (MS-FMR) in broad band frequency range (4-18 GHz) at room temperature. The present film is magnetically isotropic in plane and the saturation magnetization ($4\pi M_S$) was found to be 7790 Oe from frequency dependence of resonance field (H_r) analysis. The out-of-plane angular dependence of H_r at different frequencies could be successfully modeled with experimental data by taking free energy density function (E) for thin film, where the total energy was contributed by Zeeman energy, effective demagnetization energy and perpendicular magnetic anisotropy energy. The parameters deduced from the analysis are listed as PMA constant, $K_\perp = 2 \times 10^5$ erg/cm^3, effective magnetization, $4\pi M_{eff} = 7145$ Oe and Landé g factor, $g = 2.1$. The Gilbert damping constant (α) was analyzed from out-of-plane angular dependence of FMR line width (ΔH) by using Gilbert-type intrinsic damping and extrinsic damping due to anisotropy dispersion of magnitude and direction of effective magnetization.[2,3] The 'α' values increases monotonically with decrease in frequency and were found to vary from 6×10^{-3} to 1.2×10^{-2} in the frequency range of 10-4 GHz.

Materials having high magnetocrystalline anisotropy constant (Ku) are generally desirable for high density magnetic recording applications due to their thermal stability even with smaller grain size. The Ku of hcp Co_3Pt alloy films is as high as 2x107erg/cm^3, and the temperature required for obtaining high perpendicular magnetic properties is only 300 °C. Therefore, Co_3Pt alloy film has significant potential to be utilized in ultra-high density (1Tb/in2) magnetic recording media. It has been reported that Co-rich Co-Pt films with perpendicular magnetic properties can be achieved by introducing a Pt underlayer or Ru/Pt bilayers. The lattice parameter of Ag is close to Pt and both structures are fcc. Furthermore, compared to a Pt underlayer, the Ag does not change the composition ratio of Co to Pt in the Co_3Pt magnetic layer, and the cost of Ag is much lower than that of Pt. In this study, $Co_{80}Pt_{20}$ films were deposited onto Ru/Ag bilayer films. The perpendicular magnetic anisotropy was achieved by depositing $Co_{80}Pt_{20}$ film onto Ru/Ag bilayer films using an argon working pressure of 3 mTorr to sputter the Ru layer at ambient temperature. Its perpendicular coercivity and perpendicular squareness are 3980 Oe and 0.76, respectively. When the working pressure increases to above 10 mTorr, the perpendicular magnetic anisotropy of the films deteriorates greatly. However, both perpendicular coercivity and perpendicular squareness of the film can be increased to 4530 Oe and 0.82 respectively if the $Co_{80}Pt_{20}$ film is deposited on a higher texture Ru(0002)/Ag(111) bilayer that has been annealed at 300 300 °C. When this $Co_{80}Pt_{20}$/Ru/Ag multilayer film is subsequently post-annealed at 300 300 °C, the perpendicular magnetic properties are improved further. The perpendicular coercivity and perpendicular squareness of the film are further increased to 5040 Oe and 0.87 respectively, which reveal its significant potential as perpendicular magnetic recording media for ultra-high density recording.

TU.G-P04 - perpendicular magnetic anisotropy of very thin L_{10} FePt films

Perpendicular Magnetic Anisotropy (PMA) materials, like L10 FePt thin films [1, 2], are under intense study because of their high potential for applications in spintronics and magnetic storage. In this work, we investigated FePt films, with thickness between 1 nm and 5 nm, deposited on MgO (001) substrates at 500oC using magnetron sputtering. The films were characterized by means of X-ray diffraction, atomic/magnetic force microscopy (AFM/MFM), and anomalous Hall effect measurements. It is shown that the films have L10 structure down to a thickness of 2.7 nm and clearly exhibit PMA, with remanent to saturation magnetisation ratio (Mr/Ms) equal to 1 and perpendicular coercivity Hcp equal to 14.8 kOe at 2.7 nm and 16 kOe at 5 nm FePt layer thickness. However, as the FePt film thickness is reduced, Mr/Ms and Hcp rapidly decrease, indicating the emergence of in-plane anisotropy and the presence of both L10 and A1 phases. The surface morphology is typical of polycrystalline metallic films, with surface roughness between 0.5 and 0.8 nm and grain size between 15 nm and 25 nm. The only exception is the 1 nm thick film, which has 1.2 nm surface roughness, indicating that it is not continuous and revealing the island growth mechanism of FePt. Finally, MFM imaging of the 2.7 nm and 5 nm thick films reveals a magnetic domain size between 200 nm and 300 nm, much wider than the average grain size, indicating strong magnetic coupling between adjacent grains. It is concluded that as the FePt layer is getting thinner, higher energy is needed for the formation of the L10 phase, thus leading to the need of depositing FePt at higher substrate temperature.

It is known that a perpendicular magnetic anisotropy is induced by a hetero interface of non-magnetic and ferromagnetic materials [1]. To clarify the origin of the perpendicular magnetic anisotropy near the interface, a direct measurement of the electronic and magnetic properties of ferromagnetic materials near the interface is required. Recently, hard X-ray photoemission spectroscopy (HAXPES) [2] has been used to investigate electronic structures of buried layers [3] due to large inelastic mean-free-path (IMFP) of photoelectrons [4] in solids. We fabricated two samples of MgO(2 nm) and Pt(2 nm) capped Fe(20 nm) on MgO(001) substrates by sputtering in order to investigate the interface magnetic properties of MgO/Fe and Pt/Fe by means of HAXPES. The HAXPES measurements were performed at BL15XU of SPring-8 [2]. The Fe 2p3/2 HAXPES spectra for the both the samples showed a broad main peak with a clear shoulder structure in comparison with that for bulk polycrystalline Fe, although the spectra were measured in the normal emission geometry, in which the spectra were bulk sensitive. When we measured the spectra with near interface sensitive geometry (off-normal emission angle of 60 deg), the shoulder structure of Fe 2p3/2 spectra were evolved in comparison with that measured in the normal emission geometry. These results strongly suggest that near interface Fe has the larger orbital moment than bulk Fe. Thus we can conclude that this larger orbital moment of Fe is the origin of the perpendicular magnetic anisotropy near the interfaces of MgO/Fe and Pt/Fe.

TU.G-P07 - Structure and spin texture of FeCo ultrathin films on $Cu_3Au(001)$

A. Cotta [1], A. Ponce [1], W. Macedo [1]

1. Centro de Desenvolvimento da Tecnologia Nuclear, Belo Horizonte, Brazil

Tetragonally distorted $Fe_{1-x}Co_x$ alloy films epitaxially grown on different face centered cubic substrates are a model system for perpendicular magnetic anisotropy (PMA). Depending on the level of tetragonal distortion in the system, the epitaxy can result in a strong PMA and films with perpendicular magnetization [1]. For equiatomic Fe-Co films on Rh(001), for example, the easy-magnetization axis can remain perpendicular up to 15 ML at room temperature (RT) [2]. Cu_3Au has an in-plane lattice constant of 3.75 Å, being very close to the predict value to result in FeCo films with a large PMA. A very recent work has shown that 11 ML FeCo on $Cu_3Au(001)$ present in plane magnetization and, based on RHEED results, speculates that FeCo films thinner than 9 ML should present a tetragonal distortion suitable for perpendicular magnetic anisotropy [3]. In this work, we have determined the spin texture of FeCo films grown on $Cu_3Au(001)$ at RT by molecular beam epitaxy (MBE) in ultra-high vacuum. The 57FeCo films were prepared at room temperature by codeposition (disordered films) and by deposition of alternated Fe and Co monolayers (ordered films). The substrate and the films were characterized by using XPS, LEED and RHEED. Ex-situ conversion electron Mössbauer spectroscopy (CEMS), vibrating sample magnetometry and in-situ magneto-optical Kerr effect (MOKE) measurements were also conducted. The structure and magnetism of FeCo films up to 14 ML were investigated. Our results indicate that codeposited (disoredered) $FeCo/Cu_3Au(001)$ films show in plane magnetization. Films prepared by alternated ML of Fe and Co (ordered) present a strong PMA up to 7 ML. MOKE measurements on films with alternate Fe and Co atomic layers show an oscillatory behavior of the coercivity depending on the surface layer, suggesting stronger perpendicular anisotropy for Fe-terminated films when compared with Co-terminated films.

TU.G-P08 - Influence of high density plasma processes on magnetic properties and microstructures of FePt alloy films

$L1_0$ FePt film is considered a potential candidate for the future perpendicular magnetic recording media because its large magnetocrystalline anisotropy constant (K_u) of $7x10^7$ erg/cm^3. However, the structure of the $L1_0$ FePt phase is face-centered-tetragonal (fct) and normally has (111) preferred orientation, which makes the magnetic anisotropy of the film incline toward the film plane. In order to apply FePt film to perpendicular magnetic recording media, achievement of a high (001) texture of the $L1_0$ FePt films is necessary. Usually, the (001) textured FePt film could be achieved by depositing the film onto MgO, Cr and CrRu underlayers. However, these multilayer films would result in the higher cost and undesirable interdiffusions between the FePt magnetic layer and underlayers during post annealing process.

In this study, single-layered FePt films were deposited directly onto Corning 1737 glass substrates by both direct current magnetron sputtering (DCMS) and high power impulse magnetron sputtering (HIPIMS). These films were then post-annealed at 700 °C for 30 min in a vacuum of $1.0x10^{-6}$ Torr. It was found that single-layered FePt films with random orientation were achieved by using DCMS. However, FePt films with (001) texture showing high perpendicular magnetic properties were obtained by HIPIMS. Their perpendicular coercivity, saturation magnetization and perpendicular squareness are as high as 14.2 kOe, 624 emu/cm^3 and 1, respectively, which reveal its great potential for use as next-generation perpendicular magnetic recording media for ultra-high density recording.

Magnetic materials with a large anisotropy constant are promising candidates for the exhibition of higher ferromagnetic resonance frequencies and therefore a possible extension of the operation frequencies of various magnetic devices. The magnetoelastic effect that arises due to a lattice misfit between a magnetic material and a substrate is one of the most effective approaches for enhancing the magnetic anisotropy of films. In this presentation, we report on the negative magnetic anisotropy of an epitaxial $NiFe_2O_4$ (001) film grown on $MgAl_2O_4$ (001) substrate. The film was grown by reactive rf-magnetron sputtering technique using an alloy target of NiFe with a composition of 1:2. Prior to the growth process, the substrate was heated to 400C to remove surface contamination. Growth temperature was kept at 300C and sputtering power was 100W. In situ RHEED experiments confirmed that the film was epitaxially grown. Magnetization measurements revealed that the easy axis lies in-plane and the hard axis is normal to the film. The saturation magnetization (Ms) was 227 emu/cm^3 at room temperature. The anisotropic field for the out-of-plane MH-loop was close to 70 kOe which is more than 20 times greater than the demagnetization field of the film, indicating the existence of additional magnetic anisotropy with a negative constant. Effective anisotropy energy (Kueff) estimated from the difference between the two MH-loops was -7.94 emu/cm^3. In addition, the torque experiment was also performed at room temperature to evaluate Kueff. The torque curves were analyzed by Miyajima's method and the extrapolated values of Kueff and Ms were -7.78 Memu/cm^3 and 269 emu/cm^3, thus showing good agreement with the MH-loop analysis. The observed large Kueff can be attributed to the magnetoelastic effect caused by the relatively large lattice misfit between $NiFe_2O_4$ and $MgAl_2O_4$.

TU.G-P10 - Rotatable magnetic anisotropy in anisotropy-graded FePt films induced by ion irradiation at low incidence angle

Alternating gradient force magnetometry (AGFM), Brillouin light scattering (BLS) from thermally excited spin waves, and magnetic force microscopy (MFM) have been used to investigate the static and dynamic magnetic properties of a 15-nm-thick FePt film after Ar+ irradiation, performed at two different incidence angles, 85 and 45 degrees, with respect to the film normal. Ion irradiation turns the L10, chemically ordered, magnetically hard phase, into the A1, chemically disordered, magnetically soft phase [1], inducing an anisotropy gradient along the film normal. On changing the ion incidence angle, the ion penetration depth and the relative thicknesses of the soft and hard phases have been modified. We found that the sample irradiated at 45 degrees is characterized by a profound softening of the perpendicular magnetic anisotropy near the surface plane. Moreover, BLS measurements, performed at remanence as a function of the in-plane rotation angle, indicate the presence of a rotatable magnetic anisotropy [2]: namely, an anisotropy whose direction can only be rotated by changing the saturating field direction. The presence of this anisotropy can be ascribed to the competition between the moderate perpendicular magnetic anisotropy and the easy-plane shape energy. Finally, from the fit of the BLS frequency versus the intensity of the in-plane field H, the effective rotatable anisotropy field Hrot was estimated to be Hrot≤510 Oe for H≤2 kOe. The tunability of the zero-field frequency, obtained by Ar+ irradiation varying the incidence angle of the ion beam, may have large applications for microwave magnetic devices.

Many amorphous RE-TM alloys exhibit perpendicular magnetic anisotropy (PMA) [1] of discussed origin. The most accepted source of their PMA is single ion anisotropy at the RE sites [2]. Several Nd_xCo_{1-x} amorphous thin films of different nominal compositions and Nd-Co multilayers with $\lambda<1$ nm have been grown by DC-magnetron co-sputtering. EXAFS measurements only evidenced a large disorder at the Nd sites and segregation of Co atoms [3], while XMCD measurements demonstrate that the PMA is located at the RE 4f orbitals indeed [4]. The $\langle L_z\rangle/\langle S_z\rangle$ ratio in Nd is very close to the theoretical one at normal incidence, though it is not isotropic as expected for a 4f orbital, but always smaller in plane. Furthermore, the Co subnetwork presents an in-plane anisotropy crossed to it. The values of $\langle\mu_{Nd}\rangle$ support the existence of an asperomagnetic structure whose cone angle slightly changes with orientation. On the other hand, the effective exchange interaction Co-Nd ($J_{Co\text{-}Nd}$) determines the size of $\langle\mu_{Nd}\rangle$. We compare a multilayer (M) and a homogenous alloy (HA) with 21-22% Nd, but only M shows strong PMA. Despite their similar $\langle L_z\rangle/\langle S_z\rangle$ anisotropies for both specimens, their different values and thermal evolutions of $\langle\mu_{Nd}\rangle$ suggest that $J_{Co\text{-}Nd}(M)\geq 3\cdot J_{CoNd}(HA)$. Therefore, $J_{Co\text{-}Nd}$ is a key factor to make the PMA of the Nd sublattice overcome the shape anisotropy and the Co planar anisotropy.

TU.G-P12 - Synesthetic ferrimagnet of cubic Heusler/tetragonal Heusler Mn_3Ga bilayers with perpendicular magnetic anisotropy

R. Ranjbar [1], K. Suzuki [1], A. Sugihara [1], Q. Ma [1], T. Miyazaki [1], S. Mizukami [1]

1. WPI Advanced Institute For Materials Research, Tohoku University, Sendai, Japan

Bilayer structure consisting of magnetic films with perpendicular magnetic anisotropy (PMA) and in-plane magnetic anisotropy show fully PMA when interfacial exchange coupling is strong enough. Such bilayers with negative interfacial exchange coupling, the so-called synesthetic PMA ferrimagnets are practically important to use in perpendicular magnetic tunnel junctions (p-MTJs) for high density spin-transfer-torque magnetoresistive random access memory (STT-MRAM) [1, 2]. Synesthetic PMA ferrimagnets consisting of L10 MnGa alloy with PMA and an ultra-thin ferromagnetic metal/alloy layer are one of the good candidate. We recently reported that the interfacial exchange coupling of the bilayer of L10 MnGa and Co-rich Fe-Co is antiferromagnetic and the strength is -3.0 erg/cm^2 and also tunnel magnetoresistance is 60% (120%) at room (low) temperature [3]. Here, we studied the bilayer of tetragonal Heusler D022 Mn_3Ga and cubic Heusler alloys (Co_2FeAl, Co_2FeSi, Co_2MnAl, and Co_2MnSi). Heusler (20 nm) / D022 Mn_3Ga (30 nm) bilayer films were fabricated with different post annealing temperature on (100) MgO substrate buffered and capped with Cr by using an ultrahigh vacuum magnetron sputtering system. The strongest antiferromagnetic coupling Jex of -3.2 erg/cm^2 was observed in the Co_2MnSi / Mn_3Ga bilayer, in which the L21 ordered Co_2MnSi was epitaxially grown on Mn_3Ga layer and its saturation magnetization of 800 emu/cm3 [4, 5]. To achieve ultra-thin synthetic ferrimagnet, the thickness of Co_2MnSi Heusler alloy and D022 Mn3Ga were decreased. The bilayer with 1-nm-thick Co_2MnSi and 7.5-nm-thick D022-MnGa shows good PMA which makes this bilayer as good choice for making free electrode of p-MTJ based on MnGa alloy. This work was partially supported by the development of an infrastructure for normally-off computing technology project from NEDO and ASPIMATT (JST). R.R also thanks to Y. Kondo for his technical assistance and to the WPI program and JGC-S scholarship (Nikki).

TU.G-P13 - Real-space calculations of uniaxial magnetic anisotropy at surfaces of bcc Fe films and of Y2Fe14B compounds

J.I. Inoue [1], T. Yoshioka [1], H. Tsuchiura [1]

1. Department of Applied Physics, Tohoku University, Sendai, Japan

The fundamental origin of the magnetic anisotropy (MA) may be attributed to lowering of crystal symmetry and the spin-orbit interaction (SOI), and intensive search for high performance permanent magnets is currently conducted both experimentally and theoretically. Nevertheless, materials dependence of MA is unpredictably complicated. The complication could be partly due to structural inhomogeneity in magnets, such as grain boundaries and lattice disorder. Therefore, a theoretical approach to treat effects of grain boundaries and random lattice structures is desirable. To this end, we have developed real-space formalism to calculated MA energy for any lattice structures by expanding the thermodynamic potential in terms of SOI by using multi-orbital tight-binding model. By using the method, site-resolved MA is easily obtained with high numerical accuracy. The applicability has already been examined by comparing the numerical results with those obtained in the first-principles method [1]. Here we apply the method to calculate the uniaxial MA at bcc Fe (001) surfaces with several surface structures, and that at surfaces of $Y_2Fe_{14}B$ compounds. Our findings are as follows:

(1) The out-of-plane MA at bcc Fe (001) surface is strongly enhanced due to surface resonant states as compared with bulk MA. As a result, dependence of the out-of-plane MA at surface on charge density becomes stronger than that of bcc bulk Fe.

(2) The uniaxial MA at surface sites of $Y_2Fe_{14}B$ compounds is also enhanced. For example, in-plane MA at 4c-Fe sites on (001) surface becomes twice as large as the bulk value, and the uniaxial MA at 8j2-Fe sites on (010) surface is enhanced as compared with the bulk value. These results may implicate important roles of surface/interface Fe sites on the MA and magnetization process of ferromagnetic thin films and grains.

TU.G-P14 - Magnetic properties of amorphous Tb_{x}Co_{1-x} thin films grown in an in-plane external magnetic field by combinatorial magnetron sputtering

Gabriella Andersson [1], Y, Sebastian George [1] N, Andreas Frisk [1] N, Fridrik Magnus [1]

1. Uppsala University, Department Of Physics And Astronomy, Uppsala, Sweden

The magnetic properties of amorphous Tb_xCo_{1-x} thin films, with x ranging from 0.07 to 0.3, have been investigated using vibrating sample magnetometry (VSM), magneto-optical Kerr effect (MOKE), and magnetic force microscopy (MFM). The samples were deposited by DC magnetron sputtering on 10 mm by 60 mm rectangular strips of Si, with a native oxide layer. The combinatorial deposition from separate Tb and Co targets, placed at either end of the Si strip, yielded a continuous composition gradient along the strip, and an accompanying thickness gradient spanning 45-60 nm. Amorphous $Al_{70}Zr_{30}$ was used for buffer and cap layers. During deposition, a 100-mT external B-field was applied parallel to the substrate surface, perpendicular to the composition gradient, i.e. across the strip. Identical samples were also grown without this external field. As expected from previous studies [1], the amorphous TbCo films exhibit strong perpendicular magnetic anisotropy (PMA). However, we do observe changes in saturation field and coercivity with varying composition. Furthermore, there is a clear difference in domain structure, as observed by MFM, between samples grown with and without the in-plane B-field, indicating that this field has an impact on the magnetization, in spite of the strong PMA. MOKE magnetization loops confirm the presence of a small in-plane magnetization component. The effect of the growth field on the domain structure is most pronounced for the lower Tb concentrations (x = 0.07 - 0.09). VSM magnetization loops exhibit two-step switching, which is not observed in the corresponding MOKE data. This suggests that the lower and upper parts of the TbCo layers have different magnetic properties, which in turn may be a mechanism for creating the observed in-plane component.

We report on torque magnetometry results to study the magnetic anisotropy of cobalt and iron-cobalt nanowires, grown by electrochemistry into nanoporous alumina templates. We look at the effects of shape and magnetocrystalline anisotropy. For comparison we also measured a 50 nm thick Permalloy film with in-plane anisotropy. We developed a technique of "torque rotations", that is, we rotate the sample in a fixed magnetic induction, B, (between 100 G and 14 T) and fixed temperature (between 2 K and 300 K) and analyse the resulting torque vs. angle, θ, curves by comparing them to simulated torque rotations. We use various free energy models and for a given B minimize them to obtain the direction of equilibrium magnetization, M. We show that the high-B torque rotations are independent of B, can be described as sin(2*θ), and reflect the leading anisotropy term (K*V, where V is the magnetic volume). On the contrary, the small-B rotations scale with B and have a distorted form. The transition from one behavior to another happens around the anisotropy field (K/M). In very small fields (below coercivity) the torque rotations change again and have sin(θ) shape, as the magnetic moment is unmoved by B. This allows us to determine the total magnetic moment m=M*V, too.

TU.G-P16 - Fabrication of Mn_3Ga nanodisks using polystyrene nanosphere lithography

4. INRIM, Torino, Italy

MnyGa (y=2,3) in the metastable tetragonal D022 phase exhibits unique properties, which can be exploited for numerous spintronic devices such as spin-transfer-torque RAM [1]. This phase is also interesting for the development of permanent magnets with maximum energy products halfway between $Nd_2Fe_{14}B$ and $Ba(Sr)Fe_{12}O_{19}$ [2]. Mn_xGa_{1-x} (x=0.75,0.70) films were grown by RF sputtering on heated $SrTiO_3$ (100) substrates. Through the control of growth parameters, thickness (10 - 40 nm) and composition, epitaxial films showing the tetragonal phase oriented primarily with the c-axis out of the film plane were obtained. The films exhibit perpendicular magnetic anisotropy with coercive fields in the range of 1 - 2 T and saturation magnetization between 100 - 250 kA/m. The saturation magnetization decreases with increasing x, consistent with previous reports; this trend arises from the antiferromagnetic alignment of Mn moments between the two Mn sublattices present in the D022 structure and preferential removal of Mn from only one sublattice with decreasing x.
Mn_xGa_{1-x} nanodisks were fabricated by assembling a monolayer of polystyrene nanospheres (PN) with a mean starting diameter of 800 nm on the thin film; subsequently, the PN size was reduced by reactive ion etching to obtain final dots of 500 - 600 nm in diameter. A sputter etching process in Ar+ plasma was used to remove the excess Mn_xGa_{1-x} film between the PNs. After the wet-lithography process, the nanodisks maintain the perpendicular magnetic anisotropy as shown by SQUID magnetometry and Magnetic Force Microscopy. The patterning process however results in partial structural disorder to the nanodisks, as evidenced by a kink around zero field in the perpendicular hysteresis curve.

TU.G-P17 - Perpendicular magnetic anisotropy of Co_2FeAl Heusler alloy thin films grown on flexible kapton substrates

M. Gabor [1], T. Petrisor jr. [1], C. Tiusan [1], M. Belmeguenai [2], F. Zighem [2], D. Faurie [2]

1. Center for Superconductivity, Spintronics and Surface Science, Technical University of Cluj-Napoca, Cluj-Napoca, Romania
2. Laboratoire des Sciences des Procedes et des Materiaux, CNRS-Universite Paris XIII, Villetaneuse, France

The functional properties of devices on non-planar substrates are receiving increasing interest because of the new flexible electronics based-technologies. Magnetic thin films deposited on polymer substrate show tremendous potentialities in new flexible spintronics based-applications.
Within this context, the results of our study overcome several challenges. On flexible Kapton substrates we have successfully grown ferromagnetic polycrystalline thin films constituted by Co2FeAl (CFA) Heusler alloy with large spin polarization and low Gilbert damping. By varying the thickness, the anisotropy of these films has been stabilized either in-plane or perpendicular-to-the plane. Then, correlating static (magnetometry) and dynamic magnetic studies (ferromagnetic resonance-FMR), we demonstrate the bending strain effect on the magnetic anisotropy properties of the CFA films. Ferromagnetic resonance analysis reveal significant bending effect on the magnetic anisotropy in 20nm thick CFA Heusler thin film grown on Kapton and glued on curved sample carriers with various radii. We attribute the measured effect to the interfacial strain transmission from the substrate to the film and to the relative large in-plane magnetostriction coefficient ($\lambda^{CFA}=13.8\times10^{-6}$) [1]. These results have an important predictive character: if one targets the integration of the CFA in a flexible planar magnetorezistive device, the magnetostriction coefficient should be 10 times smaller in order to maintain the optimum magnetic anisotropy characteristics.
Furthermore, we demonstrate the realization of perpendicular magnetic anisotropy (PMA) in ultrathin polycrystalline CFA films grown on Kapton flexible substrates, attributed to the CFA/MgO interfacial anisotropy [2]. We show that the PMA is less influenced by the bending strain effect and remains stable up to relative large substrate curvatures. This point out the important potential of CFA to be integrated in PMA spintronic devices grown on flexible substrates.

TU.G-P18 - Magnetic anisotropy of $Fe_{1-y}X_yPt\text{-}L_{10}$ [X = Cr, Mn, Co, Ni, Cu] bulk alloys.

R. Cuadrado [1], T.J. Klemmer [2], R.W. Chantrell [1]

1. Department of Physics, University of York, York, United Kingdom
2. Seagate Technology, Fremont, California, United States

We demonstrate by means of fully relativistic first principles calculations that, by substitution of Fe by Cr, Mn, Co, Ni, or Cu in FePt-L_{10} bulk alloys, with fixed Pt content, it is possible to tune the magnetocrystalline anisotropy energy by adjusting the content of the non-magnetic species in the material. The changes in the geometry due to the inclusion of each element induces different values of the tetragonality and hence changes in the magnetic anisotropy and in the net magnetic moment. The site resolved magnetic moments of Fe increase with the X content while those of Pt and X are simultaneously reduced. The calculations are in good quantitative agreement with experimental data and demonstrate that models with fixed band structure but varying numbers of electrons per unit cell are insufficient to describe the experimental data for doped FePt-L_{10} alloys.

TU.G-P19 - Effect of Copper underlayer on perpendicular magnetic anisotropy in Co/Ni multilayers

M. Stebliy [1], A. Kolesnikov [1], A. Ognev [1], A. Samardak [1], A. Davydenko [1], L. Chebotkevich [1], A. Lara [2], F. Aliev [2]

1. School of Natural Sciences, Far Eastern Federal University, Vladivostok, Russia

The investigation of thin films and nanostructures with perpendicular magnetic anisotropy (PMA) is timely in terms of practical applications in spintronics and orbitronics. Co/Ni multilayers are promising materials due to low Gilbert damping (~ 0,02), small switching currents and high thermal stability. Here we study magnetic properties and magnetization dynamics (by using VNA-FMR) of $[Co(0.3\ nm)/Ni(t_{Ni})]_5$ multilayers with PMA produced by magnetron sputtering on $Ta/Cu(t_{Cu})$ buffer layers, where t_{Ni} = 0.4 to 0.55 nm, t_{Cu} = 0 to10 nm. Our study reveals that magnetic anisotropy is strongly enhanced with introduction of copper underlayer (t_{Cu} =4.8 nm) with respect to a control sample. Detailed analysis of the influence of Cu underlayer thickness and number of multilayers will be provided in order to determine relative importance of strain vs. purely electronic effects on magnetic anisotropy. Measurements of samples with different thicknesses of Cu show that a thicker copper layer also increases the switching field.

TU.G-P20 - Sputtering energy and perpendicular magnetic anisotropy of CoFeB

B. Kim [1], D. Kim [1], Y.J. Jang [1], J. Kim [1], K. Rhie [1]

1. Department of Display and Semiconductor Physics, Korea University, Sejong, South Korea

Perpendicular-Magnetic tunnel junction (p-MTJs) structure is a good candidate for nonvolatile magnetoresistive random access memory (MRAM) devices [1, 2]. Both high quality of multi-layers and large anisotropic constant K are the essential requirements. The effect of sputtering energy for better perpendicular magnetic anisotropy (PMA) of CoFeB [3] is studied. SiO2/X(2)/CoFeB(1.3)/MgO(2)/Ta(2) (in nm.) samples are grown by conventional magnetron sputtering techniques, where X is FeZr and Ta. The sputtering energy was controlled by changing sputtering pressure and distance between samples and sputtering gun. The sputtering particles may lose energy they arrive substrate, because they experience multiple scattering by Ar particles along the path to the substrate. Therefore, sputtering particle energy at substrate is small when both working pressure and distance is high. In a low sputtering energy case, sputtered particles cannot make a uniform surface and voids may be formed inside a film, which results lower film density. We observed that the film growth pattern changes from 2 dimensional to 3 dimensional growth by crossing a critical sputtering condition. The best pressure and distance to make the best film quality is less than 5mTorr and below 10.5 cm, respectively. Low resistivity and high anisotropic constant K could be achieved by controlling the sputtering energy.

Nowadays, active research efforts are being carried out to stabilize out-of-plane magnetization in thin films and nanostructures. In this context, the change of the preferential direction of the magnetization from the commonly observed in-plane orientation to the direction perpendicular to the plane is usually referred to as perpendicular magnetic anisotropy (PMA). In this work we report the appearence of PMA in $Fe_{1-x}Ga_x$ thin films grown onto ZnSe/GaAs(100). $Fe_{1-x}Gax$ is well known for its magnetostrictive properties leading to industrial applications. Here, we show a that magnetostrictive properties coexist with PMA in $Fe_{1-x}Ga_x$ thin fims. This arising anisotropy is related to the tetragonal metastable phase in as-grown samples recently reported [1]. By means of ferromagnetic resonance studies we measured PMA values up to 5x10^5 J/m3. PMA is a the origin of the magnetic stripe pattern observed by magnetic force microscopy (MFM). interestingly, PMA vanishes when the cubic structure is recovered upon annealing at 300◦C.
Despite the important values of the magnetoelastic constants measured via the cantilever method, the consequent magnetoelastic contribution to PMA is not enough to explain the observed anisotropy values in the distorted state. Ab initio calculations show that the chemical ordering plays a crucial role in the appearance of PMA. Through a phenomenological model we are able to explain that an excess of next nearest neighbour Ga pairs (B2-like ordering) along the perpendicular direction arises as the source of PMA in $Fe_{1-x}Ga_x$ thin films.

TU.G-P24 - Estimation of Fe buffer layer for higher perpendicularly anisotropic magnetic property of L_{10}-FePt grains fabricated by Rapid Thermal Annealing

M. Imazato [1], A. Ogasawara [1], A. Tsukamoto [2]

1. Graduate School Of Science And Technology Nihon University, Chiyoda, Tokyo, Japan
2. College of Science and Technology, Nihon University, Japan, Chiyoda, Tokyo, Japan

We already reported that isolated several tens of nano-meters FePt grains were fabricated by Rapid Thermal Annealing (RTA) and Rapid cooling process (RCP) for Pt / Fe double layered ultra-thin film on SiO_x[1)]. In this report, we aim to obtain perpendicularly higher anisotropic magnetic property originated from $L1_0$ ordered phase for FePt grains. We tuned composition of Fe_xPt_{100-x} (x = 50 ~ 63.7) deposited as Pt / Fe double layers on thermally oxidized Si substrate. The thickness of deposited double layer was 1.88 nm. After the fabrication of isolated FePt grains by RTA and RCP, relations between each compositions and corecivity (H_c) were {x, H_c} = {50,≈0T}, {55,< 0.2T}, {57,2.6T}, {62,4.2T} and {63.7,3.8T}, respectively. As the case of x = 57, 62 and 63.7, large values of *H*c were appeared. For x = 62, simple hard magnetic hysteresis loop was observed. However, in x = 57 and 63.7, soft magnetic like properties also were observed below 1 Tesla and alsodisordered and non c-axis orientated peaks in XRD were mainly measured. Thus, we considered that the hard magnetic property was came from$L1_0$-FePt phase in x = 62. Then, double layer was presumed to classify as $Fe_{50}Pt_{50}$ alloy layer of $L1_0$ ordered phase and 0.41 nm thick Fe buffer layer. Furthermore, we deposited different thick Pt / Fe double layered film (2.29 nm, $Fe_{60}Pt_{40}$). It consists from 0.41 nm of Fe buffer layer and 1.88 nm of Pt / Fe ($Fe_{50}Pt_{50}$) layer. We obtained FePt grains with high H_c about 4.7 Tesla and observed barely soft magnetic like contribution. These results indicate that Fe buffer layer (thickness = 0.41 nm) on thermally oxidized Si substrate was well effective for fabrication of perpendicularly higher anisotropic magnetic property originated from $L1_0$ ordered FePt phase.

TU.G-P25 - Out of plane magnetic anisotropy and anisotropic magnetoresistance in epitaxial $La_{5/8-y}Pr_yCa_{3/8}MnO_3$ (y=0.4) thin films

Lalit M. Kandpal [1], Y, P. K. Siwach [1] N, V. P. S. Awana [1] N, H. K. Singh [1]

1. CSIR-National Physical Laboratory, New Delhi, India

In the archetypical phase separated manganite $La_{5/8-y}Pr_yCa_{3/8}MnO_3$ (y=0.4), the out of plane anisotropic magnetic and transport properties, which has not been paid much attention could provide a linkage between phase separation and anisotropy. In order to explore the linkage between phase separation and anisotropy, 42 nm thick epitaxial films were prepared by RF magnetron sputtering on (001) oriented $SrTiO_3$ substrates. The angular scaling of magnetization- magnetic field (M-H) data shows that the easy axis lies in the plane of the film while the hard axis is normal to it. The temperature dependent zero field cooled (ZFC), field cooled cooling (FCC) and field cooled warming (FCW) magnetization (M-T) measured at H= 100 Oe applied parallel to film plane along the longest direction (Mll) and normal to the film plane (ML) reveals large difference Mll and ML. This coupled with the M-H data confirms large out of plane magnetic anisotropy. Other prominent features that distinguish Mll and ML are, (i)considerably lower hysteresis in FCC-FCW ML-T, (ii) the peak in FCW Mll-T at TP=42 K is shifted to Tp=18 K in ML-T, (iii) the glass transition observed in Mll-T at Tg=31 K disappears in ML-T. These results clearly show that the relative fraction of the coexisting phases, viz., ferromagnetic metallic (FMM) and antiferromagnetic/charge ordered insulator (AFM/COI) and hence degree of phase separation are sensitive to magnetic anisotropy. Colossal out of plane anisotropic observed also at T>TC but the AMR peaks disappear. The magnetic anisotropy is magnetoresistance (AMR) of -142 % and -115 % is observed in cooling and warming cycles. At T<TC the AMR-H data shows pronounced hysteresis and a peak which occurs at higher H in the field increasing cycle. The AMR-H hysteresis is due to coupled consequence of the magnetocrystalline and surface anisotropies and the FMM and AFM phases respond differently to it.

TU.G-P27 - Temperature dependence of perpendicular magnetic anisotropy in CoFeB thin films

The uniaxial perpendicular magnetic anisotropy (PMA) of ferromagnetic layers is one of the most important factors that influence the performance of spintronic devices such as magnetic memory, magnetic sensors, and spin torque oscillators. Recently the Co-Fe-B alloys became popular in spintronics due to its strong PMA upon annealing [1] and the easy fabrication of CoFeB/MgO/CoFeB magnetic tunnel junctions (MTJs) with large tunneling magnetoresistance (TMR) [2]. The PMA in CoFeB possesses a second-order uniaxial term [3] that can be used to achieve ultrafast switching [4]. Understanding the factors controlling PMA in CoFeB thin films is of great importance for the development of MTJ-based spintronic devices. Here we report our studies on the temperature dependence (5 K - 295 K) of PMA in Ta/ $Co_{20}Fe_{60}B_{20}$/MgO thin films with different $Co_{20}Fe_{60}B_{20}$ thicknesses by using ferromagnetic resonance (FMR) measurements. The temperature dependence of the first order PMA field B1 shows a linear behavior, of which the slope of linear fit decreases monotonously with increasing thickness d and scales with d^(-3). B1 at 0 K obtained by extrapolation increases with increasing thickness in the thickness range studied. For the CoFeB film with thickness of 1.3 nm that is close to the critical thickness 1.25 nm [5], an easy cone orientation of magnetization is realized at low temperatures, due to that the first and second order PMA fields are of the same order of magnitude. Based on the temperature dependences of the first and second order PMA fields, a thickness-temperature diagram of the $Co_{20}Fe_{60}B_{20}$ thin film was obtained, which illustrates different regions for easy-plane, easy-cone, and easy-normal orientations of magnetization, which would benefit further understanding of manipulation of PMA in CoFeB thin films for spintronic applications.

Magnetization reorientation driven by femtosecond, visible light pulses has been recently found in thin Pt/Co/Pt sandwiches and explained in terms of irradiation induced formation of Co-Pt alloy on the Co/Pt interface, exhibiting high perpendicular magnetic anisotropy [1]. In the present work we investigated the Pt/Co/Pt thin films whose in-plane magnetization state was modified by single, extreme ultraviolet (EUV) light pulses. The Co layers 3 nm or 10 nm thick placed in-between the Pt bottom and top layers with thickness close to 25 nm and 3 nm, respectively, were deposited by MBE method onto (0001)-oriented sapphire substrates. The samples were irradiated by 3 ns pulses from laser-plasma source with the most intense emission centered at wavelength 11 nm (see [2] for details). The structure of samples was characterized by X-ray diffraction and reflectivity methods. The polarized neutron reflectivity (PNR) is an effective tool to study depth profiles of in-plane magnetization in multilayers and, to some extent, depth profiles of constituent element distribution. The PNR measurements were performed at LLB with the use of PRISM spectrometer. Prior to the irradiation a presence of smooth and sharp interfaces was confirmed by all three methods above mentioned. The analogous results obtained for irradiated samples showed changes in their structures. Due to the formation of Pt-Co alloy the maximal value of magnetization in-plane slightly decreased. The thinner sample was more uniform than the second one. Results obtained for the thicker sample suggest a presence of a significant Co concentration gradient inside thick Pt buffer and more complex depth profile of in-plane magnetization.
This work was partially supported by the grant No. DEC-2012/06/M/ST3/00475 from National Science Centre (Poland).

TU.H-P02 - Specific heat and thermal expansion of $LaCo_{1-x}Ga_xO_3$ cobaltates

N.K. Gaur [1], R. Thakur [1], R.K. Thakur [1]

1. Barkatullah University, Bhopal, India

The interest in $LaCoO_3$ cobaltates is associated with an occurrence of thermally induced transitions from low-spin (LS) to high-spin (HS) or intermediate-spin (IS) state as well as with a possibility to vary the transport and magnetic properties by heterovalent substitution on the La and/or Co sites. The parent compound lanthanum cobaltate $LaCoO_3$ shows an insulating ground state based on the diamagnetic LS state of Co^{III} ions. At room temperature $LaCoO_3$ and lanthanum gallate $LaGaO_3$ possess rhombohedrally distorted crystal structure of perovskite. The main focus of the present paper is to investigate the effect of isovalent substitution in $LaCoO_3$ of diamagnetic gallium ions Ga^{3+} with a completely filled 3d shell ($3d^{10}$) for paramagnetic ions Co^{3+} with a partially filled 3d shell ($3d^6$) on the elastic and thermal properties formed $LaCo_{1-x}Ga_xO_3$ as promising materials for fabricating membranes and other articles for electronic technology.

The specific heat and thermal expansion coefficient of $LaCo_{1-x}Ga_xO_3$ ($0.01 \leq x \leq 1$) has been studied as a function of temperature ($10K \leq T \leq 1000K$) by means of a Rigid Ion Model (RIM) after modifying its framework to incorporate the van der Waals interactions. In this paper the functional relation between charge and size mismatch and the thermal properties is determined and compared with the available reports. The Debye temperatures obtained from the lattice contributions are found to be in somewhat closer agreement with the available experimental data. The thermal expansion and specific heat values revealed by using MRIM are in closer agreement with the available experimental data for some concentrations (x) of $LaCo_{1-x}Ga_xO_3$. In addition, the results on the bulk modulus (B), cohesive energy (ϕ), molecular force constant (f), Reststrahlen frequency (u_o) and Gruneisen parameter (γ) are also discussed.

TU.H-P03 - Micromagnetic simulations of nanocomposites and their neutron scattering response

S. Erokhin [1], A. Michels [2], D. Berkov [1]

1. General Numerics Research Lab, Jena, Germany
2. Physics and Materials Science Research Unit, University of Luxembourg, Luxembourg

Due to our recent achievements in micromagnetic simulations of nanocomposites [1], it is possible to study the magnetization state in a relatively large volume of a magnetic nanocomposite material. This talk includes physical examples of modelling of magnetic structure of soft nanocomposites and the corresponding small-angle neutron scattering (SANS) cross section, demonstrating the accuracy of our method. First, we present numerical studies of a nanocomposite of the Nanoperm type, consisting of iron-based crystallites embedded in an amorphous magnetically soft matrix. This alloy with high permeability demonstrates an unusual angular anisotropy of the experimental SANS cross-section. In order to find out the reason of this phenomenon, we have performed large-scale numerical simulations of the Nanoperm magnetization state in various fields. Our results have unambiguously demonstrated that this effect is due to the internal magneto-dipolar field arising around hard inclusions. The second example is a porous ferromagnet that possess the maximal magnetic inhomogeneity among nanocomposites due to the jump of the magnetization on the boundary between pore and material. This extreme case makes possible to show explicitly the anisotropic nature of magnetic correlations in this type of nanocomposites, employing numerical studies of spatial correlations functions of the magnetization distribution. Numerically calculated SANS cross-sections agree very well with experimental data obtained on real materials.
Our method allows to extract the individual contributions to the total magnetic SANS cross-section, which is a complicated combination of all magnetization components decorated by the interaction of neutrons with magnetodipolar stray field of magnetic moments. This analysis opens up new possibilities to obtain fundamental insights into the magnetic neutron scattering. This research was supported by the DFG Project BE 2464/10-3.

TU.H-P04 - Critical behaviors at low-field of Fe-Ni-Zr alloy ribbons

T.D. Thanh [1,2], N.H. Dan [2], T.L. Phan [3], S.C. Yu [1]

1. Chungbuk National University, Cheongju, South Korea
2. Vietnam Academy of Science and Technology, Hanoi, Vietnam
3. Hankuk University of Foreign Studies, Yongin, South Korea

In this work, we present a detailed study on the critical behavior at low-field (below 10 kOe) of the ferromagnetic-paramagnetic (FM-PM) phase transition in $Fe_{90-x}Ni_xZr_{10}$ alloy ribbons with x = 0-15, which were prepared by a rapid-quenching method. The results reveal that the samples are almost amorphous with a very small volume fraction of the nano-crystalline. We point out that these alloy ribbons undergoing a second-order phase transition and the Curie temperature (T_C) depends strongly on Ni-concentration (x) increasing from 245 K (for x = 0) up to 403 K (for x = 15). Basing on isothermal magnetization data, $M(H)$, the values of the critical exponents β, γ, and δ around FM-PM phase transition were determined by using the modified Arrott plots and critical isotherm analyses. The $M(H)$ behavior in the critical region obeys the universal scaling law, $M(H, \varepsilon) = \varepsilon^{\beta} f_{\pm}(H/\varepsilon^{\beta+\gamma})$, which implies that plotting $M/|\varepsilon|^{\beta}$ versus $H/|\varepsilon|^{\beta+\gamma}$ makes all $M(H)$ data points falling into two universal branches corresponding to $T < T_C$ and $T > T_C$. The results obtained show that in the case of low Ni-concentrations, the β value (β = 0.367 and 0.396 for x = 0 and 5, respectively) is close to that expected for the 3D-Heisenberg model revealing an existence of short-range FM interactions in $Fe_{90}Zr_{10}$ and $Fe_{85}Ni_5Zr_{10}$ alloy ribbons. In contrast, the falling of the β values in between the values of mean-field theory (β = 0.5) and the 3D-Heisenberg model (β = 0.365) for high Ni-concentration samples (β = 0.436 and 0.444 for x = 10 and 15, respectively) indicates a coexistence of short- and long-range FM interactions. It means that the presence of Ni favors establishing FM long-range order. The nature of this phenomenon is carefully discussed.

TU.H-P06 - The Memory in Magnetic Systems

C. Appino [1]

1. Inrim, Torino, Italy

Most of the features of ferromagnetic materials are embedded in their hysteresis loop [1]: a matter compelling one to focus the attention on the memory properties of magnetic systems. Starting from the landmark work of Preisach, where the memory effects of scalar hysteresis are suitably accounted for by means of the so called Preisach plane, a vector generalization to ensembles of Stoner-Wohlfarth particles has been recently proposed [2]. In this approach the stability properties of particles are described by adopting the conventional astroid representation, a strategy also exploited to discuss incoherent particle rotations [3]. On the other hand, in order to include the possibility of reversal by domain wall motion, a modification of the coherent rotation mechanism, graphically represented by a "truncated astroid", has been proposed as well [4]. Within this framework, we present a general mathematical tool able to track the history of any magnetic system, with reversal of magnetization driven by reversible and irreversible rotations and domain wall displacements. Coupled to a vector hysteresis model, the procedure outlined allows one to decrease to a large extent the computational time needed to reproduce the hysteresis loop. Eventually, this instrument supplies a set of thermodynamic variables providing an estimate of the magnetic energy loss entailed by irreversible processes, and the consequent entropy production.

TU.H-P07 - Forced volume magnetostriction of $Y_2Fe_{17-x}M_x$ (M=Al,Sl,Ga)

T. Kamimori [1], D. Haruna [1], H. Tange [1]

1. Faculty Of Science, Ehime University, Matsuyama, Japan

The substitutions of nonmagnetic elements for Fe in intermetallic compound R2Fe17 increase the Curie temperature, TC. This phenomenon is understood as Invar magnetism, (dTC/dV)>0. In realy, substitutions of Al and Ga for Fe increase both lattice volume and TC. The values of (dTC/dV) are 7.5(103K/nm3) for the Al substitution and 14 for Ga. On the contrary, the substitution of Si for Fe contracts lattice volume and increases TC, (dTC/dV)= -63 < 0. This is against the Invar magnetism. In this study, forced volume magnetostriction, ∂ω/∂H, was measured in Y2Fe17-xMx (M=Al,Si,Ga) compounds by means of 3-terminals capacitance method under magnetic field up to 1.5T. In all cases, the values of ∂ω/∂H observed at R.T. were positive and decrease with increment of TC by the substitutions. In all substitutions, the values of dTC/d(∂ω/∂H) at R.T. are between -1.7(102KT-1) and -3.7. These phenomena indicate the substituion of Al,Si,Ga for Fe weaken magnetovolume effect of Y2Fe17 with increment of TC.

It is well-known, the origin of Invar effect is magnetovolume effect as expansion with appearance of magnetization. The results in this study indicates the increment of TC by sbustitution of non magnetic elements for Fe in R2Fe17 is not by the Invar effect itself but by the declining of the Invar magnetism.

TU.H-P09 - New medium frequency MnZn Ferrite with low losses over a broad temperature range

G. Kogias [1], V. Zaspalis [1]

1. Center For Research And Technology-Hellas, Thessaloniki, Greece
2. Aristotle University of Thessaloniki, Thessaloniki, Greece

New and existing applications possess stronger demands on the performance of the magnetic cores, searching for both efficiency and miniaturization. The working conditions of the equipments require specific properties from the transformers and inductors in order to minimize magnetic power loss in the system. A relatively recent trend in the application market of magnetic components asks for the development of magnetic materials with low losses over broad temperature ranges. Some of these applications are automotive DC/DC converters in hybrid and electric vehicles, DC/DC converters in telecommunication and computing equipment, microinverters of photovoltaic systems or high power LED drivers for public lighting. In this article the development of a medium frequency MnZn ferrite polycrystalline material exhibiting low losses over broad temperature ranges is reported. The initial permeability is 1700 (10 kHz, 0.1 mT, 25°C) and the power losses at 500 kHz, 100 mT are 640 kW m-3 (25°C) and 650 kW m-3 (100°C). The improvements have been realized through optimizations in the design of the antiferrimagnetic unit cell lattice. The addition of Sn ions results to the increase of specific resistivity and as a result the losses at medium frequencies are decreased. The addition of Co ions possesses opposite anisotropy constant of the host lattice and with its introduction compensates the already existing lattice anisotropy. As a result it changes the temperature dependence of the anisotropy constant of the host lattice and leads to the increase of permeability and the decrease of losses. The previous results of the developed MnZn ferrite with low power loss values over a broad temperature range, establish it ideal for the above applications.

TU.H-P10 - Vector model for losses in non-oriented steel sheets

C. Appino [1]

1. Inrim, Torino, Italy

The presence of two-dimensional (2D) magnetization processes in devices and electrical machines calls for the development of vector model for loss prediction. Starting from the Del Vecchio-Charap work [2], we developed a static model able to reproduce the 2D evolution of magnetization in soft non-oriented steel sheets: the most interesting case for applications. The material is assimilated to an ensemble of biaxial grains, each associated with a hysteron having two orthogonal easy axes. In each of them, the field driven irreversible switch of magnetization between the easy directions (Barkhausen jump: BJ) is governed by the value of local coercive field (about ten times smaller than the anisotropy fields); the ensemble of all these BJs accounts for the domain wall displacement. After the BJ, the local magnetization is brought to its energy minimum by the antagonism between anisotropy and Zeeman energy, so determining the reversible magnetization component. Domain wall reversible processes (bending) are not considered, whereas the role of macroscopic and internal demagnetizing fields is accounted for. The system average magnetization is obtained after integrating the outputs of single hysterons, each weighted by probability density functions suitably characterizing the material properties (i.e.: grain orientations, coercive and anisotropy fields). We have been able to reproduce the loss vs. polarization W(Jp) evolution in several non-oriented materials, subjected to alternating and rotating fields. In particular, under circular induction, the W drop at high Jp was always found, without introducing “ad hoc” fitting functions. It is remarkable that the outlined approach can be extended to systems magnetized in dynamic conditions.

TU.H-P11 - magnetic and structural evolution of $Nd_2Fe_{14}B$ nanoparticles doped with Co and Ni during surfactant-assisted ball-milling

J.S. Trujillo Hernandez [1], J. Anselmo Tabares [1], G.A. Pérez Alcázar [1]

1. Universidad Del Valle, Cali, Colombia

In this work, powder produced by arc melting of the alloy $Nd_{16}(Fe_{76-x}Co_x)B_8$ with x = 0, 10, 20 and 25 (size distribution under 20 micrometers) was milled in a high-energy planetary ball-mill (Fritsch Pulverisette 5 with hardened steel balls) at a rotational speed of 300 rpm. The milling was performed in a protective argon atmosphere with the ball-to-powder weight ratio of 20/1 for milling times varying from 1 to 2 h. Hexane (55% of powder weight) was introduced in the mill as a solvent together with oleic acid (12% of powder weight) as surfactant. The powders obtained after milling was washed with ethanol. X-ray diffraction (XRD), Mossbauer spectroscopy (MS), and Vibrating Sample Magnetometry (VSM) measurements were performed in order to characterize the properties of the obtained samples. A PanAnalytical diffractometer with a Cu anode, a constant acceleration mode Mössbauer spectrometer with a 25 mCi 57Co (Rh) source, and a PPMS of Quantum Design were used, respectively, to obtain these measurements. The role of milling time and the presence of the surfactants proved to be critical for the final size, shape, structure and magnetism of the nanoparticles. In the beginning milling mostly improves exchange coupling between the $Nd_2Fe_{14}B$ phase and soft magnetic phases. However, higher energy product value were achieved for nanostructures with sizes closer to the monodomain limit of $Nd_2Fe_{14}B$ (50e100 nm).

TU.H-P12 - The effect of high energy ball - milling on the morphology and magnetic properties of $Ho(Ni_{0.5}Co_{0.5})_3$ compound

A. Bajorek [1,2], P. Skornia [1,2], K. Prusik [2,3], M. Wojtyniak [2,3], G. Chełkowska [1,2]

1. A. Chelkowski Institute of Physics, University of Silesia, Katowice, Poland
2. Silesian Center for Education and Interdisciplinary Research, University of Silesia, Chorzów, Poland
3. Institute of Materials Science, University of Silesia, Chorzów, Poland

The aim of the presented study was to focus on the effect of mechanical grinding on the morphology and magnetic properties of $Ho(Ni_{0.5}Co_{0.5})_3$ intermetallic compound in order to improve its applicable magnetic parameters. First the polycrystalline $Ho(Ni_{0.5}Co_{0.5})_3$ bulk compound was crushed and pre-milled with a standard agate mortar. Than, such a mixture was grinded up to 80 h with frequency 30 Hz using Mixer Mill 400 (Retsch). The wet milling has been performed in dimethylformamide (DMF) using the Eppendorf vials and balls with a diameter of 2 mm made of ZrO_2 with balls to powder ratio about 10:1 by weight. After each stage of milling the morphology of the grinded material was investigated by using: dynamic light scattering DLS (Zetasizer Nano ZS Malvern Instruments), the scanning electron microscopy SEM (Jeol JSM 6480) and the X-ray diffraction XRD (Empyrean PANalytical). Additionally, after the last stage (80h) the transmission electron microscopy TEM (Jeol JEM 3010 UHR) and the atomic force miscroscopy AFM were applied. The magnetic properties has been determined based on wide-ranging SQUID magnetometer (Quantum Design MPMS, temperature from 1.9K to 400K and magnetic field up to 7T) series of different magnetic measurements.
The increase in the milling time leads to the reduction in the size of crystallites and the gradual amorphization of the starting material. Additionally, the presence of the nanoflakes with thickness even less than 100 nm was evidenced. Moreover, the increase in milling time results in the slight variation of the coercivity (H_C) and the *remanent-to-saturation* (M_r/M_S). The shape of the hysteresis loops varies across pulverization exhibiting a characteristic kink for higher milling time. Such a behaviour is due to the ultrafine grained structure and inhomogenities among magnetically ordered grains formed during HEBM.

TU.H-P13 - Partitioning of rare earth dopant and magnetic properties of RF3-doped Nd-Fe-B hot-pressed magnet

J.Y. Kim [1], H.W. Kwon [1], J.G. Lee [2], J.H. Yu [2]

1. Pukyong National University, Busan, South Korea
2. Korea Institute of Materials Science, South Korea

With increasingly escalated need for high coercivity in many permanent magnet applications, rare earth fluoride (RF3) salts have been widely used for enhancing coercivity in the hot-pressed and die-upset Nd-Fe-B-type magnet. Melt-spun Nd-Fe-B flakes are mixed with RF3 and then hot-pressed and hot-deformed. Rare earth dopant from the doped RF3 substitutes some of Nd in either $Nd_2Fe_{14}B$ matrix grain or Nd-rich grain boundary phase or both phases in the flake, thus enhancing coercivity. In this article, partitioning of the rare earth dopant in the Nd-Fe-B-type hot-pressed magnets doped with various RF3 and its effect on the magnetic properties were investigated. Commercial melt-spun flakes (MQU-F : $Nd_{13.6}Fe_{73.6}Co_{6.6}Ga_{0.6}B_{5.6}$) were mixed with 1.6 wt% RF3 (R = La, Ce, Pr, Nd, Dy) and then hot-pressed. Partitioning of the rare earth dopant was examined by SEM equipped with EDX and X-ray diffraction. RF3 (R = Pr, Nd, Dy)-doping led to an overall coercivity enhancement with respect to the un-doped magnet. The most profound coercivity enhancement (5.0 kOe) was achieved in the DyF_3-doped magnet pressed at 735 C, and this was attributed mostly to the substitution of Nd in $Nd_2Fe_{14}B$ matrix grains in the flake by the dopant Dy from the DyF3. NdF3- and PrF3-doping was most beneficial for enhancing coercivity (3.0, 3.5 kOe) in the magnet pressed at 700 C and below 670 C, respectively, and the improvement was attributed largely to the modification of Nd-rich grain boundary in the flakes by the dopant Nd, Pr. RF3 (R = La, Ce)-doping caused radical coercivity reduction in the magnet hot-pressed at higher temperature above 735 C, and this was attributed to the substitution of Nd in $Nd_2Fe_{14}B$ matrix grain in the flake by the dopant La, Ce. Variation of magnetic properties caused by the RF3-doping was correlated with partitioning of the rare earth dopant.

TU.H-P14 - Direct imaging of Fe nanoclusters in a melt-spun FeSiBPCu alloy by aberration corrected high-resolution transmission electron microscopy

K. Sato [1], K. Takenaka [1], A. Makino [1], Y. Hirotsu [1]

1. Institute For Materials Research, Tohoku University, Sendai, Japan

The newly developed FeSiBPCu nanocrystalline soft magnetic alloy contains more tan 80at%Fe; which is the upper limit of the Fe content for single amorphous phase formation [1]. A proper heat treatment of an as-quenched ribbon is the key to obtain the excellent soft magnetic properties in this alloy (Hc = 7-10 A/m, Bs = 1.88-1.94 T). It has been suggested that small Fe clusters formed at an as-quenched state could act as the nucleation site for the α-Fe grains during the crystallization. However, detailed structure of an as-quenched FeSiBPCu alloy still remains an open question. In this study we hence intend to characterize atomic structures of a melt-spun $Fe_{85.2}Si_2B_8P_4Cu_{0.8}$ alloy by using spherical aberration (Cs) corrected high-resolution transmission electron microscopy (HRTEM). The Cs was adjusted to approximately -1 µm and thus the theoretical optimal defocus becomes as small as 1.6 nm, which can effectively minimize possible imaging artifact. As a result, existence of a few nanometer-sized clusters was found in an amorphous matrix. The number density of such clusters reached as high as 9×1012 cm-2. Some of the clusters show four-fold or six-fold atomic arrangements, implying existence of crystalline Fe clusters with the bcc structure [2]. Possible structural change due to electron irradiation can be excluded in the HRTEM observation using a CCD camera with a short acquisition time of 1s. Electron diffraction pattern obtained from a wide area shows only halo rings arising from amorphous structure. Thus modern Cs-corected HRTEM unambiguously revealed the formation of a “heteroamorphous” structure in the as-quenched FeSiBPCu alloy. These extremely small nanoclusters with high number density must be responsible for a formation of high-density α-Fe nanocrystals produced by post-annealing.

TU.H-P15 - The effect of film thickness on the forming process and switching parameters of sol-gel prepared cobalt ferrite thin films

C. Liu [1], M. Mustaqima [1], D.H. Kim [1], B.W. Lee [1]

1. Hankuk University Of Foreign Studies, Seoul, South Korea

The resistive switching (RS) phenomenon refers to the reproducible switching between a high resistance state (HRS) and a low resistance state (LRS) observed in a metal/oxide/metal (MOM) configuration. In the past 10 years, the RS effects in binary oxide materials such as NiO, TiO2, and TaOx has been studied intensively for their potential applications in nonvolatile resistive random access memory (RRAM). More recently, ferrite materials have been discovered as potential RRAM materials showing excellent RS behaviors. Due to their ferromagnetic property and electrically insulating characteristics, ferrite materials have been considered as a good candidate for combining the magnetic and electrical switching behaviors in one device.
In this work we report the preparation of textured cobalt ferrite (CoFe2O4, CFO) thin films by sol-gel and spin-coating and the study on the RS properties of Pt/ CoFe2O4/Pt structures. The (111)-oriented polycrystalline CoFe2O4 thin films were prepared on Pt/TiO2/SiO2/Si substrate by spin-coating. Scanning electron spectroscopy revealed that the average layer thickness of one coating is about 60 nm. The thickness of the CFO thin film was adjusted by the number of coating varied from 1 to 4. All Pt/1-layered CFO/Pt structures showed a quite low resistance of a few ohms and no switching was observed. Most of the MOM structures based on 2-layered CFO thin films showed increased resistance around 10 Ω in the initial states, and unipolar resistive switching (URS) without forming process was observed. When the layer number increased to more than 3, the initial states of the Pt/CFO/Pt structures were of high resistance higher than 50 kΩ, and stable and repeatable URS with a HRS/LRS ratio about 1000 can be induced with a forming process. Based on the thickness dependence of the URS behavior observed, we analyzed the RS behaviors of the textured CFO thin films in detail with respect to the forming voltage and the conducting mechanism. Our results revealed that Pt/CFO/Pt structures with 2 or 3 layers of CFO thin films show the most stable RS behavior with a much narrow distribution in the set voltage.

TU.H-P16 - A novel experimental determination of the magnetometric self- demagnetization factor

N. Hillier [1], M. Hall [1], S. Turner [1], S. Harmon [1]

1. National Physical Laboratory, Teddington, United Kingdom

Machine designers and advanced material manufacturers are in need of a robust, practical and accurate measurement technique, capable of determining permanent magnet properties for operating conditions. Recent techniques based on pulsed field magnetometry offer this capability, with the measurement of the full BH loop taking less than 100 ms. However, for these techniques to reach the required accuracy and robustness, detailed investigation into the associated correction factors is required. One such correction, which is associated with the geometry and susceptibility of the test sample, is the magnetometric self-demagnetization factor, ND. This correction and the associated phenomenon of self-demagnetization are explained in detail in the work of Chen et al. [1] and have thus far been theoretically calculated using an inductance model. This work will introduce a novel experimental determination of ND based upon a measurement of the working point polarisation, Jm , and the second quadrant demagnetization curve. In this study, a series of cylindrical NdFeB samples were investigated, with aspect ratios ranging from 1 up to 3, where 1 represents a cylinder 10 mm in length and 10 mm in diameter. The experimental and theoretical values of ND are presented and found to have discrepancies of up to 40%. This significant difference is attributed to over simplifications of the susceptibility used in the theoretical models. Data from the Pulsed Field Magnetometer (PFM) at the National Physical Laboratory is then processed using these values, with the experimentally determined ND resulting in behaviour closer to that of the known material behaviour. This paper will present for the first time these measurements of ND and discusses the complex self-demagnetization correction required to obtain material properties using a PFM.

TU.H-P17 - Power density increasing design for railway vehicle traction motor using Halbach magnet array structure

H.W. Lee [1], H.W. Jun [2], K.D. Lee [2]

1. Korea National University Of Transportation, Chungju, South Korea
2. Hangyang University, Seoul, South Korea

Generally, traction motors for railway vehicles are inferior to that of electric vehicle in terms of power density. Traction motors for railway vehicles are relatively free of spatial constraints than motors electric vehicles, but in terms of whole system efficiency, increasing power density of traction motor is helpful. In this paper, neodymium magnet was used in permanent magnet synchronous motor design. The neodymium magnet is widely used in industry because its high energy density compared to other permanent magnet material. In this paper, using Halbach magnet array structure, power density of traction motor for 40kW class tram was elevated. This paper introduce detailed design process of the Halbach magnet array structure applied model, and check the effects on output characteristics by parameters like rotor shape, airgap diameter and pole ratio. Also, electrical output characteristics were compared between typical SPMSM model and Halbach magnet array model, which has same output. With electromagnetic analysis, the amount of power density elevation was confirmed, compared to Halbach model and typical SPMSM model. In addition, although there is a risk of occurring high torque ripple, achieve the same output characteristic as the prior SPMSM type motor by applying proper pole ratio.

TU.H-P18 - Application of the Jiles-Atherton model for the temperature dependence of magnetic hysteresis loops of amorphous alloys with perpendicular anisotropy

R. Szewczyk [1]

1. Industrial Research Institute For Automation And Measurements PIAP, Warsaw, Poland

Cores made of amorphous alloys with perpendicular anisotropy are widely used as cores for precision current transformers. Such cores exhibit linear B(H) characteristics with nearly constant permeability, and negligible coercive field of magnetic hysteresis loop.
However, both permeability and saturation flux density of such cores are temperature dependent. It should be highlighted, that this dependence has significant impact on characteristics of measuring devices, such as current transformers. On the other hand, the accurate model of temperature dependence of characteristic of anisotropic cores was still not presented. However, correction of Jiles-Atherton model of anhysteretic magnetization [1, 2] creates new possibility of such modelling. Magnetic hysteresis loop B(H) of Nanoperm M-680 core produced by Magnetec was measured in the temperature range from -30 up to +150 ºC. During the increase of temperature, the increase of amplitude permeability and significant decrease of saturation flux density B was observed.
On the base of experimental results, the modelling of B(H) characteristics was carried out. Parameters of the Jiles-Atherton model of anisotropic anhysteretic magnetization were determined during the optimisation process, utilizing the simplex search method. As a result, very good agreement between experimental results of measurements of B(H) characteristics and the results of modelling was achieved.
Results of modelling indicated the nearly linear decrease of average anisotropy energy density, when the temperature increases. Moreover, parameter a describing average domain wall density exhibits minima for the temperature about 40 ºC.
Presented results confirm that the corrected Jiles-Atherton model enables modelling of temperature dependence of magnetic B(H) hysteresis loops of amorphous alloys with perpendicular anisotropy. This model may be very useful for Spice-based modelling of measuring devices, such as precise current transformers.

TU.H-P19 - Influence of grain boundaries on magnetization-reversal within Nd-Fe-B magnets

I. Kitagawa [1], J. Ushio [1], A. Sugawara [1], T. Nishiuchi [2]

1. Central Research Laboratory, Hitachi Ltd., Kokubunji, Tokyo,Japan
2. Magnetic Materials Research Laboratory, Magnetic Materials Company, Hitachi Metals Ltd., Tokyo, Japan

Creating a Nd-Fe-B magnet with high coercivity is a tremendous challenge. Understanding the correct picture of the magnetization-reversal process occurring in the magnet is one key to increasing the coercivity. To grasp the correct picture of the magnetization-reversal process, magnetization reversal in a multi-crystal-grain Nd-Fe-B magnet was studied by micromagnetics simulation.
In order to elucidate the mechanism of magnetization reversal, two computational models were used. One is for a numerical estimation of dependence of the intergrain interaction on the grain boundary (GB) width, magnetization of the GB phase and angle between easy axes of adjacent grains. We used a planar two-grain magnet model consisting of two plate-like grains connected by a GB phase. The other model examines intergrain interaction through the magnetization-reversal process occurring inside a realistic microstructure investigating the reversal mode changed by the property of GB. Moreover, a large-scale micromagnetics simulation package based on a voxel-mesh model, in which the demagnetization-field calculation is accelerated by massive graphics-processing units (GPUs) was also developed. The simulation results show that interaction energy through the grain-boundary phase increases with decreasing grain-boundary width. Grains with a nonmagnetic GB are isolated when the grain-boundary width is larger than 20 nm. Grains with a ferromagnetic GB are more strongly coupled than those with a nonmagnetic GB. The decrease in the interaction energy causes the reversal process to change from domain-wall-motion type to isolated-single-grain type. The simulation, moreover, reveals that the interaction energy decreases with increasing angle between the easy axes of adjacent grains. The magnetization-reversal process in a Nd-Fe-B sintered magnet is dominated by domain-wall motion, which is promoted by the ferromagnetic GB. Reducing magnetization in the GB phase is thus an effective way to enhance coercivity.

TU.H-P20 - Effect of pre-sintering on the magnetic properties of NdFeB sintered magnets diffusion -treated with Cu/Al mixed DyH_2 powder

M.W. Lee [1], H.S. Lee [1], T. Jang [1], T.H. Kim [2], S.R. Lee [2], H.J. Kim [3]

1. Sunmoon University, Asan, Chungcheongnam-do, South Korea
2. Korea University, Seoul, South Korea
3. R&D center of Jahwa electronics, Cheongwon-gun, South Korea

Grain-boundary diffusion treatment has been purposed as a heavy rare-earth (HRE) element saving method, where HRE atoms are allowed to diffuse from the surface of a NdFeB sintered magnet to its interior through grain boundaries upon heating. Since the magnet used for this treatment is almost fully dense, HRE atoms cannot easily diffuse into the magnet resulting in relatively shallow diffusion of HRE atoms. A pre-sintering process (PSP), for which a magnet is sintered as a primary step below 900 ^{o}C prior to a fully dense sintering at a higher temperature could improve the diffusion depth of HRE atoms like Dy by decreasing the density of NdFeB sintered body to 70 ~ 80 %. Furthermore, it is known that the elements of low melting point such as Cu and Al also improve the diffusivity of HRE atoms by improving wettability of Nd-rich grain boundary phase. The solubility of Cu to $Nd_2Fe_{14}B$ phase is almost negligible whereas Al has some solubility to this main phase. In this work, we investigated the effect of pre-sintering process on the diffusion behavior of Dy in a NdFeB sintered magnet which was diffusion treated with Cu/Al mixed Dy source. The pre-sintering of a magnet was performed at 900 ^{o}C in vacuum and then the pre-sintered body was dipped in the solutions of DyH_2, DyH_2+Cu, and DyH_2+Al, respectively. The dipped pre-sintered body were then fully sintered at 1060 ^{o}C for 2 hrs followed by a subsequent annealing. The pre-sintering apparently improved the diffusivity of Dy atoms. The penetration of Dy into the magnet extended to 1500 μm from the surface when the DyH_2+Al solution was used as a Dy source resulting in the increase of coercivity more than 3 kOe. The experimental results will be discussed in detail in this presentation.

TU.H-P21 - Synthesis and Magnetic Properties of $SrZn_xFe_{(2-x)}Fe_{16}O_{27}$ ($0.0 \leq x \leq 2.0$)

J.H. You [1], S.J. Choi [1], S. Lee [1], S.I. Yoo [1]

1. Seoul National University, Seoul, South Korea

Since strontium W-type hexaferrite (SrW) is stable at the high temperature region of 1350–1440℃ in air, it is hard to obtain a pure phase of SrW at room temperature. Thus, there are some reports on the stabilization of SrW phase by substitution of Fe^{2+} ions with other divalent metal ions such as Mn, Zn, Co, and Ni. However these reports are on the full substitution for Fe^{2+} ions. Therefore, the effect of partial substitution on the properties has never been reported. Since we could obtain SrW pure phase at room temperature by annealing and subsequent furnace-cooling in a reduced oxygen atmosphere, we tried to prepare the Zn-substituted SrW bulk samples with the compositions of $SrZn_xFe_{(2-x)}Fe_{16}O_{27}$ ($0.0 \leq x \leq 2.0$) in a reduced oxygen atmosphere, and identify the effects of Zn^{2+} substitutions on their magnetic properties. Furthermore, we tried to investigate the phase stability region change of $SrZn_xFe_{(2-x)}Fe_{16}O_{27}$ with varying x. For this purpose, samples were annealed at the temperature region of 1100–1350°C for 2 h in $PO_2 = 10^{-3}$ atm. As a result, the saturation magnetization of the samples increased with increasing x from 0 to x = 1.5, and the phase stability region decreased with increasing x.

TU.H-P23 - Effect of milling energy and soft phase pre-milling on the microstructure and interphase exchange coupling of $Nd_2Fe_{14}B$/α-Fe nanocomposites

S. Mican [1], R. Hirian [1], O. Isnard [2], I. Chicinaş [3], V. Pop [1]

1. Babes-Bolyai University, Faculty Of Physics, Cluj-Napoca, Romania
2. Institut Néel, CNRS, Université Grenoble Alpes, Grenoble, Cédex 9, France
3. Materials Sciences and Engineering Dept., Technical University of Cluj-Napoca, Cluj-Napoca, Romania

The effects of milling energy and soft phase pre-milling on the microstructure and interphase exchange coupling of $Nd_2Fe_{14}B$+10wt% α-Fe nanocomposites were investigated. The α-Fe crystallite size is critical for obtaining an efficient interphase exchange coupling. We thus try a pre-milling of the soft phase in order to obtain smaller α-Fe crystallite sizes. Also, the problem of damaging the $Nd_2Fe_{14}B$ crystal structure during milling was addressed by using different milling energies. $Nd_2Fe_{14}B$+10wt% α-Fe powder samples were prepared through mechanical milling for 6h with Ø 10mm and Ø 15mm balls respectively. The starting soft phases consisted of commercial and 4h mechanically milled (MM) Fe powder annealed at 400ºC for 4h. The milled nanocomposite samples were annealed under Ar at 700, 750 and 800ºC for short times (0.5 to 3 minutes). X-ray diffraction (XRD) measurements showed the destruction $Nd_2Fe_{14}B$ crystal structure, however, this effect was less pronounced after milling with Ø 15mm balls. The restoration of the $Nd_2Fe_{14}B$ crystal structure after annealing was confirmed by XRD. The α-Fe crystallite sizes increase with annealing temperature/time, being roughly the same for both milling energies. Smaller α-Fe crystallite sizes were found for samples containing pre-milled Fe. The magnetic behavior was investigated from hysteresis curves and *dM/dH* vs. *H* plots. The samples milled at higher energies show a better interphase exchange coupling, however, milling at lower energies determined higher coercivities due to the reduced damaging of the $Nd_2Fe_{14}B$ crystal structure. The best exchange coupling was obtained for samples annealed at 700°C for around 2 minutes, with a maximum coercive field of about 0.5T. By increasing annealing temperature/time, the interphase exchange coupling weakens due to increasingly larger α-Fe crystallites. Taking into account the milling energy and preparation conditions, the $Nd_2Fe_{14}B$/α-Fe exchange coupling is analyzed.

TU.H-P24 - Structural and magnetic properties of mechanically milled $Mn_{50}Al_{46}M_4$ (M = Mn, Ni) alloys

R. Hirian [1], S. Mican [1], O. Isnard [2], I. Chicinaş [3], M. Coldea [1], V. Pop [1]

1. Babes-Bolyai University, Faculty Of Physics, Cluj-Napoca, Romania
2. Institut Néel, CNRS, Université Grenoble Alpes, Grenoble, Cédex 9, France
3. Materials Sciences and Engineering Dept., Technical University of Cluj-Napoca, Cluj-Napoca, Romania

The metastable τ-phase (tetragonal $L1_0$ structure) of the Mn-Al system was reported to have interesting magnetic properties for permanent magnet applications, the most stable composition being $Mn_{54}Al_{46}$. It was shown that the magnetic properties of the τ-phase can be improved through doping and mechanical milling. In this work, the structural and magnetic properties of milled $Mn_{50}Al_{46}M_4$ (*M*=Mn, Ni) alloys were investigated. The samples were prepared through induction melting, followed by mechanical ball milling up to 5h. The milled samples were annealed at 1050ºC for 1h under Ar atmosphere followed by quenching in water. The as-cast samples were found to be phase mixtures. For M=Mn the τ-phase was the main phase, while for *M*=Ni the κ-phase (CsCl-type structure) was a majority phase. The as-milled samples showed a progressive broadening of the XRD peaks with milling time due to increased strain and defect density. Following annealing, the 5h MM samples were composed mainly of the τ-phase (M=Mn) and κ-phase (M=Ni) respectively.
The coercivity of the $Mn_{54}Al_{46}$ alloy increases with milling time, a value of 0.3T being obtained for a milling time of 0.5h. For milling times longer than 0.5h the coercivity decreases rapidly due to crystal structure damage which diminishes the anisotropy. The 5h MM annealed samples showed higher remanence and lower coercive field values than the as-milled samples, however both coercivity and remanence values were higher than those of the as-cast sample.
The as-milled $Mn_{50}Al_{46}Ni_4$ samples show the same magnetic behaviour vs. milling time as the one observed for $Mn_{54}Al_{46}$. However, the coercivity and remanence values are lower, due to the presence of the soft magnetic κ-phase. The 5h MM sample annealed at 1050ºC for 1h showed both lower coercivity and remanence values than the as-milled samples, due to the κ-phase being the majority phase in this sample.

TU.H-P25 - Tic additive in neodymium iron boron magnets

Z. Mural [1], Y. Ilke Cakmakoglu [1], J. Link [2], L. Kollo [1], R. Veinthal [1]

1. Department of Materials Engineering, Tallinn University Of Technology, Tallinn, Estonia
2. National Institute of Chemical Physics and Biophysics, Tallinn, Estonia

Since the discovery of the $Nd_2Fe_{14}B$ compound in 1980s, continous efforts are being made to enhance the magnetic properties of RE-based magnets by optimizing it's microstructure and chemical composition. One of the strategies to increase coercitivity of the magnets is by decreasing its grain size. The effect of small amounts (0.1 - 0.5 wt.%) of TiC nanoparticles on grain coarsening during sintering was studied in this work. Standard powder metallurgy route was used to prepare NdFeB magnets. The nanoparticles were added before or after jet milling. Adding the nanoparticles after the jet milling by simple mixing could not disperse the particles, resulting with agglomerates in the final microstructures. Introducing the nTiC prior to the jet milling was effective and nanoparticles were dispersed in the the final alloy, concentrating in the neodymium rich phase of the alloy. Although some grain refining effect was observed, no significant effect from nTiC additive on magnetic properties was found.

TU.H-P26 - Permalloy thin films on palladium activated self assembled monolayer for magnetics on silicon applications

R. Anthony [1,2], J. Rohan [1], C. Ó Mathúna [1,2]

2. 2Department of Electrical and Electronics Engineering, University College Cork, Cork, Ireland

Magnetic thin films of Permalloy (Py) have been extensively deposited as soft core materials for integrated magnetic components (micro-inductors and transformers) [1]. However, existing electroplating methods require an additional conductive seed layer resulting in undercutting of the core during patterning. We report an electroless deposition process for Py thin films on oxidised silicon substrates for magnetics on silicon applications. P-type Si (100) samples were immersed in an amino-propyltrimethoxy silane solution to form an adhesive self-assembled monolayer which was activated by palladium to realise a thin catalytic layer [2] (fig. 1). This was followed by electroless deposition of Py in a borane based bath. Well adhered smooth Py films up to 500 nm have been obtained at a deposition rate of 1.8 nm/second with 8.5 nm surface roughness.

The measured resistivity of ~ 37 µOhm-cm is higher than electroplated Permalloy thin films (~ 20 µOhm-cm). Energy dispersive X-ray analysis suggested ~25% Fe and ~75% Ni with negligible B content, typically less than 1% [3]. These isotropic deposits (fig. 2) possess easy and hard axes coercivities ~4.5 and ~6.95 Oe, respectively, as measured in BH loop tracer. High frequency characteristics were studied with a wide-band complex permeameter (up to 9 GHz). For a 110 nm thick deposit as expected from the skin depth equation, the initial permeability of the film measured at null field was ~2750. Considerable increase in frequency roll off (fig. 3(a) and 3(b)) compared to previously reported Py films [4] is observed. This can be attributed to the presence of boron in the films which increases the resistivity, thereby reducing the high frequency eddy current losses.

The process for deposition of Py on non-conductive oxide films is ideal for MEMS structures with recessed regions, and applicable for deposition of other soft magnetic thin films on oxides.

TU.H-P27 - Magnetic anisotropy and stress sensitivity of thin-gauge non-oriented electrical steels

S. Turner [1], N. Hillier [1], M. Hall [1], S. Harmon [1]

1. National Physical Laboratory, Teddington, United Kingdom

The demand for high-performance electric motors, running at speeds in excess of 6000 rpm, has led to the production of thin gauge non-oriented electrical steels (0.2 mm and below) becoming more common place. Such materials restrict the generation of classical eddy current contributions, which increase with the square of frequency, and so offer a significant reduction in overall core loss. However, the processing required to reduce the gauge induces an unwanted magnetic anisotropy, which has a detrimental effect on permeability, power loss and performance under an applied stress. In this paper, the beneficial effects of thin gauge non-oriented electrical steels at higher frequencies are weighed against the corresponding detrimental influences of magnetic anisotropy and tensile stress. The results are compared to properties of thicker gauge laminations, demonstrating the advantages and disadvantages associated with each gauge. The DC magnetic properties of 0.2 mm non-oriented electrical steels were measured in both the rolling and transverse directions using a permeameter, where the latter shows a reduction in the maximum relative magnetic permeability of greater than 30%. These findings agree with ac measurements of specific total loss and apparent power for a peak polarization of 1.5 T measured at 50 Hz using both SST and Epstein frame methods. The DC magnetic properties under constant uniaxial tensile stress were also examined, by applying loads of up to 200 MPa in 50 MPa increments to strips cut in either the rolling or transverse direction. The magnetic properties were measured by applying a quasi-static DC magnetic field up to 3 kA/m, generating a full hysteresis loop at each increment. A 0.4% decrease in permeability per MPa was observed for both directions.

TU.H-P28 - Effect of Nd-Fe layer on the hard magnetic properties for Nd-Fe-B thin films

T. Furuuchi [1], M. Doi [1,2], T. Shima [1,2]

1. Tohoku Gakuin University, Sendai, Japan

Since the discovery of $Nd_2Fe_{14}B$ compound, Nd-Fe-B permanent magnets have been widely used for the applications such as sensors, actuators and motors, since they possess large magnetocrystalline anisotropy (K_{u1} = 4.5x10^6 J/m^3 at room temperature) and relatively high magnetization (M_s = 1.6 T) among all permanent magnets. The operating temperature of the traction motors for HEVs is approximately 200 ºC, so heavy rare earth such as Dy and Tb is used for Nd-Fe-B sintered magnets for HEV motors. However, due to the scarce and localized natural resources of these elements, we are facing to the drastic reduction of the usage of these elements.

The present study demonstrates the effect of the thickness for particulate Nd-Fe-B thin films and also the effect of the composition of Nd-Fe cap layers, which constitute the grain boundary phase, for the Nd-Fe-B thin films on the structure and magnetic properties.

All the samples were prepared by co-sputtering of Nd (3N), $Fe_{80}B_{20}$ (at%) and Fe (4N) targets using an ultra high vacuum (UHV) compatible dc magnetron sputtering system. Structural analysis was performed by X-ray diffraction (XRD) with Cu-Kα radiation. The magnetic properties were measured by a superconducting quantum interference device (SQUID) magnetometer.

From magnetization curves for Nd-Fe-B thin films at various film thicknesses, the squareness of the magnetization curve was improved for the film with $t_{Nd\text{-}Fe\text{-}B}$ = 10 nm, and also relatively high coercivity H_c of 18.6 kOe was obtained. Subsequently, Nd-Fe alloy films was prepared for characterize magnetic properties in detail. No large H_c was observed for all the films. With increasing Nd content x in the Nd-Fe films, a saturation magnetization decreased and became zero at x ≥ 72.9. Detailed structure and magnetic properties for Nd-Fe-B thin films with Nd-Fe alloy layer will be discussed at the conference.

TU.H-P29 - Microstructure and magnetic properties of highly condensed anisotropic MnBi system

Y.C. Chen [1], G. Gregori [2], S. Sawatzki [3], B. Rheingans [4], F. Qu [4], S. Ener [3], O. Gutfleisch [3], H. Kronmüller [1], Gisela Schütz [1], Eberhard Goering [1]

1. Max-Planck-Institut für Intelligente Systeme, Stuttgart, Germany
2. Max-Planck-Institut für Festkörperforschung, Stuttgart, Germany
3. Institute of Materials Science, Technische Universit, Darmstadt, Germany
4. Institute of Materials Science, Universität Stuttgart, Stuttgart, Germany

The low-temperature phase (LTP) of MnBi a promising rare-earth-free permanent magnet material due to high uniaxial magnetocrystalline anisotropy and an unusual positive temperature coefficient of coercivity (Hc).1 However, it is still challenging to synthesize high performance powder and highly-compacted bulk samples so far. In this study, we will present that our MnBi powder shows remarkable magnetic properties, which are close to the reported maximum energy product (BH)max values (~ 17.7 MGOe).2 The high-LTP-content MnBi powder could be easily mass-produced with low-energy ball milling, leading to small particle size ranging from 0.1~5 μm.

To fabricate bulk magnets, the green samples were prepared through cold-pressing under an alignment field of 18 kOe. Subsequently, the high-performance anisotropic sintered samples were achieved by either hot-compaction or spark-plasma-sintering techniques. Different processing parameters such as sintering temperatures, pressing pressure and holding times were found to have great effect on the magnetic properties of the as-prepared magnets. A systematic work has been completed to investigate the physical properties of the as-prepared powders and corresponding compacted samples by using XRD, ICP-OES, SEM, DSC, MOKE and SQUID. It was found that the distinct microstructure of the hot- and SPS-compacted magnets give rise to different temperature-dependent magnetic properties and thermal stability. The coercivity behavior of these specimens was further studied by First Order Reversal Curves (FORC) measurements as a function of temperature. Combined with the results analyzed via hardening mechanism, we will provide a clear explanation for the influence of microstructure on the magnetic properties of hard magnetic behavior in the bulk MnBi systems.

TU.H-P30 - Effect of stress on hysteresis loops of crystalline and amorphous materials

O. Perevertov [1]

1. Institute Of Physics, Academy Of Sciences, Na Slovance 2, Prague, Czech Republic

We compare influence of stress on magnetic hysteresis loops of iron-based steels and amorphous ribbons. Recently we have shown that for grain-oriented and non-oriented steels under all kinds of stresses changes in hysteresis loops measured at any direction could be described by the stressed-induced effective magnetic field, which was the product of two functions, a function of magnetization and a function of the stress [1]. In addition, the function of the stress was reduced to stress difference. So, we could get with very good accuracy the hysteresis curves for any stress from any two measured hysteresis curves simply by subtracting two curves and normalizing this function of magnetization by the stress difference to get the effective field per 1 MPa. Hysteresis loops on stressed amorphous ribbons have shown that this simple effective field approach developed for steels did not work for ribbons , the calculated curves were significantly different in shape from the measured ones. For steels the magnetocrystalline anisotropy is larger by orders of magnitude than any stress-induced anisotropy, so that the magnetization will be aligned along the crystal easy axes. The stress only causes an extra energy difference between the easy crystal axis. In contrast to steels, an amorphous ribbon usually consists of many regions with local uniaxial anisotropies given by local stresses. The applied stress changes this local anisotropies distribution. So, to describe accurately hysteresis loops of stressed amorphous ribbons it is necessary to use special models, different from that for polycrystalline materials. This work was supported by the Czech Science Foundation under Project 14-36566G.

5. NRC Kurchatov Inst, Moscow, Russia

The transition metal oxyborates with ludwigite crystal structure (space group Pbam) have been extensively studied due to a large variety of electrical and magnetic behaviours [1]. Unfortunately local electronic and magnetic properties of transition metals in these crystals remain practically unexplored. Here we report on the XAFS/XMCD studies of $Co_3O_2BO_3$ and $Co_2FeO_2BO_3$ oxyborate single crystals performed at the K- and L3,2-edges of both cobalt and iron. These compounds are ferrimagnets with uniaxial anisotropy: $Co_3O_2BO_3$ (TC = 42 K), $Co_2FeO_2BO_3$ (TN1 = 115 K, TN2 = 70 K) shows an extraordinary increase in coercive field [1]. The XAFS/XMCD experiments have been performed at several beamlines (ID12 at the ESRF, UE46_PGM-1 at the BESSY II, K1.3b station at the NRC KI) under high magnetic fields and low temperatures. By comparing the XMCD results with the bulk magnetizations, the valence-specific magnetizations of Co^{2+} and Fe^{3+} ions are obtained [2]. Co^{2+} and Fe^{3+} ions show negative and positive valence-specific magnetizations, respectively. The signs of the valence-specific magnetizations of Co^{2+} and Fe^{3+} remain opposite, even if the system is in a paramagnetic phase. This is evidence of the robust antiferromagnetic interaction between Co^{2+} and Fe^{3+} ions. Surprisingly the field dependence of Co^{2+} and Fe^{3+} XMCD signals does not reproduce the high coercive field, as was observed macroscopically [1]. The observed data could be tentatively explained by a model considering the magnetic moments in Co and Fe sublattices being ordered antiparallel, while on top of that the cobalt sublattice being skewed. Possible correlation between the bulk magnetizations and the valence-specific magnetizations is discussied. This study was supported by the Russian Foundation for Basic Research (project nos. 13-02-00958-a, 13-02-00358-a, 14-02-31051-mol-a), and by the Council for Grants of the President of the Russian Federation (project nos. NSh-2886.2014.2, SP-938.2015.5). The work of one of coauthors (M.S.P.) was supported by the Krasnoyarsk Regional Fund of Science and Technical Activity Support, and by the program of Foundation for Promotion of Small Enterprises in Science and Technology (“UMNIK” program).

TU.H-P32 - Fabrication and characterization of iron phosphate-coated Fe metal powder

H.E. Kim [1], J.H. You [1], S. Choi [1], S.W. Lee [1], S.K. Kwon [2], S.I. Yoo [1]

1. Seoul National University, Seoul, South Korea
2. Samsung Electro-Mechanics, Suwon, South Korea

Iron (Fe) metal powder with high saturation magnetization and low coercivity has been used as the core materials of inductors and transformers for high frequency applications. However, it is unavoidable to generate eddy current under AC field and critical at high frequencies. To minimize an eddy current loss, Fe metal powder has been coated with an insulating material.

For the same purpose, we tried to fabricate a core-shell structure composed of Fe core and iron phosphate shell. The iron phosphate coating was performed by the phosphating method with acetone solvent. The conditions of the iron phosphate coating, such as phosphate concentration and reaction time, were controlled in order to obtain a thin and uniform coating layer. Furthermore, to avoid the agglomeration of Fe metal powder, the solutions were stirred using a mechanical stirrer and/or an ultrasound treatment. The magnetic properties of Fe metal powder coated with iron phosphate were sensitive to these processing conditions. The 1mol% iron phosphate-coated Fe metal powder was observed the effectively reduced core loss values. However, the 1mol% iron phosphate-coated Fe metal powder with ultrasound treatment exhibited the decreased permeability and Q factor values while the coated powder with mechanical stirrer were observed no reduction of permeability and Q factor values. Details will be presented for a discussion.

TU.H-P33 - Study on hysteresis properties and domain behaviours in high purity Fe-(4-6)wt% Si alloys

Z. Lei [1], T. Horiuchi [1], I. Sasaki [1], C. Kaido [2], M. Takezawa [1], Y. Horibe [1], T. Ogawa [3], H. Era [1]

1. Kyushu Institute Of Technology, Kitakyushu, Fukuoka, Japan
2. Kitakyushu National College of Technology, Kokuraminamiku, Kitakyushu, Fukuoka, Japan
3. Fukuoka Industrial Technology Center, Fukuoka, Japan

High purity metallurgy has been desired for producing iron-silicon alloy in order to reduce hysteresis loss, which is drastically affected by inner impurities and crystallographic orientations. Currently, the impurities in iron silicon is minimized by a metallurgy method called Cold Crucible Levitation Melting (CCLM) which can separate melted alloy from crucible by magnetic induction. Combining the previous method as well as raw iron and silicon with a purity of 99.99wt% and 99.999wt%, high purity Fe-(4, 5 and 6)wt%Si specimens were achieved. Additionally, a new specimen called 3N Fe-4wt%Si was made by mixing Fe-4wt%Si with 0.1wt% carbon by CCLM. The permeability, coercivity and hysteresis loss of these four alloys were measured by automatic DC magnetization device. Furthermore, static domain structure and dynamic displacement-rotation behaviour under different applied fields, and effect of grain boundaries and precipitates on domain are studied by Lorentz TEM.
Permeability results shows that maximum permeability of 3N Fe-4wt%Si, Fe-(4, 5 and 6)wt%Si are 0.004, 0.010, 0.008 and 0.029 H/m, respectively. The average diameter of near-spheroidal grains in all specimens are similar with value of approximately 5 mm, which should not be considered as an influencing factor. Therefore, it can be seen that addition of carbon can decrease whereas increase of silicon can improve permeability. The relationships of flux density and hysteresis loss in Fe-(4, 5 and 6)wt%Si are all linear while in 3N Fe-4wt%Si it is nonlinear when flux density is below 1.2 T, which implies the pinning effect of impurities on domain displacement or rotation below certain applied field. The static domain structure results shows that domain patterns such as slab-like pattern with near-equivalent width and lancets pattern are observed, and complexity of domain patterns has close relationship with crystallographic orientations of grains and precipitates in the specimens.

TU.H-P34 - Comparison of the magnetic properties of submicron-sized strontium hexaferrite powders prepared with a top-down or a bottom-up approach

M. Topole [1], P. Jenuš [1], C. Granados [2], P. McGuiness [1], M. Christensen [2], K. Žužek Rožman [1], S. Kobe [1]

1. Department for nanostructured materials, Jozef Stefan Institute, Ljubljana, Slovenia
2. Center for Materials Crystallography, Department of Chemistry and iNANO, Aarhus University, Denmark

In a search for the best strontium hexaferrite material with a particle size in the sub-micron range, suitable for use in a variety of magnetic applications, two possible methods of production were studied. 1) A top-down approach using high-energy planetary ball milling was introduced to reduce the particle size of a commercially available, strontium hexaferrite powder. 2) A hydrothermal synthesis was used for the bottom-up approach. For method 1) wet milling with ethanol as the milling medium was employed. The milling times were 4, 8 and 12 h. All of the powders were then dried in air at 60 °C for 12h and, in order to release the strain induced by the milling, annealed in air at 1100 °C for 1 hour. Scanning electron microscopy showed that submicron-sized particles were obtained. The best sample proved to be the one milled for 8 hours, where the BHmax was increased by 2%, compared to the original material. For the hydrothermal synthesis [1] 2), three different final temperatures were used (220, 230 and 240 °C) to obtain a pure phase of strontium hexaferrite with a submicron particle size. The materials synthesized with the hydrothermal method were also annealed at 1000 °C for 1 h for a fairer comparison with the milled powders. The hydrothermally synthesized sample with the purest hexaferrite phase composition was the one synthesized at 230 °C. When annealed at 1000 °C for 1 hour, its coercivity and remanence increased by more than a factor of two. The BHmax was increased from 1.90 to 9.23 kJ/m^3.

TU.H-P35 - Frozen orbital moment at rare earth M4,5 absorption edges in Nd based rare earth permanent magnets

S. Tripathi [1], Y. Chun Chen [1], T. Tietze [1], S. Schuppler [2], P. Nagel [2], M. Merz [2], G. Schütz [1], E. Goering [1]

1. Max Planck Institute For Intelligent Systems, Germany
2. Institute for Solid-State Physics, Karlsruhe Institute of technology, Eggenstei Leopoldshafen, Karlsruhe, Baden-Württemberg, Germany

Rare earth permanent magnets (REPM) provide the highest energy product (50MGOe) at room temperature, however recently dramatic increase in prices for RE metals has occurred. We performed element specific XMCD investigation, in order to quantitatively determine the sub lattice magnetization of every single element, their interplay, influence on the magnetic properties and to check the applicability of the XMCD sum rules for M4,5 edge in the soft X-ray regime. We investigated highly textured $Fe_{15}Nd_2B$ thin films (3400 Å) in comparison with reference soft magnetic multilayers of Fe (3.6 Å)/Nd (3.6 Å) (60 bilayer) at 6.5T. The most remarkable observation is the nearly vanishing orbital moment at the Nd site in the textured $Fe_{15}Nd_2B$ thin film, while the multilayer system orbital moment (ml=2.71 $\mu B/atom$) is quite close to the expected Hund's rule value. As XMCD only probes rotatable magnetic moments, our results suggest strong pinning of RE orbital moments, even under magnetization reversal conditions. Thus sum rules allows to calculate accurately the spin magnetic moment values even for M4,5 edges. One can estimate the spin moment accurately using the correction given in [1]. This correction is mandatory for the proper estimation of the spin magnetic moment. Furthermore, from our experimental results it can be concluded that XMCD is a good tool to characterize the 4f spin magnetic moment values of rare earth compounds

Permanent magnets constitute an essential part of our modern societies, for motors and generators as well as for other electronic devices. The ever-growing technological demand has driven, since their discovery, the difficult task of improving the properties of these materials. Since 1960's, they are mainly based on rare earth (RE) alloys. Today, a focus is made on developing free RE magnets by improving the intrinsic anisotropy of RE free ferro- or ferrimagnetic high TC compounds by including other anisotropy sources such through shape anisotropy or intergrain exchange-coupling. Other original issues are explored consisting on the production of new ferromagnets such as cobalt carbide [1] and manganese alloys [2]. In this context, we propose to prepare exchange biased oxide-based core@shell nanoparticles and to consolidate them using Spark Plasma Sintering in order to design a new generation of magnets. The polyol process is a soft chemistry route. It is particularly efficient for seed mediated growth of nanocrystals in solutions [3]. It permitted us to prepare cobalt ferrite and cobalt monoxide composite nanostructured powders with the desired morphology and the required magnetic properties. These powders were sintered at 500°C under an uniaxial pressure of 100 MPa for 10 minutes. Interestingly, the resulting ceramics exhibit at low temperature enhanced coercivity and remanence, when they are cooled under a high magnetic field (>1T) below the CoO Néel temperature (298K). The deduced magnetic energy product (BH)max from the hysteresis loops, recorded in these conditions, is found to be equivalent to that of bulk hexaferrites but one order smaller than that of state-of-art NdFeB alloys.

TU.H-P37 - Evidence of dipolar magnetic interaction in melted $Fe_{50}Al_{50}$ samples

G. A. Perez Alcazar [1], H. Bustos [2], J. S. Trujillo [1], D. Oyola [2], Y. A. Rojas [2]

1. Departamento De Fisica, Universidad Del Valle, Cali, Colombia
2. Departamento de Fisica, Universidad del Tolima, Cali Colombia

Powders of the $Fe_{50}Al_{50}$ melted and heat treated samples were separated at different mean particle sizes as well as characterized based on their structural and magnetic properties. All the samples showed Fe-Al BCC and α-Fe phases as well as the same nanostructure. The powder with biggest particles, with particle size bigger than 105 μm, presents the additional minority presence of FeO and Al_2O phases. The powders were found to be ferromagnetic at room temperature with a mean hyperfine magnetic field that increases with increasing particle size. The origin of this magnetic behaviour is attributed to the increment of magnetic dipolar interactions between the magnetic moment of each particle and the field produced by other magnetic moments of their surrounded particles. This field also increases as the particle size increases. Besides the dipolar magnetic interaction between particles, the Fe-Al and α-Fe grains present a ferromagnetic coupling between them.

TU.H-P38 - Fe-Pt / Fe-Co Nanocomposite films fabricated by electrochemical method

Nanocomposite magnets have attracted considerable attention due to their high magnetic properties [1]. Control of their structure at nanoscale is important for achieving efficient exchange coupling among the hard and soft magnetic phases. There is one possibility to realize ordered nanostructure of the hard and soft magnetic phases by depositing other magnetic materials into vacant spaces between assembled magnetic nanoparticles (NPs). To achieve this aim, we have studied on electrochemical fabrication of nanocomposites containing magnetic NPs [2]. In this study, we fabricated nanocomposite films consisting of Fe-Co NPs in a L10 Fe-Pt matrix. The films were fabricated by a combination of electrophoretic deposition of Fe-Co NPs and electroplating of Fe-Pt. Then, the films were annealed to obtain L10 Fe-Pt. We investigated the magnetic properties and structure of the films. The M-H curves of the fabricated films showed magnetic single behavior. The coercivity of the films decreased from 10 to 6.5 kOe with an increase in the volume fraction of Fe-Co NPs (0 to 10 vol.%), while the magnetization increased from 660 to 760 emu/cc. In δM-H measurements, δM was initially positive due to the existence of exchange coupling, but it became negative after the reversal. This negative value indicates that magnetic interactions become dominant due to the presence of Fe-Co phase. This δM-H behavior is similar to behaviors in previous reports on nanocomposites applying magnetic nanoparticles [3]. Therefore, the nanocomposite films working exchange coupling between Fe-Co and L10 Fe-Pt phases were realized by this combination method.

Metallic glasses exhibit unique properties, including the high strength and the excellent soft magnetic properties (low coercive force and high permeability), which makes them attractive for practical applications. Recently, the Fe and Co rich composition with high glass forming ability was found out. Such metallic glasses exhibit the combination of the high strength and soft magnetic properties. For practical use knowledges about their mechanical properties are important. The strength is generally related to the microhardness. Due to the homogeneity of glassy structure, the micromechanism of the deformation in a small volume is similar as on the macroscopic level. To study the serrated plastic flow in different metallic glasses, nanoindentation experiments were performed for amorphous ribbons with different microhardness and glass forming ability. The metallic ribbons $Fe_{40}Ni_{40}B_{20}$, $Cu_{47}Ti_{35}Zr_{11}Ni_6Si_1$ and $Zr_{65}Cu_{17.5}Ni_{10}Al_{7.5}$ were studied at different loading rates from 0.05 to 100 mN.s-1. We describe in details the differences in elemental discontinuities on the loading curves for the studied alloys. We found that the discontinuities began at the certain deformation independently on the ribbon properties. More developed discontinuities at higher deformations are created for the materials with lower microhardness and so lower strength.

TU.H-P40 - Magnetic SANS study of a sintered Nd-Fe-B magnet: estimation of defect size

E. A. Périgo [1], E. Paul Gilbert [2], A. Michels [1]

1. University of Luxembourg, Luxembourg
2. Bragg Institute, ANSTO, Lucas Heights, Australia

The magnetic microstructure of an isotropic sintered Nd-Fe-B permanent magnet has been studied at room temperature by means of unpolarized magnetic-field-dependent small-angle neutron scattering (SANS). Although the microstructure of the material consists of micron-sized $Nd_2Fe_{14}B$ crystallites that are separated by a (low volume fraction) nanometer-sized Nd-rich phase, the SANS signal contains a significant contribution due to spin misalignment, which is evidenced by an enhanced scattering signal along the applied-field direction. The origin of this spin misalignment is presumably related to the perturbing effect of the Nd-rich interphases. Analysis of the SANS data in terms of the autocorrelation function of the spin misalignment provides an almost field-independent length scale $l_C \sim 40$ nm, which, for soft magnetic materials, is usually taken as a measure for the size of inhomogeneously magnetized regions around lattice imperfections. Comparison of our results with a phenomenological expression for l_C based on micromagnetic theory suggests that the large anisotropy field of the $Nd_2Fe_{14}B$ phase (which is of the order of 8 T) reduces the size of gradients in the spin microstructure, so that, for hard magnetic materials, l_C represents the (field-independent) size of the characteristic defect in the microstructure.

TU.H-P41 - Steinmetz law in AC magnetic fields for iron-phenolformaldehyde resin soft magnetic composites

D. Olekšáková [1], V. Vojtek [2], P. Kollár [2], J. Füzer [2], R. Bureš [3], M. Fáberová [3]

3. Institute of Materials Research, Slovak Academy of Sciences, Košice, Slovakia

The validity of Steinmetz law, describing the energy losses as a function of maximum flux density 0.1 T to 1.3 T has been verified in frequency range 100 Hz to 1.2 kHz for iron based soft magnetic composites (SMCs) with the effort to find a physical meaning of the coefficients in Steinmetz law. The Bertotti's statistical model was used for modification of Steinmetz law for DC magnetic field in which hysteresis energy loss Wh = Kh.(Bmax)x, (where Bmax is the maximum flux density, Kh and x are constants) to the model for total energy losses, which appear when AC magnetic field is applied on soft magnetic composites. In this case for the total energy losses Wt is the dynamic energy loss Wd added to hysteresis loss Wt = Wh + Wd. For such a case we used for dynamic loss Wd = Kv.(Bmax)y.f, where Kv and y are constants. The validity of this model was experimentally proven for investigated Fe-based SMCs at maximum flux density 0.3 T to 1.2 T. Finally, new "linear-elliptical model" based on "linear" model, for explanation of the hysteresis loss, described in [1], was created for explanation of total loss maximum flux density dependence in Fe-based SMCs and proved in frequency range 400 Hz to 1.2 kHz.

3. RWTH Aachen, Aachen, Germany

In the present study, we report on the correlation between the magnetic properties and the distribution of the DyF_3 in the melt-spun $Nd_2Fe_{14}B$ ribbons coated with the DyF_3 suspension, spark-plasma sintered (SPS) and annealed. The magnetic properties were measured at room temperature using a Steingroever permeameter. The addition of the DyF3 up to 2.2 wt.% showed a positive and increasingly rapid effect on the coercivity (Hci) of the heat-treated samples. The maximum Hci of 1663 kA/m represents a 25% increase compared to the untreated sample. To observe the diffusion of DyF_3 as a function of heat-treatment process and correlate it with the magnetic properties, samples were investigated using aberration-corrected scanning transmission electron microscopy (FEI Titan 80-200). The analyses were carried out in the so-called wheel side regions of the SPS and the annealed samples. The energy dispersive X-ray spectroscopy (EDXS) maps of annealed samples revealed a Dy,Nd-Fe-B-rich shell structure around Nd Fe-B core, while the SPS sample did not contained any Dy,Nd-rich shells around the Nd-Fe-B grains. Since the reliability of the EDXS analysis is compromised by overlapping of the Fe-K, Dy-L and Co-K lines, the electron energy loss (EEL) spectra of the same grains were recorded in order to separate the contribution of these elements and to provide reliable compositional maps. To unwrap the spectra the vertex component algorithm was applied and thus we determined Fe-L2,3/Co L2,3, Nd-M4,5, Dy-M4,5, F-K and O-K maps. In the case of annealed sample we observed the Dy,Nd-Fe-B phase formation in the shell around the pure Nd-Fe-B (core) grains. We can conclude that the 25% increase in Hci is strongly linked to the heat-treatment process where Dy diffuses along grain boundaries into the outer parts of Nd-Fe-B grains and partially substitutes Nd to form a core-shell-like grains.

TU.H-P43 - Optimizing the magnetic properties of bulk Mn-Ga by severe plastic deformation and magnetic field annealing

Mn3-δGa thin films are regarded as a candidate for spin-torque transfer applications [1]. The distinguished perpendicular anisotropy of Mn_3Ga thin films results from the high positive effective anisotropy constant, Keff = 1.2 MJ/m^3 [2] and in this work we focused on how effectively one can convert the observed high anisotropy constant to coercivity for bulk samples. We demonstrate here an alternative production routine to the conventional sample preparation (arc melting and annealing) for the stabilization of $Mn_{70}Ga_{30}$ system in metastable D022 phase. We apply cold-rolling and annealing - with and without applied magnetic field - and study systematically the magnetic properties of $Mn_{70}Ga_{30}$. The best $Mn_{70}Ga_{30}$ material has been produced by arc melting followed by rolling and magnetic field-assisted annealing (24 h at 730 K in 1 T). The described procedure maximizes the content of the tetragonal D022 phase (known to be ferrimagnetic), raising the remanence to 0.239 T at room temperature. At the same time, the coercivity is as high as 1.24 T [3]. The MOKE and field dependent magnetic measurements indicates that the demagnetization mechanism most likely is the reversal of the magnetization by nucleation of reversed domains.

TU.H-P44 - Effect of WS_2/Al co-doping on the microstructural and magnetic properties of Nd-Fe-B sintered magnet

K.H. Bae [1], T.H. Kim [1], S.R. Lee [1], H.J. Kim [2], M.W. Lee [3], T.S. Jang [3]

One of possible ways to increase the coercivity of Nd-Fe-B magnets without addition of Dy is to refine the grain size as well as the improving the uniformity and crystallinity of Nd-rich grain boundary (GB) phase. The addition of refractory element (RFE) such as Mo, W, or Nb could suppress the grain growth during sintering or post-sintering annealing process. Especially, the RFE-sulfide powder addition is effective for Dy-saving because the formation of Dy segregated rare-earth rich (RE-rich, Nd-Dy-O) phase could be suppressed. The precipitates should be selectively formed only at the GB for efficient grain growth pinning. In this study, we investigated the effects of WS_2 (0~1.2 wt.%) addition together with Al (0.3 wt.%) on the microstructural and the magnetic properties of the magnet. Especially, the relationship between WS_2/Al co-doping condition and the magnetic properties are studied. The magnets (29.0Nd-3.0Dy-bal.Fe-1.0B-2.5M (wt.%)) were sintered at 1070°C, and then the magnets were optimally annealed. The coercivity of the 0.6 wt.% WS_2/Al co-doped magnet increased the most (20.67 → 22.4 kOe) as compared to that of the solely WS_2-doped magnets. The average grain size of the 0.6 wt.% WS_2/Al co-doped magnet was the smallest (6.4 μm) as compared to those of the un-doped (7.6 μm) and 0.6 wt.% WS_2-doped (6.9 μm) magnet. The W-precipitates are selectively formed at the GB in the 0.6 wt.% WS_2/Al co-doped magnet because the fluidity of liquid Nd-rich phase increases by the Al addition. In addition, the formation of RE-rich phase was suppressed in the WS_2/Al co-doped magnet because of the reaction between the WS_2 and the RE-rich phase. However, the grain size was not decreased further with increasing the WS_2 content over 0.6 wt.% The over-doped magnet deteriorated the magnetic properties because the precipitates are formed at the interior of the grains as well as at the GBs. Conclusively, coercivity enhancement of 8.3% could be obtained by addition of WS_2 (0.6 wt.%) together with Al (0.3 wt.%) resulting in the 0.8 wt.% Dy-saving.

TU.H-P45 - DC reversible and irreversible magnetization processes in Fe-based composite materials

P. Kollár [1], Z. Birèáková [1], J. Füzer [1], M. Fáberová [2], R. Bureš [2]

1. Institute of Physics, Faculty of Science, Pavol Jozef Šafárik University, Košice, Slovakia
2. Institute of Materials Research, Slovak Academy of Sciences, Košice, Slovakia

Soft magnetic composites (SMCs) are a remarkable kind of soft magnetic materials consisting of small ferromagnetic particles insulated from each other. They exhibit very good electromagnetic properties as low classical losses and relatively low total energy losses (due to an insulating layer between iron powder particles) at medium and higher frequencies. On the other hand the increase of non-ferromagnetic content of the composite material increases the value of inner demagnetizing field leading to the decrease of the permeability.
The proportion of reversible and irreversible magnetization processes in iron-phenolphormaldehyde resin composite samples with different in magnetic particle size and resin content was studied. The investigation were focused on the magnetic permeability and DC and AC energy losses. The increase of the fraction of reversible magnetization processes (determined by means of the permeability measurements) at the expense of the irreversible magnetization processes, with the increasing resin content and with the reducing magnetic particle size, is explained by higher demagnetizing fields produced by magnetic particle surfaces resulting in lower number of movable domain walls. The magnetization process is then the more realized by magnetization vector rotation.
The similar fact was obtained also from the energy losses investigation - the excess losses were found to be higher for samples with higher resin content and lower particle size, explained by lower numbers of movable domain walls due to higher demagnetizing fields (meaning less irreversible processes) as well. The empirical relations between irreversible relative permeability and DC energy losses were found based on the Steinmetz law, the linear functions approximation and the Rayleigh law, enabling to predict the irreversible permeability in a wide range of magnetic induction values.

TU.H-P46 - Different metastable states of $Hf_2Co_{11}B$ alloy as precursors for rare-earth free permanent magnets

A. Musial [1,2], Z. Iniadecki [1], J. Marcin [3], J. Kováè [3], I. Skorvanek [3], B. Idzikowski [1]

1. Institute of Molecular Physics, Polish Academy of Sciences, M. Smoluchowskiego, Poznan, Poland

3. Institute of Experimental Physics, Slovak Academy of Sciences, Watsonova, Koљice, Slovakia

New materials for the permanent magnets, especially the rare-earth free alloys, are of high importance for scientific community. Main focus is put on compounds, which exhibit a combination of high remanent magnetization, intrinsic coercive field and large energy product. High Curie temperature is also crucial factor which can be decisive in practical use.
The attention of this work has been focused on $Hf_2Co_{11}B$ alloys. Amorphous and partially crystalline ribbons were produced using melt-spinning technique. Calorimetric measurements show three crystallization steps with the maxima temperatures at 594°C, 614°C and 654°C in amorphous sample. First two stages are connected with the crystallization of Hf_2Co_{11} rhombohedral and orthorhombic phases. Thereafter $HfCo_3B_2$ phase appears. The X-ray diffraction patterns of partially crystalline sample in as-quenched state consist of peaks from Hf_2Co_{11} phase in both mentioned forms with possible evidence of small amounts of $HfCo_2$ and fcc-Co. The occurrence of two Hf_2Co_{11} phases is confirmed by temperature dependence of magnetization measurements. Two inflections corresponding to Curie temperatures of the orthorhombic and hard magnetic rhombohedral structures ($T_{Crhombo}$ = 488°C, T_{Cortho} = 554°C) are visible on the M(T) curve.
The ribbon annealed from partially crystalline state is characterized by higher coercive field and magnetic anisotropy as compared to the sample annealed from initial amorphous state. We connect it with the existence of quenched-in nanocrystals of hard magnetic phase. Annealing at optimal conditions (T_a = 570°C, τ_a = 60 min) allowed to improve coercive field from 1.2 kOe to about 3 kOe and energy product from $|BH|_{max}$ = 5.3 kJ/m^3 to 21.2 kJ/m^3 in partially crystalline alloy. These results are in good agreement with those reported in Ref. 1.

TU.H-P47 - A study on the anisotropic diffusion of Dy in the grain boundary diffusion processed Nd-Fe-B sintered magnet

T.H. Kim [1], K.H. Bae [1], S.R. Lee [1], S. Jin Yun [1], S. Ho Lim [1], H.J. Kim [2], M.W. Lee [3], T.S. Jang [3]

1. Dept. of Materials Science and Engineering, Korea University, Seoul, Republic of Korea
2. R&D Center of Jahwa Electronics Co. Ltd., Cheongwon, Republic of Korea
3. Dept.of Advanced Materials Engineering, Sunmoon University, Asan, Republic of Korea

Developing a core-shell microstructure of Dy, which can be obtained by the grain boundary diffusion process (GBDP) using Dy-X (X = H or F) dip-coating or Dy vapor sorption method, is a promising way to enhance the Hc of the Nd-Fe-B sintered magnet without Br reduction. Dy-rich shells are preferentially formed depend on the crystal orientation of $Nd_2Fe_{14}B$ phase at the Nd-rich grain boundary phase (GBP) interfaces. Anisotropic diffusion of Dy depends on the orientation of the magnet itself was also observed. We investigated the anisotropic diffusion mechanism of Dy in the DyH_2 dip-coated magnet in terms of crystallographic relationship between the GBP and the $Nd_2Fe_{14}B$ phase. A method for further improving the Hc was suggested considering the anisotropic diffusion of Dy in the GBDP magnet. It was observed that the Dy-rich shells are formed only on particular side of the $Nd_2Fe_{14}B$ phase at the Nd-rich GBP interface. Notably, we observed that the Dy-rich shell is formed when the c-axis of the $Nd_2Fe_{14}B$ phase and the GBP are in parallel. In contrast, the Dy-rich shell is hard to form when the c-axis of the $Nd_2Fe_{14}B$ phase is perpendicular to the GBP. According to the simulation results, the energy barrier for the migration of Dy along the c-axis of the Nd2Fe14B is 3.46 times larger than that along the a-axis of the $Nd_2Fe_{14}B$. In the point of the magnet orientation, the Hc of the GBDP magnet was enhanced (22.7íµ23.8 kOe) when the surface area perpendicular to the c-axis of the magnet (ACª¬) was increased (70íµ140 mm2). This result is contrary to the result of anisotropic diffusion of Dy in the $Nd_2Fe_{14}B$ crystallographic orientation viewpoint. The detailed mechanism of anisotropic diffusion of Dy during the GBDP will be discussed in the point of the crystallographic orientation of the $Nd_2Fe_{14}B$ phase and the change in the ACª¬ before dip-coating process.

TU.H-P48 - Microwave properties of MnCuZn substituted $BaFe_{12}O_{19}$ in 0-26.5 GHz range

Z. Mehmedi [1,2], H. Sözeri [1], H. Kavas [3], U. Topal [1], A. Baykal [4], B. Aktas [5]

5. Gebze Technical University, Gebze-Kocaeli, Turkey

Barium hexaferrite particles were synthesized by replacing three cations having two valancies with two Fe^{3+} ions in the form of $BaFe_{11.5-x}(Mn_{0.25}Cu_{0.25}Zn_{0.5})_xO_{19}$, x=1, 2 and 3. Solid state reaction route was followed during the synthesis process. 1% boron was added to precursor before sintering as a catalyst to inhibite crystal growth and magnetic properties of the particles. Structural properties were investigated using X-ray diffractomer and scanning electron microscope. Magnetic properties were measured by vibrating sample magnetometer. A vector network analyzer was used in reflection/transmission mode to determine scattering parameters (S11 and S21) of samples placed in an airline in 0-18 GHz range and in between waveguides in 18-26.5 GHz. Magnetization and coercivity of samples decrease as MnCuZn content increases which can be explained by site preferences of substituted cations and their low magnetic moments compared to Fe^{3+} ions. The microwave energy was absorbed at two different frequencies in $BaFe_{9.5}(Mn_{0.25}Cu_{0.25}Zn_{0.5})2O19$ at 10.5 and 22.5 GHz with reflection losses of -23 dB and -15 dB, respectively. The mechanisms of the RLs are due to matching thickness at 10.5 GHz and magnetic/dielectric losses at 22.5 GHz.

TU.H-P49 - Investigation of microwave properties of Cu^{2+} substituted NiZn-ferrite with sample thickness in 0-26.5 GHz range

F.Genç[1,2], H. Sözeri[1], H. Kavas[3], U. Topal[1], A. Baykal[4], B. Aktaş[5]

1. TUBITAK-UME, National Metrology Institute, Gebze-Kocaeli, Turkey
2. Department of Physics, Gebze Technical University, Gebze-Kocaeli, Turkey
3. Department of Physics, Istanbul Medeniyet University, Goztepe, Istanbul, Turkey
4. Department of Chemistry, Fatih University, B.Cekmece, Istanbul, Turkey

Cu^{2+} substituted NiZn-ferrite powders were synthesized by solid state reaction route. 1 wt.% B_2O_3 was added to the precursor before sintering at 1100°C for 2 hours. Phase formation and morphology of the powders were investigated X-ray diffactometry and scanning electron microscopy. Magnetic and microwave properties of samples were determined by vibrating sample magnetometer and vector network analyzer, respectively. Magnetization of the sample increases as nickel concentration increases up to x=0.45 in $Ni_xZn_{0.8-x}Cu_{0.2}Fe_2O_4$ with Ms value of 70 emu/g, and then, starts to decrease to 50 emu/g. Microwave measurements revealed that $Ni_{0.3}Zn_{0.5}Cu_{0.2}Fe_2O_4$ sample with 3mm thickness has better absorption properties. It has two reflection losses at frequencies of 12 and 18.5 GHz with -22.5 and -15 dB in magnitude. It was observed that as sample thickness increases absorption of microwaves occurs at low frequencies.

TU.H-P50 - Dielectric properties of $AgY_{1-x}Gd_x(WO_4)_2$ solid solutions

B. Sawicki [1], E. Tomaszewicz [2], M. Piątkowska [2], T. Groń [1], P. Urbanowicz [1], H. Duda [1], Z. Kukuła[1]

1. Institute of Physics, University of Silesia, Katowice, Poland
2. *Department of Inorganic and Analytical Chemistry, West Pomeranian University of Technology, Szczecin, Poland*

Double molybdates and tungstates $ARE(MO_4)_2$ (A = monovalent metal, *e.g.* an alkali metal or Ag, and Tl, RE – trivalent rare-earth metal, and M = Mo or W) are good laser hosts, and have potential applications in quantum electronics, visual display, and solid-state lighting. Low-temperature polymorphs of $AgY_{1-x}Gd_x(WO_4)_2$ solid solutions crystallize in monoclinic symmetry belonging to the *C*2/*m* space group. The electrical resistivity and thermoelectric power measurements showed the insulating properties and *n*-type conduction [1]. The *I-V* characteristics showed a large emission of electrons for $(Co,Mn)Pr_2W_2O_{10}$ and $Cd_{1-3x}Gd_{2x}\square_xMoO_4$ [2].
The main purpose of this study was to investigate the dielectric spectroscopy of $AgY_{1-x}Gd_x(WO_4)_2$ solid solutions for x = 0.025 and 1.0. These studies showed low relative dielectric permittivity: $\varepsilon_r \sim 4.4$ for x = 1.0 and $\varepsilon_r \sim 6.1$ for x = 0.025, that substantially does not depend on temperature and frequency, due to the existence of deep trapping centers associated with high energy form of silver vacancies [3].
This work was supported by Ministry of Scientific Research and Information Technology (Poland) and funded from science resources: No. 1S-0300-500-1-05-06 and No. DS-518-10-020-3101.

TU.H-P51 - Dynamics of magnetization processes in complex permeability spectra of fe-based soft magnetic ribbons and powder cores

J. Fuzer [1], S.Dobak [1], P. Kollar [1]

1. Institute of Physics, Faculty of Science, Pavol Jozef Šafárik University, Košice, Slovakia

Nowadays, amorphous and nanocrystalline soft magnetic alloys are a well-known group of magnetic materials, which are commercially produced on a large scale and exploited in a wide range of electronic applications, e.g. power transformers, inductive devices, magnetic sensors and actuators. In this study, the different character of magnetization mechanisms in as-quenched and annealed $Fe_{73}Cu_1Nb_3Si_{16}B_7$ ribbon and derived nanocrystalline powder cores was studied by using complex permeability spectroscopy. To apply an AC magnetic measuring field, a copper wire was wound around the core as a toroidal coil with several turns. To apply a DC magnetic field Helmholtz coil and electromagnet were used, respectively. An impedance analyzer (HP 4194A) equipped with a test fixture and controlled by a PC was used for measurements of these impedance parameters of the samples. The amplitude Hm of the AC magnetic field was calculated from the current flowing through the coil and geometrical dimensions of the core. The real and imaginary parts of the complex permeability were calculated on the basis of a series equivalent circuit.
We investigated the dynamics and relaxation of the reversible and irreversible domain wall movements, as the dominant magnetization processes in the samples, by means of the effects of the increasing AC and DC magnetic field amplitude on the complex permeability in a wide frequency range. In an amorphous ribbon, which was a precursor for preparation of powder cores, we observed two well-recognizable relaxation-dispersion regions corresponding to the domain wall displacements and bulging, respectively. The similar behavior was found for the annealed ribbon sample. However, in the bulk powder cores, only one dispersion region was present. From obtained spectra, the characteristic internal magnetic properties of the samples, such as relaxation frequencies of stepwise extinct magnetization processes and pinning fields, are extracted.

TU.H-P52 - Magnetic properties of mixed and vacuum/pressure impregnated Fe/SiO_2/shellac composites

J. Fuzerova [1], J.Fuzer [2], P. Kollar [2], E.Dudrova [3], M.Kabatova [3]

1. Faculty of Mechanical Engineering, Technical University of Kosice, Slovakia
2. Institute of Physics, Faculty of Science, P.J. Safarik University, Kosice, Slovakia
3. Institute of Materials Research, Slovak Academy of Sciences, Kosice, Slovakia

Ring and cylindrical samples were made from Fe/(0.4-2wt.%)SiO2/polymer composite materials based on irregularly and/or spherically shaped iron powder particles coated with sol-gel SiO_2 layer or with an addition of SiO_2 nano-powder. Soft magnetic composites (SMC) were prepared by two ways, by vacuum/pressure impregnation of low-temperature sintered Fe/ SiO_2 compacts with shellac dissolved in ethanol as well as with thermoplast SL450 and for comparison also using a conventional procedure - by mixing the Fe/ SiO_2 powder with shellac dissolved in ethanol. In the present study, the effect of the iron particle shape way of adding SiO_2 and the effect of polymer type used to the nature of the insulating layer was investigated focusing on the complex permeability spectra, the DC and AC energy losses. The continuity and distribution of insulating layer in composites strongly depends on the shape of iron particles. The electric resistivity is a significant factor that influences eddy currents closely related to a damping of domain wall motion. A rather large resistivity extends a range of the sizeable real permeability to higher frequencies, where eddy current losses (classical and those due to domain wall motion) dominate the overall power losses. It is noteworthy that the magnetic properties strongly depend on the density, number of pores and non-magnetic phase. Creating a continuous insulating SiO_2/shellac layer with well insulating iron particles has led to acceptable values of electrical resistivity and coercivity, 776 μΩ.m and 178 A/m. This study demonstrates the possibility of producing the Fe based soft magnetic composites exhibiting good magnetic properties with tunable electric and magnetic properties.

TU.H-P53 - Specific heat of polycrystalline Ni_2InVO_6

T. Groń [1], E. Filipek [2], A.Pacześna [2], H. Duda [1], A. Ślebarski [1], M. Fijałkowski [1]

1. *Institute of Physics, University of Silesia, Katowice, Poland*
2. *Department of Inorganic and Analytical Chemistry, West Pomeranian University of Technology, Szczecin, Poland*

It is well known that oxide materials, which possess interesting physical and chemical properties, are necessary for various technical applications, *i.e.* as catalysts, pigments, elements of gas sensors and storage batteries. Ni_2InVO_6 is formed in the ternary $NiO–V_2O_5–In_2O_3$ system oxides [1]. Our previous magnetic studies showed the spin-glass-like behaviour below the freezing temperature T_f = 5.0 K [2]. Specific heat *C(T)* was measured in the temperature range 1.8-240 K and in the external magnetic field up to B = 6 T using a Quantum Design PPMS platform.
The temperature specific heat capacity measurements showed a noticeable change in the slope of curve *C(T)* and the broad peak in the curve *C(T)/T* at T_f. This effect is clearly dependent on the applied magnetic field. Dependences of the differential d[C(T)/T]/dT both in the zero magnetic field, and in the field of 6 T clearly showed the anomalous behaviour at T_f. So, the temperature dependence of heat capacity *C(T)* and the anomalous shift of d[C(T)/T]/dT towards low temperatures suggest the antiferromagnetic character of the magnetic glass state.

AŚ and MF thank the National Science Centre (NCN) for financial support, on the basis of Decision No. DEC-2012/07/B/ST3/03027.

3. Scientific and Practical Materials Research Centre of National Academy of Science of Belarus, Minsk, Belarus

The effects of spin waves (SW) propagation in *ion-beam evaporated* yttrium iron garnet (YIG) films on gadolinium gallium garnet (GGG) and silicon (Si) substrates were examined for the first time. YIG films with thickness in the range of 0.2-0.6 micron were fabricated by deposition from yttrium oxide and iron oxide compound target using oxygen ion beam with following annealing. YIG/GGG has magnetization 1750 G and FMR linewidth 21 Oe while corresponding parameters of YIG/Si were 1450 G and 90 Oe. SW excitation and detection were performed with the coplanar micro-sized antennas fabricated directly on YIG films by lift-off technique. Measurements were done using a vector network analyzer along with a microwave probe station for tangential bias magnetic field geometry.
For both YIG/GGG and YIG/Si structures we observed excitation and propagation of the magnetostatic surface waves (MSSW). In the case of YIG/GGG the transmission signal corresponding to MSSW propagation was observed at distance between the antennas up to 200 micron and for wave numbers up to 5000 rad/cm whereas MSSW propagation in YIG/Si was only for 50 micron with maximum wave numbers around 2000 rad/cm. Gilbert dumping derived from measured data for different distances between antennas in YIG/GGG structure was around 0.0025 and could reflect not only intrinsic losses but influence of two-magnon scattering due to film roughness.

This paper deals with progress in stabilization of amorphous or nanostructured state of bulk $Co_{58}Fe_5Ni_{10}B_{16}Si_{11}$ alloy prepared by different methods: plasma spray deposition and dynamic compaction. We focused on empirical rules for the achievement of local atomic configurations, structure with certain amorphous/nanocrystalline phase ratio, soft magnetic properties. The investigations of structure and magnetic properties of bulk samples were carried out by X-ray diffraction, electron microscopy and correlation magnetometry. The amorphous/crystalline phase ratio was estimated using the technique of magnetic phase analysis. The regimes of dynamic compaction and plasma spray deposition were selected so that the diffraction pattern, heat and temperature of crystallization, saturation magnetization (Mo - 600 G), spin-wave stiffness (D - 117 meV A2), and Curie temperature (Tc) of the bulk samples are identical to the same characteristics of amorphous $Co_{58}Fe_5Ni_{10}B_{16}Si_{11}$ ribbon produced by rapid quenching. It was found that the bulk amorphous coating and compact can be characterized as a heterophase system in which phase 1 with Tc ~ 2600 C comprises 90% of the volume and the phase 2 with Tc ~ 5300 C. The relaxation annealing of the $Co_{58}Fe_5Ni_{10}B_{16}Si_{11}$ bulk coating leads to a phase transition in this alloy in the precrystallization temperature range. At Tann~ 3000 C a ferromagnetic nanocrystalline phase 3 with Tc ~ 3300 C arises. The magnetic properties of the coating are correlated with changes in the microstructure. The appearance of nanocrystalline phase during relaxation heat treatment leads to a decrease of the coercivity and to an increase of the permeability. The coercivity and local magnetic anisotropy field of plasma spraying coating is less than that of the compact produced by dynamic compaction.

TU.H-P56 - Behaviors of magnetic properties and hardness in precipitation and recovery process on deformed Fe-Cu alloy

H. Kikuchi [1], T. Sasaki [1], F. Ito [1], T. Murakami [1]

1. Iwate University, Morioka, Japan

Nondestructive evaluation using magnetic measurements is effective for investigating the integrity of nuclear reactor pressure vessel: good correlations exist generally between magnetic and mechanical properties, because both depend on the underlying microstructures. However, this good correlation has not observed on the deformed and aged Fe-Cu alloy experimentally, and the mechanism is unknown. An important issue to evaluate is how microstructural features contribute qualitatively and quantitatively to the magnetic and mechanical properties. Therefore, we prepared cold-rolled Fe-Cu alloys to induce dislocations, and annealed the alloys at 573 and 773K to alter the distribution of dislocations and to generate Cu precipitations. Then we evaluated the changes in coercivity and hardness, and discussed the relation between those properties and microstructural changes. The coercivity decreases with increasing aging in both treated temperature, and the slope of the reduction at 773K is larger than that at 573K. The hardness increases rapidly at the initial stage at 573K, while it increases gradually and peaks at 1000 hours at 773K. The increase in hardness is attributed to Cu precipitations, which is insensitive directly to domain wall movement, that is, magnetic properties. Previously, the idea has proposed: the precipitates occur preferentially around dislocations and compensate the internal stress around dislocations, which is attributed to decreases in coercivity. However, in this study, the hardness increases drastically due to Cu precipitation, whereas the coecivity decreases gently at 573K compared with at 773K. If Cu precipitation is dominant, the coercivity at 573K is expected to decrease more. This indicates Cu precipitation does not contribute to the decreases in coercivity. It is well known that recovery progresses in pure Fe matrix during aging and it contributes to the decreases in coercivity. This recover plays main role in the decrement of coercivity on the deformed and aged Fe-Cu alloy.

TU.H-P57 - Large-scale micromagnetics simulation for magnetization reversal process in Nd-Fe-B nanocrystalline magnets under periodic boundary condition

H. Tsukahara [1], K. Iwano [1], N. Inami [1], T. Ishikawa [1], C. Mitsumata [1,2], K. Ono [1]

1. High Energy Accelerator Research Organization, Tsukuba, Japan
2. National Institute for Materials Science, Japan

The permanent magnet having high coercivity has been under intensive study because of their importance for high efficiency electric motors. Mechanism of the coercivity remains unclear and has been investigated during a long period. Especially, it have been expected that an origin of a discrepancy of the coercivity between experimental values and theoretical results that is calculated by magnetic anisotropy is magnetic defects [1]. Although magnetization reversal process is investigated solving Landau-Lifshitz-Gilbert using finite element method, the coercivity discrepancy cannot be explained quantitatively.
We performed large-scale micromagnetics simulation whose size is 1024x1024x1024 nm^3 with 2 nm mesh using Hitachi SR16000M1 supercomputer solving Landau-Lifshitz-Gilbert equation under periodic boundary condition to simulate bulk magnet and also to avoid macroscopic demagnetization. An effective field is constructed by an anisotropic, exchange, external and dipolar field. We choose different value for exchange stiffness constant between inter and intra grain interactions. Grains for Nd-Fe-B nanocrystalline magnet have about 160 nm in diameter and 50 nm in thickness. Fluctuation of crystal grain axis is realized using Box-Muller's method.
Simulation results show that the dipolar interaction plays an important role in magnetization reversal. As the external field approaches to a critical magnetic field, i.e. coercivity, the dipolar energy decreases in contrast to anisotropic energy. Thus the magnetic fluctuation is governed by the dipolar interaction. Additionally the coercivity of Nd-Fe-B nanocrystalline magnet is very sensitive to a fluctuation of the grains. When the easy axis of each grain has no fluctuation, the coercivity is 60 kOe. On the other hand, the coercivity becomes 38 kOe with a very small fluctuation. This work was partly supported by the JST under Collaborative Research Based on Industrial Demand "High Performance Magnets: Towards Innovative Development of Next Generation Magnets."

TU.H-P58 - Effect of current density for electroplated films prepared in a des-based bath

T. Yanai [1], K. Shiraishi [1], K. Azuma [1], Y. Watanabe [1], M. Nakano [1], H.Fukunaga [1]

1. Nagasaki University, Japan

We have reported Fe and Fe-Ni films prepared from Deep-Eutectic-Solvent-based plating baths [1-2]. The DES-based baths showed high current efficiency (> 90 %), and we confirmed that the DES is a hopeful solvent for electroplating of Fe-based alloys. In this study, we evaluated the effect of the current density on the various properties of the as-plated Fe-Ni films.
The DES was prepared from the mixture of ethylene glycol (10 g) and choline chloride (10 g). FeCl2-4H2O (x g). NiCl2-6H2O (15 - x g) were added into the DES. The bath temperature was fixed at 373 K. The current density was varied from 13 to 667 mA/cm2, keeping the total amount of the electric charge at 60 C.
We evaluated the effect of the current density on the Fe content of the as-plated films. The Fe content increased with increasing the current density from 13 to 70 mA/cm2, and then showed almost constant values in the higher current density. This result indicates that high current density is suitable to plate the Fe-Ni films since the variation of the film composition against the current density is small. We also evaluated the effect of the current density on the current efficiency of the plating process. In this evaluation, the Fe content of the films were controlled at approximately 22 at.% by the change in the value of x since low coercivity was observed around this composition. We obtained high current efficiency (> 90 %) in a current density range from 30 to 133 mA/cm2.. From these results, we found that the moderate high current density (Approx. 100 mA/cm^2) is suitable to obtain the Fe-Ni films efficiently.

TU.H-P59 - Magnetoelastic characteristics of the 13CrMo4-5 constructional steel and possibility of its modelling for non-destructive testing

D. Jackiewicz [1], R. Szewczyk [1], A. Bienkowski [1], M. Nowicki [2]

1. Institute of Metrology And Biomedical Engineering, Warszawa, Poland
2. Industrial Research Institute for Automation and Measurements, Warszawa, Poland

The magnetoelastic effect is very promising for non-destructive testing of construction elements, especially trusses. However, the main barrier for this application is lack of knowledge about magnetoelastic characteristics of constructional steels, as well as limited mathematical model-oriented description of magnetoelastic effect.
Rescaled truss structure was used for the investigation. It is made of the 13CrMo4-5 constructional steel, widely used in the energetic industry. The hysteresis loops measurements are done on the specially developed hysteresisgraph. The truss was supported on the bottom edge nodes. The mechanical force was vertically exerted on the upper central node of the truss by the oil hydraulic press.
Under the tensile stresses, value of the flux density B in the stretched sample first increase, and then, after reaching the Villari point, it starts to decrease. Moreover, under the compressive stresses, value of the flux density B in the compressed sample nonlinearly decreases. It should be highlighted, that these changes are relatively higher for lower values of the amplitude of magnetizing field Hm. This occurs due to the fact, that for lower values of magnetizing field H, participation of magnetoelastic energy in the total free energy in the sample's material is significantly higher.
Next, on the basis of measurements, magnetic hysteresis loops were modelled with Jiles-Atherton extended model. Results of the modelling utilising extended Jiles-Atherton model are consistent with results of experimental measurements, which is confirmed by high values of the determination coefficient, which exceeds 98% for each of the B(H) magnetic hysteresis loop. Due to the high values of changes of magnetic characteristics under the stresses, and good agreement with the model, presented methodology is very promising for non-destructive methods of stress assessment in the steel constructional elements.

TU.H-P60 - Phase formation and magnetocaloric effect in (Pr,Nd)-Fe alloys prepared by rapidly quenched method

N. Dan [1], N. Ha [2], N. Yen [1], P. Thanh [1], T. Thanh [1,3], L. Phan [3], S. Yu [3]

2. Hong Duc University, 565 Quang Trung, Dong Ve, Thanh Hoa, Vietnam
3. Chungbuk National University, Cheongju 361 - 763, Republic of Korea

$Pr_{2-x}Nd_xFe_{17}$ (x = 0 - 2) ribbons with thickness of about 15 µm were prepared by melt-spinning method. The alloy ribbons were then annealed at different temperatures (900 - 1100^oC) for various time (0.25 - 2 h). The formation of the $(Pr,Nd)_2Fe_{17}$ (2:17) crystalline phase in the alloys strongly depends on the Pr/Nd ratio and annealing conditions. Annealing time for the completed formation of the 2:17 phase in the rapidly quenched ribbons is greatly reduced in comparison with that of bulk alloys. Curie temperature, T_C, of the alloys can be controlled in room temperature region by changing Pr/Nd ratio. Maximum magnetic entropy change, $|\Delta S_m|_{max}$, of the alloys is quite high (> 1.5 $J.kg^{-1}K^{-1}$ with ΔH = 12 kOe) in room temperature region. On the other hand, the full width at haft the maximum peak of the magnetic entropy change is quite large (FWHM > 50 K) making it possible for application in magnetic refrigerators at room temperature.

TU.H-P61 - Extraction and valorization of rare earth permanent magnets comprised in waste electrical and electronic equipment: the extrade project.

N. Maât [1], V. Nachbaur [1], J. Juraszek [1], R. Lardé [1], M.Jean [1], J. Le Breton [1], N. Menad [2]

1. CNRS-Groupe De Physique Des Matériaux UMR 6634, France
2. BRGM Bureau de Recherche Géologiques et Minières, Orléans, France

Rare earths are a group of chemical elements which are currently used in a very large number of technological applications and innovations. They have been classified, since July 2010, as strategic materials for the European Union, and their supply has become a capital issue for development and industry.
Exploitation of “urban mines”, in this case the electrical and electronic waste, has therefore emerged as a preferred choice, motivated by the substantial use of these elements by the industrialized countries.
In this context, the current research focuses on the improvement of the magnetic materials included in electrical and electronical waste, and their reintegration into the industrial circuit. The considered processes shall permit, from used Nd-Fe-B magnets, to synthesize new magnets with sufficient magnetic properties for applications.
Currents methods for recycling industrial scrap are based on hydrometallurgical, pyrometallurgical or solvent-extraction processes. Hydrogen decrepitation is also investigated in laboratories for recycling permanents magnets comprised in WEEE. Advantages and drawbacks of these processes are discussed here.
The Extrade project aims to develop new directions for retreatment of used magnets. As an alternative way we expose a process to remove the nickel metallic protective layers and recover the magnetic phase Nd2Fe14B. The process is based on a solvothermal treatment in hydrocarbons. Particular attention is paid to protocols that must be implemented to limit their oxidation during the various steps of the process.

This work is part of the project ANR-13-ECOT-0006-06 “EXTRADE”

TU.H-P62 - Milling and sintering of Nd-Fe-B magnets comprised in weee: a way for recycling rare earth permanent magnets.

N.Maât [1], V. Nachbaur [1], J. Juraszek [1], R. Lardé [1], M. Jean [1], J. Le Breton[1]

1. Groupe de Physique des Matériaux, UMR 6634 CNRS, Université et INSA de Rouen, Saint Etienne du Rouvray, France

Rare earths are chemical elements used in a very large variety of devices and applications. Due to their high supplying costs, recycling is currently investigated both by industries and laboratories. Exploitation of urban mines has emerged as a solution for reducing rare earths consumption, with economical, environmental and geopolitical advantages. Currently, Nd-Fe-B permanent magnets are the most powerful magnetic materials commercialized. They are ubiquitous in common and high tech devices, and can be found in large quantities in waste stream. In our project we focus on Nd-Fe-B magnets comprised in WEEE (Waste Electrical and Electronic Equipment), and more particularly in hard disk drives. Due to the waste stream heterogeneity, classical production processes have to be adapted for processing new magnets from old ones. In this paper particular attention is paid to oxidation of the Nd2Fe14B magnetic phase during milling and sintering steps. Milling in hydrocarbons, aqueous or organic solvent is investigated. Powder purity and average grain size are analyzed. Samples are characterized by X-ray diffraction, SEM analysis, Mössbauer spectrometry and VSM measurements. The highest purity is obtained in ethyl acetate, wherein Nd2Fe14B phase is completely preserved with an average particle size of 10/ am. Sintering of recycled powders is performed with a Spark Plasma Sintering apparatus, which is slightly different from classical sintering processes. Influences of both powder purity and particle size on crystallographic, structural and magnetic properties of the sintered material are investigated. To avoid dissociation of the Nd2Fe14B phase upon sintering, high purity of the starting powder is required. The best results are obtained with powders having 10/ am diameter, sintered at 830^{o}C for one hour under 40 MPa, and subsequently annealed at 950^{o}C under vacuum for one hour.

This work is supported by the french “Agence Nationale de la Recherche”, in frame of the project ANR-13-ECOT-0006-06 'EXTRADE'.

TU.H-P63 - Coercivity enhancement in Ce-Fe-B magnets by Nd-Cu infiltration

M. Ito [1,2,3], M. Yano [1], N. Sakuma [1], H. Kishimoto [1], A. Manabe [1], T. Shoji [1], A. Kato[1], N. Dempsey[2,3] D. Givord[2,3,4]

3. Univ. Grenoble Alpes, Institut Néel, Grenoble, France
4. Instituto de Fisica, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil

High performance permanent magnets are key components of electrical motors in electrical and hybrid cars, and the generators of wind turbines. These magnets almost exclusively consist of the $R_2Fe_{14}B$ (R = rare-earth, Nd and Dy) phase. Nd and especially Dy are considered to be critical elements due to increasing demands. As a consequence, Ce-based intermetallic phases attract attention because of their potential applications in permanent magnets and the greater abundance of Ce compared to Nd and Dy. However the intrinsic magnetic properties, namely Curie temperature, saturation magnetization and anisotropy field, of $Ce_2Fe_{14}B$ are far inferior to those of $Nd_2Fe_{14}B$. To use Ce, the partial substitution of another R for Ce in rare-earth sites of $Ce_2Fe_{14}B$ and the optimization of microstructure are required to improve the extrinsic properties, in particular coercivity. In this study, Ce-based nano-structured core-shell-phase magnets were fabricated from rapidly quenched $Ce_2Fe_{14}B$ melt-spun ribbons. The melt-spun ribbons were sintered at 1020 K under a pressure of 100 MPa, then hot-deformed to a height reduction of about 80%. The hot-deformed magnets were infiltrated with liquid Nd-Cu eutectic alloy at 970 K for 165 minutes. These nano-structured magnets consist of core-shell grains separated by a grain boundary phase, the cores being semi-hard Ce-based 2-14-1 with the shells having a higher anisotropy owing to partial substitution of Nd for Ce. Microstructure observation by transmission electron microscopy, composition analysis by energy dispersive X-ray and magnetic property measurements have been performed.
From magnetization measurements made in the range 300 - 450 K, it was found that the coercivity of multi-phase magnets were improved compared to non-infiltrated and single-phase magnets (only core phase). These results indicate that the enhancement of coercivity was brought about by magnetic isolation of 2-14-1 phases by infiltration and the suppression of magnetization reversal by the high anisotropy shell.

TU.H-P64 - Magnetic and microstructural properties of MnBi thin films grown by an UHV sputtering system

H. Moon [1], S. Kim [1], M. Song [1], H. Lee [1], W. Lee [1]

1. Department of Materials Science and Engineering, Yonsei University, Seodaemun-gu, Seoul, Republic of Korea

Low-temperature phase (LTP) of MnBi has attracted much attention because it has a larger coercivity than that of Nd-Fe-B at high temperature [1]. Moreover, it gives high potentiality as a hard magnetic core combined with soft magnetic shell, giving rise to further enhancement of $(BH)_{max}$ in exchange-coupled core-shell magnet. It is estimated to overcome that of Nd-Fe-B. In this regards, there have been many efforts [2] to obtain the LTP-MnBi thin films for the exchange-coupled magnets. We synthesized LTP thin films on a glass substrate by UHV sputtering and vacuum annealing at 350°C. The deposition rate and annealing process were optimized to fabricate the single-phase of LTP. The magnetic and microstructural properties of the LTP-MnBi films were investigated as a function of Bi and Mn thicknesses. XRD results confirmed that all the films were well grown with the c-axis orientation. The highest value of $(BH)_{max}$ ~ 6.6 MGOe at room temperature was obtained in Bi(30nm)/Mn(20nm). We found that the ratio of Bi/Mn strongly has an effect on the magnetic properties of LTP-MnBi films. We will discuss exchange-coupled MnBi with various soft layers such as FeCo and Fe.

TU.H-P65 - A model for the dysprosium diffusion from a surface layer in NdFeB magnets

M. De Campos [1], J. de Castro [1]

1. Federal Fluminense University, Brazil

It has been reported that Dysprosium addition by surface diffusion is an effective way to improving the coercivity of NdFeB magnets, saving the scarce Dysprosium. However, the Dysposium diffusion is only effective for $Nd_2Fe_{14}B$ samples with less than 5mm [1]. Nakamura et al [1] reported that after 20 hours (at 850oC) of heat treatment, coercivity of a depth below 5 mm was unaffected. Thus, kinetics is very important detail in this process. Additions of dysprosium as sulfides or oxides [2] near grain boundaries seem to be more effective for samples with larger volume, due to kinetic reasons. This article presents a model, based on 2nd law of Fick, for evaluating the surface diffusion of dysprosium from a Dy deposited layer or coating at the top of a NdFeB ternarium magnet. Variables as grain size and thickness of grain boundary phase are considered. The simulation confirms the results of Nakamura et al [1], and suggests that including Dy as Dy_2O_3 or Dy_2S_3 additives [2] may be more viable for improvement of coercivity with short time of heat treatment.

TU.H-P66 - Suitable nanostructures for the application of the SW-CLC Model

M.De Campos [1], S. Romero [2]

1. Federal Fluminense University, Brazil
2. Institute of Physics - University of Sao Paulo, Brazil

The Stoner-Wohlfarth-Callen-Liu-Cullen (SW-CLC) model was originally proposed for amorphous magnetic alloys [1]. Application of SW-CLC for hard magnetic materials was pioneered by Hadjipanayis and Gaunt for PtFe [2] and by Hadjipanayis and Gong [3] for a $Nd_2Fe_{14}B$ exchange coupled magnet. The SW-CLC model is only applicable for specific nanostructures. As discussed by Kneller and Hawig [4], the dimension of the soft phase has to be less than twice the domain wall thickness of the hard phase. Besides, the hard phase should be less than the single domain particle size, condition required by the Stoner-Wohlfarth model. The present study discusses the specific nanostructures where the SW-CLC model can be applied. A possibility is spherical grains of hard phase enveloped by a shell of the soft phase. Another possibility is very small grains of the nanophase inside the grains of the hard phase (inclusions). These inclusions of soft phase need to be separated by a distance of the order of twice the domain wall thickness [4]. Experimental conditions for application of the SW-CLC model are also discussed. Measurements obtained in Hysteresigraph are not adequate, because results obtained with this equipment show distortion the 1st quadrant of the hysteresis. The SW-CLC model should fit at least the 1st quadrant of the hysteresis. Thus, measurements obtained in VSM (Vibrating Sample Magnetometer) are more appropriate. For a better 1st quadrant experimental determination, samples with low demagnetizing field, (as for example parallelepipeds with dimensions 5 x1 x1 mm) are recommended.

TU.H-P67 - Fabrication and magnetic properties of $Fe_{81.4}Si_3B_{10}P_5Cu_{0.6}$ nano-crystalline powder cores

Y. Zhang [1], J. Luan [1], N. Yodoshi [1], P. Sharma [1], A. Makino [1]

1. Institute for Materials Research, Tohoku University, Sendai, Japan

Low core loss materials with high frequency characteristics and complex shapes can be obtained by powder metallurgy method. Usually Fe based materials with uniform nano-crystalline structure of α-Fe phase can exhibits high magnetic flux density and soft magnetic properties. Recently, amorphous powders were prepared by a newly method of spinning water atomization process (SWAP), which has a higher cooling rate than the conventional gas/water atomization methods. In present study, the $Fe_{81.4}Si_3B_{10}P_5Cu_{0.6}$ amorphous powders were compacted by cold-pressing and nano-crystallized by annealing. XRD and TEM were employed to identify the structure and the nano-crystalline grain size of the powder cores. The thermal stability and nano-crystallization behavior were analyzed by DSC. For the magnetic properties, hysteresis loop, magnetic permeability and core loss were measured by VSM, impedance analyzer and AC B-H analyzer, respectively. As a result, we focused on fabricating the powder cores of $Fe_{81.4}Si_3B_{10}P_5Cu_{0.6}$ with the particle size below 20 μm quenched by SWAP. After compacting and annealing at different temperature of ~ 440 - 500 °C, nano-crystalline α-Fe grains can be obtained in the powder core annealed at 480 °C. The average grain size related to the full-width at half-maximum of XRD peak is closed to 23 nm by estimated for core annealed at 480 °C. Primary crystallization of α-Fe is completely finished as shown in the DSC curves. A constant initial permeability more than 50 was obtained upto the frequency range of tens of megahertz. At high frequency (> 100 kHz), powder cores exhibit low core loss due to relatively low eddy current loss resulting from the resin insulation.

TU.H-P68 - A soft/hard magnetic nanostructure based on multisegmented coni nanowires

A. Pereira [1,2], J. L. Palma [1, 2], M. Vazquez [3], J. Casagrande Denardin [1,2], J. Escrig [1,2]

2. Center for the Development of Nanoscience and Nanotechnology (CEDENNA), Santiago, Chile
3. Institute of Materials Science of Madrid, CSIC, Madrid, Spain

In this work we have introduced a new soft/hard nanostructure based on multisegmented CoNi nanowire arrays having diameters of around 110 nm and made of five segments with nominal compositions of Co, $Co_{66}Ni_{33}$, $Co_{50}Ni_{50}$, $Co_{33}Ni_{66}$ and Ni, each of which has a length of 800 nm, so that the total length of the multisegmented nanowire is 4 mm. These arrays have been synthesized by means of potentiostatic electrodeposition into the pores of hard-anodic alumina templates. The morphology, chemical composition and microstructure of the multisegmented CoNi nanowires were determined by high-resolution scanning electron microscopy, energy dispersive X-ray microanalysis, and powder X-ray diffraction method, respectively. The room temperature magnetic behavior of the multisegmented nanowire arrays is also studied and compared with CoNi nanowire arrays with homogeneous composition (non-segmented nanowires), synthesized in the same templates and having the same dimensions as the segmented ones. These nanostructures could be used to control the movement of magnetic domain walls. In this way, these nanostructures can be an alternative to store information or even perform logic functions.

TU.H-P69 - Enhancement of magnetic property of Nd-Fe-B powders prepared by reduction-diffusion process

D. Kim [1], C. Chen[2], Y.k Seo[1], C.n Choi[1]

1. Korea Institute of Materials Science, Republic of Korea
2. Korea University of Science and Technology, Republic of Korea

Nd-Fe-B magnets have been fabricated by powder metallurgical routes, rapid quenching and reduction-diffusion (R-D) process. Compared with other methods, use of a relatively inexpensive Nd oxide as raw material and direct production of alloy powders suitable for further procedures can be pointed out as main advantages of R-D process. A novel route to prepare Nd-Fe-B magnetic powders by utilizing both spray drying and reduction-diffusion processes was designed and investigated in this study. Precursors were prepared by spray drying method using the aqueous solutions containing Nd salt, Fe salt and boric acid with stoichiometric ratios. Desalting of the precursors, milling and reduction in H_2 atmosphere were performed, followed by R-D process. It was revealed that the amount of Calcium (Ca) as reducing agent added in R-D step played an important role in the formation of $Nd_2Fe_{14}B$ phase, because vigorous H_2 evolution and dissociated hydrogen might be diffused into the lattice of $Nd_2Fe_{14}B$ interstitially to form $Nd_2Fe_{14}BH_x$ (x=1-5) during washing of powders in water obtained after R-D with excessive amount of Ca. This is one of the critical reasons for low magnetic property of powders synthesized by R-D process. In order to make the powders smaller and homogeneous size, we carried out ball milling in ethanol before washing with water. Finally, $Nd_2Fe_{14}B$ powders with high coercivity of more than 10 kOe were produced by adjusting the amount of Ca in reduction-diffusion (R-D) process. They showed spherical in shape with a mean size of 1μm and maximum energy product (BH_{max}) was attained 17.8 MGOe.

TU.H-P70 - Coercivity enhancement in La coated Nd-Fe-B thin films

K. Koike [1], H. Ishikawa [1], D. Ogawa [1], H. Katao [1], T. Miyazaki[2], Y. Ando [2], M. Itakura [3]

3. Interdisciplinary Graduate school of Engineering Science, Kyushu University, Japan

Achieving higher coercivity in sintered Nd-Fe-B magnets without using heavy rare-earth elements is one of the most crucial and urgent subjects, in view of the rapidly growing demand for high-performance motors such as those in electric or hybrid vehicles. At least two approaches have been known so far to increase coercivity in sintered Nd-Fe-B magnets. First one is the grain size refinement of the main $Nd_2Fe_{14}B$ phase. The second approach is the interface control between the main and grain-boundary phases.

In order to investigate the relation between such interface state and the coercivity in sintered Nd-Fe-B magnets, we have been fabricating samples with the model interface between $Nd_2Fe_{14}B$ and grain-boundary phases by using a thin-film technique [1-3]. We reported the coercivity enhancement phenomena in Nd-Fe-B films when the Nd overlayer was deposited and annealed at 500˚C [1]. However, the origin of such a coercivity enhancement is still not clear. In this paper, we fabricated the similar Nd-Fe-B films but with the La overlayer and investigated their magnetic properties in order to approach the coercivity mechanism.

The Nd-Fe-B (20 nm)/La (20 nm) thin films were deposited on Al_2O_3(0001) substrate by using UHV sputtering technique. The coercivity of as-deposited Nd-Fe-B films without the La overlayer showed 9 kOe. We then deposited the La overlayer on this film. But the coercivity remained almost unchanged.

On the other hand, when annealed at 470°C, the coercivity of the Nd-Fe-B/La film increased significantly and reached 15 kOe. The SIMS, XRD, and high resolution TEM observation in this high coercivity film suggested the existence of hcp-La_2O_3 phases in the La layer.

4. Chungbuk National University, Cheongju, Republic of Korea

Ni-Mn-Z (Z = Sn, Sb, Al) Heusler alloys in forms of ingot and ribbon were prepared by using arc-melting and melt-spinning methods, respectively. Structure-property relationships in these systems of Heusler alloys were systematically investigated and compared. The results showed that structure, magnetic property and giant magnetocaloric effect (GMCE) of the alloys are strongly influenced by fabrication conditions such as quenching rate, annealing temperature, annealing time. The coexistence of ferromagnetic (FM) and antiferromagnetic (AFM) orders can be observed in these systems with appropriate compositions and fabrication conditions. The magnetic phase transitions can be controlled by changing composition and annealing conditions of the alloys. GMCEs with large magnitude and wide working temperature range have been obtained on these alloys showing their application potential for magnetic refrigeration technology.

TU.H-P72 - Effects of ordered phases on the structure and magnetic properties of fe-9%si-2%cr powder

P. Jang [1], G.Choi [2]

1. Cheongju University, Cheongju, Republic of Korea
2. Changsung CorpORATION, Incheon, Republic of Korea

Miniaturized inductors with good electromagnetic properties have being required in recent mobile devices, for which operating frequency should be higher than 10 MHz and low electrical resistivity is also required for high dc current. The electrical resistivity of well-known Fe-6.5%Si alloys with excellent dc magnetic properties is too low for the high frequency application. Fe-Si powder cores with high silicon content have high electrical resistivity. However, ordered phases such as B2 and DO3 existing in disordered A2 phase appears in the alloys. The effects of size and distribution of the ordered phases on the electromagnetic properties of the Fe-Si alloys have not been well-studied. In this study, Fe-9%Si-2%Cr powder with a mean size of 14.4 um was gas-atomized and then annealed at 25 – 650oC in nitrogen gas for 1 hr. In XRD analysis A2 and B2 phases existed in the as-atomized powder. The DO3 started to precipitate and volume fraction of B2 phase decreased after 550oC annealing which can be well-explained by the Fe-Si equilibrium phase diagram. However, B2 phase did not disappeared even after 650oC annealing. The size of DO3 phase is 13 and 84 nm after 550 and 650oC annealing, respectively. The fine distribution of the DO3 phase can increase the electrical resistivity because of the high electron scattering in the interface between DO3 and A2 phases. DC magnetic properties were not so much influenced by the annealing so that the saturation magnetization and coercivity of the annealing powder were 150 A·m2/kg and 240-320 A/m, respectively.

TU.H-P74 - Structure and magnetic properties of sputtered smxco100-x (20< x<32) films prepared at low temperatures

F.M.F. Rhen [1,2], S. Belochapkine [2], F.P. Missell [3]

3. Centro de Ciéncias Exatas e Technologia, Universidade de Caxias do Sul, Caxias do Sul, Brazil

There is growing interest in using magnetic components in microelectromechanical systems (MEMS). If a MEMS device with two magnetic parts is scaled down by a factor k, the force between the two magnets scaled up by a factor k, making them favourably for integration over magnet-coil devices, in which interaction is scale invariant [1]. CMOS compatible technologies require processing temperatures typically below 400ºC. The preparation of Sm-Co alloy with TbCu7 structure by sputtering has been demonstrated at low processing temperature of 350ºC [2], showing the potential of this alloy for MEMS applications integrated with CMOS.
Here, we prepared SmxCo100-x (20x32) by sputtering onto heated silicon substrates at 350ºC (623 K). The structure was investigated by X-rays diffraction (XRD) and transmission electron microscopy (TEM). Room temperature magnetic properties were measured with a vibrating sample magnetometer. We found that the (110) and (100) preferential orientations coexist in the films in different proportions depending on the Sm content. Coercivity and hysteresis loop shape are dependent on the Sm content and are correlated with the crystallographic orientation of SmCo5 crystallites in the films.
Our investigation reveals that hexagonal SmCo5 with preferential (110) orientation in the films is promoted by an excess of Sm during the sputtering process. Overall, these results show that hard magnetic properties of thick films with SmCo5 phase can be obtained by sputtering at low temperatures with coercivity of up to m0HC = 1.12 T.

TU.H-P75 - Effect of RF-Power on magnetic properties and FMR line width of RF-Sputtered Zn-Ferrite thin films

B. Sahu [1], N. Venkataramani [2], S. Prasad [1], R. Krishnan [3]

Zn-Ferrite ($ZnFe_2O_4$) shows a size dependent magnetic order with low FMR linewidth (ΔH), only when it is in nano sized. Nanocrystalline $ZnFe_2O_4$ films are known to show better FMR line shape and low ΔH when deposited by RF-sputtering, as against PLD. In this paper we report the effect of rf-power (P) and ex-situ annealing temperature (T_A) on magnetic and FMR properties of rf-magnetron sputtered films. The films were deposited in Ar atmosphere at ambient temperature on corning glass substrate with P varying between 30 to150 watts. The as deposited films were annealed at T_A from 250-650 °C in air for 2hrs. The thickness of the films increased from 100 to 670 nm as P increased from 30 to 150 watt. The grain sizes also increased both with P and T_A. The spontaneous magnetizations ($4\pi M_S$) at 300 K increased from 480 G to 1930 G as P changed from 30 to 130 watt. For P=150 watt, the $4\pi M_S$ was 1760 G. $4\pi M_S$ values initially increased with the T_A up to 250 °C, then decreased, showing a paramagnetic like behavior for T_A>450 ^{o}C. Parallel and perpendicular FMR measurement were carried out at 9.44 GHz. The peak to peak ΔH did not show monotonous behavior with the P and T_A. It was found that the films deposited at higher P, show larger ΔH. However, upon annealing ΔH decreases at higher rate for them than those deposited as low P. Minimum ΔH of 170 Oe for parallel and 115 Oe for perpendicular was obtained for the sample with P=150 watt and T_A=450 °C. These results can be explained on the basis of grain size dependence of magnetic order. The present results show that it is important to optimize both P and T_A for obtaining low linewidth in $ZnFe_2O_4$ thin films.

TU.H-P77 - Magnetic properties and X-ray photoemission of $NaCo_{2-x}Ca_xO_4$ (x = 0.0, 0.1 and 0.2)

Spinel structure have drawn a lot of research interests for their exhibition of many unusual physical properties including high magnetic moment, magneto-resistance, half metallic behavior, potential applications in chemical sensors [1], catalytic activity [2], photo-conductive materials [3] and thermoelectric effect [4] which has great potential in the field of cooling, heating, generating power, and recovering waste heat. Co_3O_4 is an antiferromagnet (T_N~30 K) [5]. Co rich compounds in spinel oxides could be of interesting in view of the diversity in magnetic properties (ferrimagnet, antiferromagnet and antiferromagnetic spin glass) and magneto-transport phenomena (colossal magnetoresistance). In present work, we have studied magnetic properties of polycrystalline $NaCo_{2-x}Ca_xO_4$ (x = 0.0, 0.1 and 0.2). The purpose of this paper is to study how the doped alkali metal Ca affects the magnetic property. Polycrystalline samples $NaCo_{2-x}Ca_xO_4$ were synthesized by conventional solid state reaction. The crystal structure was detected by x-ray diffraction (XRD) using Cu-$K\alpha$ radiation. Magnetic properties for those samples were investigated by means of a superconducting quantum interference device (SQUID) magnetometer. X-ray photoelectron spectroscopy (XPS) measurements were carried out to observe valance band energy on the sample. Figure 1 shows maximum magnetic hysteresis polycrystalline $NaCo_{2-x}Ca_xO_4$ (x = 0.0, 0.1 and 0.2) under external field of 20 kOe at 5 K. Figure 2 demonstrates binding energy on sample polycrystalline $NaCo_{2-x}Ca_xO_4$ (x = 0.0, 0.1 and 0.2). As Ca^{2+} increase chemical shift goes to lower binding energy indicting addition of electron. Considering charge neutrality into account, the sample will have chemical distribution may transform from $Na^{1+}Co^{3+}Co^{4+}O_4^{2-}$ to $Na^{1+}Ca^{2+}Co^{2+}Co^{3+}O_4$. Coupling magnetic interaction of Co^{3+}/Co^{4+} to Co^{2+}/Co^{3+} shows strong correlation to the enhancement of magnetization. Therefore, it is interesting to discuss in detail the mechanism of magnetic enhancement with *X*-ray photoemission result in full report work.

TU.H-P78 - Magnetic properties of hexaferrites obtained by spark plasma sintering of $SrFe_{12}O_{19}$ nanoparticles

JM. Le Breton [1], N. Maât [1], V. Nachbaur [1], E. Folcke [1], FX. Lefevre [2], Y. Bréard [2], A. Pautrat [2]

2. CRISMAT - UMR 6508 CNRS, Université de Caen et ENSICAEN, France

The replacement of rare earth magnetic materials by more available and affordable materials is a very current topic. One way to obtain rare-earth free new permanent magnet materials is to increase the magnetic properties of $SrFe_{12}O_{19}$ hexaferrites by nanostructuration.
$SrFe_{12}O_{19}$ nanostructured powders were obtained by hydrothermal processing of strontium and ferric nitrates in a Teflon lined bomb at 170°C for 20h, with appropriate concentrations of starting materials. The as-prepared powders were sintered by spark plasma sintering (SPS) at 350°C under 700MPa. Both powders and sintered materials were characterized by X-ray diffraction, scanning electron microscopy and magnetic measurements.
The sintered materials appear to be homogeneous. They are composed of platelets elongated perpendicular to the pressing direction. Their size, about 200 nm large and about 50 nm thick, is similar to that of the starting powders, indicating that no grain growth occurred during SPS. The magnetic properties of the sintered materials were measured parallel and perpendicular to the pressing direction. A coercive field $\mu_0 H_C$ is about 1800 G is obtained (the coercive field of the starting powders is very low, being less than 50 G). A slight magnetic anisotropy is observed, related to the anisotropic shape of the grains. The saturation magnetization of the powders is preserved, being about 60emu/g.
Financial support of the French “Agence Nationale de la Recherche” (ANR), through the program “Investissement d’avenir” (ANR-10-LABX-00-01) LabExEMC3 is gratefully acknowledged.

TU.H-P79 - Crystallization process and magnetic properties of Fe-rich nanocrystals embedded on amorphous magnetic ribbons

J. Duque [1], B. Peixoto [1], G. Mecena [1], S. Silva [1], C. Mendonça [1], T. Meneses [1]

1. NPGFI, Federal University of Sergipe, Sergipe, Brazil

In this work we use thermal analysis methods, X-ray diffraction and magnetization measurements to carry out a systematic study on amorphous magnetic materials. In this sense, as-quenched amorphous samples of $Ni_{40}Fe_{40}P_{14}B_6$ and $Fe_{76,5}Cu_1$ $Nb_3Si_{13,5}B_6$ were used. We have interpreted the crystallization kinetics in terms of the Johnson/Mehl/Avrami (JMA) nucleation-growth model. X-ray diffraction data as function of temperature reveal that our samples consist of single phases of Fe-rich nanocrystals embedded in a residual amorphous phase. Magnetic measurements as function of temperature show a sharp decreases of the magnetization around 200 and 3500C to $Ni_{40}Fe_{40}P_{14}B_6$ and $Fe_{76,5}Cu_1$ $Nb_3Si_{13,5}B_6$, respectively, likely related to the Curie temperatures. TGA and magnetization curves show additional increases in the high temperature region which are attributed to the growth of the Fe-rich magnetic phases.

TU.H-P80 - Direct and converse magnetoelectric effect in BSPT-NFO co-fired laminate composite

D.Kumar S [1], Ramesh G [1], Subramanian V [1]

1. Indian Institute of Technology Madras, India

The magnetoelectric (ME) properties of laminate composite consists of 0.373 BiScO3- 0.627 PbTiO3 (BSPT) as ferroelectric phase and NiFe2O4 (NFO) as ferrite phase is studied. The bi-layer laminate is prepared by stacking the individually calcined phases followed by co-fired technique at two different temperatures (i) 1100°C (B-N 1100) and (ii) 1200°C (B-N 1200). The effects of sintering temperature on ME coupling between the phases were investigated. The scanning electron microscopy (SEM) and energy dispersive X-ray (EDX) analysis across the interface indicates diffusion between the phases enhances with increase in sintering temperature. A well saturated ferroelectric loop is observed in both the samples and the saturation polarization decreases with increase in sintering temperature. The direct ME (DME) coefficient of B-N 1100 and B-N 1200 laminate shows a maximum value of 30 mV/(cm.Oe) and 20 mV/(cm.Oe) respectively where as the converse ME (CME) coefficient shows a maximum value of 0.04 (mG.cm)/V and 0.16 (mG.cm)/V respectively. Interestingly, the B-N 1100 sample shows a maximum DME effect whereas B-N 1200 sample shows a maximum CME effect which might be due to effect of sintering on the magnetic phase and the diffusion between the phases.

TU.H-P81 - Combinatorial development of Fe-Co-Nb thin film magnetic nanocomposites

V. Alexandrakis [1], W. Wallisch [2], S. Hamann [1], G. Varvaro [3], J. Fidler [2], A. Ludwig [1]

1. Ruhr-University Bochum, Faculty of Mechanical Engineering, Institute of Materials, Bochum, Germany
2. Institute of Solid State Physics, Vienna University of Technology, Vienna, Austria
3. Istituto di Struttura della Materia, CNR, Monterotondo Scalo, Roma, Italy

To date, rare earth (RE)-based magnetic materials are the best performing permanent magnets (PMs); they cover 65% of the market, while less expensive hexaferrites, characterized by a lower (BH)max value but still high Tc, provide another 34% of the total [1]. Nowadays, RE supplies have become a bottleneck, thus stimulating an intense activity for the search of new materials with a reduced or even zero content of RE either to match/surpass the properties of the state-of-art RE-PMs or to bridge the gap between hexaferrites and RE-based PMs. Discovery of novel materials for PMs is challenging, as the performance of a PM mainly depends on coercivity and remanence, which are extrinsic properties strongly affected by both composition and microstructure, being then extremely difficult to be predicted by calculations. High-throughput experimentation and combinatorial fabrication of materials' libraries offer a quick assessment of materials properties, giving a guidance about which materials are promising for novel PMs. In this communication, combinatorial and high-throughput methods were applied for the fabrication and characterization of Fe-Co-Nb thin film composition spread type materials libraries. Nb was chosen as an alloying element for Fe-Co as it is in abundance with a low price and forms non-cubic binary structures with both Fe and Co. Structural analysis indicated the formation of a new ternary compound (Fe,Co)3Nb with a hexagonal crystal structure embedded in a FeCo-based matrix. The magnetic measurements revealed that the film behave as a hard-soft magnetic composite, thus indicating that the new (Fe,Co)3Nb phase is ferromagnetic. The reversal mechanism was also investigated and was found to be domain wall pinning type.

TU.H-P85 - Optical and magneto-optical properties of Bi substituted Nd iron garnets prepared by metal organic decomposition method

E. Jesenska [1,2], M.Sasaki [1], T. Hashinaka [1], G. Lou [1], M. Zahradnik [2], L. Ohnoutek [2], R. Antos [2], M. Veis [2], T. Ishibashi [1]

1. Nagaoka University of Technology, Japan
2. Charles University In Prague, Prague, Czech Republic

Magnetic garnets have recently attracted a renewed attention as they manifest several magneto-electric, spintronic and magneto-optical (MO) phenomena, such as induction of polarization or magnetization by electromagnetic field, spin Seebeck effect, spin Hall magneto-resistance as well as high Faraday effect [1,2,3,4]. Because of their well-defined optical and magnetic properties, rare-earth magnetic garnets are interesting materials for applications in magnetic recording, non-reciprocal photonic devices (including optical isolators and circulators) and MO visualizers. Several techniques are used to grow their high quality thin films. Among them metal organic decomposition (MOD) method appears to be very promising, because it is inexpensive, simple, and guarantees highly uniform chemical composition and purity, combined with chemical stability [5]. Although yttrium iron garnets are mostly studied, neodymium iron garnets seems to have interesting properties, such as strong out-of-plane magnetic anisotropy.
In this work, we present systematic optical and MO studies of $Nd_2BiFe_{(5-x)}Ga_xO_{12}$ and $Nd_{0.5}Bi_{2.5}Fe_{(5-x)}Ga_xO_{12}$ (x=0, 0.25, 0.5, 0.75, 1) thin films prepared by MOD method on $Gd_3Ga_5O_{12}$ (111) substrates. Spectroscopic ellipsometry and MO spectroscopy were employed as characterization techniques. Faraday and Kerr MO spectra clearly demonstrated that the increasing Ga concentration decreases the spin-orbit coupling and influences the MO effect. A confrontation of ellipsometric and MO experimental data with advanced theoretical calculations provided a spectral dependence of complete permittivity tensors of studied materials in a wide spectral range.

TU.H-P87 - Co ferrite thin films on MgO (100) prepared by metal-organic decomposition method

T. Ishibashi [1], M. Sasaki [1], M. Ninomiya [1], T. Tsurui [1], K. Shinozaki [1], T.Komatsu [1], H.Yanagihara [2], E. Kita [2]

1. Nagaoka University of Technology, Japan
2. University of Tsukuba, Japan

Recently, stress-induced large magnetic anisotropy has been reported in the epitaxial Co ferrite thin films on MgO (100) substrates prepared by sputtering technique[1], showing the possibility of ferrite materials for strong permanent magnet or high-density magnetic recording media without using rare earth metals nor noble metals. In order to explore new ferrite materials, metal organic decomposition (MOD) method is promising because of good productivity with accurate chemical composition and uniformity. In this paper, we report on Co ferrite thin films prepared by MOD method. MOD solution with a composition of Co : Fe = 1: 3 (Kojundo Chemical Lab Co.,Ltd.) was spin-coated on MgO (100) substrates with 3000 rpm for 30 s, followed by drying at 100ºC for 10 - 30 min. In order to decompose organic materials and obtain precursor films, samples were pre-annealed at 450ºC for 30 min. Finally, the samples were annealed at 700ºC in air for 1 - 13 h for crystallization. The 400 diffraction peaks of Co ferrite were observed in the XRD measurement, indicating that Co ferrite films grown along <100> on the MgO (100) substrates. Magneto-optical spectra showed characteristic structures of Co ferrite having peaks at 1.8, 2.1, 2.2 eV. TEM combined with EDX measurement revealed that homogeneous thin films with a thickness of 42 nm were grown on the substrates and the chemical composition was Co : Fe = 1 : 4. Magnetic anisotropy field was found to be larger than 50 kOe. On the other hand, coercivity was as small as 4 kOe. We conclude that the MOD method is promising for preparation of ferrite films.

TU.H-P88 - Refining of Mo permalloy powders (MPPs) by hydrogen and magnetic properties of core made of refined MPPs

Ji Young Byun [1], Kwang Deok Choi [1], G. Choi [2]

1. Material Architecturing Center, Korea Institute of Science and Technology, Republic of Korea

It has been well known that the hydrogen annealing of permalloy plates at high temperatures of 1,100-1,200°C enhances their magnetic properties drastically due to removal of non-metallic elements of carbon, oxygen, sulfur, etc. The same process, however, cannot be applied for refining the permalloy powders, because high-temperature annealing results in sintering of the powders. The approach in the present work was to add CaO powders to the Mo permalloy powders (MPP). Experimental results of hydrogen-annealing of the MPPs showed that CaO powders in the mixture of CaO and MPPs prevented MPPs from sintering, even though the mixture was treated at high temperatures of 900-1,000℃. Water-soluble CaO can be easily removed from the reaction mixture by magnetic separation in water medium. (S+O) contents in MPP were reduced from 900 ppm to less than 300 ppm when the mixtures were kept above 1 hr at 1000℃ or 4 hrs at 950℃ or 9hrs at 900℃. This indicates that each MPP is exposed to the hydrogen and (S+O) in the permalloy is removed by reactions with hydrogen to form H_2O and H_2S. Core losses of powder cores made of hydrogen-refined MPPs were observed to be lower than those of cores made of unrefined MPPs. Effects of the annealing temperature and time and the CaO amount in powder mixture on the contents of sulfur and oxygen, hardness, and grain size will be presented in detail in the poster.

TU.H-P89 - crystal field parameters for rare-earth permanent magnets: wannier function approach

T. Yoshioka [1], H. Tsuchiura [1], P. Novak [2]

1. Department of Applied Physics, Tohoku University, Sendai, Japan
2. Institute of Physics of ASCR, Prague, Czech Republic

Crystal electric fields (CEF) acting on the 4*f* electrons of rare-earth (RE) ions in RE permanent magnets play a dominant role in determining their magnetic anisotropy. The interaction between the anisotropic 4*f* electronic clouds of RE ions and the CEF of surrounding charges control the magnetic moments along a specific crystalline direction. The large magnetic anisotropy energy of RE magnets produced by the CEF is strongly believed to mainly dominate their coercivity. Thus, precise information of CEF is needed to study and to improve the magnetic anisotropy and coercivity of RE magnets.
Theoretically, there still remain problems to treat the 4*f* electrons of RE ions. The open-core method may give good results when 4*f* electrons are well-localized. Unfortunately, however, some RE magnets have been known to be not the case. Quite recently, a new method has been developed to carry out an accurate calculation of CFPs by using Wannier functions.[1] Now it is interesting to estimate the CFPs of RE magnets by using this method.
The CFPs for crystalline $R_2Fe_{14}B$ have been obtained by the Wannier function approach, which enables us to visualize the 4*f* electron clouds. By diagonalizing CEF Hamiltonian based on the Wannier functions, we have confirmed that the low energy wave functions for R=Nd and Dy are expanded to the *a*-*b* plane, which result in the single-ion anisotropy along the c-axis. The 4*f* electron clouds in Nd ions are more expanded to radial direction than that in Dy ions reflected by the lanthanide contraction. On the other hand, we also calculate the CFPs of Nd ions around the surface of the crystalline $Nd_2Fe_{14}B$ and have found that the Nd ions exposed on the (001) surface have 4*f* electron clouds extended to the c-axis accompanying the c-plane magnetic anisotropy. The results for CFPs are consistent with previous theoretical study. [2]

TU.H-P90 - Effects of annealing on the structure and magnetic properties of Fe-Si-Cr flakes and composite sheets

P. Jang [1]

1. Cheongju University, Cheongju, Republic of Korea

Gas atomized Fe-Si-Cr powder was used in the application of a bypass sheet in near field communication. The powder was ball-milled, annealed at different temperatures and then manufactured to the sheet. Changes in microstructure and magnetic properties were investigated by XRD, VSM and impedance analyzer. The as-milled Fe-Si-Cr flake consisted mainly of disordered A2 and ordered B2 phases while the atomized powder consisted of A2, B2 and DO_3 phases. Increases in the annealing temperature caused the formation of a DO_3 phase. At temperatures higher than 923 K, the final flake consisted of only A2 and DO_3 phases. Grain size increased abruptly from 823 K, while the size of the DO_3 phase increased rapidly from 623 K. Coercivity of the flake decreased after annealing, with the lowest coercivity obtained after 923 K annealing while saturation magnetization showed a minimum value of 928 kA/m after 523 K annealing. Sputtered Fe-12%Si films showed a highest electrical resistivity value of 191 $\mu\Omega$·cm after 623 K annealing while the resistivity of Fe-4%Si sputtered films decreased almost linearly with annealing temperature. Therefore it could be concluded that high permeability of the 623 K sheet at 13.56 MHz and low permeability of the 923 K sheet at 80 MHz were due to the high resistivity as well as nanostructure of the 623 K flake.

TU.H-P91 - Theoretical evaluation of temperature dependence of magnetic anisotropy constants of $R_2Fe_{14}B$ compounds

D. Miura [1], R. Sasaki [1], A. Sakuma [1]

1. Applied Physics, Tohoku University, Japan

Sintered Nd-Fe-B permanent magnets have the largest maximum energy product of all permanent magnets, and are vital materials of high-performance magnetic devices. Unfortunately, the Nd-Fe-B magnet is unusable under the high temperature environment (above 500K) due to the lacking coercive force. In general, it is believed that the coercive force of rare-earth magnets including Nd-Fe-B magnets is dominated by magnetocrystalline anisotropy originated from both the cyrstalline electric field (CEF) and the exchange field acting on the 4f electronic system in rare-earth ions. However, there are few calculations for the temperature dependent magnetic anisotropy constants (MACs) based on the microscopic footing mentioned above. Our aims are to theoretically reproduce temperature dependence of various magnetic properties of $R_2Fe_{14}B$ (R stands for a rare-earth element) compounds and understand the coercive mechanism of rare-earth magnets from microscopic viewpoints. In this work, we calculate MACs (K1, K2, K3) of $R_2Fe_{14}B$ compounds on the basis of a microscopic model. The Hamiltonian for the 4f electronic system in an R ion consists of the spin-orbit interaction, the CEF term and the exchange interaction with Fe spins. We define the MACs as the expansion coefficients, with respect to powers of trigonometric functions, of the Helmholtz free energy for the 4f electronic system. From analysis of temperature and angle dependence of the free energies, we can reproduce well the temperature dependences of the MACs agreeable with the experimental results in the quantitative level. Also we refer to the effects of first excited J multiplet on the MACs, and find it is important in a low-temperature region and becomes ignorable with increasing temperature.

TU.H-P92 - The influence of ac joule heating on the magnetic properties of thin finemet cold-drawn microwires

H. Chiriac[1], S. Corodeanu[1], A. Donac[1], V. Dobrea[1], G. Ababei[1], M. Lostun[1], T.A. Ovari[1], N. Lupu[1]

1. National Institute of Research and Development for Technical Physics, Iasi, Romania

Amorphous and/or nanocrystalline microwires with enhanced soft magnetic properties are excellent as sensitive elements in sensors for the detection/measurement of ultra-low magnetic fields [1]. This type of sensing device could be also used for detecting small displacements, vibrations, and various mechanical deformations. In this paper, we studied the magnetic and magnetoelastic properties of FINEMET nanocrystalline wires with diameters ranging from 40 µm down to 10 µm, obtained by cold drawing FINEMET amorphous wires of 105 µm in diameter prepared by in-rotating-water spinning. Their unique magnetic properties are discussed considering the stresses induced during preparation and cold drawing, the stresses relief following annealing, the annealing-induced structural transformations (e.g., nanocrystallization) and the corresponding changes in the magnetic anisotropy. The different magnetic behavior observed after conventional annealing at 500^0C and, respectively, 550^0C, with the permeability reaching the maximum after annealing at 500^0C and the giant magnetoimpedance (GMI) response being maximum after annealing at 550^0C, can be ascribed to the different evolution of the nanocrystallization process in the center of the wire and on the surface, as confirmed by UHR-TEM studies. Furthermore, the cold drawn wires were annealed by Joule heating using a.c. currents of different frequencies (1÷10 MHz) to control the area of the cross section of the wire in which the nanocrystalline structure appears. The longitudinal magnetic permeability measurements corroborated with the GMI response and the surface measurements by magneto-optical Kerr magnetometry shown that, in the case of current annealing a well-defined circumferential or even oblique anisotropy are induced. The TEM studies emphasized also smaller nanograins on the surface compared with the inner core of the wires subjected to a.c. current annealing. Using different frequencies for the a.c. currents it was possible to control the magnitude of the longitudinal magnetic permeability and GMI response, accordingly with the requirements for different sensing applications.

TU.H-P93 - Magnetoelastic properties of amorphous $Co_{66}Fe_4Ni_1B_{14}Si_{15}$ alloys in compressive and tensile stress sensors applications

J.Salach [1]

1. Institute of Metrology And Biomedical Engineering, Warsaw University of Technology, Warsaw, Poland

Amorphous magnetic materials are known very well in magnetic and electronic components. However, they are not widely known for their magnetoelastic properties for stress sensors applications. Reason of this state is character of these materials, which are typically in the form of ribbon or wire. Meanwhile, to obtain a high resolution of magnetoelastic sensors, uniform stresses distribution and closed magnetic circuit is necessary.

Paper presents the results of investigation of magnetoelastic properties of amorphous $Co_{66}Fe_4Ni_1B_{14}Si_{15}$ alloy. Ribbon was rolled up in a ring shaped samples and then annealed in temperature of selected values. The temperature was chosen in order to obtain the high permeability material without losing the high mechanical strength. Thus, a temperature of 350oC and 365oC was chosen. For comparison of of tested material magnetoelastic properties change, it was also investigated in as-quenched state. Investigation of magnetoelastic properties was performed for a range of tensile stress form 0 up to 3 MPa. This range was due to the mechanical strength of testing device. For compressive stresses, the attainable range was from 0 up to 10 MPa. These results indicate, that investigated materials have high magnetoelastic sensitivity, and after special preparation can be used for application in magnetoelastic sensors of compressive and tensile stresses. Significant changes of flux density in the samples suggest stable indication of proposed sensor, and resistance to external interference.

TU.H-P94 - Strain-controlled MO effect on highly Bi-substituted neodymium iron gallium garnet thin films

M. Sasaki [1], G. Lou [1], T. Hashinaka [1], A. Meguro [1], M. Ninomiya [1], T. Ishibashi [1], T.Taniyama [2]

2. Tokyo Institute of Technology, Tokyo, Japan

Controlling magnetization of magneto-optic (MO) materials by voltage instead of electric current is expected to reduce power consumption and miniaturize functional elements in MO devices such as magneto-optic spatial light modulator (MO-SLM). One of the methods to control magnetization is to use reverse magnetostrictive effect using piezoelectric actuator [1] [2] [3]. In this study, highly Bi-substituted neodymium iron gallium garnet (NBIGG) thin films prepared on gadolinium gallium garnet (GGG) single crystal substrates were studied as a strain-mediated magnetoelectric coupling element. $Nd_{0.5}Bi_{2.5}Fe_{4.5}Ga_{0.5}O_{12}$ thin films were prepared by metal-organic decomposition method. The NBIGG films were cemented on the PZT polycrystals with two Au electrodes with a gap of 1mm. Tensile strain in the direction of the electrical field was applied to the NBIGG thin films, which was measured by a strain gauge on the PZT and was estimated to be approximately 3.5x10-4 at applied voltage 1.7kV. Strain-induced changes of coercivity Hc and saturation field in hysteresis loop were measured by the magneto-optical Kerr microscope. We found that Hc increased by maximum 10% and saturated Kerr rotation angle also changed by maximum 40% when the applied voltage was increased from 0V to 1.7kV. We also found that magnetic domain structures under the strain were not uniform because of spatial distribution of residual stress. We consider that it was caused by non-uniformity of adhesive or other artifact.

TU.H-P95 - Structural and magnetic properties of magnetically semi-hard (Fe_xCo_{1-x})3B compounds

S. Pal [1], S. Ener [1], M. Skokov [1], O. Gutfleisch [1,2]

1. TU Darmstadt, Materialwissenschaft, Darmstadt, Germany
2. IWKS Hanau, Fraunhofer-Projektgruppe für Wertstoffkreislöufe und Ressourcenstrategie, Hanau, Germany

There has been some efforts in fabricating nano-composite exchange-spring magnets by combining large remanence (soft) phases, such as Fe and Fe-Co and strong-anisotropy (hard) phases, in order to improve the energy product (BH)max value. However, the soft phases affect coercivity negatively. It is expected that, apart from the magnetization improvement, the coercivity of nano-composite permanent magnets would be improved through the replacement of soft magnetic phase by a semi-hard magnetic phase. Here, we present a study on the (Fe_xCo_{1-x})3B (x = 0.0, 0.1, 0.2 and 0.3) compounds with the aim of synthesizing Fe_3B compound with tetragonal structure which is a metastable phase and exists in a narrow temperature range of 1150-1250 K. The (Fe_xCo_{1-x})3B compounds have been prepared by substitution of Fe atoms for Co atoms in Co_3B. A single phase orthorhombic structure was obtained by X-ray diffraction measurement for all compositions. Magnetic domain images obtained by Kerr microscopy show distinctive domains and reveal the presence of uniaxial magnetocrystalline anisotropy. The anisotropic nature was confirmed by the demagnetization curve measurements of the magnetically oriented single-crystalline particles which were obtained after crushing the ingots. The anisotropy constants and anisotropy field of the samples of magnetically oriented single-crystalline particles have been calculated. An anisotropy field of 2.2 T was obtained for Co_3B (x = 0.0), the anisotropy field was found to decrease with increasing Fe content reaching to a value of 1.5 T for x = 0.3. The Curie temperature for (FexCo1-x)3B compound was found to increase from 750 K for x = 0.0 to 923 K for x = 0.3. These compounds with uniaxial magnetocrystalline anisotropy are promising materials to be used as semi-hard magnetic phase for the preparation of nanocomposite exchange-spring magnets.

TU.H-P96 - Effect of the Mn/Bi ratio on the microstructure and magnetic properties of melt-spun MnBi LTP alloys

M. Grigoras [1], M. Lostun [1], G. Ababaei [1], H. Chiriac [1], N. Lupu [1]

1. National Institute of Research & Development For Technical Physics, Iasi, Romania

Recently, the free rare-earth permanent magnets become an attractive research topic. Among these, the low-temperature-phase (LPT) pure MnBi turned out to be a competitive candidate since it shows hexagonal NiAs-type crystal structure at RT and exhibit large magnetocrystalline anisotropy and positive temperature coefficient of coercivity [1]. The coercivity increases with temperature, reaching a maximum of 2.5 T at 540 K [2], making MnBi-based magnets an attractive alternative, especially for high temperatures applications. However, MnBi relatively saturation magnetization of about 75 Am2/kg at RT limits the (BH)max to about 136 kJ/m3. To improve the magnetic properties, many efforts have been made to prepare MnBi compounds with pure LTP, but this proved to be a challenge up to now. In this respect, we report here the effect of the Mn/Bi ratio on the hard magnetic properties and microstructure of Mn100-xBix melt-spun ribbons prepared by rapid solidification (x=40¸60 at.%). The alloy ingots were prepared by arc-melting from the constituent elements, followed by induction-melting in order to obtain better uniformity. MnBi-ribbons were obtained by melt-spinning using a copper wheel at different velocities. The ribbons were then annealed in vacuum, for different periods of time, at temperatures between 563 K and 673 K in order to obtain the pure LPT. We have managed to achieve a coercivity near 0.85 T at RT in $Mn_{50}Bi_{50}$ melt-spun ribbons, annealed at 573 K for 20 h, while the saturation magnetization was 61 Am2/kg. The microstructure of the annealed $Mn_{50}Bi_{50}$ melt-spun ribbon revealed a fine and uniform grains structure, with an average size of about 40 nm. By modifying the Mn/Bi ratio, the magnetic properties are enhanced and the grain structure refined.

TU.H-P97 - Grain boundary engineering of thin FeCo films: a route towards new hard magnetic materials

A. Backen [1,2], D.Le Roy [1,2], N. M. Dempsey [1,2], D. Givord [1,2,3]

1. Institut Néel, CNRS, UPR 2940, Grenoble, France

3. Instituto de Fisica, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil

Minimizing the content of rare earth (RE) elements in hard magnetic materials is one of the major challenges in magnet research today. High-coercivity RE-Fe-B magnets with heavy RE content below typically 1-2 % are being prepared by grain boundary diffusion processing. This permits an enhancement of the surface/interface hard magnetic properties, without affecting the magnetic properties within the grains themselves. We have applied this approach with the objective of preparing new types of hard magnetic materials, with properties intermediate between those of high performance RE-Fe-B and those of hard ferrites. FeCo-based alloys are very interesting in this context, because of their high spontaneous magnetization. FeCo sputtered films have been prepared with thickness in the range 20 - 200 nm. These films exhibit a columnar microstructure, which should be favorable for grain boundary diffusion from capping and buffer layers into the main layer. In films in which the FeCo layer is sandwiched between two Nd layers, annealing for 10 h at 675°C, leads to the development of a coercive field of up to 50 mT at 50 K. In these films, the FeCo peaks are no longer observed in XRD scans, and small peaks suggest the formation of the Nd_2Fe_{17} phase. To avoid the consumption of FeCo, the FeCo layer may be separated from the Nd layer, by another transition metal layer, immiscible with Fe and Co, namely Ag. During annealing, the Nd diffuses into Ag, forming a low temperature eutectic. Nd is thus only available at the surface of the FeCo layer. For very thin layers FeCo layers (20nm), an increase in coercivity up to 65 mT is obtained after annealing. In the case of 200 nm-thick FeCo layers, the coercivity after annealing is about 13 mT. In both cases, the observed coercivity is almost temperature-independent which suggests the influence of shape anisotropy.

TU.H-P98 - Nanosized powder with preserved soft magnetic properties obtained by high energy and cryomilling techniques.

A. Aragón [1], M.Guzik [2], S. Deledda [2], A. Hernando [1], P. Marín [1]

1. Instituto De Magnetismo Aplicado (UCM-ADIF), Las Rozas (Madrid), Spain
2. Institute for Energy Technology, Kjeller, Norway

Fe-based nanocrystalline alloys are well known because of their good soft magnetic properties, which make them suitable for specific applications. Several reports have shown that mechanical ball milling is an optimal processing technique to obtain amorphous or nanocrystalline powder to be used in compactation. [1-4] In this work, different milling techniques as High Energy Ball Milling (dry and wet) and cryomilling, have been used to obtain nanometer particle size powder of nanocrystalline Fe and FeCo based ribbons. We have studied the influence of selected milling technique in microstructure and magnetic soft properties of the final product have been studied. Induction of nanocrystallization before milling increased the brittleness of sample. Surfactant-assisted milling prevented particle agglomeration and milling at liquid nitrogen temperature decreased particle size in a shorter time. An average particle size between 300 nm and 9 M was obtained. All samples showed low coercivity and high magnetic saturation values: 3-30 Oe and 125-150 emu/g for Fe-rich, and 10-70 Oe and 170-202 emu/g for FeCo-rich powder. Among all the samples, cryomilled ribbons presented the higher susceptibility values. This is explained by the increase of work hardness during milling performed at low temperatures, because of the augmented number of lattice defects. These structural properties in conjunction with the submicron grain size improve tensile strength and hardness of compacted samples.

TU.H-P99 - Magnetic and structural analysis of mechanically alloyed Fe-Co based nanocrystalline alloys

J.J. Suñol [1], J. Bonastre [1], J. Saurina [2]

1. University of Girona, Girona, Spain

Mechanical alloying was used to prepare several FeCo based soft magnetic alloys as powder mixtures in a high-energy planetary ball mill under argon atmosphere. These materials have high saturation magnetization and also high Curie temperature. Structural, microstructural and magnetic behavior was followed by scanning electron microscopy (SEM), X-ray diffraction (XRD), differential scanning calorimetry (DSC) and vibrating sample magnetometry (VSM). Nanocrystalline structure was achieved at 40 hours of milling. It was found that the partial substitution of Fe by Co in nanocrystalline alloys is a way of extending their outstanding soft magnetic properties to higher temperatures. Furthermore, the nanocrystalline the nanostructured materials have a significant fraction of atoms in grain boundaries and crystallographic defects (voids, dislocations) which influences their magnetic properties. In these alloys, annealing improves soft magnetic behavior by reducing mechanically induced internal stress. Powdered samples were consolidated and sintered to obtain bulk materials in order to analyze their properties. However, high annealing temperatures should be avoided to prevent significant grain growth. Crystallization was also analyzed to determine the thermal stability from crystallization (activation energy, crystallization phase diagram) and to design experimental conditions to develop alloys with controlled nanocrystalline size.

TU.H-P100 - Study of AC magnetic properties and core losses of Fe/Fe_3O_4 - epoxy resin soft magnetic composite

Laxminarayana T. A. [1], Subhendu Kumar Manna [2], Fernandes B. G. [3], Venkataramani N. [1]

1. Department of Metallurgical Engineering and Materials Science, Indian Institute of Technology Bombay, Mumbai, India
2. Department of Physics, IIT Madras, Chennai, India
3. Department of Electrical Engineering, Indian Institute of Technology Bombay, Mumbai, India

Soft magnetic composite (SMC) is an electrically insulated iron powder that can be used for high frequency electrical devices due to its low core losses and 3D magnetic flux. SMC for this study was prepared by coating of ultrafine Fe_3O_4 particles, synthesized by co-precipitation method, on atomized iron powder of particle size < 53 µm using epoxy resin as an intermediate binder between iron and Fe_3O_4. SEM images and XRD pattern confirmed the uniform coating of ultrafine Fe_3O_4 particles on the surface of iron powder. Further a toroid of OD = 35 mm, ID = 25 mm was prepared by cold compaction of coated iron powder under a compaction pressure of 1050 MPa and subsequently cured at 150˚C for 1 hour in Argon atmosphere. For comparison of properties, a toroid with uncoated iron powder was also compacted at 1050 MPa and annealed at 600˚C in Argon atmosphere. DC resistivity and AC B-H loops were recorded on these toroids. The coated iron has a resistivity greater than 20000 µΩcm, measured by four probe method. Magnetic Hysteresis loop and core loss of the toroids were measured by B-H Loop tracer in the frequency range 0 to 1500 Hz. Coated and uncoated iron cores exhibited a core loss of 91 W/kg and 693 W/kg respectively at 500 Hz and 1 Tesla. For uncoated iron powder a drastic change in losses observed as frequency is increased due to the dominant eddy current losses at high frequency. A new method to prepare coated iron powder that yielded properties comparable to commercial SMC sample like somaloy130i-1P from Hoganas, Sweden is reported. DC Induction value of coated iron powder and somaloy130i-1P at 10000 A/m are 1.35 Tesla and 1.4 Tesla respectively, with Core loss of 206 W/kg and 147 W/kg respectively at 1000 Hz and 1 Tesla.

TU.H-P101 - Tailoring the magneto-transport properties of ferromagnetic amorphous wires

T. Ovari [1], S. Corodeanu [1], H. Chiriac [1]

1. National Institute of R&D For Technical Physics, Iasi, Romania

Co-based nearly zero magnetostrictive amorphous wires have been shown to exhibit a large magneto-impedance effect. Here we investigate the effect of tensile stresses on the magneto-impedance response of amorphous wires with various diameters, aimed for stress and vibration monitoring sensors, to understand the effect of wire dimensions and stress magnitude on their magneto-transport characteristics, and to optimize their properties for such applications. We measured the magneto-impedance effect in wire samples having 80, 100, and 120 microns in diameter, respectively. The experimental set-up allowed us to measure samples simultaneously subjected to dc magnetic field and mechanical stress, at various frequencies of the ac driving current between 1 and 50 MHz. The maximum tensile stress was 500 MPa. To describe the magneto-impedance effect, we employed the magneto-impedance ratio (MIR), defined as the relative variation of impedance at each value of the applied field. We observed that for the thinnest sample, the maximum MIR at 50 MHz increases over three times with applied stress. Frequency is also important: the maximum MIR increases from 160% to nearly 450% for the sample with 100 microns in diameter, when the frequency increases from 1 to 10 MHz. This trend is maintained as the frequency increases to 50 MHz, where the stronger skin effect pushes the MIR over 500%. In conclusion, wire size is a key factor in the magnitude of the magneto-impedance effect. Its non-linear influence on the magneto-transport behavior originates in the magnitude and orientation of the magnetoelastic anisotropy, its dependence on wire diameter, and its changes with applied stress. The results are essential for the practical choice of materials to be employed in vibration and stress monitoring applications, and for tailoring the magneto-transport properties of amorphous wires.

TU.H-P102 - Cobalt doping effect on Ni-Zn-Cu ferrites produced by reactive sintering

A. Mercier [1], G. Chaplier [1], A. Pasko [1], V. Loyau [1], F. Mazaleyrat [1]

1. SATIE, ENS Cachan, CNRS, France

The process Spark Plasma Sintering (SPS) can be used for reactive sintering, i.e. it is possible to synthesize and to sinter the material in a single step which greatly reduces production time. For example, it is possible to produce spinel ferrite parts by this technique. A mixture of simple oxides is placed in a graphite die between two pistons. The spinel phase is formed at the first heating stage (580°C), and then the ferrite is sintered during the second heating stage (800°C). Unlike the classical process, it is not necessary to go through the intermediate stage of calcination [1], and the total process duration is only 25 minutes.
It was demonstrated that Co-substitution in Ni-Zn-Cu ferrites can improve the magnetic properties in general and the losses at high frequency in particular [2]. However, there is a great dependency on the temperature, and for a given cobalt rate, there is a local maximum permeability matching the spin reorientation transition [3].
In addition, the properties depend on the sintering process. To our knowledge, there is still no study of the influence of cobalt in spinel ferrites manufactured by SPS. The chemical formula is $Co_x(Ni_{0.24}Cu_{0.20}Zn_{0.56})_{1-x}Fe_2O_4$ where the Co-substitution x varied from 0 to 7 centimoles. The magnetic measurements show that there is a maximum of the permeability for a doping of 3 centimoles. At room temperature, the static permeability μs=7 and merit factor μsfr=1.5Ghz. However, XRD shows that unreacted simples oxides remain that probably influence negatively the properties. The measurement of the permeability and the losses will be presented in a temperature range from 0 to 100 Celsius degrees.

TU.H-P103 - Structural, morphological & magnetic studies on pristine and Gd-doped $YBiO_3$ particles

D. Bhatnagar [1], R. Chatterjee [1]

1. Magnetics & Advanced Ceramics Laboratory, Physics Department, Indian Institute of Technology Delhi, New Delhi, India

$YBiO_3$ has attracted attention of researchers due to its properties like high ionic conductivity, excellent photo-catalyst properties, as buffer layer for superconductor films and in recent times as possible topological insulator material. However the structural and magnetic behaviour of $YBiO_3$ is still not well explored. In this work, pristine and gadolinium (Gd) doped $YBiO_3$ particles were successfully synthesized through co-precipitation technique. Yttrium, Gadolinium and bismuth nitrate salts were chemically reacted at optimized conditions, forming nanometer-sized precipitates. After calcination and sintering treatment polycrystalline powders were obtained.

Microstructure of the samples was investigated using scanning electron microscopy (SEM). The X-ray diffraction measurement (XRD) confirmed that the particles crystallized with face centred cubic (FCC) fluorite structure in single phase. The refined XRD data shows that the lattice parameter increases from 5.42 *Å* (for x=0 sample) to 5.44 *Å* (for x=0.02 sample). With further increase in Gd doping (x=0.05 sample), the lattice parameter decreased to 5.42 *Å*. The observation of lattice scale imaging in high resolution transmission electron microscopy (HRTEM) data indicates good quality of the samples and the structural parameters obtained from selected area electron diffraction (SAED) pattern matched well with the XRD results.

Raman spectra of all samples ($0 \leq x \leq 0.05$) showed five Raman active phonon modes; consisting of one A_{1g}, one E_g, and three T_{2g} modes. Apart from this, magnetic properties of pristine and Gd-doped $YBiO_3$ samples were also explored using MPMS SQUID magnetometer. $(YGd)BiO_3$ samples showed soft (~10 Oe) saturating M-H loops indicating weak ferromagnetism; whereas, the parent $YBiO_3$ shows temperature dependent diamagnetic behaviour at higher field values.

TU.H-P104 - Problems of measuring and modeling of compressive stresses influence on magnetic properties of Fe-based amorphous alloy in rayleigh region

M. Kachniarz [1], R. Szewczyk [2], A. Bienkowski [2], J.Salach [2]

1. Industrial Research Institute For Automation And Measurements PIAP, Warsaw, Poland
2. Warsaw University of Technology, Institute of Metrology and Biomedical Engineering, Warsaw, Poland

Fe-based amorphous alloys are used in many technical applications, like cores of the inductive components for electronics and sensors of mechanical stresses. For this applications it is important to study the influence of mechanical stress on the magnetic properties of Fe-based amorphous alloys (so called Villari effect).
Rayleigh region is referring to the first part of initial magnetization curve. It is the region of low magnetizing fields, where initial magnetization curve and hysteresis loop are described by second order equation with two coefficients: initial magnetic permeability and Rayleigh coefficient. Investigation of magnetic and magnetoelastic properties of amorphous alloys in Rayleigh region is important because most of inductive components is working under low magnetizing fields. For the investigation, Fe-based as quenched amorphous alloy 2605 S3A of chemical composition $Fe_{77}Cr_2B_{16}Si_5$ was chosen. The special measurement setup was developed using hydraulic press to apply compressive stress to the material.
Obtained results indicates that compressive stress has significant influence on the magnetic properties of investigated amorphous alloy. On the basis of obtained Bm(Hm) characteristics, the dependence of initial magnetic permeability and Rayleigh coefficient on the compressive stress was designated. This dependence was modeled with polynomial equations. Developed model allow to calculate values of initial magnetic permeability and Rayleigh coefficient and simulate the shape of Rayleigh hysteresis loop depending on the compressive stresses acting on the material. Obtained modelling results show high compatibility with measurement data which indicates that developed model can be used to simulate influence of compressive stress on the magnetic properties of Fe-based amorphous alloys in Rayleigh region.

TU.H-P105 - Transformaton of the magnetic nature of Li -Fe spinels due to substitution with Ba and Ti ions

P. Bhatia [1]

1. Gurunanak College of Arts , Science And Commerce, Mumbai, India

Spinel ferrites have been established as magnetic materials which occupy smaller volume, have low production cost and are easier to manufacture using ceramic technology. The ability of the spinel to distribute cations in the octahedral and tetrahedral sites in different manners, gives rise to varied physical and chemical properties. In the present work it is thought interesting to investigate the role of Li+, Ba^{2+}, Fe^{3+}, and Ti^{4+} in a spinel by reducing a pseudobrookite to a spinel using the formula (Li x Fe2-x) (Bay Ti1-y)O4 where x+y=1, with a view to combine different properties which these cations impart in different environment. $Li_{0.9}Fe_{1.1}Ba_{0.1}Ti_{0.9}O_4$ (SP1) and Li0.7Fe1.3 Ba0.3Ti0.7O4 (SP2) are formed and their structural and magnetic behaviour are reported here. X-Ray Diffraction patterns indicate the single phase spinel formation belonging to $LiFe_5O_8$ group . However, SP1 is cubic and SP2 exhibits tetragonal symmetry. Ba^{2+} prefers the tetrahedral sites. Interionic distances, radii of tetrahedral and octahedral interstices are determined. Their magnetic hysteresis loops are studied and the corresponding parameters related to magnetic nature of the two spinels are reported . The sharp, narrow hysteresis loops are typical of soft ferrites.
The larger saturation magnetization Ms, Coercive force Hc and magnetic moment of SP2 are in accordance with the cation distribution and larger quantity of Fe. The Fe content has increased substantially on the B site, strengthening the exchange interaction which perhaps is responsible for the absence of canting in SP2. On the other hand, Ti-rich spinel SP1 shows presence of canting as well as multi domains. Curie temperature is observed to be lowered with substitution and approaches the room temperature hinting at applications as a switch.

TU.H-P106 - Shape dependent spin switching and surface state in millimeter-sized single crystals of $R_2Fe_{14}B$ (R=Nd and Tb)

R. Sakaguchi[1], R. Saito[1], D. Ogawa[1], Y. Mizuno[1], K. Koike[1], Y. Ando[2], H. Kato[1]
1. Graduate school of Science and Engineering, Yamagata University, Japan
2. Graduate school of Engineering, Tohoku University, Japan

In view of the rapidly-growing demand for high-performance motors, the most crucial and urgent problem in sintered Nd-Fe-B magnets is to achieve much higher coercivity without heavy rare-earth elements. What we should remember is that the magnetic anisotropy of $Nd_2Fe_{14}B$ is large enough to exhibit higher coercivity without adding Dy.
We have grown $Nd_2Fe_{14}B$ films with different values of lateral grain size d. The coercivity showed monotonous increase with decreasing d from 7 kOe (d=300 nm) to 16 kOe (70 nm). When we deposited the 60-nm-thick Nd overlayer on these films and annealed at 500 degree C, the coercivity was enhanced with the increment of about 10 kOe irrespective of the d value [1]. These results thus suggest the independence of the size and the interface effects in a spin-switching process in the $Nd_2Fe_{14}B$ system.
If this conjecture is correct, then even bulk-sized single crystals would exhibit finite coercivity by an appropriate interface control. In this work, we prepared millimeter-sized single crystals of $Nd_2Fe_{14}B$ and $Tb_2Fe_{14}B$, and investigated systematically the spin-switching properties by using SQUID and MOKE techniques.
We shaped the crystals into the two kinds of rectangular plates with the tetragonal (001) or (100) plane as a largest surface, without any protective coating. The SQUID measurements on the Nd2Fe14B crystals showed that coercivity is negligibly small for both (001)- and (100)-cut plates. On the other hand, MOKE observation for the (100)-cut plate exhibited the finite “local coercivity” of about 1 kOe. In the case of $Tb_2Fe_{14}B$, even the SQUID measurement on the (100)-cut plate revealed the large coercivity of 5.2 kOe in striking contrast to the negligibly small coercivity of the (001)-cut plate. These results suggest a shape-dependent correlation between the crystallographic orientation of the 2-14-1 surface and the spin-switching process.

TU.H-P107 - Nanoanalytical TEM studies and micromagnetic modelling of (Nd,Pr)-Fe-B magnets

G. Zickler [1], P. Toson [1], A. Asali [1], J. Fidler [1]

1. Institute of Solid State Physiscs, Vienna University of Technology, Vienna, Austria

The search for candidates of suitable magnetic materials and their expected behaviour as reduction of the dysprosium/terbium content is of great economic and scientific interest. On the basis of numerical finite element micromagnetics (FEM) we have analysed the influence of the microstructural features, such as intergranular grain boundary phases (GB) and misalignment of the hard magnetic grain, on the optimization of magnetization reversal processes in order to improve the coercive field of (Nd,Pr)-Fe-B magnets. The microstructural model of the grains and intergranular phases, which is used for theoretical simulations, has been derived from a detailed nanoanalytical TEM/STEM study of Dy/Tb free magnets with different rare earth (RE) content and coercive field. Different types of grain boundaries are distinguished, such as the ones which are responsible for the nucleation processes of reversed domains and the ones acting as hindrance for reversed domain expansion. Special attention is laid on the EDX and EELS analysis of GB with a thickness ranging from 2 - 5 nm. This analysis identified the GB to have about 40 at.% of Iron and 50 at.% of RE, which is in good agreement with resent three dimensional atom probe experiments [1]. FEM simulations have been carried out in order to study the influence of internal demagnetizing fields determined by the microstructure on the magnetization switching behaviour. Special emphasis was put on the influence of the GB and their magnetic properties, due to their substantial influence on the nucleation of reverse magnetic domains and the pinning of domain walls. GB with soft ferromagnetic properties have the most effective influence on the decrease of the coercive field.

TU.H-P108 - Comparison of potential approximations in electronic structure calculations of magnetic anisotropy energy of $PrCo_5$ and $Pr_2Fe_{14}B$

A. Asali [1], P. Toson [1], G. Zickler [1], J. Fidler [1]

1. Institute for Solid State Physics, Vienna University of Technology, Austria

We report on DFT calculations of the $PrCo_5$ and $Pr_2Fe_{14}B$ compounds at 0K. The goal is to compare the dependence of results on the utilized potential approximation, GGA or LDA. The electronic structure is simulated using WIEN2k [1], a full-potential, linearized augmented plane wave code. Core electrons are treated relativistically and the self-consistence force calculation already includes the scalar relativistic effects. After the SR-SCF, the spin orbit coupling (SOC) is calculated. The magnetic anisotropy energy is calculated as the difference in energy values for easy and hard axis.
In general we note that GGA calculations are more stable (lower total energy) than LDA. All moments are in μ_B.

PrCo5	Pr_spin	Pr_orbital	Pr_total	Co(3g)
GGA:	-2.05	1.11	-0.94	1.73
LDA:	-2.00	1.44	-0.56	1.63
Literature:			3.2 [2]	1.7 [2]
PrCo5	Co(2c)	Co_all	PrCo5_tot	MAE [MJ/m³]
GGA:	1.75	8.67	6.96	8.74
LDA:	1.69	8.26	7.12	-4.25
Literature:	1.7 [2]	8.5 [2]	11.7 [2]	7.6 [3] (Room Temp.)

Pr2Fe14B	Pr_spin	Pr_orbital	Pr_total	Fe_spin_mean
GGA:	-2.23	1.11	-1.12	2.39
LDA:	-2.03	1.55	-0.48	2.27
Literature:			0.8 [4]	2.2 [4]
PrFe14B	Fe_total_mean		Pr2Fe14B_total	MAE
GGA	2.43		29.74	0.46
LDA	2.31		30.27	5.94
Literature			32.3 [4]	4.0 [5]

We conclude that GGA calculations are more precise for the $PrCo_5$ system. For $Pr_2Fe_{14}B$ systems our preliminary results show a better agreement for LDA with the experimental value.

The financial support of the EC-FP7 project ROMEO (309729) is acknowledged. The computational results have been achieved using the Vienna Scientific Cluster.

TU.H-P109 - First principles study for the effect of spin fluctuation on the crystalline magnetic anisotropy in L10-type ordered alloys

N. Kobayashi [1], K. Hyodo [1], A. Sakuma [1]

1. Department of Applied Physics, Tohoku University, Japan

For the application of high-density magnetic devices, thermal stability of magnetization in materials is one of the key factors. In almost hard-magnetic materials below Currie temperature, the thermal effect on magnetization is emerged as the fluctuation of its direction.
In this study, we investigated the influence of the spin fluctuation at finite temperature on the uniaxial magnetic anisotropy constant (K_u) on $L1_0$-type ordered alloys, such as FePt and CoPt. For the calculation, we employed the tight-binding linear muffin-tin orbital (TB-LMTO) method within the local spin density functional theory. The spin fluctuation was considered based on the disordered local moment picture (DLM), and the spin disorder was expressed through the random substitution ratio "x" in $(Fe\uparrow)_{1-x}(Fe\downarrow)_x Pt$, where the Fe $\uparrow$ and Fe $\downarrow$ respectively means the Fe atom having magnetic moment pointing to upward and downward. The disordered magnetization was taken into account by using coherent potential approximation (CPA).
The result showed that K_u decreased monotonically with the substitution ratio x as well as the total magnetic moment $\langle M \rangle$. From this data, we analyzed the relationship between K_u and $\langle M \rangle$, and found that K_u is proportional to n-th power of $\langle M \rangle$ ($n \fallingdotseq 2$) in both FePt and CoPt. This trend is similar to the experiment [1] and the previous first-principles calculation [2] using the functional integral method for the finite temperature magnetism. We conclude that the behavior of K_u of these alloys at finite temperature is well explained by a simple assumption of the Ising type fluctuation for the thermal excitation.

TU.H-P110 - Ab-initio study on the hard magnetic properties of MnBi

P. Toson [1], A.Asali [1], G.r Zickler [1], J.Fidler [1]

1. Institue of Solid State Physics, Vienna University of Technology, Vienna, Austria

The low-temperature phase (LTP, space group 194) of MnBi has interesting properties suitable for permanent magnetic applications [1]. At low temperatures its spin configuration is in-plane but at T = 80K a spin reorientation takes place and the magnetocrystalline anisotropy energy (MAE) increases with increasing temperature up to 2.1kJ/m³ at T = 500K. At T = 593K a first-order phase transition occurs reducing the c/a ratio [2]. These properties motivate a systematic study of the magnetic properties of MnBi in dependence on the change of lattice parameters with temperature.
Ab-initio calculations have been performed with the full-potential augmented plane wave code Wien2k [3] (V_{xc}: GGA, 10000 k-points). After a convergence of the scalar-relativistic calculation has been achieved (criterion: 10^{-9} Ry), the relativistic orbital contraction of the Bi s-states and the spin orbit coupling for two magnetisation directions have been introduced to determine the MAE. Orbital moments have been calculated afterwards with the density matrix.
The calculated magnetic moments μ_{Mn} = 3.88μ_B ($\mu_{Mn,spin}$= 3.79μ_B, $\mu_{Mn,orb}$ = 0.09μ_B) are higher than previously calculated moments (3.39-3.69μ_B) but are in good agreement with experimental results (3.82-4.25μ_B). Bi moments are aligned antiparallel to the Mn moments with μ_{Bi} = -0.12μ_B. The MAE at low temperature is overestimated (calculated: -3.1 MJ/m³, experimental: -0.2MJ/m³) but consistent with other DFT calculations [4]. The high temperature MAE of 2.14MJ/m³ is in good agreement with experimental results (2.1MJ/m³). Increasing the unit cell volume by 1.7% (with constant c/a ratio 1.43) causes an increase of MAE by 13.4% and a decrease of saturation polarisation by -0.8%. Increasing the c/a ratio by 4.4% causes a decrease in MAE by 21%.

TU.H-P111 - Directly obtained τ phase MnAl for permanent magnets

H. Fang[1], S. Kontos[2], J. Cedervall[1], P. Svedlindh[2], K. Gunnarsson [2], M. Sahlberg[1]

1. Uppsala University, Department of Chemistry – Ångström Laboratory, Uppsala, Sweden
2. Uppsala University, Engineering Sciences, Box 534, SE-75121 Uppsala, Sweden

Tetragonal MnAl based materials (τ phase) are promising candidates to become a high performance permanent magnets. These materials might partly replace the conventional hard ferrites, Alnicos and bonded Nd-Fe-B magnets due to low cost and large availability of Mn and Al. A major challenge of the low temperature formed ferromagnetic τ-phase MnAl is its low stability. Carbon doping has proved to be an effective way to stabilize the ferromagnetic τ phase and significantly increase the magnetization of the material.
$Mn_{54}Al_{46}$ and $(Mn_{0.55}Al_{0.45})_{100}C_2$ alloys were synthesized through high temperature synthesis process. Both the $Mn_{54}Al_{46}$ and $(Mn_{0.55}Al_{0.45})_{100}C_2$ alloys directly formed the τ phase, thus bypassing the intermediate ε-phase. The XRD phase analysis shows that carbon doping dramatically promoted the formation and stability of τ phase in the $(Mn_{0.55}Al_{0.45})_{100}C_2$ alloy. The 9T VSM characterization is in agreement with the XRD phase analysis, with M_{sat}=0.56MA/m (108emu/g), H_c=0.045MA/m, K=1.3MJ/m^3, $BH_{(max)}$ = 50 kJ/m^3.
In order to increase the coercivity, samples were milled from 2 to 14 hours to decrease grain size. The milled samples were subsequently relaxed at 500℃ for 1 hour. Phase analysis revealed that the milled samples were almost pure τ-phase, and that grain size decreased with increased milling time.

TU.H-P112 - Annealing effect on magnetic properties of hot-deformed Nd-Fe-B magnets

J. Lee [1], H. Cha [1,2], L. Shu [1,2], J. Yu [1], H. Kwon [3]

1. Powder&Ceramics Division, Korea Institute of Materials Science, Changwon, Republic of Korea
2. School of Materials Science and Engineering, Pusan National University, Geumjeong-gu, Busan, Republic of Korea
3. Department of Materials Science and Engineering, Pukyong National University, Busan, Republic of Korea

Recently, there is emerging concern regarding the development of highly coercive Nd-Fe-B magnets without HRE elements due to their uneven distribution in the earth crust and low output, causing their prices to soar. To achieve high coercivity without HRE elements, it is now well know the control of microstructures such as grain size and grain boundary is of significant importance. Based upon these backgrounds, hot deformation has been employed to produce ultrafine-grained bulk Nd-Fe-B magnets. In this process, melt spun flakes are subjected to hot-pressing and subsequent die-upsetting process, which causes c-axis texture of $Nd_2Fe_{14}B$ grain parallel to the pressing direction and the mechanism of texture formation has been extensively studied. Plenty of work is also reported regarding the role of intergranular phases on the coercivity with or without GBDP. On the other hand, the annealing effect of hot-deformed Nd-Fe-B magnet has not been well understood. In this study, we investigated the annealing effect on microstructure and magnetic properties of hot-deformed Nd-Fe-B magnets. The hot-deformed magnets were subjected to heat-treatment at various temperatures for 1h in vacuum (1st-PA) and then again annealed at constant temperature, 600℃ (2nd-PA). The coercivity was largely enhanced about 2.4 kOe by annealing at 600℃. However, the coercivity was decreased at temperatures other than 600 and 700℃. After 2nd-PA, the coercivity of magnets which 1st-PA treated at above 700℃ were also decreased despite the 2nd-PA temperature was low than melting point of Nd-rich phase. Low-temperature annealing could induce some defect or strain at interface between main phase and grain boundary phase due to difference of volume expansion at the below melting point of Nd-rich phase. In the case of high temperature, 800℃ could cause grain growth and change in Nd-rich phase, resulting coercivity drop.

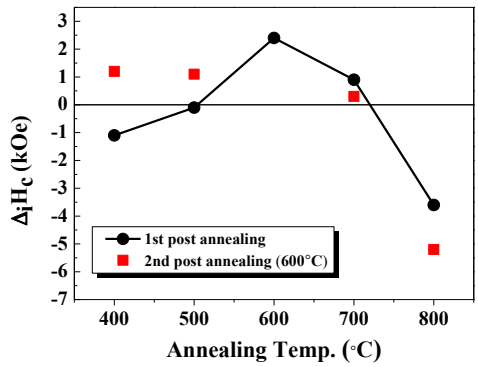

Fig. 1 Dependence of die-upset magnets' coercivities on various annealing temperatures

TU.H-P113 - High saturation magnetization of Fe-based amorphous / nanocrystalline ribbons

H. Yim [1]

1. Sookmyung Women's University, Seoul, Republic of Korea

A novel Fe-based soft magnetic alloys with $Fe_{67-x}Co_{20}Ti_7Zr_6B_x$ (x = 0, 2, 4, 6 %) were produced by melt-spinning technique and their thermal, mechanical and soft magnetic properties were investigated by differential scanning calorimetry, nano-indentation, and vibrating sample magnetometer, respectively. With boron addition into $Fe_{67-x}Co_{20}Ti_7Zr_6B_x$ system, thermal stability was increased. The ribbons exhibited fully amorphous phase except for the ribbon of B = 0 at. % in $Fe_{67-x}Co_{20}Ti_7Zr_6B_x$ system. The ribbon of $Fe_{67}Co_{20}Ti_7Zr_6$ with 0 at. % of B has α-Fe particle embedded in amorphous phase. This means that only minor addition of B, 2 at. % can cause a drastic change in microstructure from nano-crystalline to a fully amorphous phase in this system. Among the ribbons, the nano-crystalline alloy of $Fe_{67}Co_{20}Ti_7Zr_6$ exhibited exceptionally good soft magnetic properties such as a low coercivity of 0.308 Oe and a high saturated magnetization of 190 emu/g (1.81 T) with the as-spun condition. Also, the ribbon has only α-Fe particles embedded in amorphous phase. These results of Fe-based ferromagnetic alloy system indicate that the Fe-Co-Ti-Zr-B alloy system has promising properties that are applicable to the soft-magnetic materials industry.

TU.H-P114 - Magnetic anisotropy of $Nd_{0.5}Bi_{2.5}Fe_{5-y}Ga_yO_{12}$ (y = 0 ~ 1) thin films on glass substrates prepared by metal organic decomposition (MOD) method

G. Lou[1], M. Sasaki[1], T. Kato[2], Sat Iwata[2], T. Ishibashi[1]
1. Nagaoka University of Technology, Japan
2. Nagoya University, Japan

Recently, we have reported that $Nd_{0.5}Bi_{2.5}Fe_4GaO_{12}$ thin films on glass substrates were successfully prepared by metal-organic decomposition (MOD) method, exhibiting a large magneto-optical effect and perpendicular magnetic anisotropy [1]. In this paper, we report the magnetic anisotropy of the Nd iron garnets with various Ga substitutions.
$Nd_{0.5}Bi_{2.5}Fe_{5-y}Ga_yO_{12}$ (y = 0, 0.25, 0.5, 0.75, 1) thin films with a thickness of 200 nm were prepared on the 120 nm-thick $Nd_2BiFe_4GaO_{12}$ buffer layers on glass substrates (Eagle XG, Corning) by MOD method. MOD solutions were spin coated on glass substrates at 3000 rpm for 60 seconds, dried at 100 degrees Celsius for 10 minutes and pre-annealed at 450 degrees Celsius for 10 minutes. The thin films were then annealed for crystallization in a furnace at 700 degrees Celsius for 3 hours.
We have measured the Faraday hysteresis of $Nd_{0.5}Bi_{2.5}Fe_{5-y}Ga_yO_{12}$ thin films at the peak of the Faraday spectrum. When the Ga content is 0, the hysteresis was rectangular, indicating in-plane magnetic anisotropy, with Faraday rotation angle of 3.4 degrees and the coercive force of 0.13 kOe. By increasing Ga content, perpendicular magnetic anisotropy was obtained, where Faraday rotation angles decreased to 2.3 degrees and coercive force inceased to 0.24 kOe for Ga content of 1. These results indicated that it is possible to control the magnetic anisotropy of $Nd_{0.5}Bi_{2.5}Fe_{5-y}Ga_yO_{12}$ thin films exhibiting the large Faraday effect. Anisotropy constant K_u of the films measured by torque measurements are also disucssed.

4. Australian Nuclear Science and Technology Organization, Australia

Physics inside permanent magnets is more complicated than most of the physicists think due to inhomogeneity and multiscale structures. The coercivity mechanism of hard magnets is a good example and it has been a center of attention recently in a pursuit of better hard magnets with high coercivity. On the other hand, the initial magnetization process has not been regarded as an important topic though it is also a physical phenomena where inhomogeneity and multiscale structures play crucial roles. In addition, experimental studies other than microscopic observations and magnetization measurements have been rarely reported so far. Small angle neutron scattering (SANS) is one of the most suitable method to observe the magnetization process and microstrutures inside bulk magnets. We have conducted SANS experiments on the initial magnetization process in nanocrystalline Nd-Fe-B magnets with different microstructures to investigate the relation between microstructure and initial magnetization. Samples are nanocrystalline Nd-Fe-B magnets with no infiltration, NdCu-, and PrCu-infiltration. Cu alloy is expected to separate Nd2Fe14B grains and break the exchange interaction between the grains. SANS experiments were carried out at QUOKKA, ANSTO, Australia. Two-dimensional SANS images of the samples in the thermally-demagnetized state at 0 T show anisotropic features reflecting samples' microstructures. One-dimensional plots along directions parallel and perpendicular to the easy axis show different power law indices, indicating changes in smoothness of grain boundaries by the infiltrations. During the initial magnetization process, SANS intensities along the direction perpendicular to the easy axis increase drastically in low Q range. This reflects the development of magnetic domains. Plateau-like structure in magnetic field dependence of SANS intensities for lower Q range is observed in Cu alloy infiltrated samples, which corresponds to an effect of grain separation.

TU.H-P116 - Alnico V thin films with improved saturation magnetization and coercivity

F.Mohseni [1], M. Pereira [1], N.Fortunato [1], J. S. Amaral [1], A. C. Lourenço [1], J. M. Vieira [2]

1. Department of Physics, University of Aveiro, 3810-193, Aveiro, Portugal
2. Department of Materials and Ceramic Engineering, University of Aveiro, Aveiro, Portugal

The recent rare-earth element price crisis has motivated intensive research to develop new, high-performance rare-earth free permanent magnets [1]. Alnico V magnets, containing Al, Ni, Co and Fe, are nanostructured hard ferromagnets, a result of spinodal decomposition during heat treatments, and present coercivity values typically below 650 Oe [2]. Because of their high working temperatures and material sustainability, an increase of energy product would make Alnico a worthy substitute of Nd-based magnets. Recently, Alnico V thin-films on Silicon were shown to present coercivity values up to ~ 10 kOe. The unusually high coercivity value happens as the result of Si ions diffusion from substrate to the thin film which leads to the formation of a novel Body Centered Tetragonal Fe-Co-Si phase [3, 4]. Nonetheless, the diffusion mechanism, chemical composition and saturation magnetization of this novel phase require further studies.
The present investigation explores the effects of deposition temperature and post heat treatments on the magnetic properties and morphology of RF-sputtered Alnico V thin films on Si substrates. Samples with different thicknesses, with and without capping layers were prepared at different deposition temperatures. Post-deposition heat treatments in different Argon pressures, followed by quenching and slow-cooling, were also performed. We show that controlling deposition temperature can result in an increase of up to 40% of saturation magnetization compared to room-temperature deposited samples. Raising Argon pressure during heat treatments causes a considerable increase in coercivity, up to 4 times the coercivity of bulk Alnico V magnets. Unlike previous reports on high-coercivity Alnico V thin films, where quenching was required to obtain the novel BCT Fe-Co-Si phase, our results show no such correlation, pointing to different mechanisms at work. We discuss the origin behind these effects, and potential mechanisms to combine the observed increase in saturation magnetization and coercivity, leading to higher performance materials.

TU.H-P117 - Mechanically induced superelastic effect in magnetic Fe-Ni-Co-Al-Ta-B rapidly quenched microwires

F. Borza [1], N. Lupu [1], I. Murgulescu [1], V.Dobrea [1], H. Chiriac [1]

1. National Institute of Research & Development For Technical Physics, Iasi, Romania

Interest continues to grow in the development of high-performance materials with multifunctional properties which are very important for the miniaturization and simplification of devices, especially in the medical field such as microsurgery. One such example is the superelastic FeNiCoAlTaB shape memory alloy which exhibits tensile superelastic strains higher than 13% at room temperature in a <100> textured $Fe_{40.95}Ni_{28}Co_{17}Al_{11.5}Ta_{2.5}B_{0.05}$ polycrystal which reaches strengths of >1 GPa [1]. In the attempt to reduce the steps involved in the thermo-mechanical processing of this materials we have used a cost effective technique, rapid quenching from the melt for the fabrication of these magnetic superelastic materials as wire-shaped materials.
$Fe_{40.95}Ni_{28}Co_{17}Al_{11.5}Ta_{2.5}B_{0.05}$ wires with the diameter of 280 micrometers have been prepared by in rotating water spinning technique followed by successive cold-drawing down to 40 micrometers with the aim to achieve a higher than 97% reduction in the diameter of the wire when the superelastic effect occurs. From the magnetic point of view, cold-drawing Fe-Ni-Co-Al-Ta-B wires lead to the deterioration of soft magnetic properties at low fields (the magnetization and relative permeability decreases while the coercive field increases) but an important increase in the saturation magnetization from 0.6T to 1T has been observed in higher fields (maximum applied field of 30 kA/m). However, the most significant result is the induction of the superelastic effect of about 1% directly by cold-drawing, without intermediary thermomechanical treatments. The combination of relatively good magnetic and superelastic properties makes these materials potential candidates for applications in microsurgery as catheters. They can also replace the currently employed NiTi alloys in applications where radiotransparency is needed.

TU.H-P118 - Spin reorientation temperature of ultrafine $Nd_2Fe_{14}B$ particles: influence of exchange-coupling

S.K. Pal [1,2], K.Müller [2], L. Schultz [2], O. Gutfleisch [1]

1. TU Darmstadt, Materialwissenschaft, Darmstadt, Germany
2. IFW Dresden, Institute for Metallic Materials, Dresden, Germany

High magnetocrystalline anisotropy materials such as $SmCo_5$ and $Nd_2Fe_{14}B$, are the most important materials for application in high-energy-density permanent magnets. The $Nd_2Fe_{14}B$ compound is of significant importance for its high-energy-density value which originates from the unique combination of Nd, Fe and B atoms providing high anisotropy, magnetization and stability of crystal structure, respectively. It is of fundamental interest to study the influence of size of fine-grained particles on the intrinsic properties of $Nd_2Fe_{14}B$ compound. Spin reorientation temperature (SRT), an intrinsic property, is a temperature-induced magnetic phase transition. Here, we report on the influence of exchange-coupling on the SRT value of ultrafine $Nd_2Fe_{14}B$ particles. The ultrafine $Nd_2Fe_{14}B$ particles of size ranging from 2 µm (consisting of hundreds of grains) to 300 nm (single-crystalline particles) were prepared by surfactant-assisted ball milling of hydrogenation disproportionation desorption and recombination (HDDR) processed $Nd_2Fe_{14}B$ powder. The SRT values for ultrafine $Nd_2Fe_{14}B$ particles of different sizes have been determined. The STR value was found to increase from 129 K for HDDR powder (consisting of single-domain grains of average size 300 nm) to 134 K for ~2 µm particles consisting of hundreds of grains. The SRT value was increased further to 136 K for isolated single-crystalline particles (~300 nm size). A transformation of single-crystalline particles to polycrystalline flakes (with ~12 nm grain size) after intense ball milling results in decrease of SRT to a value of 128 K. The increase in the SRT value with decreasing particle size is thought to be due to the decrease in the extent of magnetic exchange-coupling. The decrease of the SRT value for polycrystalline nanoflakes can be attribute to the increased magnetic exchange-coupling between nanometer-sized grains in the flakes. These findings need to be considered when fabricating nanocrystalline or nanocomposite $Nd_2Fe_{14}B$ magnets for low temperature application.

TU.H-P119 - Preparation of Co-based amorphous powders by wet mechanical alloying. The influence of Si and/or B substitution by Ti and/or Zr over their properties

B.V. Neamtu [1], H.F. Chicinas [1], T.F. Marinca [1], O. Isnard [2,3], I. Chicinas [1]

3. Centre National de la Recherche Scientifique, Institut Néel, Grenoble, France

Co-based amorphous powders were synthesized by wet mechanical alloying starting from elemental powder of Co, Fe, Ni, Si, B, Ti, Zr. The magnetic properties and thermal stability of the $Co_{70}Fe_4Ni_2Si_{15}B_9$ at%. master alloy obtained by wet mechanical alloying were compared with the characteristics of the newly formed alloys in which the Si and/or B were substituted by Zr and/or Ti. The purpose of the above mentioned substitution experiments is mainly to increase the thermal stability of the amorphous phase, which will further allow higher sintering temperature. Early results reveal that regardless of the substitution type, the powders amorphisation occurs at the same milling duration (25 hours). The thermomagnetic measurements show that the Curie temperature of the amorphous phase increases with more than 50%. It was proved that substitution of 5 at.% of Si with Ti or Zr are leading to an increase of the saturation magnetization of the powder with about 49%. The values of the alloys saturation magnetization can be explained by a more dense random packed structure, leading thus to a stronger interaction of the magnetic atoms. Differential scanning calorimetry analysis evidenced that the substitution of Si with either Ti or Zr increases the crystallization temperature of the master alloy with over 100 °C. The as obtained powders can be further subjected to spark plasma sintering and due to their higher crystallization temperature, high density amorphous compacts can be obtained, for several applications, such as soft magnetic cores.

TU.H-P120 - Structural and magnetic characteristics of nanocrystalline iron-magnetite composite powder obtained by mechanosynthesis

T. Marinca [1], B. Neamtu [1], I.Chicinas [1], O. Isnard [2,3], H. Chicinas [1]

1. Materials Science and Engineering Department, Technical University of Cluj-Napoca, Cluj-Napoca, Romania
2. Universite de Grenoble Alpes, Institut Néel, Grenoble, France
3. Centre National de la Recherche Scientifique, Institut Néel, Grenoble, France

The formation of iron-magnetite (Fe_3O_4) composite powder by mechanosynthesis and its structural and magnetic characteristics have been studied. The purpose for obtaining such type of composite is to enhance the magnetic characteristics of the magnetite. Iron-magnetite composite powder was synthesized using iron and hematite (Fe_2O_3) powder. The powder have been investigated by X-ray diffraction, differential scanning calorimetry, particle size analysis and magnetisation measurements. The Fe_3O_4 is progressively formed upon increasing milling time by the reaction of hematite with iron. After 600 minutes of milling the powder consists mainly in iron and magnetite phases. The magnetite and iron phases have the mean crystallite size after 600 minutes of milling of 8 and 19 nm respectively. The Fe_3O_4/Fe composite powder is stable up to 540 ^oC independent on milling time, after this temperature a w³stite phase is formed. The powder magnetisation is diminished in the first period of mechanical milling during the formation of Fe/Fe_2O_3 composite particles. The next stage of milling leads to the formation of Fe_3O_4 phase and consequent the magnetisation of the powder significantly increases. Upon increasing the milling time from 120 up to 600 minutes a continuous increase of the powder magnetisation is noticed as a result of the progressive formation of Fe_3O_4. The magnetisation of the milled composite Fe_3O_4/Fe material is lower as compared to the theoretical one. This is due to the presence of some Fe_2O_3 residual phase and also to the surface defects. The annealing lead to the elimination of the residual phase and remove stresses induced by milling. An enhancement of the magnetic characteristics of the nanocrystalline composite powder was noticed after annealing.

TU.H-P121 - Temperature dependence of coercivity in $(Mn_{1-x}Ti_x)_{50}Bi_{50}$ alloys

C. Curcio[1], E.S. Olivetti[1], L. Martino[1], M. Kuepferling[1], V. Basso[1]

1. INRiM, Istituto Nazionale Di Ricerca Metrologica, Torino, Italy

nBi compound has a high uniaxial magnetocrystalline anisotropy which has the peculiar feature to increase with temperature up to 500 K where K_u = 2.2 MJ/m^3. This makes the compound an interesting candidate as a rare-earth-free hard magnet, especially for high temperature applications. Several strategies were developed to optimize the coercivity by refining grain size without appreciable reduction of phase fraction and magnetization. Cryomilling and surfactant addition have been shown to be effective, but the production process becomes rather complex. Partial substitutions of Mn with different transition metals or rare-earth elements may increase the coercivity, at the expense of the saturation magnetization. Here we investigate the magnetic properties of $(Mn_{1-x}Ti_x)_{50}Bi_{50}$ polycrystalline alloys in which Mn is partially substituted by Ti. Samples were obtained by a preparation route that does not require melting of a master alloy: powders of Bi and $Mn_{1-x}Ti_x$ were mixed, compacted in pellets and annealed for 1 hour in an applied magnetic field of 1 T in order to promote the phase formation and the growth of aligned grains. We find that Ti is effective in increasing the coercivity without significant loss in magnetization, suggesting a role of Ti atoms in enhancing a fine microstructure. In order to understand the mechanism of the magnetization reversal of $(Mn_{1-x}Ti_x)_{50}Bi_{50}$ we study the temperature dependence of coercivity in the range 300-630 K. Through Kronmuller plot we estimate the α_K and Neff parameters, which take into account the effect of microstructure. The temperature dependence of coercivity for x=0 shows a regime for T< 350 K with α_K=0.12 and a regime for T> 350 K with α_K=0.34. For x=0.02 a single regime with α_K=0.43 is observed, which can be associated to a nucleation mechanism responsible for the increase of coercivity with respect to the x=0 case.

TU.H-P122 - Soft magnetic composite Fe_3O_4/Ni_3Fe obtained by mechanosynthesis and annealing, structural and magnetic characteristics

H. Chicinas [1], T. Marinca [1], B. Neamtu [1], I. Chicinas [1], O. Isnard [2,3]

1. Technical University of Cluj-Napoca, Materials Science and Engineering Department, Cluj-Napoca, Romania
2. Universite de Grenoble Alpes, Institut Néel, Grenoble, France
3. Centre National de la Recherche Scientifique, Institut Néel, Grenoble, France

Soft magnetic Fe_3O_4/Ni_3Fe composite powder was obtained by mechanosynthesis and subsequent annealing, starting from Fe, Ni and Fe_2O_3 precursors. The aim is to produce a magnetic material that has soft magnetic characteristics as Ni-Fe alloy but with a higher electrical resistivity. The X-ray diffraction patterns of the milled samples, revealed the incipient formation of Fe_3O_4 for the sample milled for 3 hours. At 10 hours of milling, the formation of Ni_3Fe and Fe_3O_4 hasn't occurred completely, as a consequence a presence of a small amount of unreacted Fe_2O_3 can be found. After annealing the Fe_3O_4/ Ni_3Fe composite is fully formed. DSC measurements revealed a decrease of the temperature required for the Fe_3O_4 formation upon increasing milling time, which reveals the fact that the amount of energy required for the formation of Fe_3O_4 can be attained by mechanical milling, heat treatment, or a combined method. The first magnetization curves reveal a two stage evolution for the milled samples. In the first stage, for milling times up to 4 hours, when the Fe_3O_4 particles are starting to form, the value of magnetization has a decrease tendency. For longer milling times, due to the progressive Fe_3O_4 and Ni_3Fe formation, the value of magnetization increases. The magnetization is diminished due to a presence of residual Fe_2O_3 phase, which has also been identified on the XRD pattern, yet for the sample milled 10 hours the magnetization has the highest value, due to complete formation of Ni_3Fe and its contribution.

TU.H-P124 - The influence of severe plastic deformation on magnetic properties of some 3-d based alloys perspective for rare-earth free permanent magnets

S.Taskaev [1], K. Skokov [2], V. Khovaylo [3,4], D.Gunderov [5], D. Karpenkov [2], O. Gutfleisch [2]

After the development of Sm-Co and especially Nd-Fe-B magnets, these magnetic materials are essential components in many fields of technology, because of their ability to provide a strong magnetic flux. Nevertheless the crises of rare-earths during last few years open the discussion about rare-earths free permanent magnets [1].
The important properties of a permanent magnet include its coercivity, remanence and energy product [2]. There are essentially two means of achieving the large values of these properties necessary for today's applications. First, the microstructure of a material can be optimized (in our case with the help of high pressure torsion) to prevent the rotation of ferromagnetic domains. The second factor is the intrinsic spin-orbit coupling of electrons that forces spins to align with a particular crystallographic orientation, giving rise to the magnetocrystalline anisotropy energy of a material. Because the strength of spin-orbit coupling increases as the fourth power of an element's atomic number, maximizing the magnetocrystalline anisotropy energy is accomplished by utilizing heavier elements. Based on that, the aim of this work is to investigate the influence of high pressure torsion (HPT) on magnetic properties of some 3-d based intermetallic compounds, e.g. $Ni_{48}Fe_{48}Zr_4$, $Fe_{1.5}Co_{0.5}BTa_{0.3}$ and $Co_{80}Zr_{16}B_4$ alloys. HPT (Bridgemen's anvils) was performed under 5GPa pressure with 5 complete turns. Such high plastic deformation dramatically affect on microstructure of the samples reducing the grain size up to nanometer scale. It is shown that HPT and proper heat treatment affect to the magnetic properties of prepared compounds by a different ways. The found value of Hc=2.25 kOe on $Co_{80}Zr_{16}B_4$ HPT alloy is comparable with [3], where this compound was prepared by melt spun ribbon technique.

TU.H-P125 - Joint and separate effect of d/D and d on the magnetic properties of glass-coated amorphous ferromagnetic microwires

I.Machay [1], K. Chichay [1], A. Litvinova [1], I. Iglesias [1], N. Perov [2], V. Rodionova [1]

2. Faculty of physics, Lomonosov MSU, Moscow, Russian Federation

Amorphous ferromagnetic glass-coated microwires are interesting materials because of their unusual micromagnetic structure and magnetic properties determined by the value and the distribution of the internal stresses and the magnetostriction coefficient of the metallic core simultaneously. The main stresses arise due to the difference between the thermal expansion coefficients of the metal and the glass. The value of these stresses depends on the ratio of the metal core diameter, d, and the total diameter of the glass-coated microwire, D. Also d has a strong influence on the magnetic properties of the microwires. Usually only the influence of d or d/D is considered. For the first time in this work we examined the magnetic properties depending on the microwire sizes not as a single-variable function of d or d/D but as a function of two variables -of d and d/D. Investigated microwires (d ~ 2.5-20 μm and d/D ~ 0.1 -0.8) were made from Fe-based alloy and have magnetic bistability. We investigated the magnetostatic properties of the microwires of different lengths using VSM. The length of microwires changed from 2 to 0.05 cm. The measurements of the magnetostriction coefficient were measured by small angle magnetization rotation method. We found that magnetostatic and magnetostrictive properties are changing under the influence of both d and d/D. We established that the influence of d/D on the magnetic properties is varied at different d and magnetic parameters (magnetostriction coefficient, coercivit) have non-monotonic dependence on d/D and d. The measured value of the magnetostriction coefficient was found to be 7*10-6 - 1*10-6 when d changes by a few μm . In addition, we demonstrated the strong joint influence of d/D and d on the critical length of the bistability. The smallest length was found to be 0.2 cm for the microwires with largest d/D and smallest d.

TU.H-P126 - High frequency properties of ferrite - Fe-Si-Al alloy soft magnetic composites

B. Stergiou [1], V.Zaspalis [1]

1. Laboratory of Inorganic Materials, Centre for Research and Technology – Hellas, Greece

The need for shielding facilities and equipment against the increasingly high frequency electromagnetic waves has driven the extensive research on materials with the proper electromagnetic performance. In this direction, tailoring the properties of polymer composites with dielectric or magnetic fillers predominate in the respective studies and applications. The different approach of the present investigation lies in the synergy of ferrimagnetic ceramic and metallic materials, by the incorporation of Fe-based alloy particles in a ferrite matrix, in order to form rigid soft magnetic composites as efficient electromagnetic absorbers.
Specifically, Cu-substituted NiZn spinel ferrite powder was prepared with the conventional solid-state reactions technique and mixed with commercial Fe-Si-Al alloy powder (sendust) up to the content of 20% (v/v). For the mechanical reinforcement of the composites, they were doped with a glass compound, compacted in disc shape and finally annealed at the temperature from 600°C to 900°C.
The main objectives were to optimize the production process of the specific ceramic-alloy composites and study the effect of sendust addition on the composites' electromagnetic properties. Therefore, the employed starting powders were characterized as to their density, particle size and crystal structure. Moreover, the impact of the processing variables on the alloy structure and the microstructure of the composites was recorded by means of X-ray diffraction method, thermogravimetric analysis and scanning electron microscopy. Finally, the electromagnetic constitutive parameters of ring-shaped samples were measured in the frequency range 1MHz-6GHz and the respective return losses were calculated. The experimental findings indicate the cohesion between the ferrite and alloy compounds and the feasibility of preparing relatively dense composites at low temperature. Furthermore, despite the decrease of the magnetic properties with the addition of the alloy particles, the resultant shift of the permeability spectrum to higher frequencies highlights the potential use of such novel composites as electromagnetic wave absorbers.

TU.H-P128 - Electronic theory for the magnetic properties of $Nd_2Fe_{14}B$ compounds

In view the energy-saving and renewable technology, theoretical understanding of the coercivity mechanisms of Nd-Fe-B is urgently needed. It has been widely accepted that the large magnetic anisotropic energy due to the Nd ions is the dominant factor of the coercivity of Nd-Fe-B magnets. For deeper understanding of the mechanism, it is necessary to study the magnetic anisotropy due to the Nd ions from the viewpoint of crystal field theory. Several recent experimental studies have revealed that local atomic structures around the grain boundaries of sintered Nd-Fe-B magnets significantly affect their coercivity [1]. Theoretically, we have found that the crystal field parameters (CFP) A_2^0 of Nd ions can be negative, implying the local in-plane anisotropy, if they are exposed on the (001) surface of the crystalline $Nd_2Fe_{14}B$ [2]. We have also reported that such surface anisotropy anomaly may cause coercivity reduction of a single Nd2Fe14B particle by half of the anisotropy field H_K, based on a simple micromagnetic-type simulation [3].
In this talk, first we show the physical origin of the anomalous surface anisotropy by using newly developed CFP calculation technique, the so-called Wannierization method [4]. We find that the 4f clouds in $Nd_2Fe_{14}B$ system are usually lie within the *c*-plane, but extend along the *c*-axis direction in the surface Nd ions. We also show the results of higher-order CFPs based on the Wannierization method, and discuss the spin-reorientation phenomena and coercivity of a single $Nd_2Fe_{14}B$ particle.

TU.H-P129 - Influence of the continuousness and thickness of the shell of the magnetically bi-phase microwires on the core/shell magnetostatic coupling

I. Iglesias [1], K.Chichay [1], J. Jimenez [2], R. Pérez del Real [2], M. Vazquez [2], V. Rodionova[1]

2. Materials Science Institute of Madrid, CSIC, Madrid, Spain

Study of the multilayered magnetic systems is of great interest due to their high potential in the various applications ranging from magnetic recording media to multifunctional sensors. Magnetic behavior and peculiarities of the magnetization reversal of these systems have been studied by different methods. The magnetically bi-phase fully covered microwires have been studied since 2007. In 2014 a new type of the multilayered microwire was fabricated - partially covered bi-phase microwire. It consists of a ferromagnetic glass-coated microwire(core) and a ferromagnetic shell with magnetostriction constant of the opposite sign. The partially covered microwires are very promising for creation of the actuators. The first results of the investigation of the partially covered microwires demonstrated the dramatic difference between the magnetization reversal processes of the microwires with various continuousness. Particularly, the typical step-like behavior of the hysteresis loop for the fully covered microwires disappeared for the partially covered ones. The aim of this work was to analyze and compare magnetic behavior of partially and fully covered microwires and to establish the influence of the continuousness and thickness of the shell on the core/shell magnetostatic coupling. Partially and fully covered microwires were fabricated by combined quenching and drawing techniques and electroplating. The core and the shell were prepared from FeCo-,Fe-based and CoNi,FeNi materials, respectively. The cores have similar diameters. The shell has thicknesses ranging from hundreds of nanometers up to 5 micrometers. Magnetic measurements were carried out at room temperature by VSM. In both cases, the magnetostatic coupling of the magnetic phases results in appearance of the features on magnetization curves. The stray fields of the magnetic phases were estimated using the COMSOL for both types of microwires. The value and the distribution of these fields explain the mentioned difference. The increase in the shell thickness diminishes the difference between the magnetization processes.

TU.H-P130 - Structural and magnetic properties of substituted M-type barium hexagonal ferrite annealed at different temperatures

T. Ben Ghzaiel[1,2], W.Dhaoui[1], F. Mazaleyrat[2]

1. Université de Tunis El Manar Faculté des Sciences de Tunis, UR11ES18 Unité de Recherche de Chimie Minérale Appliquée, Tunis, Tunisie
2. SATIE, ENS Cachan, CNRS, Université Paris-Saclay, Cachan, France

With increasing cost of earth-rare metals, researches have focused on earth-rare free permanent magnets. M-type barium hexaferrites (BaM) are good candidates due to their high stability[1], large magnetocristalline anisotropy[2], high Curie temperature[3] and large magnetization[4]. In order to fulfil the properties required for this application, BaM ferrites with different substitutions were prepared to modify the structural and magnetic behaviour of M-type hexaferrite. The effect of ion substitution and annealing on the phase composition, Curie temperature and magnetic properties were investigated. In this work, $BaMeFe_{11}O_{19}$ where Me is trivalent transition metal ions (Al, Bi, Cr, Mn) were prepared by dynamic hydrothermal synthesis and then annealed at different temperatures from 900 to 1000°C for 2h. XRD results show partial formation of magnetoplumbite structure P63/mm, in the prepared samples for all substituted BaM ferrites.
The magnetic measurements of the powders with various substitutions revealed that the coercivity decreases while the magnetization increases with annealing temperature. High coercivity Hc= 4.8 KOe is observed for $BaBiFe_{11}O_{19}$. However, $BaCrFe_{11}O_{19}$ exhibited greater magnetization Ms=61.33 emu/g. Interestingly, $BaBiFe_{11}O_{19}$ curve shows two steps hysteresis loop at all annealing temperatures. This characteristic feature wasn't due to the presence of secondary phase which is attested XRD data. To understand the origin of this phenomenon, we have investigated the effect of applied temperature below 300 K on the magnetic properties. We observed that the magnetization increased with decreasing temperature from 300 to 100K but the two steps curves persisted. This phenomenon is attributed to a strong value of the fourth order anisotropy constant (k_2).

TU.H-P131 - A density functional theory study on the novel high coercivity BCT Fe-Co-Si phase

N. Fortunato [1], J. Gonçalves [1], J. S. Amaral [1,2]

1. Departamento de Física and CICECO, Universidade de Aveiro, Aveiro, Portugal
2. IFIMUP and IN-Institute of Nanoscience and Nanotechnology, Porto, Portugal

High-performance hard magnetic materials are now commonplace, with a world market dominated by rare-earth (RE) magnets. RE elements, particularly heavy REs are critical materials, mainly due to limited global deposits, low sustainability and expensive extration and processing. As such there is currently a considerable effort to develop new high-performance RE free hard magnetic materials[1].
Alnico is a permanent magnet material based on Fe, Ni, Co and Al, first discovered in the 1930's, where the coercivity arises from shape anisotropy. Alnico magnets typically show coercivities below 2kOe, and subsequently low energy products, around 10 MGOe, which compare poorly to the ~ 60 MGOe values of modern NdFeB-based alloys. Recently Hadjipanayis et al.[2] reported a high coercivity value of 6.5k Oe of Alnico thin films sputtered on silicon substrates. This was attributed to a high magnetocrystalline anisotropy of a new FexCoySiz body centered tetragonal (BCT) phase. While a Curie temperature value of ~305^{o}C and structural data of this novel BCT phase were reported, there is currently no prediction for its stoichiometry, nor total magnetic moment. We here report on a Density Functional Theory (DFT) study to present a tentative composition range for this high Coercivity BCT phase, taking into account the experimental lattice parameters, correlated with Tc estimations via a mean-field model approximation together with magnetic exchange interaction parameters obtained via the Liechtenstein method [3], and the use of the Coherent Potential Approximation, as implemented in the SPR-KKR package [4]. We discuss the predicted magnetic saturation values, as crucial performance parameters for applications. The phase stability for the studied composition ranges is taken into account, which can be an important factor when considering the external effects (strain/epitaxy) that have led to the formation of this novel phase.

Magnetic materials, which do not contain rare metals, have been extensively studied. Fe-Co alloy is one of the candidates with both high magnetic anisotropy and high saturation magnetization. The magnetocrystalline anisotropy of body centered tetragonal type Fe-Co alloys has been reported by first-principles calculation. [1] In addition, the largest anisotropy has been realized at the lattice parameters ratio c/a of about 1.25. [2] Structural analysis of Fe-Co alloys is important for understanding the relationship between magnetic properties and the structure. To determine the long-range order parameters of ordered Fe-Co alloys precisely, X-ray diffraction measurements obtaining the diffraction from the ordered-lattice layer are indispensable. However, the measured diffraction from the ordered phase is rather weak using a standard X-ray tube, because the contrast of X-ray scattering in Fe and Co is very small. For a quantitative investigation, the X-ray analysis with the photon energy tuned around the absorption edge of Fe or Co using the anomalous scattering is rather important. In this study, the structure of FeCo thin films is investigated using synchrotron radiation X-ray diffraction. The FeCo (t nm)/Ta (2 nm) (t = 5, 10, 20) thin films were deposited on MgO substrates by sputtering. X-ray diffraction measurement was performed at BL-8A/B, Photon Factory in KEK with the photon energy of 7.1 keV corresponding to the K absorption edge of Fe. Long-range order parameter S were determined from the intensity ratio of 0 0 1 diffraction spots, which was reflected from superlattice, and 0 0 2 diffraction spots, which was reflected from fundamental lattice. The order parameter S of all the FeCo thin films was about 0.6 and the order parameters are considered to be originated from the relaxed lattice strain at the interface between FeCo films and MgO substrates. Magnetic properties were also measured by VSM and X-ray magnetic circular dichroism and the relationship between the order parameter and magnetic properties were investigated. This work was partly supported by Japan Science and Technology Agency (JST).

This work deals with the study of the influence of longitudinal or transverse magnetic field annealing on the magnetic properties of rapidly solidified $Fe_{73.5}Cu_1Nb_3Si_{13.5}B_9$ bilayer ribbons prepared by a special planar flow casting method from a single crucible with two nozzles close to each other and with a partition between them. In order to prepare nanocrystalline bilayers with improved soft magnetic properties, pieces of parent amorphous bilayer ribbon ~45 µm thick were isothermally annealed in external magnetic field with intensity of 640kA/m applied in the longitudinal (LF) or transverse (TF) direction to the ribbon length. Reference samples were annealed in a zero magnetic field (ZF). The effect of thermal processing in external magnetic field was examined by hysteresis loop measurements. A heat treatment under longitudinal field resulted in reduction of the coercivity as compared to the ZF-annealing. The lowest coercivity value ~ 0.6 A/m was found for the sample annealed at temperature 823 K for 1 hour. Sheared hysteresis loops with good field linearity and low coercivity (Hc ~ 1.4 A/m) were achieved after TF-annealing. The magnetoimpedance (MI) measurements were performed over a frequency range 0.1 – 10 MHz. The dependence of the MI ratio on the applied dc-magnetic field for the LF-annealed sample exhibited single peak structure. On the other hand, GMI response for TF - annealed sample showed two distinct maxima at $\pm H_k$ ~ 230A/m. The maximum values of impedance ratio $(\Delta Z/Z)_{max}$ and the field sensitivity η_{max} were 140% and 24%/Oe, respectively. The MI changes in field annealed bilayers were found to be markedly higher as compared to their single-layer counterparts, which makes them promising candidates for magnetoimpedance sensors.

TU.H-P136 - Structure and the magnetic properties of $RFe_{4.5}Si_{1.5}$ (R=Y, Dy, Gd)

M. Gjoka [1], D.Niarchos [1], V.Psycharis [1]
1. Institute of Nanoscience and Nanotechnology, NCSR Demokritos, Athens 15310, Greece

The research on iron–based intermetallic compounds as possible candidates for permanent magnets still remains attractive. In this work we report our research on the possible new intermetalics $RFe_{4.5}Si_{1.5}$. Ingots were prepared by arc-melting elemental constituents of high purity (99.9%), with the starting composition $RFe_{4.5}Si_{1.5}$ and (R =Y, Dy, Gd), subsequently followed by annealing (wrapped in tantalum foil) in vacuum at 573-1173 K for three days and then fast quenching in water. X-ray diffraction (XRD) data of powder samples were obtained using Cu–Kα radiation. The thermal phase transitions and the thermomagnetic analysis of the samples were examined using differential thermal analysis (DTA/TGM) measurements by Diamond Perkin-Elmer instrument at a heating rate of 10 °C/min under Ar flow. Magnetization isothermal measurements at various temperatures were recorded by VSM and SQUID magnetometry. The morphology and composition of the ribbon samples were determined using scanning electron microscopy (SEM) and dispersive X-ray microanalysis (EDX).
The samples present almost one magnetic transition in the interval 298-1173K. The Curie temperatures are 458, 475 and 545 K respectively for (YDy)$Fe_{4.5}Si_{1.5}$ (sample A) , $DyFe_{4.5}Si_{1.5}$ (sample B) and $GdFe_{4.5}Si_{1.5}$ (sample C) alloys. Zero field cooled and field cold measurements of the sample C show a transition at 154 K. The room temperature magnetizations of samples at 5 T are respectively 56 Am^2/kg (A), 34 and 45.8 Am^2/kg. Qualitative analysis of XRD diffractions patterns shows that the system probably presents a complicate system. Rietveld analysis of XR diffraction patterns are in progress. From the EDAX analysis it was found that our alloys had compositions very close to the nominal one, i.e. $RFe_{4.5}Si_{1.5}$.

Tu.H-P137 - Crystal domains and magnetic glassy state in Co-ferrite nanoparticles

C.Moya [1], G. Salas [2,3], M.Morales [3], X.Batlle [1], A. Labarta [1]

2. IMDEA Nanociencia, Ciudad Universitaria de Cantoblanco, Madrid, Spain
3. Instituto de Ciencia de Materiales de Madrid, CSIC. Madrid, Spain

Ferrite nanoparticles with composition MFe_2O_4 (M=Fe,Co) are currently attracting much interest due to their potential applications in biomedicine, such as the detection of biomolecules by magnetic separation, contrast improvement in nuclear magnetic resonance imaging and the cancer treatment by magnetic hyperthermia. However, strongly sample-dependent magnetic properties have been previously reported for Co-ferrite nanoparticles, suggesting that the synthesis is affected by a number of factors limiting the reproducibility and crystal quality of the final samples, thus largely hindering their applicability [1], [2]. In our work, we present the study of three samples of 8 nm Co-ferrite particles prepared by standard methods based on the thermal decomposition of metalorganic precursors. Despite the facts that all samples have very similar stoichiometry and distribution of particle sizes, and they are all even nominally single-phase $CoFe_2O_4$ according to the conventional methods of chemical and structural characterization performed, they show strongly sample-dependent magnetic properties, ranging from bulk-like ferrimagnetism to glassy magnetic behavior. We show that the presence of crystallite domains associated with crystallographic defects throughout the particles leads to highly-frustrated ferrimagnetic cores that are responsible for the glassy phenomenology - largely spoiling the magnetic performance of the NPs-, while only samples almost free of structural imperfections show bulk-like magnetic properties.
Finally, the structural defects in monodisperse, stoichiometric Co-ferrite NPs can be understood as an additional nano-structuring procedure that tunes their final magnetic properties from bulk-like ferrimagnetism to glassy magnetism. In particular, Co-ferrite NPs with highly defective structures show outstanding magnetic properties associated with an internal enhancement of the magnetic frustration that strongly reduces both the saturation magnetization and coercive field.

TU.I-P01 - Influence of applied field direction on linearity of transition and demagnetized domain structure in stacked media

H.Saito [1], N. Tomiyama [1], R. Sugita [1]

1. Department of Media And Telecommunications Engineering Ibaraki University, Japan

In order to reduce transition noise of hard disks, clarifying demagnetized domain structure is useful, because fluctuation of transition relates to the structure. The recording layers of hard disks have stacked structure, and the domain structure depends on demagnetization field direction. In this study, we clarify the influence of applied field direction on the linearity of the transition and demagnetized domain structure in the stacked media. Used stacked media in this study were a capped medium and an exchange coupled composite medium. A signal was recorded using a magnetic printing method, where the angle theta of the printing field at the time of recording was set to 30 or 90 deg. from the perpendicular direction. In-plane component of the recording field for theta of 90 deg. was larger than that for 30 deg.. From MFM observations, it was found that the linearity of the transition for both media recorded at theta of 90 deg. was higher than that of 30 deg., although these media have very different layer structure. This result relates to demagnetized domain structure. The amplitude of the leakage field from the in-plane demagnetized both media was much lower than that from the perpendicularly demagnetized ones. In the case of the perpendicular demagnetization, the domain structure of the upper-layer-etched media was almost the same as that of the non-etched media, which shows the magnetization of both upper and lower layers was integrated, while in the case of the in-plane demagnetization, the domain structure of the upper-layer-etched media much differed from that of the non-etched media, which shows the magnetization of both layer was not integrated. It is concluded that the magnetization distribution in the transition area reflects the demagnetized domain structure, and the linearity of the transition increases with increasing the in-plane component of the recording field.

TU.I-P02 - Anomalous Hall effect studies on crystalline Tb-Fe thin films

R. Pothala [1], Markandeyulu G [1]

1. Indian Institute of Technology Madras, India

Rare earth - transition metallic thin films (Tb-Fe) in amorphous nature are suitable materials for magneto-optic high density data storage applications buoyed by the existence of uniaxial perpendicular magnetic anisotropy (PMA) at room temperature. In the present work, Tb_xFe_{100-x} (with x = 11.42, 24.82, 31.08 and 44.61) films were prepared with the substrate kept at 300 0C and PMA in crystalline films was investigated through Hall Effect measurements. Hall resistivity (HR) was measured in the temperature range 25 K - 300 K at a field of 5 kOe. The existence of PMA was observed in the films with x = 24.82%, 31.08% with positive sign of the Hall loops and for the film with x = 44.61% with negative sign of the Hall loop, both at 25 K and 300 K. The compensation composition was observed to lie between x = 32 % and 42 % of Tb which is more compared to the compensation composition reported in the case of amorphous Tb-Fe films. All the films are seen to exhibit metallic nature in the temperature range 25 K - 300 K whereas, amorphous Tb-Fe films have been reported to exhibit semimetallic nature. The higher compensation composition of Tb, metallic nature of the films and larger HR for higher Tb containing films (larger magnetic anisotropy) and more importantly, the stability of the crystalline phase indicate that the crystalline Tb-Fe films are more suitable candidates for magneto optic data storage applications than their amorphous counterparts.

TU.I-P03 - Extraordinary hall effect based magnetic logic applications

T. Liu [1], D. Lacour [1], F. Montaigne [1], S. Le Gall [2], M. Hehn [1], T. Hauet[1]

2. LPEP

Magnetic logic devices have many potential advantages compared to traditional semiconductor logic devices, such as nonvolatility, rapid speed and low-power consumption, so that they are considered for next generation spintronics applications. Nevertheless recent proposed magnetic logic devices based on Spin valves (SVs) or magnetic tunnel junctions (MTJs) are rather complex from the material and the micro- and nano-electronic process point of view which may affect cost and reproducibility. We propose two original architectures of magnetic logic devices based on the extraordinary Hall effect (EHE) which have strong potential for logic applications because of their simplicity and scalability. The first one is a reconfigurable logic gate composed of two connected Hall crosses, and the other one is a multi-bit logic comparator which is physically composed of a chain of crosses and can compare a user input with a reference encoded by the magnetization orientations of the cross cells [1]. The latest is required in many security application fields including secure microcontrollers, SIM cards, banking cards, biometric authentication chips, and near field communication, where a logic operation of comparing the user inputs with a reference code needs to be carried out. In the context of the conventional flash technology, the reference codes are usually stored in a recording device, and is extracted and injected into the logic circuit during the comparison process. This extraction process not only causes time and energy wasting but also results in the security risk of possible exposure of reference codes to malicious user.
EHE-based devices possess simple architecture, low cost fabrication process and are obtained in single magnetic layer. Its feasibility is proved in our manuscript on two prototypes made of 4 µm and 300nm width TbCo ferrimagnetic crosses chain. Although TbCo alloy may be very interesting because it provides reliable writing procedure and very high security level (if tuned to have TCO at room temperature), other materials and writing process may also be used to improve EHE signal-to-noise ratio of the reading process as well as writing process energy consumption [1].

4. Center for Complex Material Systems, Würzburg, Germany

It is well known that bistable nanomagnetic switches can be used to store information, associating each logic state to a different equilibrium orientation of the magnetization. Here we address the question of the minimum energy required to change the information content of nanomagnetic switches consisting of elongated dots of permalloy, a crucial topic to face fundamental challenges of current technology, such as power dissipation and limits of scaling. The energy dissipated during a “reset to 1” operation, also known as Landauer erasure, was accurately measured at room temperature by vectorial magneto-optical measurements in arrays of 10 nm thick Permalloy dots prepared by e-beam lithoghraphy and lift-off. Several samples were investigated, where the longer axis D of the elliptical dots was scaled down from about 900 to 90 nm. The experimental results show that the dissipated energy increases with the dot volume and is from one to three order of magnitude above the theoretical Landauer limit of of $kBT \cdot \ln(2)$. These experimental findings are corroborated by micromagnetic simulations where the Landauer erasure is performed on a single dot and the calculated energy dissipation averaged over many cycles. The simulations confirm that when D exceeds about 200 nm one observes significant deviations from the ideal macrospin behavior, because of inhomogeneous magnetization distribution and edge effects. These phenomena lead to an average dissipated energy that is appreciably larger than the Landauer limit, in agreement with the experimental findings.

TU.I-P05 - Novel oxygen showering post treatment (OSP) for the robust sub-20nm magnetic tunnel junctions (MTJs) patterning process

J. Jeong [1,2] T. Endoh [1, 3]

1. Graduate School of Engineering, Tohoku University, Japan
2. Semiconductor R&D Center, Samsung Electronics Co., Ltd., Republic of Korea
3. Center for Innovative Integrated Electronic Systems (CIES), Tohoku University, Japan

For the successful commercialization of spintronic applications, the optimal patterning technology as well as sufficient electric and magnetic properties of the magnetic tunnel junctions (MTJs) should be developed. We proposed the oxygen showering post treatment (OSP) process using non-reactive oxygen ions at the previous study to recover patterning damages of the damaged layer. However, for the sub-20nm STT-MRAM, more effective oxygen treatment should be necessary to oxidize damaged layer more selectively and to suppress over oxidations of damage-less area extremely. In this study, we studied about the best OSP conditions to maximize the electric and magnetic enhancements of the patterned MTJs around 20nm sizes by the effective damage recovery. We prepared the simple interface perpendicular anisotropy (i-PMA) MTJs and etched it as a 25nm size by hydrogen based reactive ion etching (RIE) process. With this patterned sample, we applied the non-reactive oxygen ions with various conditions of flowing time, rate and temperature to obtain the extremely controllable oxidizing condition. As a result of the OSP process to 25nm p-MTJs cell array, at the best OSP condition, the MR was increased from 99% to 116% and the Isw was decreased from 41.1uA to 28.7uA compared to those of reference samples patterned with the RIE process and treated with the ion beam etching (IBE) process. In addition to electric and magnetic enhancements of MTJs array, the OSP process also reduce electric short fails from 1.4% to 0% and improve sigma distribution (Ñ_) from 5.3 to 13 due to its selective oxidation of re-deposited metallic by-products generated by the physical etching process. With these results, it is verified that the optimized OSP process can recover patterning damages and improve MTJs properties at sub-20nm sizes. By the OSP treatment, we could develop the robust patterning process for sub-20nm STT-MRAM.

TU.I-P06 - Non-symmetricity for faster switching in p-MTJ structure

C. Engel [1], S. Goolaup[1], W. Lew[1]

1. School of Physical And Mathematical Sciences, Nanyang Technological University, Singapore

Spin-transfer torque random access memory (STT-RAM) is one of the most promising candidates for non-volatile computation in the near future due to its low power, ultrahigh endurance, non-volatility, fast speed processing and scalability. In particular, STT-RAM is attractive for replacing SRAM in L2 cache due to its ability for reducing the standby power to nearly zero by exhibiting similar power consumption and processing speed with same size. Different approaches have been introduced in order to minimize the writing power of a magnetic tunnel junction (MTJ) such as thermally assisted switching, the use of pure spin currents, STT-driven domain wall motion switching and electric field assisted switching whereas few works have looked at reducing the switching time.

In this work, we show that the introduction of geometrical asymmetricity in nanostructured perpendicular MTJ (p-MTJ) greatly influences the switching speed of the device. Our model shows that this asymmetry introduces a varying in-plane demagnetizing field along the plane of the structure. This locally reduces the stability of the out-of-plane. Our micromagnetic simulations reveal that the reversal process of the free layer in the p-MTJ structure starts from the region of non-uniform demagnetization field and propagates through the structure. This in effect reduces the current needed to switch the free layer. By comparing egg-shaped and circular p-MTJ structures, our results show that reduction of switching time of up to 47% can be easily achieved. This is a remarkable reduction for a relative simple adjustment of the shape and can speed up further computational power. This in effect shows that lithographical defects inherent in the fabrication of p-MTJ structures can lower the current density and switching time of devices.

TU.I-P07 - Micromagnetic study of exchange-coupled composite bit-patterned media

K. Son [1], D. Goll [2], G. Schütz [1], E. Goering [1]

1. Max Planck Institute for Intelligent Systems, Heisenbergstr.3, 70569 Stuttgart, Germany

2. Institute for Materials Research, University of Aalen, Beethovenstr.1, 73430 Aalen, Germany

Bit-patterned media (BPM) of exchange coupled composites (ECC) with perpendicular magnetization are possible candidates for ultrahigh recording densities. The hard magnetic $L1_0$ chemically ordered phase of FePt guarantee thermal stability with huge coercive fields. Using a soft magnetic Co layer the coercivity (H_c) could be systematically tailored for optimal data recording processes. $L1_0$-FePt and exchange coupled $L1_0$-FePt/Co composite films with different Co layers thicknesses have been prepared on MgO(100) single crystalline substrates by co-sputtering. Nanopatterns have been fabricated with thermal and ultraviolet nanoimprint lithography (TUV-NIL) and subsequent inductive coupled plasma reactive Ar-ion etching (ICP-RIE). Large arrays of regular single-domain nanodots are investigated, with 60 nm dot size / 150 nm periods. These dots have been studied by superconducting quantum interference device (SQUID) magnetometry and magnetic force microscopy (MFM). It has been ascertained for dots on patterns to have no interaction each other. The micromagnetic parameters have been determined temperature depended coercive fields distributions, which nearly follow the theoretical ideal coercive field of the micromagnetic universal relation ($\mu_0 H_c = \alpha\mu_0 2K_1/J_s - N_{eff}J_s$, microstructural parameter α ~1, and N_{eff} ~0). Compared to the single layer hard magnetic $L1_0$-FePt pattern, the coercivity and switching field distribution (SFD) of the $L1_0$-FePt/Co patterns have been significantly reduced and narrowed by a factor of ~0.4 to ~0.7, and this increases the Co thickness based on the exchange-coupling to $L1_0$-FePt. In addition, exchange-coupled composite bit-patterned media are used to continuously tune the effective magnetocrystalline anisotropy and the intrinsic magnetic parameters.

TU.I-P08 - A dual stacked perpendicular magnetic tunnel junction for logic application

H.K. Teoh [1], S. Goolaup [1], C. Engel [1], W.S. Lew [1]

1. School of Physical And Mathematical Sciences, Nanyang Technological University, Nanyang Link, Singapore

In recent years, magnetic tunnel junctions (MTJs) have attracted great interests in the development of next generation high density non-volatile memory and logic chips. In this work, we present a novel structure for logic operation that works by exploiting the magnetization dynamics of a spatial dependent distribution of current density of a magnetic tunnel junction free layer. The logic design is a stacked p-MTJ with two small input MTJ situated on top of a larger output MTJ. The process is simple for fabrication as the deposition will be one process and the patterning is just a two-step process. We define logic "1" for parallel free and polarizer layer directions whereas a logic "0" is defined for antiparallel free and polarizer layer directions. If one input MTJ is set to "0" ("1"), a current is injected in -z-direction (+z-direction). Due to our logic architecture, the output logic state is computed at the same time when input states are set into the logic structure. Our logic scheme requires a preset stage. The output junction logic state can be changed when the current density overcome the critical current density from macro spin model. This happens only when currents passed through both input junctions. Our design prevents current lines flowing in different directions from switching the output free layer due to insufficient spin torque provided. The magnetization will only reach an unstable partial switching state which, upon removal of spin current, will relax back to its initial state. It should be noted that the non-uniform spatial distribution of the current density has been exploited for the free layer of the output junction to achieve such selective switching behavior. Our micromagnetic simulations show that various logical operations [NAND(AND),NOR(OR)] can be carried out by fixing the magnetic configuration of the polarizer layer.

TU.I-P09 - Stochastic behavior of spin transfer switching in magnetic tunnel junctions for physically unclonable function systems

T. Marukame [1,2] T. Tanamoto [2], Y. Mitani [2], A. Schmid [1]

1. EPFL, Laussane, Switzerland
2.Toshiba corporation, Japan

Hardware security devices using physically unclonable function (PUF) offer significant advantages over software-based secure identification. We have proposed a PUF using magnetic tunnel junctions (MTJs) and a method for extracting PUF from spin transfer switching [1]. The randomness of MTJ switching is a promising property to realize secure hardware key generators. In this paper, we discuss the stochastic behavior observed in MTJs for compatibility with CMOS-based PUFs.
We measured a large number of CoFeB/MgO/CoFeB-based MTJs with a perpendicular magnetic layer for free and reference layers under magnetic field. Pulse voltages with duration ranging from 10 nano-sec to 1 micro-sec were used to measure the MTJ switching threshold. Each MTJ exhibited different voltage distributions for parallel to antiparallel (P-to-AP) and AP-to-P state transitions [1]. To evaluate thermal effects, the switching depending on the magnetic field vs. current (i.e., H-I curve) was investigated. The results show typical signatures of perpendicular MTJs. The gamma=dH/dI reduces with increasing current magnitude, suggesting thermal effects induced by the applied pulse. A region where gamma<0 is clearly observed under the specific magnetic field and current. The extracted gamma remains unchanged under the magnitude of the pulse, which forms a characteristic behavior in contrast to the region where gamma>0. Furthermore, we observed the two curves of AP-to-P and P-to-AP overlapping in the same region where gamma=0. Hence, stochastic switching occurs under the specific and unidirectional pulse, resulting in time-series data. The unpredictable data can be extracted from each MTJ in a setup consisting of the MTJs combined with certain CMOS delay detection circuits [2]. The stochastic properties demonstrate the eligibility of MTJs as a key component for CMOS-compatible PUFs.

TU.I-P10 - Self-initializing dual MTJ MRAM cell design

A. Khvalkovskiy [1], D. Apalkov [2], A. Mikhailov [1], V. Nikitin

1. Moscow Institute of Physics And Technology, State University, Moscow, Russian Federation
2. Samsung Electronic Corp., Semiconductor R&D Center, Republic of Korea

In a conventional perpendicular MRAM cell design, the reference layer (RL) should have a high thermal and magnetic stability and high spin polarization [1]. To meet these requirements, RLs are often made of two magnetic components, a high-Ku component based on high-Z (e.g. Pt/Pd) alloys, and CoFeB-based component at the MgO interface for high polarization. Since these two components often grow with different crystalline orientation, optimization of the RL design may become challenging [2]. This challenge becomes particularly strong for MTJ cells with two active MgO barriers called Dual MTJ (DMTJ), made of two oppositely directed RLs on both sides of the cell free layer (FL).
As we discuss in our paper, many of these challenges may be circumvented in a new MRAM cell design which we call Self-Initializing Dual MTJ (SID MTJ). SID MTJ has a “strong” RL (SRL) and a “weak” RL (WRL). SRL is a conventional RL like in a single-barrier MTJ cell, e.g. a SAF-coupled RL like in [3]. In contrast to it, WRL should have very low thermal stability; specifically, its switching current Jc_WRL should be much smaller than that of FL Jc_FL: Jc_WRL << Jc_FL. Once the write current pulse is applied, the spin transfer torque from FL initializes WRL antiparallel to SRL prior to the FL motion. As a result, the torque on FL doubles, for both switching directions, like for a conventional DMTJ cell design. WRL should be made of a low Ms*t product layer to reduce its stray field on FL. We show that SID MTJ cell with such WRL may have a matching performance to a conventional DMTJ cell, while having considerably improved growth requirements.

TU.I-P11 - Hybrid fan-out element with magnetic quantum dot cellular automata and domain wall logic

H.Nomura [1], N.Tanigaki [1], F. Nakamura [1], S. Miura [1], R. Nakatani [1]

1. Osaka University, Osaka, Japan

Magnetic quantum dot cellular automata (MQCA) [1-3] and magnetic domain wall logic (DW-logic) [4] are information processing architecture composed of magnetic materials. MQCA and DW-logic have possibilities to replace the CMOS architecture. In MQCA and DW-logic, binary state of “0” and “1” are stored with a direction of a magnetization of the nanostructure, and, logic operations are executed by applying a uniform external magnetic field (clock-field). Both architectures have advantages of information non-volatility, low-dissipation energy and operate at room temperature. However, MQCA and DW-logic have disadvantages of limitation of gate arrangements and low integration density of logic gates, respectively. Combination of the MQCA and DW-logic would compensate each disadvantage. Here we experimentally demonstrate a hybrid fan-out element with MQCA and DW-logic. Hybrid MQCA-DW-logic fan-out elements with MQCA nano-dot and v-shaped DW-logic fan-out were fabricated on Si substrate with electron-beam lithography, ion beam sputtering, and lift-off technique. The MQCA-DW-logic fan-out elements are composed of 20 nm thickness Ni-20at%Fe. Magnetization manipulation method based on magnetic force microscopy (MFM) was used to write initial binary states of the elements. Magnetization switching field of the v-shaped DW-logic fan-out was changed with the change of the binary state of the MQCA nano-dot. Thus, with appropriate strength of the clock-field, this hybrid MQCA-DW-logic element behaves as a fan-out element. Combination of MQCAs and DW-logic would comprise the advantages of both architectures and be exempt from their defects. Hybrid MQCA-DW-logic architecture would open a new way for developing a high functional devices.

TU.I-P12 - Two Dimensional Equalisation of Shingled Write Disk

M.Abdulrazaq [1,2], M.Ahmed [1], P.Davey [1]

1. University of Plymouth, United Kingdom
2. Ahmadu Bello University, Zaria, Nigeria

Shingled magnetic media presents the potential of extending the capacity of magnetic media beyond the current limit. However it faces the problem of high complex detectors for handling the high interference that occur both from symbols in the same track and from neighbouring tracks. This paper presents a Two Dimensional process for cancelling Inter-Track Interference and Inter-Symbol Interference by combining linear and maximum likelihood (ML) equalisers. The results found show that much less complexity, less delay and better BER performance can be achieved by compressing the data more across the track rather than along the track; if ML equalisation is used across the track while linear equalisation is used along track.

TU.I-P13 - Potential of field-coupled magnetic logic circuits with perpendicular anisotropy in terms of scaling and material improvements

S.Breitkreutz-V. Gamm [1], I. Eichwald [1], G. Ziemys [1], D. Schmitt-Landsiedel[1], M.Becherer [1]

1. Technische Universität München, Munich, Germany

Perpendicular Nanomagnetic Logic (pNML) is an emerging information processing technology employing the 3-dimensional interaction of field-coupled nanomagnets with perpendicular magnetic anisotropy (PMA) to perform logic operations [1,2]. The PMA is locally tuned by focused ion beam irradiation to control the domain wall (DW) nucleation spot [3]. This allows to sensitize magnets to only specific neighbors (inputs) to provide logic operation in both 2D- and 3D-arrays of field-coupled magnets [4,5]. Physical-based compact modeling of pNML [6] is applied to investigate the behavior of a 1-bit full adder circuit in terms of progressive scaling and material improvements. The utilized models base on a well-known switching probability model [7,8] for DW nucleation, which is combined with numerical coupling field calculations [6]. Therefore, the applied model enables to simulate the magnetic behavior with respect to the magnet geometry, magnetic material, fabrication variations, clocking speed and temperature. In our simulations, the error rate e of a 1-bit full adder circuit of [4] is simulated depending on the technology node n (90nm to 7nm), clocking frequency f_clock (50kHz to 1GHz), effective anisotropy K_eff (0,5 to 2,5*10^5 J/m^3), and total magnetic layer thickness t_Co (0,5 to 5nm) within N = 10^5 runs for each parameter configuration. The results show that scaling increases the coupling between the magnets and therefore improves the operational reliability (error rate decreases below e < 10^-4). Furthermore, shorter (scaled) magnets allow to increase the clocking speed f_clock to the +100MHz-range. Optimizations of the magnetic material enable to reduce the power consumption (lower switching fields) and also to significantly decrease the error rate.

TU.I-P14 - Control of magnetic inactivation layer thickness in MnGa film by kr^+ ion irradiation

D. Oshima [1], T. Kato [1], S. Takahashi [2], Y. Sonobe [2], S. Iwata [1], S. Tsunashima [3]

It has been reported that Kr^+ ion irradiation modifies the magnetism of MnGa films from ferromagnetic to nonmagnetic due to the structural change from $L1_0$ ordered to A1 disordered phase and also reported that the local ion irradiation allows to fabricate lateral magnetic nano-patterning without changing the film topography [1]. In this study, we report the depth control of magnetic phase change from ferromagnetic and nonmagnetic (we refer it to as magnetic inactivation) of MnGa by ion irradiation. Kr^+ ions were irradiated to Cr (2 nm) / MnGa (15 nm) / Cr (20 nm) / MgO(001) substrates which was prepared by rf magnetron sputtering. The acceleration energy and incident angle of the Kr^+ ions were varied to control the depth of magnetic inactivation. For normal incidence of 30 keV Kr^+ ions, magnetization of MnGa completely suppressed at a dose of 1×10^{14} ions/cm^2. With decreasing the energy, ferromagnetism of the MnGa survived after the dose of more than 2×10^{14} ions/cm^2 because of the reduction of the penetration depth of Kr^+ ions. From the survived magnetization, the depth of inactivation was estimated to be 12 and 7 nm for 10 and 5 keV irradiations, respectively. Surprisingly, we found that the shape of hysteresis loops of the survived MnGa did not change from that before irradiation. This means the sharp transition between magnetically inactivated surface MnGa and survived bottom MnGa layer. Reduction of the ion incident angle was found to be effective to reduce the depth of magnetic inactivation. When the 5 keV ions were irradiated along 70˚ from the film normal, the depth of magnetic inactivation was reduced to 1 nm, suggesting the magnetic inactivation was controlled with a thickness resolution of 1 nm. This work was supported by the Samsung Global MRAM Innovation Program.

5. CEA, LETI MINATEC, Grenoble, France

The Spin-orbit torque (SOT)-MRAM is based on the discovery that a current flowing in the plane of a magnetic multilayer with structural inversion asymmetry, such as Pt/Co(0.6nm)/AlOx, exerts a torque on the magnetization, due to the spin-orbit coupling [1]. This torque can lead to the magnetization reversal, with a switching time smaller than 200 ps [2]. The key advantage of the SOT-MRAM is that write and read are decoupled due to independent current paths [3]. The SOT-MRAM thus naturally solves the reliability issues in current STT-MRAM with a potentially infinite endurance. The possibility to independently optimize the material parameters, for writing and reading, allows maximizing the magnetoresistance ratio and adjust the impedance while keeping a low writing current. Faster writing can thus be achieved for a lower energy and the read disturb issue is naturally solved, even at small sizes. In this presentation, we will present ultra-fast (down to 300 ps) bipolar and reliable writing of perpendicular three-terminal SOT-MRAM single cells. These results show that critical current of around 200 ÁA and a sub-100 fJ write energy at 1 ns can be achieved for 50 nm technologies. To understand experimental results, we have carried out macrospin simulations of the magnetization dynamics induced by the SOT. Our results show that SOT-MRAM is fast, reliable and low power, which is promising for non-volatile cache memory application [4].

TU.I-P16 - (001) Oriented MnGa film grown on Si substrate for ion beam patterned media

D. Oshima [1], N. Tsubasa [1], T. Kato [1], S. Iwata [1], S. Tsunashima [2]

1. Nagoya University, Japan
2. Nagoya Industrial Science Research Institute, Japan

We have studied magnetic patterning of MnGa films without changing the film topography by local ion beam irradiation. The MnGa film changes its magnetism from ferromagnetic to paramagnetic because of the phase change from $L1_0$ to A1 phase by the ion irradiation [1]. This technique is quite effective to produce low cost and high density planer bit patterned media. However, in the previous report [1], the MnGa films were grown on MgO (001) single crystal substrates to obtain (001) oriented MnGa. This is not practical as magnetic recording media, thus we studied the fabrication of (001) oriented MnGa on thermally oxidized Si substrate. The sample configuration was Cr (2nm) / $Mn_{50}Ga_{50}$ (15nm) / Cr (20nm) / MgO (20nm) / $Ni_{60}Ta_{40}$ (25nm) / substrate. The MgO layer was deposited by e-beam evaporation and the other layers were deposited by rf magnetron sputtering. The films were stacked without breaking the vacuum. From the hysteresis loop measurements, the fabricated MnGa film had a perpendicular easy axis even though the film were grown on the Si substrate although the saturation magnetization was about 150 emu/cc which was about one-third of that of the previously reported MnGa film on MgO(001) substrate. The magnetically patterned structure was fabricated using the MnGa on Si substrate by e-beam lithography followed by the 30 keV Kr irradiation with a dose of 1×10^{14} ions/cm^2. From the magnetic force microscope image, the magnetically patterned structure with topologically flat surface was confirmed even for the bit patterning with a pitch size of 100 nm × 100 nm (bit size of 60 nm × 60 nm). Further improvement of the (001) orientation and surface flatness of the MnGa films will be necessary to obtain bit patterned structure with pitch size as small as that for MnGa on MgO(001) substrate.

TU.I-P18 - Investigation of p-MTJ stability for application purposes

C. Engel [1], S. Goolaup [1], H. Kheng Teoh [1], W. Siang Lew

1. School of Physical And Mathematical Sciences, Nanyang Technological University, Singapore

In this work, we studied the stability of perpendicular-magnetic tunnel junction (p-MTJ) with a synthetic antiferromagnet (SAF) as a function of the geometry and perpendicular anisotropy constant of the free layer, Kfree. Above a threshold eccentricity, the stability of the free layer is broken for distinct K values. For elliptical p-MTJ structures, the out of plane stability is broken when the ratio between the minor and major axes is 0.8. This phenomenon happens for both the parallel and antiparallel configuration of the p-MTJ. Our results show that this behavior is due to a combination of the demagnetizing and perpendicular magnetic anisotropy field. We suspect that at distinct frequencies the symmetry of uniform magnetization precessions is broken due to a coupling between the spins aligned along the major in-plane axis and spins along the out-of-plane, leading to spin waves. These spin waves are oscillating at frequencies between the out-of-plane and in-plane magnetization oscillations with gigantically increasing amplitude. In conclusion we show that for p-MTJs the interplay between shape and uniaxial anisotropy can play a crucial role in designing stable and predictable p-MTJs state. We show that for elliptical p-MTJs the frequencies of the demagnetization and perpendicular uniaxial energy are responsible for the gigantically out of plane magnetization change while the stray field from the SAF plays a minor role.

TU.I-P19 - Data input and output method for 3D-MQCA with MFM

K. Iwaki [1], R.Wakasa [1], H.Nomura [1], R.Nakatani [1]

1. Osaka University, Osaka, Japan

Magnetic quantum cellular automata (MQCA) [1], also called as nanomagnetic logic (NML), is one of a field coupled computing device, which can execute a logic operation via magneto static interaction. Recently, the focus of MQCA research has been changed from two dimensional devices to three dimensional (3D) devices [2]. For these researches, a simple and easy data input and output method, i.e., magnetization manipulation and measuring method is required. However, such method has not been developed yet. Here we propose and demonstrate 3-D magnetization manipulation and measuring method for 3D-MQCA with MFM. As a sample, Au (3 nm)/Ni-20at.%Fe (20 nm)/SiO (40 nm)/Ni-20at.%Fe (20 nm) cylindroid nanodots with major/minor radius of 70 nm/40 nm were fabricated on Si substrates with electron-beam lithography, ion beam sputtering, and lift-off technique. All experiments were performed in vacuum condition at room temperature with originally developed MFM controlled by LabVIEW and commercially available cantilevers (SI-MF40). External magnetic field was used to assist the magnetization manipulation with MFM tip. Before magnetization manipulations, magnetizations of the nanodots were initialized with external magnetic field. MFM images were measured with constant height mode, to avoid a disturbance of the magnetization of nanodots with MFM tip. During a magnetization manipulation process, a jump of a phase shift of the cantilever, which corresponds to a magnetization reversal, was observed. By changing a three dimensional position of the cantilever, it is possible to select a magnetic layer for magnetization manipulation. This three dimensional magnetization manipulation method will become a powerful tool in developing a computer architecture based on 3D-MQCA. Part of this work is supported by Advanced Nano Photonics Research and Education Center in Asia and Photonics Center in Osaka University.

TU.I-P20 - High saturation magnetization and perpendicular anisotropy of atomic layer stacking Co/Pt films sputter deposited at room temperature

N. Honda [1], T. Tsuchiya [1], H. Uchida [1], S. Saito [2], S. Hinata [2]

1. Tohoku Institute of Technology, Japan
2. Tohoku University, Japan

L11-ordered CoPt film exhibits high saturation magnetization and perpendicular magnetic anisotropy required for high density recording media(1). But, high preparation temperatures higher than 300C are needed, which would cause large agglomeration of grains. We reported a high perpendicular anisotropy field greater than 15 kOe for layer stacking Co/Pt films sputter deposited at room temperature(2). High saturation magnetization, however, was only obtained with deposition at low Ar pressures and with reduced anisotropy. We have investigated preparation conditions of layer stacking Co/Pt films for high saturation magnetization and anisotropy.
A sputtering apparatus with three magnetron cathodes was used. The atomic-layer stacking-deposition was done on a Ta(10)/Pt(10 nm) underlayer with a collimator by co-sputtering of Co and Pt while rotating the substrate holder at room temperature. Films with two or three monolayer-stacking of Co and Pt were also prepared to investigate the origin of the anisotropy. Films with a high perpendicular anisotropy field of around 15 kOe along with a high saturation magnetization of around 1000 emu/cm3, which indicates a high anisotropy of beyond 1x10^7 erg/cm3, were obtained at an intermediate Ar pressure with controlled layer thickness. Films with more than two monolayer-stacking of Co and Pt also exhibited high anisotropy fields but with reduced saturation magnetization of around that of simple dilution of Co. The origin of high perpendicular anisotropy in these films could be attributed to the surface anisotropy. High saturation magnetization of around 1000 emu/cm3 was only obtained by monolayer stacking although the films showed only a faint ordering in XRD measurement. It was concluded that high saturation magnetization and perpendicular anisotropy of atomic layer stacking Co/Pt films was caused by micro L11-ordering.

TU.I-P21 - Dynamic magnetization reversal in NiFe wires with assistance of microwave impulse combined with 100-picosecond pulsed field

G. Okano [1], Y. Nozaki [1, 2]

1. Keio University, Tokyo, Japan
2. JST-CREST, Japan

Magnetic field required for switching can be efficiently reduced at ferromagnetic resonance (FMR) frequency. The phenomenon is called microwave-assisted magnetization reversal (MAMR). There were few experimental studies on the switching dynamics because it is difficult to reduce the duration of microwave impulse as short as sub-nanoseconds. We studied the switching dynamics by using 100-picosecond-wide pulsed field in addition to 5 GHz microwave impulse.
We measured the switching field (H_{sw}) of NiFe wire (w = 200 nm, l = 4 µm, t = 50 nm) in four cases; (a) without assistance and assisted with (b) 100-picosecond pulse field alone, (c) 5 GHz microwave impulse alone, and (d) simultaneous applications of both signals in the transverse direction of NiFe wire. The pulse length is consistent with the half period of microwave field. In our previous study, we confirmed that the maximum reduction of H_{sw} appeared at 7 GHz. In the case (d), the averaged H_{sw} was lower than those of other cases. The result suggests the appearance of cooperative magnetization switching with the pulse field and microwave impulse. Thus, the cooperative switching occurs within the duration time of the pulsed field. From the multiple measurement of H_{sw}, we also found that the cooperative H_{sw} were discontinuously distributed in two field regions. Namely, there are two distinguishable processes in the cooperative magnetization reversal and it seems to be stochastic which process occurs. These results are attributable to a nonlinear dynamics of magnetization excited by a strong microwave field, i.e., an appearance of quasi-periodic or stochastic magnetization mode and a loss of uniformity in the magnetization precession due to a spin wave excitation.

TU.I-P22 - Atomic composition dependence of microwave-assisted magnetization reversal in CoCrPt-based perpendicular media

Y. Nozaki [1], T.Tanaka [2]

1. Dept. of Physics, Keio University, Japan
2. ISEE, Kyushu University, Japan

Microwave-assisted magnetization reversal (MAMR) is one of the promising candidates to improve the writability in strongly anisotropic perpendicular media. Recent studies on the MAMR in granular CoCrPt-based medium mainly focused on the dependence of switching field reduction on the frequency, amplitude, and duration time of microwave impulse. On the contrary, there are few studies on the medium dependence of the MAMR. In this study, we investigated an atomic composition dependence of MAMR in CoCrPt-based perpendicular medium. A 100-mm-long and 1.5- \mu m-wide coplanar waveguide was fabricated on a rectangular-shaped granular film consisting of 16-nm-thick CoCrPt film with a lateral size of 100 \times 1.5 \mu m^{2}. The atomic composition of CoCrPt layer was set so as to realize a thermal stability coefficient delta of 70 or 90 at room temperature. Ferromagnetic resonance (FMR) spectra of the media were measured from the frequency dependence of microwave reflection coefficient of the coplanar waveguide by vector network analyzer. The amount of magnetization reversal was evaluated from the change in the FMR frequency after applying a microwave impulse to the coplanar waveguide. The amplitude of microwave field impulse was fixed at 635 Oe which is approximately one-tenth of the static coercive field of the medium. The duration of impulse was 500 ns. The Gilbert damping constant was almost independent of the atomic composition and the value evaluated from the linewidth of FMR spectrum was 0.04. The frequency-dependent reduction in coercive field was clearly observed in both media although the reduction ratio of coercive field from the static value depended on the atomic composition. Interestingly, we found that the larger reduction ratio was realized in the medium with larger thermal stability coefficient. This is attributable to the difference in the influence of Joule heating on the switching field reduction.

TU.I-P23 - Damping constants of Ni_xFe_{100-x}(60<x<80) single crystal thin films investigated by Q-band ferromagnetic resonance analysis

T. Nishimura [1], S. Yamanaka [1], Y. Takahashi [1], N. Inaba [1], M. Ohtake [2], M. Futamoto [2], F. Kirino [3]

1. Yamagata University, Japan
2. Chuo University, Japan
3. National University of Fine Arts and Music, Japan

Gilbert's damping constant α is an important factor to develop high frequency magnetic recording system and MRAM. The α of Ni-Fe alloy polycrystalline thin films were reported to be correlated to the magnetostriction[1]. The α values of polycrystalline specimens are overestimated, because of the distribution of the crystal orientation in the specimens. We investigated the α of Ni-Fe single crystal thin films by employing a ferromagnetic resonance (FMR) analyses at a frequency of 35 GHz.

20nm-thick Ni_xFe_{100-x}(001) single crystal thin films(60< x <90) were epitaxially grown on MgO(001) single crystal substrates by a rf magnetron sputtering system. The FMR line widths ΔH of the $Ni_{88}Fe_{12}$ specimen had constant values of 195 Oe, when the spectra were measured with changing external field directions in the film plane. The α value was calculated to be 0.015 from the ΔH of 195 Oe by using the relationship of $\Delta H = 4\pi\alpha f_r/\gamma$, where g is gyromagnetic ratio, and f_r is resonance frequency. The α for the Ni-Fe specimens did not vary with the crystal directions. With decreasing Ni concentration from 88% to 80%, the α decreased from 0.015($Ni_{88}Fe_{12}$) to 0.0099($Ni_{80}Fe_{20}$). While the α gradually increased to 0.014($Ni_{63}Fe_{37}$) with the Ni concentration range from 80% to 63%. The α had the minimum value at the 80% Ni, where the magnetostriction was zero. This result probably suggests that the magnetostriction is one of the factors to bring the increase of the damping constant.

5. Max Planck Institute for Chemical Physics of Solids, Germany

Over the last decade, large number of studies have been performed to find novel magnetic materials suitable for next-generation Magnetoresistive Random Access Memory (MRAM). The basic memory element of MRAM is a nanoscale device called magnetic tunnel junction (MTJ), which is nowadays switched between its two states using spin-transfer torque (STT). MTJs need to be developed using ultra-thin films of magnetic materials displaying low magnetization, high spin polarization (SP) and high perpendicular magnetic anisotropy (PMA) in order to be non-volatile, scalable to very small sizes and programmable by means of small current densities. Moreover, the growth of atomic layers of such materials onto amorphous substrates is crucial for industrial MRAM applications. Some materials among the family of Heusler alloys have been designated as possible candidates to achieve this goal. In fact, it has been previously shown that Mn-based tetragonally-distorted Heusler compounds display very high PMA, low magnetization and have been theoretically predicted to have high SP.
This work illustrates the successful growth of ultra-thin Mn_3Ge Heusler films with tetragonal D022 structure, deposited by magnetron sputtering on Si/SiO2 substrates. These films show atomically-flat surfaces (RMS roughness of ~ 4Å) as well as low magnetization (~ 130emu/cc), with direction perpendicular to the film plane. A thickness dependence study of the Mn3Ge films is carried out, displaying giant coercive fields of ~ 5Tesla for film thicknesses down to only 5nm. Structural, topographical and magnetic properties of films grown on amorphous substrates are also compared to Mn_3Ge films deposited on Cr-buffered MgO(001) single crystal substrates: it is shown that the properties of Mn_3Ge thin films on amorphous Si/SiO_2 substrate are superior to those on MgO(001) substrate.
These preliminary results make tetragonally-distorted Mn3Ge alloy a promising material candidate as ferrimagnetic electrode for MTJs devices.

TH.A-P01 - Quantum degradation of the second order phase transitions

S. Stishov [1], A. Petrova[1], S. Gavrilkin[2], L. Klinkova[3]

1. Institute For High Pressure Physics of RAS, Moscow, Russian Federation
3. P. N. Lebedev Physical Institute of RAS, Moscow, Russian Federation
4. Institute of Solid State Physics of the RAS, Moscow, Russian Federation

The specific heat, magnetization and thermal expansion of single crystals of antiferromagnetic insulator EuTe were measured at temperatures down to 2 K and in magnetic fields up to 90 kOe. The Neel temperature, being 9 K at H=0, decreases with magnetic field and tends to zero at ~76 kOe, therefore forming a quantum critical point. The heat capacity and thermal expansion coefficient reveal lambda-type anomalies at the second order magnetic phase transition at low magnetic fields, evolving to simple jumps at high magnetic fields and low temperatures, well described in a fluctuation free mean - field theory. The experimental data and the corresponding analysis favor the quantum concept of effective increasing space dimensionality at low temperatures that suppresses a fluctuation divergence at the second order phase transition

TH.A-P02 - Ground state and magnetization process of a linear chain composed of coupled localized spins and mobile electrons

J.Lisárová [1], J.Streçka [1]

1. Department of Physics. P. J. Safárik University, Kosice, Slovakia

Exact solution of a coupled spin-electron chain composed of localized Ising spins and mobile electrons in a magnetic field is found with the use of a transfer-matrix method. The ground-state phase diagram in the chemical potential vs. magnetic field plane consists of seven phases with different number of mobile electrons per unit cell. Except of two paramagnetic phases with either zero or four electrons per elementary unit cell, the ground-state phase diagram also contains two quantum ferromagnetic phases with one or three electrons per unit cell. The most interesting ground states are found for the system with two electrons per unit cell, in which the system resides in a quantum antiferromagnetic state at low enough fields, then it shows a quantum ferromagnetic phase at moderate fields and finally the system reaches a saturated paramagnetic phase for sufficiently strong fields. The main focus of our work was the study of magnetization process of the correlated spin-electron linear chain as a function of electron density. It is evidenced that one can generate magnetization curves with intermediate plateaus at arbitrary real value of the magnetization ranging from zero up to a saturation magnetization by a suitable choice of electron density.

TH.A-P03 - Novel quantum phase transitions of the frustrated spin nanotube

T. Sakai [1], H. Nakano [2], K. Hijii [3], K. Okunishi [4]

1. JAEA, SPring-8, Japan
2. University of Hyogo, Japan
3. Kobe University, Japan
4. Niigata University, Japan

Recently some quantum spin systems on tube lattices, to called spin nanotubes, have been synthesized. They are expected to be interesting low-dimensional systems like the carbon nanotubes. As the first step of thoretical study on the spin nanotube, we investigate the S=1/2 three-leg spin tube, which is the simplest one, using the density matrix renormalization group (DMRG) and the numerical exact diagonalization (ED), conbined with a precise finite-size scaling analysis named level spectroscopy[1]. The spin gap, which is one of the most interesting macroscopic quantum effects, was revealed to be open due to frustration for sufficiently strong rung exchange couplings, in contrast to the three-leg spin ladder system which is gapless. The critical point of a quantum phase transition between the gapped and gapless phases was estimated. It is consistent with the previous effective Hamiltonian approach[1-3]. We also found a new quantum phase transition to another spin-gap phase caused by the ring exchange interaction. In addition we theoretically predicted some new field-induced quantum phase transitions. A chirality-mediated novel superconductivity mechanism is also proposed.

TH.A-P04 - Evidencies for a non magnetic anomaly at 1K emerging from ferromagnetic $Ce_{2.1}(Pd_{1-x}Ag_x)_{1.95}$ $In_{0.95}$ alloys

J.G. Sereni[1], M. Giovannini[2], M. Gómez Berisso[1], F. Gastaldo[2].

1. Low Temperature Division., CAB-CNEA and Conicet, San Carlos de Bariloche, Argentina
2. Dipartimento di Chimica e Chimica Industriale, Universitá di Genova, Genova, Italy

Magnetic and thermal properties of the Ferromagnetic (FM) $Ce_{2.1}Pd_{1.95}In_{0.95}$ solid solution were investigated to determine the $T_C \rightarrow 0$ Quantum Critical Point driven by Ag doping the Pd lattice. The increase of band electrons produced by substituting *hole-like* Pd atoms with *electron-like* Ag depresses $T_C(x)$ from T_{C0}=4.1K at x=0 down to T_C(x=0.5)=1.1K at the limit of Ag dilution. $T_C(x) \rightarrow 0$ extrapolates to a Critical Point at $x_{CP} \approx 0.62$. High temperature inverse susceptibility $1/\chi_{dc}(T)$ indicates that the effective magnetic moment $\mu_{eff} \approx 2.5\mu_B$ is close to that of the Ce^{3+} ion all along the concentration range. This feature, together with the paramagnetic temperature $\theta_P \approx -10K$, exclude significant Kondo screening effect. The $T_C(x)$ reduction is associated to a weakening of the FM magnetization and to the emergence of a specific heat C_m anomaly centered at $T_A \approx 1K$. Unexpectedly, no magnetic signal was detected by $\chi_{ac}(T)$ susceptibility measurements at T≈1K in x=0.2 and 0.3 samples with respective T_C at 3.2K and 2.6K. The magnetic entropy collected at T=4.1K(=T_{C0}) is nearly independent of Ag concentration: $S_m(4K) \approx 0.8$ Rln2, suggesting a progressive transfer of FM degrees of freedom to a growing *non-magnetic* component. This shift is reversed applying magnetic field. No antecedent was found in the literature concerning a *non-magnetic* anomaly in the range of "1K" emerging from a FM system. The formation of such anomaly is attributed to an *entropy bottleneck* originated in the divergent $C_m/T=B/T^Q$ dependence for $T>T_A$ (with Q≈2) which would exceed the available S_m=Rln2 degrees of freedom at T≈0.55K.

We report a comprehensive study of the static and dynamic properties of a strong-leg Heisenberg spin ladder in its field-induced quantum critical Tomonaga Luttinger spin liquid (TLSL) phase. For this purpose, combined bulk and inelastic neutron scattering experiments were performed on the organometallic material (C_7H_10N)_2CuBr_4 (DIMPY), realizing the strong-leg Heisenberg spin ladder Hamiltonian with particularly weak interladder interactions [1-3].
With magneto-thermodynamic measurements, we mapped out the entire (H,T)-phase diagram. The combination of the asymptotic low-temperature behaviour of specific heat and magnetization enabled to determine the field-dependence of the TLSL parameters u and K, in quantitative agreement with numerical DMRG calculations [1].
Using inelastic neutron scattering, we observed the profound spectral changes that are accompanied by the quantum phase transition at H_c1 [2], such as the transformation of sharp magnon modes into gapped and gapless continua. By focussing on the gapless contribution at lowest energies, we were able to observe striking scaling properties of the TLSL phase [3]. With high-resolution neutron time-of-flight spectroscopy, the T- and energy-dependent q-integrated local dynamical structure factor was determined and found to collapse onto a single curve, if shown in scaled variables [3]. In addition, the scaling curve itself was shown to be in excellent agreement with analytic QFT predictions. Due to the attractive rather than repulsive spinon-spinon interactions in strong-leg spin ladders, the observed thermodynamic and scaling properties are strikingly different from the ones previously observed in strong-rung spin ladders [4] or Heisenberg spin chains in zero field [5].

TH.A-P06 - Entanglement in the one-dimensional SU(2)x*XXZ* spin-orbital models

A. M. Oles[1,2], W.You[1,3], P. Horsch[3]

We present phase diagrams of the one-dimensional (1D) SU(2)x*XXZ* models with negative exchange parameter and analyze spin-orbital entanglement [1] in various ground and excited states. In the 1D SU(2)xZ_2 model with Ising orbital interactions we identify a novel phase with spin-singlet dimer correlations and large spin-orbital entanglement entropy determined for an exactly solved ground state [2], while all the other phases are disentangled. Orbital quantum fluctuations away from the Ising limit do not remove this phase but are responsible for a continuous transition to the phase with coexisting antiferromagnetic and alternating orbital order. The crossover regime between the two above phases is described by two coexisting order parameters [2]. The quantum phases with spin-singlet (orbital-singlet) dimer correlations survive in the isotropic 1D SU(2)xSU(2) model. Considering the disentangled ferro-ferro phase we find one or two spin-orbital exciton bound states characterized by logarithmic scaling of the von Neumann entropy with increasing system size, unlike the other elementary excitations from the spin-orbital continuum [3]. We suggest that spin-orbital bound states can be experimentally explored using resonant inelastic x-ray scattering.

Quantum spins in one-dimensional (1D) chains show unusual properties such as Haldane gap and spin-Peierls state, by strong quantum nature. Particularly in the system where several physical degrees of freedom are entangled in, it opens the new paradigm of the material science. In the quantum spin systems, spin singlet is the basic starting point describing a ground state of the quantum spin chain. Another interest in quantum spin systems is the cooperation between charges and spins. The high-Tc superconductivity is one of the most fascinating examples realized in 2D CuO2 sheet. Practically it is hard to realize the carrier doping in 1D material because the carrier localization occurs at low temperature. Here we present spin and hole dynamical properties in hole-doped 1D Haldane chain Nd2-xCaxBaNiO5, which is successfully hole doped 1D Haldane system [1,2]. The hole doped x=0.035 and x=0.1 carrier content were measured by means of pulsed neutron inelastic scattering. It is clearly observed the entire one-magnon band with 10 meV spin gap (Haldane gap) at magnetic zone center (MZC) [3]. The energy at zone boundary reaches 60 meV that is less comparing to undoped Haldane chain. On the other hand, the gap slightly increases in its energy. Nobel dynamical structures within the gap were observed upon carrier doping, showing incommensurating structures centered at MZC. This is originated by the doped-holes. The observed dynamical structures are composed of the contribution of quantum spin chains with spin gap and holes, quite similar to that observed in high-Tc superconductor. Also, at low temperature, the new excitation at E=4 meV and showing almost no momentum dependence has been observed. It is possibly originated from the crystal electric field of Nd^{3+} ions.

TH.A-P08 - Spin-orbital order in systems with orbital dilution

W. Brzezicki [1,2], A. M. Oles [1,3], M. Cuoco [2]
1. Marian Smoluchowski Institute of Physics, Jagiellonian University, Kraków, Poland

Correlated insulators with partly filled degenerate orbitals are unique systems with intrinsically frustrated superexchange which includes orbital directional interactions. This frustration is frequently removed by spin-orbital order which changes depending on the balance between ferromagnetic and antiferromagnetic exchange, as for instance in the paradigmatic Kugel-Khomski model [1]. Here we show that magnetic exchange and spin-orbital order in systems with t2g orbital degrees of freedom are radically changed by orbital dilution when transition metal 3d3 (S=3/2) ions replace 4d4 (S=1) ions in ruthenium oxides, for instance in Sr2RuO4. Such impurities generate new local spin-orbital order [2], either with frustrated spin defects accompanied by an immobile orbital vacancy, or doubly occupied active orbitals along 3d-4d bonds (orbital polarons). At finite (x=1/8, 1/5, 1/9) doping such defects stabilize striped patterns either with alternating magnetic domains or with islands of saturated ferromagnetic order. We find that spin-orbital entanglement [3] also plays a role and magnetic frustration can be lifted by strong quantum fluctuations in the host. The spin-orbit coupling can cause more radical modifications of the spin-orbital order [2]. We suggest how such local or global changes of the spin-orbital order induced by impurities could be detected experimentally.

We report on NMR and torque measurements in magnetic fields (H) up to 34 T on the frustrated quasi-two-dimensional spin-dimer system $SrCu_2(BO_3)_2$, known as the first physical representation of the Shastry-Sutherland Hamiltonian and the archetype of the S=1/2 dimer systems exhibiting quantum magnetization plateaus in its magnetization curve [1,2]. In zero magnetic field, the ground state is a singlet separated by an energy gap from the first degenerated triplet excited state. Above a critical field which closes the gap, the dimers lattice starts to fill with triplets states which are usually described as hardcore (hc) bosons hoping from site to site. In $SrCu_2(BO_3)_2$, the frustration strongly hinders the kinetic energy of these hc-bosons, and, at some commensurate filling of the lattice, the balance between the kinetic and the repulsive energy favors the occurrence of quantum magnetization plateaus breaking translational invariance. Our measurements reveal a sequence of magnetization plateaus at 1/8, 2/15, 1/6, and 1/4 of the saturation and two incommensurate phases below and above the 1/6 plateau. The magnetic structures inferred from NMR have been successfully described as a stripe order of triplets in all plateaus, suggesting that the incommensurate phases originate from proliferation of domain walls. We propose that the magnetization process of SrCu2(BO3)2 is best described as an incomplete devil's staircase [3]. However, new theoretical calculations based on the iPEPS technique have shown that pairs of bound triplets were leading to more stable structures [4], different than those previously described in terms of dressed triplets, which are still to be confronted to the present NMR results.

TH.A-P11 - Measurements of transport and magnetic properties of layered antiferromagnet $FePS_3$ under pressure.

Matthew Coak [1], Y, Sebastian Haines [1 2] N, Siddarth Saxena [1]

1. University of Cambridge, United Kingdom
2. CamCool Ltd UK, United Kingdom

$FePS_3$ is structurally and magnetically quasi two-dimensional, with a magnetic ground state in which spins are ordered as ferromagnetic chains coupled antiferromagnetically., with a Neel Temperature of 120K, which the application of pressure increases. At ambient pressure, it is an insulator with a direct gap of approximately 0.5 eV and a room temperature resistivity of approximately 104 Ωcm. We present the results of exploratory resistivity, magnetisation and dielectric measurements under pressure for this material. The insulating phase is suppressed at a pressure in the range 40-70 kbar giving way to a new metallic phase. As yet unexplained intermediate behaviour is seen at pressures around the transition. At high pressure, the resistivity develops linear temperature dependence similar to that observed in Cuprates. At lower temperature, there is an observed upturn in resistivity. Pressures up to 100kBar have been measured in Bridgman Anvil cells, supported by piston cylinder clamp cell data.

TH.A-P12 - Magnetic properties and structure diversity in RE_2Ni_2X hydrides

S. Maskova [1], R. V. Denys [2], I. Halevy [3], V. Yartys [2], M. Giovannini [4], L. Havela [1]

We have been studying several RE_2Ni_2Mg compounds crystallizing in tetragonal Mo_2FeB_2 structure (P4/mbm). In this structure, RE atoms form a triangular motif bringing magnetic frustration into the system. As a consequence the magnetization typically shows several metamagnetic transitions. Magnetic properties are highly dependent on the exchange interactions between nearest (N) and next-nearest (NN) neighbors. Considering the role of the balance between the N- and NN-exchange we have decided to use the hydrogenation as the tool for weakening their absolute and relative strengths. It was found that these compounds tend to absorb up to 8 H/f.u. The crystal structure is changed to monoclinic structure (space group P21/c). The magnetic ordering temperatures of all RE-compounds studied are dramatically reduced by the hydrogenation. Such general dramatic weakening of the RKKY exchange interaction should have a strong reason - most likely the impact of hydrogenation on the system of conduction electrons. The compounds with magnesium will be compared with isostructural indides and stannides which yield different types of hydrides.

TH.A-P13 - Quantum critical point of UCoAl determined by AC magnetic susceptibility

UCoAl is known as an itinerant-electron metamagnet. The first-order metamagnetic transition occurs at Hm=0.6T and its critical temperature Tcr is about 11K. The non-Fermi liquid (NFL) behavior is found in the paramagnetic state. Relatively low Hm Tcr with the NFL behavior indicate that UCoAl is situated in a proximity to ferromagnetic order and is expected to be reachable to the so-called quantum critical point (QCP) of itinerant-electron ferromagnet by applications of pressure and magnetic field. In order to verify the existence of the QCP in UCoAl we performed the AC magnetic susceptibility measurements under pressure and determined T-P-H phase diagram. The AC magnetic susceptibility can determine the critical point (CP) precisely since its real part diverges toward the CP and its imaginary part detects a hysteresis varnishing at the CP. The obtained T-P-H phase diagram and its QCP are different from the previous report by Aoki, et al. [1]. The present study indicates that QCP is located at P~2.8 GPa and H~13 T. The critical line of the metamagnetic transition changes in slope at 1.5 GPa. From the comparison between our result and the previous one, we discuss an unusual nature of the magnetic phase diagram realized in UCoAl.

TH.A-P14 - Quantum crystallization of magnetic quasiparticles in a dimer magnet $Ba_2NiSi_2O_6Cl_2$

M. Koike [1], M. Okada [1], N. Kurita [1], H. Tanaka [1], H. Uekusa [1], K. Johmoto [1], A. Matsuo[2], K. Kindo[2]

2. The University of Tokyo, Japan

A spin dimer system, in which two spins are coupled by antiferromagnetic exchange interaction, has generally a gapped singlet ground state. The triplet excitations can hop to neighboring dimers and interact one another by the transverse and longitudinal components of interdimer interactions, respectively. If the frustration between interdimer interactions is imperfect, triplets are delocalized, so that magnetization slope appears in the magnetization process. On the other hand, if the frustration is perfect, triplets are localized and crystallized, which leads to a stepwise magnetization process with a plateau occurs. In this work, we synthesized single crystals of spin-one dimer magnet $Ba_2NiSi_2O_6Cl_2$ and determined its crystal structure. The crystal structure is monoclinic and is closely related to the structure of $Ba_2NiSi_2O_6Cl_2$ [1]. With decreasing temperature, the magnetic susceptibilities for H//c and H//ab exhibit rounded maxima at T=55 K and T=71 K, respectively, and decrease towards zero. These susceptibility properties indicate the presence of large single-ion anisotropy and the singlet ground state with excitation gap. It is also found that $Ba_2NiSi_2O_6Cl_2$ exhibits a stepwise magnetization process with two plateaus at one-fourth and one-half of the saturation magnetization. The 1/2 plateau manifested by the gapped triplet ground state is almost exactly given by the simple product of triplet dimers. On the other hand, the 1/4 plateau states, where the spin triplet are localized owing to the almost perfect frustration of interdimer exchange interactions, are almost exactly given by alternate product of singlet and triplet dimers. This result suggests that the frustration between interdimer interactions of this crystal is nearly perfect. We will discuss magnetic properties of $Ba_2NiSi_2O_6Cl_2$ by comparing those of $Ba_2NiSi_2O_6Cl_2$.

TH.A-P15 - Ferromagnetism in two band metals: the very strong coupling limit

C. M. Chaves [1], E. J. Calegari [2], S. G. Magalhaes [3], A. Troper [1]

1. Centro Brasileiro de Pesquisas Fisicas, Rio de Janeiro, Brazil
2. Laboratorio de Teoria da Materia Condensada, Departamento de Fisica - UFSM, Santa Maria, RS, Brazil
3. Instituto de Fisica, Universidade Federal Fluminense, Niteroi, Rio de Janeiro, Brazil

The main purpose of this paper is to examine the occurrence of ferromagnetism in metals at the very strong coupling regime (U tending to infinity) in the single-site approximation (SSA). The metal is described by a realistic two hybridized bands, one including Hubbard correlation and the other an uncorrelated one.We parametrize the ratio of the band widths and their centers as well.
In this method (SSA) the Hamiltonian is approximated by an effective and simpler one in which only one site retains the full correlation (U) while in the others acts an internal field, the self-energy. This field does not depend on the wave vector and is self-consistently determined by imposing the translational invariance of the problem, a coherent potential approximation (CPA) procedure. We also introduce the Roth's wave vector and spin dependent band shift W.
For several total electronic occupation numbers (ntot) we compare the spin dependent free energy with the corresponding paramagnetic one at T=0. We conclude making a critical analysis of the Roth's method for this problem arguing that the existence of a stable ferromagnetic state in this regime depends on a strong competition among W. the limit U tending to infinity, V, and on the relation between the two bare bands.

TH.A-P16 - Anomalous weak ferromagnetism of non-magnetic Sc, La, Eu, Y, Lu ion substituted RB4 (R = Sm, Gd, Tb, Dy, Ho, Er)

B. Kang [1], S. Lee [1], M. Song [1], D.Kim [2], J.Kim [3], B. Cho [1]

1. School of Materials Science And Engineering, Gwangju Institute of Science And Technology, Republic of Korea
2. Department of Physics, POSTECH, Republic of Korea
3. Pohang Accelerator Laboratory, Republic of Korea

Recently, the weak ferromagnetism of $Tb_{1-x}Y_xB_4$ and $Dy_{1-x}Y_xB_4$ was reported. Rare earth tetraborides (RB4) compounds belong to a geometrically frustrated magnetic system. The network of rare-earth ions, which have the same z position (z = 0), forms the Shastry-Sutherland lattice (SSL). SSL have various ground states depending on the ratio of Jnn (exchange interaction of nearest neighbor) and Jnnn (exchange interaction of next nearest neighbor). Because the non-magnetic ion substitution induced a fluctuation to the delicate equilibrium of RB4, the result of substitution revealed the exotic weak ferromagnetism. In this study, non-magnetic Sc, Y, La, Eu, Lu ion replaced the rare-earth ion in the other RB4 (R = Sm, Gd, Tb, Dy, Ho, Er) to find universality of weak erromagnetism and increase the magnitude of weak ferromagnetism. As a result, we could find the weak ferromagnetism in R1-xRí»xB4 (R = Sm, Gd, Tb, Dy, Ho, Er), (Rí» = Sc, Y, La, Eu, Lu). The universality was confirmed. Moreover, the magnitude of weak ferromagnetism reached four times larger than Y substitution case. In order to find the origin of the weak ferromagnetism, single crystal neutron scattering and a soft x-ray magnetic circular dichroism were performed. As a result, it is confirmed that rare-earth ion manifest the weak ferromagnetism.

TH.A-P17 - Anomalous spin dynamics of coupled spin-tetramer system $CuSeO_3$

W.Lee [1], S. Lee [1], K.Choi [1], J. van Tol [2], A. Ozarowski [2], P. L Kuhns [2], Arneil P Reyes [2], Helmuth Berger [3]

1. Department of Physics, Chung-Ang University, Seoul 156-756, Republic of Korea
2. National High Magnetic Field Laboratory, Florida State University, Tallahassee, United States
3. Institute of Condensed Matter Physics, EPFL, Lausanne, Switzerland

We report high-field magnetization, 77Se nuclear magnetic resonance (NMR), and electron spin resonance (ESR) measurements of the coupled spin-tetramer system $CuSeO_3$ (P21/n), which consists of strongly coupled (dimer-like) Cu(1) spins and weakly coupled Cu(2) spins. At zero field this compound undergoes long-range antiferromagnetic order at TN = 9 K. Thus, $CuSeO_3$ constitutes a promising candidate to investigate the interplay of inter-tetramer interactions with built-in tetrahedral frustration. We observe the half-step magnetization plateau at mu0H = 42-50 T, depending on a crystallographic orientation. This is expected for a chainlike array of tetrahedral spin clusters. With decreasing temperature both the ESR linewidth and g-factor decrease monotonically down to 50 K and then show the respective critical-like broadening and shift at TN = 9 K. The nuclear spin-lattice relaxation rates, 1/T1, measured at mu0H = 9.9 and 10.1 T exhibit a critical divergence at TN = 10.0 K. Noticeably, the critical temperature at finite external field is higher than the zero-field one, suggesting the significance of singlet fluctuations. In a magnetically ordered phase, both the linewidth of antiferromagnetic resonance mode and 1/T1 show an anomaly at T* = 6.0(5) K as evident from a change of their exponent. This result is attributed to a spin reorientation and is discussed in terms of a large difference of an energy scale between the Cu(1) and Cu(2) spins.

TH.A-P18 - Bose-einstein condensation vs. crystallization of magnons in dimer magnets $Ba_2MSi_2O_6Cl_2$ (M=Co, Cu)

M. Okada [1], N. Kurita [1], H. Tanaka [1], K. Johmoto [2], K. Fujii [2], H. Uekusa [2], A. Matuo [3], K.Kindo [3], M. Tokunaga [3], H. Nojiri [4], M. Nakamura[5], S. Nishimoto[6]

4. Institute for Materials Research, Tohoku University, Japan
5. Institute of Industrial Science, the University of Tokyo, Tokyo, Japan
6. Institute for Theoretical Solid State Physics, IFW Dresden, Germany

A quantum magnet composed of spin dimers generally has an energy gap between a singlet ground state and an excited triplet state. It is known that the magnetic-field-induced magnetic ordering in the dimer magnet can be described as Bose-Einstein condensation (BEC) of Sz=1 triplets (magnons). The BEC of magnons is observed in many dimer magnets. When the hopping of magnons is strongly suppressed, magnons undergo crystallization in magnetic fields owing to the repulsive interaction. The experimental realization of the magnon crystallization is little. Recently, we synthesized new dimer magnets $Ba_2MSi_2O_6Cl_2$ (M=Co and Cu) and investigated their magnetic properties via magnetization measurements using single crystals. The crystal structures of the present systems are closely related to the structure of $Ba_2CuSi_2O_6$. In analogy with the case of $Ba_2CuSi_2O_6$, the exchange network in $Ba_2MSi_2O_6Cl_2$ is expected to be a two-dimensional. With decreasing temperature, the magnetic susceptibilities of $Ba_2MSi_2O_6Cl_2$ exhibit rounded maxima and decrease rapidly, indicating the gapped ground states. We found that $Ba_2CoSi_2O_6Cl_2$ shows a sharp stepwise magnetization process with 1/2 magnetization-plateau, irrespective of the field direction. Because all the dimers are crystallographically equivalent, the possibility that there are two kinds of isolated dimer of the same number is ruled out. Thus, the stepwise magnetization process is attributed to the crystallization of magnons. The absence of magnetization slope indicates that the frustration in interdimer interactions is almost perfect. In contrast to $Ba_2CoSi_2O_6Cl_2$, $Ba_2CuSi_2O_6Cl_2$ exhibits no plateau in the magnetization process, which is indicative of weak frustration in the interdimer interactions. The non-linear slope of magnetization curve between two critical fields, where BEC of magnons occurs, is well reproduced by the exact diagonalization for the two-dimensional (2d) dimer array. $Ba_2CoSi_2O_6Cl_2$ and $Ba_2CuSi_2O_6Cl_2$ are magnetically described as strongly and weakly frustrated quasi-2d dimer magnets, respectively.

TH.A-P19 - Magneto-electric effects in the interacting dimer system TlCuCl3

K. Kakihata [1], Y. Sawada [1], S. Kimura [1], K. Watanabe [1], M. Hagiwara [2], H. Tanaka [3]

1. Institute For Materials Rseach, Tohoku University, Japan
2. Center for Advanced High Magnetic Field Science, Osaka University, Japan
3. Tokyo Institute of Technology, Japan

$TlCuCl_3$ is known as the three-dimensionally coupled S = 1/2 antiferromagnetic dimer system, composed of Cu^{2+} spins. This material has a finite energy gap D/k_B ~ 7.5 K between the singlet state and the first excited triplet states. The magnetic excitation is described as Bosonic quasiparticle "triplon", which is the triplet excited on a dimer propagating through a crystal. When the energy gap is collapsed by applying a magnetic field of $H_g = D/gm_B$ ~ 6 T, the quasiparticles are induced in the ground state, and then the Bose-Einstein condensation occurs, resulting in antiferromagnetic order[1, 2]. The wave function of the field-induced phase on a dimer is described by a superposition of the singlet and triplet states, and such a superposition gives a finite expectation value of the vector spin chirality. Therefore, we expect that the spontaneous electric polarization is induced by the spin current mechanism[3] in the magnetically ordered phase of $TlCuCl_3$. To confirm this expectation, we have performed pyroelectric current measurements to observe the polarization using 15 and 18 T superconducting magnets at Institute for Materials Research in Tohoku University. As a result, we succeeded in observing the appearance of the spontaneous electric polarization the field-induced antiferromagnetic ordered phase when the sample is cooled down in magnetic and electric fields applied perpendicular to (010) and (10-2) planes, respectively. The evaluated value of the electric polarization is approximately 7 mF/m^2 at 2 K and at 14 T. Therefore, we conclude that the spontaneous electric polarization is induced in the magnetically ordered phase of $TlCuCl_3$.

5. Department of Physics, Faculty of Science, University of Zagreb, Zagreb, Croatia

We report NMR investigation of three archetypal, quasi-1D, antiferromagnetic quantum spin systems in which the magnetic-field-induced phase transition can be described as Bose-Einstein condensation (BEC). The two spin-1/2 ladders compounds, $(C_5H_{12}N)_2CuBr_4$ called 'BPCB' [M. Klanjsek et al., PRL 101, 137207 (2008)] and $(C_7H_{10}N)_2CuBr_4$ called 'DIMPY', are respectively representative of the repulsive and attractive interaction in a description in terms of the hard-core bosons. They are perfect model systems for quantitative studies of the Tomonaga-Luttinger Liquid description, enabling us to relate the temperature dependence of the low-energy spin fluctuations, measured through 1/T1 NMR relaxation rate, to the type of interaction. NMR data have thus provided the first direct evidence for the attractive interaction [M. Jeong et al., PRL 111, 106404 (2013)]. Our subsequent high-field measurements demonstrated that the field dependence of 1/T1 provides a simple experimental criterion to distinguish between the two regimes. The third compound, NiCl2-4SC(NH2)2 called 'DTN', contains chains of S=1 spins subject to single-ion anisotropy, making its low-energy Hamiltonian equivalent to the one of BPCB. While DTN is less one-dimensional, it allows better experimental access to the low-temperature 3D regime. In DTN and BPCB the 1/T1 data have provided the first detailed insight on quantum-critical spin dynamics, establishing the scaling behaviour and its universality for the quasi-1D regime [S. Mukhopadhyay et al., PRL 109, 177206 (2012)]. Further analysis and new data showed that the 1D regime of scaling observed in BPCB perfectly agrees with the state-of-the-art numerical predictions for hard-core bosons in 1D, while the 3D regime observed in DTN can be favourably compared with the mean-field-based theoretical prediction for hard-core bosons in 3D. The NMR data on the BEC phase in DTN provided the first insight into its low-energy dynamics. Finally, in the Br-doped DTN we established the first NMR signature of the disorder-induced Bose-glass phase.

TH.A-P21 - Magnetic polarization of the americium J = 0 ground state in $AmFe_2$

N. Magnani [1], R. Caciuffo [1], F. Wilhelm [2], E. Colineau [1], R.Eloirdi [1], J. Griveau [1], J. Rusz [3], P. Oppeneer [3], A. Rogalev [2], G.H. Lander [1]

3. Department of Physics and Astronomy, Uppsala University,Sweden

Ordered magnetism is a result of spin polarization of the electrons, but there are two elements in the periodic table in which the intrinsic magnetic moment is zero despite the electrons being spin-polarized: europium and americium. For the free Eu(III) and Am(III) ions the f-electron count is six, the spin and orbital moments have the same magnitude and opposite direction, and the resulting J = 0 ground state is non-magnetic. Nevertheless, since a large spin polarization is present, the application of a magnetic field can induce a moment by mixing with excited states. Europium, however, has a tendency towards the magnetic divalent configuration and loses its magnetism only under high pressure. Americium, in contrast, exhibits a stable trivalent oxidation state and, like most of its compounds, shows temperature independent susceptibility and no ordered magnetism.
One can expect that long-range order of the moments induced in the virtually nonmagnetic sublattice will be evident when these ions are embedded in a strong ferromagnetic matrix, because of the large molecular field created by the exchange interaction. Using the technique of x-ray magnetic circular dichroism, we show that this is the case in $AmFe_2$. Our result not only confirms the previous indication on the total Am moment from neutron diffraction experiments, but by probing the orbital and the effective spin moment separately, it allows us to attribute the resultant induced moment (antiparallel to the Fe one) to significantly localized 5f electrons, a situation very different to the isostructural UFe_2.

TH.A-P22 - Magnetic properties of single crystals of the S=2 quasi-1d heisenberg antiferromagnet MnCl_3(bpy)

M. Hagiwara [1], S.Shinozaki [1], A. Okutani [1], D.Yoshizawa [1], T. Kida [1], T.Takeuchi [2], O. Risset [3], D.Talham [3], M. Meisel [4]

4. Department of Physics and National High Magnetic Field Laboratory, University of Florida, Gainesville, United States

Recent theories have unveiled topological differences between one-dimensional (1D) Heisenberg antiferromagnets (HAFs) with odd and even integer spins [1, 2]. With this renewed interest, we report the experimental results of single crystal samples of $MnCl_3$(bpy) (bpy=2, 2'-bipyridine) (monoclinic *Cc*), which is regarded as a $S = 2$ quasi-1D HAF. The magnetic susceptibilities (H = 0.1 T, 2 K ≤ T ≤ 300 K) along the a^*, b, and c axes show broad maxima around 100 K. However, the magnetic signal along the c-axis (chain direction) decreases steeply with T < 100 K, while the responses along the other directions decrease gradually to $T \approx$ 25 K, where they increase rapidly at lower temperatures. A sharp peak is observed at 11 K for the b-axis, which may correspond to the anomaly observed in a powder sample [3]. The specific heat shows a tiny peak around 11 K, suggesting long-range order. For H || c-axis, a spin-flop transition is seen at 22 T, while the magnetizations along the other directions show monotonic increases. Hysteresis along the b-axis below 4 T is interpreted in terms of the crystal structure.

TH.A-P23 - AC susceptibility evidence for a tricritical point in the ferromagnet $NdOs_4As_{12}$

A. Rudenko [1], Z. Henkie [1], T. Cichorek [1]

1. Institute of Low Temperature And Structure Research, Polish Academy of Sciences, Poland

Revised theories of the quantum phase transition in metallic ferromagnets point at similar results irrespective of the microscopic origin of the magnetization, i.e., the quantum phase transition from a metallic paramagnet to a ferromagnet in the absence of quenched disorder is generically discontinuous or of first order, in contrast to the second-order transition with mean-field critical behavior predicted by the Hertz theory. In particular it holds also for ferromagnets with localized magnetic moments [1].
Recent specific-heat experiments on ferromagnetic $NdOs_4As_{12}$, with a Curie temperature T_C = 1.0 K and a $\Gamma_{67}^{(2)}$ quartet ground state of the Nd^{3+} multiplet, revealed its anomalous low-temperature properties in finite magnetic fields [2]. While a smooth increase of T_C was observed with magnetic field applied along the easy magnetic [100] axis, for B II [111] we have found a qualitatively different behavior: the ferromagnetic peak is not resolved at around 1 K and, most remarkably, a clear anomaly is observed at ~ 0.7 K in B = 0.25 T. In a sharp contrast to $NdOs_4As_{12}$, the antimony-based counterpart $NdOs_4Sb_{12}$ (T_C = 0.9 K and a Γ_5 doublet ground state) exhibits an isotropic behavior in externally applied fields. Here, we present AC susceptibility evidence for a field-driven tricritical point in ferromagnetic $NdOs_4As_{12}$: With gradually increasing DC field up to 300 Os applied along the hard magnetic [111] axis, both the real and imaginary components of AC susceptibility are shifted towards lower temperatures. Such a response of AC magnetometry has not been observed for B II [100] and in $NdOs_4Sb_{12}$ as well.

TH.A-P24 - Ferromagnetic state of SU(3) hubbard model on the Lieb lattice

W. Nie [1], W. Zhang [2], H. Zhai [1]

1. Institute For Advanced Study, Tsinghua University, China
2. Department of Physics, Renmin University, China

The investigation of itinerant electrons' ferromagnetism is one of the central and challenging topics in condensed matter physics. Due to the subtle sign problem of fermions, rigorous proofs for ferromagnetism of fermionic Hubbard model are very limited [1-3], which are bench marks for the magnetic properties of the ground state. One noted example is that Lieb has proved the unsaturated ferromagnetism for the Hubbard model with SU(2) symmetry on the Lieb lattice at half filling, when the repulsive interaction is finite[3].
The systematic study of SU(N) Hubbard model at large-N limit was initiated in the context of high-T superconductivity as a theoretical tool [4]. The realization of SU(N) Hubbard has not only been theoretically proposed [5], but also has been experimentally realized by loading ultracold Yb atoms in optical lattice [6]. It calls for the theoretical prediction for the magnetic property of the ground state of SU(N) Hubbard model, for the experimental observation.
In this work, we investigate the magnetic property of the ground state of the Hubbard model with SU(3) symmetry on the Lieb lattice, with finite repulsive interaction. Our mean-field calculation shows, the ground state shows ferromagnetic order from 1/3 to 2/3 filling.

Quantum antiferromagnets are ideal candidates for the thorough study of the effects of disorder on strongly-interacting quantum systems. It is known that a dimerized S=1/2 spin system can be exactly mapped to a lattice gas of bosons with hard-core repulsion and that these bosons can condense, leading to exotic magnetically ordered states. This mapping enables us to analyse disordered quantum antiferromagnets using the existing framework developed to characterise the disordered Bose-Hubbard model. Using this, we can connect the magnetic glass phases seen in experiments with the much-studied Bose glass and Mott glass phases of disordered bosons on a lattice.
Here we present an analytic calculation of the phase diagram of a 3D dimerized quantum antiferromagnet with intra-dimer bond disorder. First we develop the formalism in the clean system, mapping it to a lattice gas of bosons and using a strong-coupling expansion around the atomic limit, followed by a momentum-shell renormalization group analysis to obtain the phase diagram. We then extend the formalism to look at the effects of disorder, establishing the phase diagram and examining the magnetic glass phases obtained as a result. We discuss their connection to recent experiments on disordered quantum antiferromagnets, as well as their analogues in optical lattice systems.

TH.A-P26 - Neutron diffraction study of proton disorder in D2O - ice

Water ice (H2O) at low pressure can be understood as a hexagonal structure where each Oxygen atom covalently bonds to two Hydrogen atoms. Further, each bond between Oxygen atoms is occupied by only one Hydrogen atom. These are the famous ice - rules that give rise to a highly disordered ground state with a residual entropy of R Ln (3/2). We have measured the diffuse scattering of a large D2O ice crystal using neutron diffraction. Here we present an analytical model of the hydrogen configuration in water ice in contrast to previous Monte-Carlo studies.

TH.A-P27 - $BaAg_2Cu[VO_4]_2$ quantum magnet: local probe studies (ESR and NMR)

E.Vavilova [1], Y. Krupskaya [2], M. Schäpers [3], A. Wolter-Giraud [3], H. Grafe [3], V.Kataev [3], A. Müller[4], B. Büchner [3]

3. IFW-Dresden, Germany
4. University of Houston, United States

$BaAg_2TM[VO_4]_2$ is a new material class with the flexible spin exchange topology. The unit cell of $BaAg_2Cu[VO_4]_2$ exhibits two crystallographic non-equivalent V sites located in a VO_4 tetrahedra. These VO_4 tetrahedra are connected to alternating non-equivalent Cu chains with slightly different bond angles. It creates two types of Cu chains with ferro- and anti-ferromagnetic intra-chain coupling. High-field ESR and NMR are the sensitively probes of local magnetism in $BaAg_2Cu[VO_4]_2$ that allows to investigate the internal field distribution in the different chains and FM and AFM correlations at low temperatures. The compound demonstrate the structure-driven tunability of magnetic couplings and can be a flexible toy model for studies of Heisenberg quantum magnets

TH.A-P28 - Slow thermodynamics in the phase separated state of the bilayered manganite $(La_{0.4}Pr_{0.6})_{1.2}Sr_{1.8}Mn_2O_7$

H. Taniguchi [1], Y. Nakamura [1], H. Takahashi [1], T. Konno [1], M. Matsukawa [1], R. Suryanarayanan [2]

1. Iwate University, Japan
2. Univ. Paris-Sud, Paris, France

Perovskite-type manganites fascinate many researchers with their various exotic phenomena. For example, double-layered $La_{1.2}Sr_{1.8}Mn_2O_7$ exhibits ferromagnetic-metal (FMM) to paramagnetic-insulator (PMI) transition and colossal magneto-resistance (CMR) effect. The transition temperature is suppressed by substituting Pr at La sites, and $(La_{0.4}Pr_{0.6})_{1.2}Sr_{1.8}Mn_2O_7$ exhibits metamagnetism.

To better understand thermodynamic properties of phase separated manganites, we investigated the time dependence of the remanent specific heat in $(La_{0.4}Pr_{0.6})_{1.2}Sr_{1.8}Mn_2O_7$. First, the field dependence of the specific heat was measured at several fixed temperatures. In increasing field, the specific heat was notably suppressed at a certain field, indicating the transition from PMI to FMM, which is accompanied by entropy reduction. Interestingly, the suppressed specific heat did not recover enough in decreasing field down to 0 T.

This result implies that the paramagnetic-insulating and ferromagnetic-metallic phases coexist with spatially separated. The thermodynamic phase diagram obtained from the specific heat data coincide well with that from the magnetization.

Next, we focused on the remanent specific heat and observed its relaxation at several temperatures. The relaxation curves were found to be fitted well by stretched exponential functions. This result is similar to the cases of other physical quantities like magnetization, and indicates a complicated relaxation process in $(La_{0.4}Pr_{0.6})_{1.2}Sr_{1.8}Mn_2O_7$. The relaxation time estimated from the fitting is remarkably long: it exceeds one day below 25 K.

To summarize, we examined the thermodynamic phase diagram and thermal relaxation process in the phase separated state of the bilayered manganite $(La_{0.4}Pr_{0.6})_{1.2}Sr_{1.8}Mn_2O7$ single crystal, utilizing the specific heat measurements under magnetic field. Our findings indicate the existence of slow thermodynamics associated with magnetic frustration between double exchange and superexchange interactions.

TH.A-P29 - Pinning effect in chiral soliton lattice $CrNb_3S_6$

6. RIKEN Center for Emergent Matter Science (CEMS), Wako, Japan

$CrNb_3S_6$ is one of the chiral magnets, and forms chiral soliton lattice (CSL) by applying small magnetic fields perpendicular magnetic modulation vector q. It has been investigated by magnetic, electric transport properties measurements on single crystals and by first-principles calculations [1-2]. Quantized spatial periods of the CSL, which corresponds to topological charges, can be controlled continuously by applying magnetic fields. In order to study the magnetic-field dependence of the magnetic structure for the CSL in more detail, we performed a small-angle resonant soft x-ray scattering in a single crystal $CrNb_3S_6$ by using Cr L_3-edge at BL-16A in KEK-PF, Japan.
We observed gradual decrease in the spatial period as increasing magnetic fields and higher harmonic magnetic reflections ($2q$ and $3q$) at 0.23 T, indicating the transformation of magnetic structure from the helix to the CSL. On the other hand, the spatial period was found to increase in a stepwise manner in the field-decreasing process, suggesting that the CSL is strongly pinned at some metastable states during transforming from the CSL to the helical magnetic structure [3].

Cobalt oxides have attracted attention due to their anomalous electric/magnetic properties such as a large thermoelectric power [1]. Among the cobalt oxides, a quasi-one-dimensional cobaltate $Ba_3Co_2O_6(CO_3)_{0.7}$ has fairly large thermoelectric power, comparable to that of $NaxCoO_2$ and electrical resistivity with metallic behavior above 300 K [2] and the magnetic susceptibility increases below ~100 K along the face-sharing CoO6 chains [3, 4]. In order to clarify the relationship of its thermoelectric properties to the electronic states, we have investigated the electronic structure of $Ba_3Co_2O_6(CO_3)_{0.7}$ by using three-dimensional angle-resolved photoemission spectroscopy.
Here, we found at least three dispersive features with Co 3d character near the Fermi level (EF). We also observed two dispersive bands along the CoO_6 chain at the binding energy of 1 ð 3 eV that show quasi-one dimensional electronic structure, while there is one band around 0.5 eV that has two-dimensional anomaly. From the temperature dependence, we found the spectral weight near the valence band maximum (EF ~ 0.5 eV) increases at temperatures above 150 K, while one around 1 eV decreases. The results suggest that the thermodynamic properties of $Ba_3Co_2O_6(CO_3)_{0.7}$ originates from strong CoO_6 inter-chain interaction.

TH.A-P32 - Substitution effects in an itinerant electron metamagnetic compound $SrCo_2P_2$

I.Masaki [1], C. Michioka [1], H. Ueda [1], A. Matsuo [2], K. Kindo [2], K. Yoshimura [1,3]

1. Graduate School of Science, Kyoto University, Japan
2. Institute for Solid State Physics, The University of Tokyo, Japan
3. Research Center for Low Temperature and Materials Sciences, Kyoto University, Japan

Layered compounds ACo_2P_2 (A = alkaline earth metals, rare earth metals) with $ThCr_2Si_{2\text{-type}}$ structure (I4/mmm) generally have ferromagnetic interactions in CoP layers. For example, $LaCo_2P_2$ shows ferromagnetic ordering [1]. $SrCo_2P_2$ is a nearly ferromagnetic metal without magnetic ordering at zero magnetic field [2]. With applying high magnetic field, $SrCo_2P_2$ shows an itinerant metamagnetic transition from an enhanced Pauli paramagnetic state to a ferromagnetic state [3]. Such the metamagnetic transition can be observed in the vicinity of an itinerant ferromagnetic quantum critical point. Actually, $SrCo_2P_2$ is in the vicinity of ferromagnetic quantum point, as Jia et al. reported ferromagnetic quantum critical behavior and the quantum critical point in $SrCo_2(P_{1-x}Ge_{1-x})2$ system [2].
In this work, we focused on the itinerant electron metamagnetic transition of substituted $SrCo_2P_2$ systems. We synthesized $(Sr_{1-x}La_x)Co_2P_2$ and $SrCo_2(P_{1-x}Ge_{1-x})2$ substituted systems and studied their magnetic properties. $(Sr_{1-x}La_x)Co_2P_2$ shows ferromagnetic ordering in $x > 0.5$. On the other hand, $SrCo_2(P_{1-x}Ge_{1-x})_2$ have a ferromagnetic ground state with an intermediate substituted region of $0.3 < x < 0.675$, which is consistent with previous report [2]. The metamagnetic transition cannot be observed up to 60 T in more than only 5% La and 10% Ge substitutions. The ferromagnetic phase with La and Ge substituted compounds and the field-induced ferromagnetic phase are separated in the magnetic phase diagram. These results suggest that the carrier doping effects drastically in this metamagnetic transition and that both ferromagnetic and field-induced ferromagnetic phases should originate in different bands.

We report on a comprehensive angular- and temperature-dependent electron spin resonance (ESR) study of $Cu(C_8H_6N_2)Cl_2$, a spin-1/2 strong-rung two-leg ladder compound. At temperatures above $T^* = 8$ K, only a single ESR line is observed. Below T^*, the ESR line splits into two components, reflecting the presence of a finite anisotropy. The splitting is explained by taking into account a magnetic dipole-dipole interaction. The temperature dependence of the ESR linewidth above T^* is analyzed in the frame of a bosonization approach suggesting the exchange anisotropy as the main source for the ESR line broadening.

TH.A-P34 - Unusual magnetic ordering of the frustrated triangulated-kagome antiferromaget, Cu_9 (cpa) $6Cl_2 \bullet nH_2O$

A. Matsuo [1], H. Kikuchi [2], T. Asano [2], H. Nakata [2], N. Kasamatsu [2], K. Kunieda [2], Y. Fujii [3], Y. Inagaki [4], K. Kindo [1]

4. Department of Applied Quantum Physics, Kyushu University, Japan

Geometrically frustrated systems, in particular kagome lattice, are interesting subjects due to the novel physics that can appear in the magnetic fields. Among many investigated actual materials, Cu9(cpa)6Cl2•nH2O (cpa=2-C-carboxypentonate) is noteworthy because of its unique structure, that is, Cu2+ ions form triangulated-kagome lattice in which a triangular lattice in kagome lattice is occupied by four small triangular lattices. This unique structure is theoretically expected to show new magnetic properties such as a 4/9-plateau in its magnetization curve [1]. We determined the concentration of water molecules “n” is 20 by the chemical analysis and investigated its magnetic properties using magnetic susceptibility, specific heat and high field magnetization measurements. Although Weiss temperature of this magnet is large, no magnetic long-range ordering (LRO) is observed above 2 K. The specific heat measurement of this magnet was performed down to about 0.3 K and no sharp peak accompanied by the occurrence of LRO is observed. On the other hand, very broad and small peak is observed at around 3 K. As increasing magnetic field this broad peak diminishes and disappears. The high field magnetization at 4.2 K measured up to 60 T in the pulsed magnetic field shows the relatively steep slope until 10 T and the monotonically increase to 60 T and reaches less than 1/3 of the saturation moment. All the results, especially magnetic susceptibility and specific heat indicate this magnet is a good frustrated system.

TH.A-P35 - Selection rule of the direct transition in the spin gap system studied by high field ESR measurements

S. Kimura [1], K. Watanabe [1], M. Hagiwara [2], H. Tanaka [3]

1. Institute For Materials Research. Tohoku University, Japan
2. Center for Advanced High Magnetic Field Science, Osaka University, Japan
3. Tokyo Institute of Technology, Japan

The direct transition between the singlet and triplet states in spin gap systems, observed by electron spin resonance (ESR) measurement, is a useful phenomenon to investigate such systems, because the field dependence of the spin gap can be revealed in high accuracy. The direct transition is forbidden in principle for usual magnetic dipole transition, because the total spin quantum number should be conserved for the magnetic dipole transition. The Dzyaloshinskii-Moriya interaction or the staggered magnetic field, which is antisymmetric with exchanging the neighboring spins, was proposed as the origin of the finite probability of the direct transition [1]. However, to clarify the mechanism of the direct transition experimentally, the selection rule of the direct transition should be investigated in detail by the ESR measurements illuminating polarized electromagnetic wave to the sample. In this study, we have carried out the high field ESR measurements of the interacting dimer system KCuCl3 in illuminating both linearly and circularly polarized electromagnetic waves at 162 GHz. KCuCl3 is known to show the direct transition to the first excited states at wave vectors q = [000] and [001] [2]. Our measurements have observed curious polarization dependence of the ESR signal for the direct transition at q = [001]. Different from a usual magnetic dipole active ESR signal, the signal from the direct transition, observed in the static field parallel to the b-axis, is revealed to show absence of circular dichroism.

2. Centro Brasileiro de Pesquisas Fisicas (CBPF), Rio de Janeiro, Brazil
3. Instituto de Fisica, Universidad de Antioquia (UdeA), Medellin, Colombia

$FeGa_3$ stands out among Fe-based intermetallic compounds for its diamagnetic semiconducting behavior with energy gap of 0.5 eV, and more so due to striking effects caused by chemical substitutions. Ge-doping ($FeGa_{3-y}Gey$) rapidly leads to a paramagnetic metallic state, followed by a magnetically ordered state for $y > 0.13$, with TM reaching 75 K for $y = 0.41$. This evolution of the electronic ground state is accompanied by anomalous magnetic behaviors that are under intense debate in the literature, including the nature of the magnetic interactions (localized vs. itinerant, ferro- vs. antiferromagnetic), non-Fermi liquid behavior, effective mass renormalization and the presence of a Quantum Critical Point. Here we present a combined study involving growth and thermodynamic characterization of $FeGa_{3-y}Gey$ single crystals, Mössbauer spectroscopy and density functional theory (DFT) simulations, towards a better understanding of these magnetic anomalies. Low-field, temperature-dependent magnetization curves show predominantly ferromagnetic transitions for samples with $y > 0.13$, but also a smaller antiferromagnetic component which is suppressed under higher fields. Mössbauer spectra of a sample with $y = 0.27$ show two types of Fe ions with different magnetic hyperfine parameters and magnetic moments, despite the single crystallographic Fe site in the structure. DFT simulations were able to capture all these features: the distribution of Fe moments and the FM response depends on the Ge concentration but also on the Ge distribution on the Ga sites. At small Ge concentrations a localized distribution of moments in the neighboring Fe ions is favored, and in some cases an AFM component is found. We discuss the combined results in terms of a scenario wherein increasing Ge-doping leads to an evolution from mostly localized moments at small concentrations to a combination of both localized and itinerant moments in the magnetically ordered state, with respectively high and low magnetic moment distributions.

TH.A-P37 - Novel memory effects observed after temporary heating/cooling in Heisenberg spin glasses and spontaneous restoration of the spin configuration existing before

H. Mamiya [1]

1. National Institute for Materials Science, Tsukuba, Japan

Spin-glass has been one of the most-studied glassy systems; however, little is known regarding their nature. In this study, we carefully reexamine the features of the slow relaxations in order to clarify the nature by a detailed comparison with the energy landscapes predicted by the theories. Samples are materials regarded as a kind of Heisenberg spin glass: a dilute magnetic alloy Cu97Mn3, a dilute magnetic semiconductor Cd55Mn45Te, and a geometrically frustrated magnet ZnFe2O4. In our typical experiments, each sample was initially subjected to a magnetic field for a significant duration (aging.) Then the field was cut off and decay of thermoremanent magnetization was recorded on various thermal histories. Consequently, we found that the decay was extremely accelerated when the sample was temporarily heated/cooled midway through the isothermal relaxation. In contrast, in the cases that the sample was sufficiently aged in the magnetic field, the thermoremanent magnetization surprisingly increased despite absence of magnetic field when the temperature returned to the original after the temporary heating/cooling. In other words, the memory in the aging period returned despite once being rejuvenated. These phenomena were commonly observed in the three samples. Because the magnetization mirrors evolution of the spin configuration, these acceleration and reversion of the decay indicate that the configuration is destabilized when the temperature changes and it is spontaneously restored when the temperature is returned to the original. Whereas such destabilization and restoration do not occur if the spin glass is simply frozen, it is possible in an energy landscape with a temperature- sensitive funnel-like structure in the explored region. This finding has thus provided fresh insight into the stereotype of glassy systems: a disordered configuration frozen in numerous meta-stable states.

TH.A-P38 - Spin liquid ground state in a vanadium based S=1/2 trimerized kagome compound

J. Orain [1], F. Bert [1], P. Mendels [1], L. Clark [2], F. Himeur Aidoudi [2], P. Lightfoot [2], R. Edward Morris[2]

1. Laboratoire de Physique des Solides, UMR 8502 CNRS, Université Paris-Sud, Orsay, France
2. School of Chemistry and EaSTChem, University of St. Andrews, St. Andrews, United Kingdom

The search for quantum spin liquid states such as the resonant valence bond state (RVB) formed by the macroscopic resonance between the various spin singlet coverings of the lattice, is a major challenge in both experimental and theoretical condensed matter research [1]. The prime candidate to host this state of matter is the S=1/2 Kagome antiferromagnet (KAFM) in two dimensions. Among the rare experimental realizations of the KAFM model the recently syn- thesized compound, [NH4]2[C7H14N][V7O6F18] (DQVOF) [2], is the first one to host magnetically active V^{4+} (d1) ions rather than more usual Cu^{2+} (d9) thus allowing to investigate the effects of different perturbations to the ideal Heisen- berg Hamiltonian. Further, this compound seems to be the first experimental realization of the trimerized Kagome model, formed by two different equilaterals triangles, initially theoretically studied by M. Mambrini and F. Mila [3]. Our low temperature magnetization and specific heat results suggest that DQVOF is a good candidate for the S=1/2 KAFM physics despite a complex structure [4]. Besides, the low temperature specific heat and ÁSR studies evidence a gapless spin liquid behaviour down to 40mK. Recent NMR studies unveil the intrinsic susceptibility of the Kagome layers which is hidden in the macroscopic measurements by the Curie like interlayer V^{3+} contribution. Under strong magnetics fields, those studies revealed a spin gap of about 15 K (J/4). As a consequence, this material exhibits an exotic excitation spectrum, with a continuum of non magnetic excitations, quite remi- niscent of the short range RVB physics which could be remarkably favoured by the trimerization of the Kagome model.

TH.A-P39 - Sign reversal and non-monotonic magnetocaloric effect in $EuRhAl_4Si_2$

A. Maurya [1], P. Bonville [2], T. Arumugam [1], S. Dhar [1]

1. Tata Institute of Fundamental Research, India
2. CEA, CE Saclay, DSM/IRAMIS/SPEC/LNO 91191 GIF-SUR-YVETTE, France

The structure and magnetic properties of tetragonal quaternary $EuRhAl_4Si_2$ have been reported recently. It orders antiferromagnetically at ~12K. The isothermal magnetization along the two principle directions is highly anisotropic despite Eu^{2+} being an S-state ion which lacks crystal electric field anisotropy to the first order. The variation of entropy change, which is a measure of magnetocaloric effect, with field and temperature, calculated from the isothermal magnetization data taken at various temperatures along the principal crystallographic directions present equally unusual behavior in this compound. In the ordered state the entropy change is highly nonlinear below spin flip fields; however in the paramagnetic region, it is negative irrespective of the strength of applied magnetic field. From iso-field data, for H//[100], entropy change is initially positive before a crossover temperature of 7-10 K for fields 2T-7T, reaching a maximum of -16 J/Kg K at 12 K. For H//[001] the observed entropy change at 7T and at 12 K is -21 J/Kg K, which is large and comparable to the largest known values in this temperature range. The variation of the entropy vs. field plots strongly depends upon the direction of the applied magnetic field.

TH.A-P40 - Spin, charge and lattice dynamics in the frustrated Shastry-Sutherland system TmB4

S. Gabáni [1], I. Takáčová [1], K. Siemensmeyer [2], A. Bogach [3], N. Sluchanko [3], N. Shitsevalova [4], J. Prokleška [5], V. Sechovsk² [5], K. Falchbart [1], A. Ievdokimova [4]

3. General Physics Institute RAS, Moscow, Russian Federation
4. Institute for Problems of Materials Science NASU, Kiev, Ukraine
5. Faculty of and Mathematics and Physics, Charles University, Prague, Czech Republic

The metallic frustrated system TmB_4 with a so called Shastry-Sutherland lattice (SSL) exhibits a strong Ising-like anisotropy which orients the Tm^{3+} magnetic moments along the c-axis, and a rather complex phase diagram below $T_N \approx 11.7$ K can be observed. In the ordered antiferromagnetic state the magnetization M for magnetic field H // c reaches saturation M_S at about 40 kOe accompanied by various small hysteresis loop and fractional plateaus at e.g. $M/M_S \approx 1/9, 1/7, 1/6$ … (at different temperatures) followed by the main magnetization plateau at $M/M_S = 1/2$ (for all temperatures less then T_N). Those fascinating and theoretically explained [1-4] plateaus reflect various magnetic stripe structures and non-equilibrium magnetization dynamics.
In this contribution we have investigated the dynamic magnetization process of TmB_4 by measurements of M vs H at different field sweep rate of 200, 20 and 2 Oe/s at the lowest temperature 1.8 K. It is clearly demonstrated that the value of nonzero small plateau ($M/M_S < 1/2$) is elevated with the increase of stable temperature and with the decrease of magnetic field sweep rate. The received results are inconsistent with theoretical predictions by Glauber dynamics [2].
Moreover, experimental studies of the field dependence of charge mobility and of magnetostriction at 1.8 K and up to 80 kOe were carried out to specify the important role of conduction electrons in the indirect exchange interaction between Tm^{3+} magnetic ions and role of magnetoelastic interaction in the SSL of TmB_4, respectively.

5. The Rudolf Peierls Centre for Theoretical Physics, Oxford University, Oxford, United Kingdom

The study of emergent phenomena in interacting quantum systems is one of the main research topics of condensed-matter physics. Here we report experimental results of the quasi-1D Ising-like antiferromagnet $SrCo_2V_2O_8$.

The spin chains in $SrCo_2V_2O_8$ are formed by edge-shared CoO_6 (Co^{2+}; $3d^7$, effective S = 1/2) octahedra along the c axis and are separated by nonmagnetic VO_4 (V^{5+}; $3d^0$, S = 0) tetrahedra. In zero field, it orders antiferromagnetically below 5 K. The magnetic structure [characterized by k = (0 0 1)] consists of AFM chains along the c axis, that are arranged ferro-/antiferromagnetically along the a/b axes. In the pure 1D state ($T > T_N$), inelastic neutron scattering reveals a gapped continuum of spinons (spin-1/2 excitations) that are modeled nicely by the S=1/2 *XXZ* antiferromagnetic (AFM) chain with intrachain interaction constant J =7.0±0.1 meV and anisotropy parameter ε=0.50±0.02. Below TN, the continuum transforms into a hierarchy of discrete excited states indicating the confinement of the spinon-pairs due to the linear interacting potential imposed by the weak interchain couplings. Interestingly, such discrete excitations are found for both the transverse and longitudinal polarizations. The unusual sharp longitudinal modes are stabilized by the anisotropy and interchain interactions. The sequence of excited states matches the zeros of the Airy function.

In an applied magnetic field the AFM ground state of $SrCo_2V_2O_8$ is suppressed and emerges in to a quantum-critical state known as the Tomonaga-Luttinger liquid (TLL). At low temperatures, weak interchain couplings stabilize novel ordered states at finite temperatures in the TLL regime which inherit the properties of the dominant fluctuation modes. This results into a sequence of four order-order quantum phase transitions as a function of magnetic field up to the saturation field of H_s = 32 T.

TH.A-P42 - Magnetic properties of the new rare earth pyrochlore $Nd_2Zr_2O_7$

J. Xu [1], A. T. M. Nazmul Islam [1], A. Bera [1], B. Klemke [1], J. Niedziela [2], M. Frontzek [3], Y. Su [4], E. Feng [4], B. Lake [1]

Geometrically frustrated magnetic materials are ideal candidates for exhibiting large quantum mechanical spin fluctuations and the emergence of novel magnetic ground states. Over the past 20 years, many interesting and often exotic magnetic and thermodynamic phenomena have been observed in the Pyrochlore oxides which consist of highly frustrated corner-sharing tetrahedra, such as dipolar spin ice, quantum spin ice, spin liquid and spin glass. [1] Most of the studies were concentrated on the heavy Rare Earth titanate Pyrochlores which have large moments, like $Dy_2Ti_2O_7$, $Ho_2Ti_2O_7$ and $Tb_2Ti_2O_7$.[2-4] Here we investigate the light Rare Earth Zirconate Pyrochlore, $Nd_2Zr_2O_7$, using bulk properties measurements and neutron scattering. $Nd_2Zr_2O_7$ orders antiferromagnetically below 0.4K and has a negative Curie-Weiss temperature of ~-27K and effective moment of μ_{eff}~3.4μ_B/Nd. It orders in the 'all-in-all-out' magnetic structure but with a much reduced Nd moment of 1.2μ_B at 0.1K (compared to 3.3μ_B expected for full ordering). Inelastic neutron scattering indicates that there is a large gap (~23meV) between the ground state and the first crystal field excitation state and thus strong Ising anisotropy is expected. The pinch point which is characteristic for spin ice, is also present in our neutron diffuse scattering data both below (~0.3K) and above (~0.45K) T_N. This may be because above T_N, it is a cooperative paramagnet with powder-law spin correlations due to dipolar interactions and even below the ordered state, more than 2/3 of the full moment is still fluctuating.

TH.A-P43 - Effective spin-1/2 model for $Tb_2Ti_2O_7$

S. Curnoe [1], S. Mukherjee [2]

1. Memorial University of Newfoundland, St. John's, Canadá
2. Brock University, Saint Catharines, Canadá

The methods of finite group theory (symmetry) are a powerful means of reducing the complexity of highly symmetric crystals such as the rare-earth pyrochlores.
A symmetry-preserving map between non-Kramers Tb_3+ states and spin-1/2 states on a tetrahedron is used to derive an effective spin-1/2 exchange model for non-Kramers Tb_3+ states in the pyrochlore $Tb_2Ti_2O_7$. Estimates of the exchange constants reveal that $Tb_2Ti_2O_7$ is described by a quantum spin ice Hamiltonian.

TH.A-P44 - Interplay of charge and spin fluctuations of strongly interacting electrons on the frustrated kagome lattice

K. Roychowdhury [1]

1. Mpipks, Dresden, Germany

We study electrons hopping on a kagome lattice at third filling described by an extended Hubbard Hamiltonian with on-site and nearest-neighbor repulsions in the strongly correlated limit. As a consequence of the commensurate filling and the large interactions, each triangle has precisely two electrons in the effective low-energy description, and these electrons form chains of different lengths. The effective Hamiltonian includes the ring exchange around the hexagons as well as the nearest-neighbor Heisenberg interaction. Using large-scale exact diagonalization, we find that the effective model exhibits two phases: If the charge fluctuations are small, the magnetic fluctuations confine the charges to short loops around hexagons, yielding a gapped charge-ordered phase. When the charge fluctuations dominate, the system undergoes a quantum phase transition to a resonating plaquette phase with ordered spins and gapless spin excitations. We find that a peculiar conservation law is fulfilled: the electron in the chains can be divided into two sublattices, and this division is conserved by the ring exchange term. We also discuss the possible directions of realizing a topological liquid in the similar bosonic models where importantly some of the long-range interactions are included.

TH.A-P45 - Thermodynamics of frustrated magnets: High-temperature expansion revisited

J. Richter [1], A. Lohmann [1], H.J. Schmidt [2]

1. Institute for Theoretical Physics, University Magdeburg, Magdeburg, Germany
2. University Osnabrueck, Department of Physics, Osnabrück, Germany

We present the high-temperature expansion (HTE) up to 10th order of the specific heat C and theuniform susceptibility χ for Heisenberg models with arbitrary exchange patterns and arbitrary spin quantum number s. We encode the algorithm in a C++ program provided at http://www.unimagdeburg.de/jschulen/HTE10/ which allows to get explicitly the HTE series for concrete Heisenberg models [1,2]. We use our HTE scheme to study the specific heat and the susceptibility of frustrated quantum magnets. In particular, we consider magnetic systems with highly degenerate classical ground states, such as the kagome, the checkerboard, the square-kagome, the J1-J2, as well as the pyrochlore antiferromagnets. We investigate to what extent strong frustration is evident at moderate and high temperatures. Moreover, we discuss the influence of the spin quantum number s on the thermodynamic properties and compare this way quantum and classical systems.

TH.A-P47 - Chirality domain wall generated by the spin Z_2 vortex in 2d frustrated Heisenberg spin system

Pawel Rusek [1]

1. Department of Theoretical Physics, Wroclaw University of Technology, Wroclaw, Poland

In frustrated spin system the rotational symmetry is completely broken. The order parameter , a rotation matrix, allows for existence of the Z_2 spin vortex(a singular point in 2d) in a system. The topology of the Z_2 spin vortex requires the change of chirality(spins on a plaquette rotates clock -or counter-clock wise) of underlying spins to the opposite chirality on a closed path surrounding vortex. We show that in presence of a dipole spin anisotropy the region where the twist and, in the end, chirality of underlying spins change (rapidly) is shrank to the thin band(in 2d), of a dipole length width, terminating on the Z-2 spin vortex. This band is the topologically stable soliton û the chirality domain wall. The structure of chirality domain and chirality domain wall in the spiral phase of underdoped La û based cuprates is discussed.

TH.B-P01 - Energy gap and mixed valence state in $Sm_{1-x}B_6$ and $Sm_{1-x}La_xB_6$ kondo insulators

S.Gabáni[1], G. Pristáš[1], J. Bednarčík[2], E. Welter[2], V. Filipov[3], N.Shitsevalova[3], K.Flachbart[1]

1. Institute of Experimental Physics SAS, Košice, Slovakia

3. Institute for Problems of Materials Science, NASU, Kiev, Ukraine

SmB_6 is a heavy fermion semiconductor with a narrow energy gap E_g at the Fermi level, also denoted as Kondo insulator, which has recently been considered to be a topological Kondo insulator, the first strongly correlated electron system to exhibit topological surface conduction states.
In this contribution we have investigated the energy gap in Sm deficient $Sm_{1-x}B_6$ (with x = 0.03, 0.05, 0.08, 0.1 and 0.2) sintered samples and in single crystalline solid solutions $Sm_{1-x}La_xB_6$ (with x = 0.16, 0.28, 0.4, 0.6) using sensitive ac-resistivity $\rho_{ac}(T)$ measurements between 2 and 300 K, as well as the mixed valence state v_{Sm} of samarium ions in these solid solutions by X-ray absorption near edge structure (XANES) studies between 4.2 and 300 K.
From local activation energy calculated as $W(T) = d(\ln\rho_{ac}(T))/d(1/k_BT)$ we were able to determine the values of E_g. It was shown that E_g maintains up to a concentration x = 0.2 of vacancies and up to a concentration x = 0.4 of La-ions in doped samples, and that in both cases E_g decreases with the increasing x. XANES investigations, on the other hand, revealed that the mixed valence state v_{Sm} of Sm-ions ($v_{Sm} \approx 2.53$ for SmB_6 at 4.2 K) increases with increasing vacancy level whereas it decreases with increasing concentration of La^{3+} ions.
The received dependences are in agreement with numerical calculations based on the spinless Falicov-Kimball model.

TH.B-P03 - Magnetic polarons in EuB_6

S. Roessler [1], J. Mueller [2], Z. Fisk [3], S. Wirth [1]

1. Max Planck Institute for Chemical Physics of Solids, Dresden, Germany
2. Institute of Physics, Goethe-University Frankfurt, Frankfurt, Germany
3. Department of Physics, University of California, Irvine, United States

Rare-earth hexaborides are an extremely interesting class of materials with a variety of exotic properties ranging from heavy fermion metallic behavior in CeB_6 to Kondo insulators with possible topological surface states in SmB6 and YbB_6. Properties of these systems stem from the relative positions of the f-bands and the conduction bands with respect to the Fermi level, as well as their interactions. Here, the former result from the localized 4f moments, while the latter originate from either the 5d bands of the rare earth or sp bands of the B6 molecular orbitals. EuB_6 is a ferromagnetic semimetal with unusual properties. It orders ferromagnetically with two consecutive phase transitions at Tc1 = 15.3 K and Tc2 = 12.6 K reaching the full ordered moments of 6.9(2) μB of the 8S7/2 ground state of the Eu^{2+} at 1.5 K [1]. The paramagnetic to ferromagnetic transition is accompanied by an insulator-to-metal transition as well as a colossal magnetoresistance (CMR). A model of coalescing magnetic polarons has been invoked to explain these unusual magneto-transport properties [2,3].
Here we present ac-susceptibility (also conducted in applied magnetic fields) dc-magnetization isotherms, and atomically resolved scanning tunneling microscopy/spectroscopy (STM/S) on EuB_6 single crystals. The ac-susceptibility shows a clear onset of a ferromagnetic transition at Tc1 and a strong shift of Tc1 to the higher temperatures in applied magnetic fields. Modified Arrott plots with conventional critical exponents display non-linear isotherms, which is in accordance with the shift of Tc1 in magnetic fields. The conductance maps measured in zero field at T > Tc1 display electronic phase separation with enhanced conductance regions on a length scale of 2-3 nm. These results strongly support the scenario of magnetic polarons.

TH.B-P04 - Anisotropic thermopower of the antiferromagnetic kondo semiconductor $CeOs_2Al_{10}$ doped with 5d electrons and holes

T. Takabatake [1,2], Y. Yamada [1], J. Kawabata [1], T. Onimaru [1], Y. Muro [3]

1. Graduate School of Advanced Sciences of Matter, Hiroshima University, Japan
2. Institute for Advanced Materials Research, Hiroshima University, Japan
3. Faculty of Engineering, Toyama Prefectural University, Japan

Hybridization of 4f electrons with conduction band opens a gap in the renormalized band of Kondo semiconductors (KSs) such as CeNiSn, $Ce_3Bi_4Pt_3$, and $CeOs_4P_{12}$. These KSs remain paramagnetic at low temperatures. However, a KS $CeOs_2Al_{10}$ has been found to order antiferromagnetically at TN = 28.5 K [1], which temperature is even higher than that of the Gd counterpart. In order to understand the mechanism of the unusual AF order in the presence of hybridization gap, we have studied the effects of 5d electron and hole doping on the electrical resistivity and thermopower S. In electron-doped $Ce(Os_{1-x}Ir_x)_2Al_{10}$, TN gradually decreases with increasing x to 0.15, while TN in hole-doped $Ce(Os_{1-y}Re_y)_2Al_{10}$ disappears at a small level of doping y = 0.05 [2]. On cooling below TN in $CeOs_2Al_{10}$, Sa and Sc jump slightly while Sb drops from 30 to -7 microV/K, suggesting loss of a part of the Fermi surface. With increasing x, the hybridization gap feature in the resistivity disappears at x = 0.1 and development of AF correlations of localized 4f electrons manifests in the negative peak in Sa and Sc. With increasing y, by contrast, the gap feature disappears at y = 0.05 and the valence fluctuation feature manifests in the large and broad maximum in S along the three axes. These results indicate that $CeOs_2Al_{10}$ is located at the border between the Kondo regime of localized 4f electrons and valence fluctuation regime of itinerant 4f electrons, and the Fermi surface changes significantly by the AF ordering. In the doped systems, the parallel decreases in TN and the magnitude of the hybridization gap reveal that the gap is necessary for the unusual AF order at high TN.

TH.B-P05 - Novel kondo lattices $CePd_3Al_3$ and $CePd_4Al_4$

D. Kaczorowski [1], D. Gnida [1], A. Tursina [2], E. Khamitcaeva [2], A. Gribanov [2]

1. Institute of Low Temperature and Structure Research, Polish Academy of Sciences, Poland
2. Department of Chemistry, Lomonosov Moscow State University, Russian Federation

The novel cerium ternaries $CePd_3Al_3$ and $CePd_4Al_4$ crystallize with the tetragonal structures being closely related to one another. Together with $CePd_2Al_2$, they form a new homologous series built of structural units of the $CaBe_2Ge_2$- and CsCl-type units. They order antiferromagnetically below 3.5 K and 2.6 K, respectively, and exhibit Kondo lattice behaviors with the characteristic energy scale of a few Kelvins. The low-temperature thermodynamic and electrical transport properties of both materials are similar to those recently reported for $CePd_2Al_2$.

TH.B-P06 - Friedel oscillations in strongly correlated fermionic systems- RDMFT-CTQMC approach

B. Chatterjee [1], K. Makuch [1], K. Byczuk [1]

1. Institute of Theoretical Physics, Faculty of Physics,University of Warsaw, Poland

Friedel Oscillations (FO) in the presence of a single impurity is studied in the one- and two-dimensional Hubbard model. The model is solved within the real space dynamical mean-field theory using the Continuous Time Quantum Monte Carlo solver. Effects of temperature and electronic correlations on the behavior of FO are studied. We observe that the amplitudes of FO are damped and the period changes with increasing the interaction. FO becomes sharper with decreasing the temperature and also change with the dimensionality. A comparative study of the results with that from our previous studies using different approaches is presented.

TH.B-P07 - Structural and high-field 57Fe mössbauer investigations on $FeSb_2$

M. Reissner [1], K. Hradil [2], W. Steiner [1]

1. Institute of Solid State Physics, TU Wien, Wien, Austria
2. X-Ray Center, TU Wien, 1060 Wien, Austria

Although intensively investigated since several decades, $FeSb_2$ shows still some contradicting results which have to be cleared. $FeSb_2$ crystallizes in the marcasite structure, where Fe has only one crystallographic site, surrounded by distorted Sb-octahedra, which are corner shared in the ab-plane and edge shared along the c-axis. These octahedra are squeezed along the apical axis. In agreement the Mössbauer spectra, can be fitted by only one quadrupole split sub-spectrum. Problems appear, however, for Mössbauer spectra taken in external magnetic fields (up to 13.5 T and at temperatures between 4.2 K and 250 K), where spectra become extremely complex [1]. An interpretation in terms of only one sub-spectrum is no longer possible and superposition of several sub-spectra was necessary to obtain reasonable fits. Neutron diffraction experiments at different temperatures on a single crystal together with X-ray powder diffraction investigation confirm that no secondary phases exist which could be responsible for the extra sub-spectra. The fact that in all published structure analyses rather high thermal coefficients were obtained, indicates that the refinement was not fully finished revealing possible presence of disorder. Further hints for such disorder result from analysis of the radial-density function obtained from high energy X-ray investigations, pointing out that approximately 30% of the Fe atoms are shifted in the basal plane out of the centre of the octahedra. Details of the results of the crystallographic investigations and their relation to the results of the high field Mössbauer analysis will be presented. The fact that the results of the magnetic and transport measurements on our sample fits well to those reported in literature indicates that the found disorder seems to be typical for this material and has to be taken into account in any future theoretical consideration.

4. JCNS at MLZ
5. MPI-CPfS

$CeCu_2Ge_2$, the counterpart of the heavy-fermion superconductor $CeCu_2Si_2$, exhibits an incommensurate antiferromagnetically long-range ordered ground state with tau = (0.28 0.28 0.54) below T(N) = 4.1 K. The magnetism is strongly affected by a Kondo screening of the Ce 4f-moments by conduction electrons. The similar energy scale of both, Kondo and exchange interactions, results in a complex magnetic phase diagram and gives rise to potential quantum critical phenomena at very low temperatures. We present elastic neutron diffraction data using polarized as well as unpolarized neutrons obtained on a $CeCu_2Ge_2$ single crystal employing the cold triple axis spectrometer PANDA at FRM II as well as the instruments D23 at ILL and DNS at FRM II. At the lowest temperature for zero external magnetic field the magnetic structure can be described by an amplitude modulated spin density wave with the Ce moments lying in the basal plane with no c-component.
The field dependence of the magnetic propagation vector was measured at T = 300 mK in the (HHL) plane with vertical magnetic fields applied along [1-10]. We observe no change of the magnetic ordering vector for fields up to 7.5 T. In a small field range between 7.7 T and 7.9 T two magnetic Bragg peaks coexist, the first related to the original propagation vector and the second related to a slightly shifted propagation vector. Between 7.9 T and 12 T the intensity of the Bragg peak related to the second propagation vector diminishes for further increasing fields and disappears a 12.6 T.
Above 13 T, yet still well below the value of 25 T of the saturation for magnetic fields in (110) direction, the zero-field like magnetic order is lost and magnetic intensities are not to be found at incommensurate positions in the (HHL) plane anymore.

TH.B-P10 - Kondo physics in a Ni impurity embedded in O-doped Au chains

S. Di Napoli [1], M. Barral [1], P. Roura-Bas [1], A. Llois [1], A. Aligia [2]

In modern nanoscience, understanding and tailoring the electronic transport through atomic-size conductors is a duty, as it represents a powerful tool for detecting nanomagnetism. Atomic-size contacts can be experimentally obtained by different techniques, particularly in a mechanically controllable break junction (MCBJ) experiment, where the formation of one dimensional atomic chains of several kinds of elements is possible. It has been recently demonstrated that impurity-assisted chain growth leads to a strongly enhanced tendency towards chain formation, specially if the dopants are light *p-like* elements.
In this work we study the effects of the presence of oxygen atoms on the symmetry of the Au conduction bands close to the Fermi level as well as on the spin state of a Ni impurity. This symmetry determines the nature of the screening of the spin of the impurity, giving rise to the possibility of the system to exhibit an ordinary or exotic Kondo effect. In particular, we analyze the low energy physics of the system, which corresponds to a Kondo model of a spin S=1 screened by two conduction channels, parametrized from *ab initio* calculations. The poor man's scaling technique is applied to obtain the Kondo temperature of the system.

TH.B-P11 - Anisotropic chemical pressure effect on the antiferromangetic kondo semiconductor $Ce(Ru_{1-x}Fe_x)_2Al_{10}$

An antiferromagnetic (AFM) Kondo semiconductor CeRu2Al10 has been studied intensively because of the peculiar AFM order at the unusually high transition temperature TN = 27 K. This AFM order disappears suddenly either under pressure at Pc = 4 GPa or by Fe substitution at xc ~ 0.8 in single crystalline Ce(Ru1-xFex)2Al10 grown by an Al self-flux method [1,2]. However, the decrease of TN is gradual with x for the polycrystalline samples [3,4]. We have studied the origin of this discrepancy using both single- and poly-crystalline samples. Electron-prove microanalyses on our single-crystalline Ce(Ru1-xFex)2Al10 with 0.5 ≤ x ≤ 0.8 revealed phase separation into Ru-rich region at the center of a crystal and Fe-rich one near the surface. On the other hand, no phase separation was found in polycrystalline samples. The magnetic susceptibility, electrical resistivity and specific heat measurements on the polycrystals confirmed that the AFM order disappears gradually at x = 0.7, in agreement with TN(x) reported previously for polycrystals [3,4]. We should remind that application of hydrostatic pressure and Fe substitution result in different lattice contractions. The rate of contraction by the hydrostatic pressure is almost isotropic up to Pc [5], while that by Fe substitution is strongly anisotropic; a/a ≈ c/c ≈ 2b/b [3]. Therefore, the contrasting changes in TN(x) suggest that the anomalous AFM order in CeRu2Al10 is more sensitive to the c-f hybridization in the ac plane than that along the b-axis.

TH.B-P13 - Modification in magnetic properties of epitaxial $FeSb_2$ thin film on MgO

A. Duong [1], Y. Shin [1], S. Rhim [1], V. Nguyen [1], S. Cho [1]

1. Department of Physics and Energy Harvest-Storage Research Center, University of Ulsan, Ulsan, Republic of Korea

$FeSb_2$ is Kondo insulator with a narrow band gap. In addition, it has high Seebeck coefficient and thermoelectric power factor (PF) at low temperature. [1-3] More specifically, the PF is larger than that of Bi_2Se_3 by a factor of 65. Since it is Kondo insulator with highly correlated electrons, highly peaked density of states is from eg orbitals. It possesses interesting magnetic property: It is diamagnetic at low temperature, where a crossover to paramagnetism occurs at 100 K. [4-6] In here, we report on the modified magnetic properties in epitaxial $FeSb_2$ thin film on MgO (100) substrate using molecular beam epitaxy (MBE). XRD pattern showed orthorhombic structure with the lattice constants of a=5.815, b=6.517, and c=3.190 Å, exhibiting the 1.74% compressive strain owing to large lattice mismatch between $FeSb_2$ and MgO. Magnetic phase has been changed from diamagnetism in bulk to canted antiferromagnetism in the epitaxial thin film. Temperature dependence of magnetization shown a Neel temperature (T_N) at around 50 K. Negative Magnetoresistance at below 50 K indicates a magnetic ordering in $FeSb_2$ thin film.

TH.B-P14 - Physical properties of single-crystalline $LaBe_{13}$, $NdBe_{13}$, and $SmBe_{13}$

H. Hidaka [1], K. Mizuuchi [1], S. Yamazaki [1], N. Miura [1], C. Tabata [1], Y. Shimizu [2], T. Yanagisawa [1], H. Amitsuka [1]

1. Graduate School of Science, Hokkaido University, Japan
2. The Institute for Solid State Physics, The University of Tokyo, Japan

For more than three decades, the heavy-fermion (HF) compound UBe_{13} has attracted much attention because of emergence of unconventional superconductivity and non-Fermi liquid behavior. However, experimental studies on other MBe_{13} compounds (M = rare earth and actinide) are small in number, especially on light rare earth systems, although they are important to understand a background feature of UBe_{13}. The MBe_{13} compound crystallizes in the $NaZn_{13\text{-type}}$ cubic structure, where the M ions are surrounded quasi-spherically by 24 Be atoms, namely cage-like structure. Therefore, there is a possibility that the MBe_{13} systems exhibit novel physical phenomena attributed to the cage-like structure, such as higher multipole ordering, magnetic-field insensitive HF state, and anharmonic oscillation of the guest ion called as rattling. In the present study, we have succeeded to grow single crystals of $LaBe_{13}$, $SmBe_{13}$, and $NdBe_{13}$ by Al-flux method, and investigated their thermal, magnetic, and electrical transport properties of single crystalline samples, for the first time. Specific heat of non 4f-electron system $LaBe_{13}$ has a low-energy Einstein-phonon contribution (Einstein temperature ~ 170 K), which may be originated in the cage-like structure. In both $NdBe_{13}$ and $SmBe_{13}$, the temperature dependence of electrical resistivity shows a metallic behavior without a Kondo-like increase, suggesting a weak c-f hybridization. The localized 4f-electronic states in both compounds have been confirmed by the specific heat and magnetic-susceptibility measurements. In addition, a magnetic ordering has been observed at a transition temperature TM = 2.6 and 8.8 K respectively in $NdBe_{13}$ and $SmBe_{13}$, which are consistent with the previous reports. By analogy with other MBe_{13} compounds showing a helical-magnetic ordering, we discussed a possibility that these compound also undergo the helical ordering at TM.

TH.B-P17 - Anomalous hall effect in ferromagnetic $L1_0$-MnAl with orbital two-channel kondo effect

L. J. Zhu [1,2], S. H. Nie [1], P. Xiong [3], and J. H. Zhao [1]

3. Department of Physics, Florida State University, Tallahassee, United States

The understanding of the anomalous Hall effect (AHE) has remained far from complete despite its long history over 130 years. The experimental studies of its scaling between longitudinal resistivity (ρ_{xx}) and anomalous Hall resistivity (ρ_{AH}) allows for clarifying the microscopic mechanisms and underlying physics. Most recent experiments firmly established a scaling of $\rho_{AH} = a_0 \rho_{xx0} + b\rho_{xx}^2$ (ρ_{xx0} is the residual resistivity) in a variety of single-crystalline films (Fe, Co, Ni, $L1_0$-$Mn_{1.5}Ga$, etc.) where phonon scattering dominates the temperature-dependence of resistivity [1,2]. However, the AHE in presence of chemical disorder and localization has been buried in persistent confusion. The *intrinsic* anomalous Hall conductivity *b* which is widely believed to originate from the band-structure effects of a perfect crystal was observed to be significantly influenced by chemical disorder in $L1_0$-$Mn_{1.5}Ga$ [2]. Hopping conduction was reported to give an AHE scaling of $\rho_{AH} \sim \rho_{xx}^{0.5\sim0.3}$ in $Ti_{1-x}Co_xO_{2-\delta}$, $Fe_{3-x}Zn_xO_4$ and (Ga,Mn)As and $\rho_{AH} \sim \rho_{xx}^0$ in polycrystalline FePt, respectively. It has also been an open questions whether weak localization and electron-electron interaction have contribution to ρ_{AH}. So far, a unified understanding of the AHE in localized systems has remains a shortage.
Here, we report the AHE in perpendicularly magnetized $L1_0$-MnAl epitaxial films with variable chemical ordering and orbital two-channel Kondo (2CK) effect [3]. The AHE is observed to scale with $\rho_{AH}=a_0\rho_{xx0}+b\rho_{xx}^2$ at high temperatures where phonon scattering prevails, while shows significant deviation at low temperatures where orbital 2CK effect are important. This is the first evidence of contribution of orbital 2CK effect to the AHE. A remarkable tuning of the intrinsic anomalous Hall conductivity is also revealed by varying the degree of chemical ordering, indicating a topological modification of the Fermi surface [4], which is consistent with the observation in $L1_0$-$Mn_{1.5}Ga$.

2. ISSP, Tokyo University, Japan
3. Graduate School of Material Science, University of Hyogo, Japan

We investigated temperature and magnetic field dependences of the point-contact spectra of heavy fermion compounds $CeCu_6$ and $CeAl_3$. We prepared fixed point-contact devices on the surface of the poly-crystalline samples. Spectrum was obtained in the form of differential resistivity (dV/dI) as a function of bias voltage. The spectra of $CeCu_6$ and $CeAl_3$ changed below Tmax, at which there are maximum on the temperature dependence of electrical resistivity, and TK. At the lowest temperature at 0.4 K, both spectra showed a large conductance peak. It was newly observed that both increasing rates of the magnitude of dV/dI at zero bias changed from negative curvature to positive one at each critical magnetic field of metamagnetization, although both conductance peaks on these spectra enlarged with increasing magnetic field regardless of lower or higher than the critical magnetic field.

TH.B-P19 - Anisotropy of the Kondo effect revealed by Raman scattering spectroscopy

Microscopic description of Kondo lattice systems, such as heavy-fermion materials, often assume a local, i.e., momentum-independent, hybridization between the conduction band and the local-moments on a regular lattice. In this picture, the anisotropy of the Kondo effect is not taken into account whereas such unconventional hybridization may influence the entire phase diagram of heavy fermion compounds [1]. Moreover, only very few studies report experimental signature of such effect, either in Kondo insulators or metals, and these remain indirect. We report here clear experimental evidence of anisotropic Kondo effect in metallic heavy-fermion compound URu_2Si_2, thanks to the ability of Raman spectroscopy to unveil the symmetry of the electronic excitations. We have performed polarized electronic Raman scattering on single crystals of URu_2Si_2 in all the allowed symmetries. We observe a gap opening only in two symmetries: in Eg symmetry below 100 K and in A1g symmetry from 300 K. The former one, certainly related to the Kondo coherence, is consistent with optical conductivity measurements [2]. Thanks to the calculation of Raman vertices in URu_2Si_2, we discuss the k-dependence of the Kondo physics. Our results reveal a strong anisotropy of the Kondo physic in k-space.

TH.B-P20 - To the origin of the singlet ground state of the fe impurity in the archetype kondo system: cufe

R. Radwanski [1,2], D. Nalecz [1], Z. Ropka [2]

1. Institute of Physics, Pedagogical University, 30-084 Krakow, Poland
2. Center of Solid State Physics, Snt Filip 5, 31-150 Krakow, Poland

Studies of the origin of an unexpected increase of the resistivity with decreasing temperature below about 25 K of copper containing small amounts of Fe, denoted as CuFe, has opened large experimental and theoretical field known at present as the Kondo effect. In meantime, the Kondo effect theoretical problem has been extended to different theories (Kondo lattice, multichannel Kondo effect, ...) becoming the foundation of thousand of papers devoted to heavy-fermion phenomena and strongly correlated electron systems. In the original explanation Kondo in 1964 pointed out the importance of the magnetic resistivity related with the spin degree of freedom of the magnetic impurity. The antiferromagnetic interaction of the localized spin with conduction electrons, according to the common understandings, leads to the singlet ground state of the localized spin and a cloud of conduction electrons with opposite spins fully screening the localized spin by conduction electrons. This disappearance of the local moment below temperature denoted as Kondo temperature, is seen, for instance, in the magnetic susceptibility which deviates at low temperatures from the Curie law becoming saturated for T approaching 0 K. We have re-analyzed low-temperature properties of copper with small amounts of Fe impurities, which have led years ago to the Kondo-effect theory, pointing out the formation of a singlet ground state. We claim that in CuFe (here we discussed only CuFe) there is a singlet ground state formed at the atomic scale on the Fe impurity. This singlet atomic ground state comes out if one takes into account simple crystal-field interactions and the spin-orbit coupling. Slightly above, in energy of 10-15 K, there is a magnetic doublet with a moment close to 3.0 uB containing, which assures large dynamics of the Fe impurity. The found singlet ground state is favored by the Jahn-Teller effect.

TH.B-P21 - $CePd_2Zn_3$ - a new kondo lattice antiferromagnet

M. Valiska [1], J. Prokleska [1], P. Proschek [1], V. Sechovsky [1]

1. Department of Condensed Matter Physics, Charles University, Prague, Czech Republic

Single crystals of $CePd_2Zn_3$ have been successfully grown by Bridgman method using a sealed Mo capsule with a BN crucible. Single-crystal X-ray diffraction confirmed the hexagonal $PrNi_2Al_{3\text{-type}}$ structure with the space group P6/mmm [1] with unit cell parameters a = 539.14 pm and c = 430.12 pm at RT. The crystals were subjected to measurements of magnetization (M), specific heat (Cp) and electrical resistivity (rho) as functions of temperature (T = 0.3 - 300 K) and magnetic fields (B = 0 - 14 T) applied along the principal crystallographic directions. The low temperature anomalies of specific heat, magnetization and resistivity point to a transition to antiferromagnetic (AF) state (TN = 1.95 K). Strong magnetocrystalline anisotropy with easy magnetization basal plane similar to other known isostructural CeT_2X_3 (T = transition metal, X = p-electron metal) counterparts has been revealed both in paramagnetic and AF state. The negative derivative of resistivity in the temperature interval 6 - 16K which is suppressed by a magnetic field of 8 T applied along the a-axis suggests that $CePd_2Zn_3$ is a Kondo lattice compound. Evolution of the Cp vs. T anomaly and large negative magnetoresistance with increasing the magnetic field applied along the a-axis reflect a metamagnetic transition at Bc around 1 T at which the AF coupling is overcame by the magnetic field. Measurements of evolution of resistivity and specific heat of crystals exerted hydrostatic pressure towards the QCP are in progress. Results will be discussed in context of magnetism in the isostructural CeT_2X_3 compounds adopting the hexagonal $PrNi_2Al_{3\text{-type}}$ structure.

TH.C-P01 - Doping dependent magnetism and exchange bias in $CaMn_{1-x}Nb_xO_3$

V. Markovich [1], I. Fita [2], A. Wisniewski [2], R. Puzniak [2], C. Martin [3], D. Mogilyansky [4], G. Jung [1], G. Gorodetsky [1]

1. Department of Physics, Ben-Gurion University of the Negev, 84105 Beer-Sheva, Israel
2. Institute of Physics, Polish Academy of Sciences, Warsaw, Poland
3. Laboratoire CRISMAT, UMR 6508, ISMRA, Caen, France
4. The Ilse Katz Institute for Nanoscale Science and Technology, Ben-Gurion University of the Negev, Beer-Sheva, Israel

Magnetic and structural properties of $CaMn_{1-x}Nb_xO_3$ have been investigated. The substitution of Nb for Mn results in one-electron doping accompanied by monotonous increase of lattice parameters and unit-cell volume with increasing *x*. Low temperature magnetic ground state evolves from antiferromagnetic (AFM) one with weak ferromagnetic (FM) component for x = 0.02 - 0.08 to charge ordered *C*-type AFM with minority *G*-type AFM at x = 0.1. Spontaneous magnetization increases sharply with increasing *x*, reaches a maximum of 4.1 emu/g at T =10 K for x = 0.08, and then decreases rapidly to 0.2 emu/g at x = 0.1. For x = 0.04 an anomalous diamagnetic behavior is observed in field cooled magnetization and remanent magnetization below Néel temperature T_N. Exchange bias (EB) effect, manifested by vertical and horizontal shifts in field cooled hysteresis loops appears in $CaMn_{0.9}Nb_{0.1}O_3$. The intrinsic EB phenomenon is caused by interface exchange coupling between nano-sized FM clusters and surrounding *G*-type AFM phase. The growth of FM phase volume under applied pressure is linked to progressive suppression of negative magnetization for x = 0.04 and to reduction of the EB effect for x = 0.1. EB shifts decrease monotonously with increasing temperature and vanish above 70 K, while coercive field disappears above 90 K, around T_N. Our results indicate that EB effect in x = 0.1 is due to Dzyaloshinsky-Moriya interactions. Hysteresis loops recorded at high maximal fields show a nonlinear increase of magnetization indicative of metamagnetic-like transition. Growth of the FM phase volume and transformation from *C*-type to *G*-type AFM in high magnetic field induced metamagnetic transition appears to be linked to complete suppression of EB effect in $CaMn_{0.9}Nb_{0.1}O_3$.

TH.C-P02 - Molecular spin dynamics analysis of complex magnetic structure on the FCC lattice in itinerant electron system

Y. Kakehashi [1], S. Nohara, S. Chandra, T. Uchida [2]

1. University of the Ryukyus, Japan
2. Hokkaido University of Science, Japan

Magnetic alloys on the fcc lattice such as gamma Fe-base and Mn-base alloys exhibit complex magnetic structures because of the strong frustration between the long-range ferro- and antiferro-magnetic interactions on the fcc lattice. Their formation mechanism has not yet been clarified theoretically and it is one of the current issues in magnetism. In order to understand the complex magnetic structure from the theoretical point of view, we have investigated the magnetic structure of the Hubbard model on the fcc lattice by means of the Molecular Spin Dynamics (MSD) method [1,2]. We present here the numerical results of magnetic structure. The MSD is based on the functional integral technique combined with the isothermal MD and allows us to determine automatically the complex magnetic structure for a given electron number n and temperature T. With use of 8x8x8 fcc unit cells surrounded by 53248 atoms and T/|t|=0.001, we performed the MSD calculations. For the Coulomb interaction strength U/|t|=8, for example, we find that the strong ferromagnetism is stabilized from n=2.0 to 1.3. From n=1.3 to 1.2 we find a simple ferromagnetism with a small amount of holes in the up-spin band. Below n=1.2, the ferromagnetism collapses and the system shows the complex ferrimagnetism with small magnetization. Between n=0.9 and 0.6, we find complex anti-ferromagnetic structures and spin-density waves: 3Q multiple spin density waves in the vicinity of n=0.90, the 2Q multiple spin density waves around n=0.75, and the complex antiferromagnetic structure with amplitude modulation for n=0.70. Finally the paramagnetic state is realized below n=0.60. We elucidate these changes by means of the Fourier analysis.

TH.C-P04 - Low-temperature spin-glass behaviour in a diluted dipolar Ising system

J. J. Alonso [1]

1. Universidad de Málaga, Spain

Using Monte Carlo simulations, we study the character of the spin-glass (SG) state of a site-diluted dipolar Ising model. For concentration $x < 0.65$ these systems are known to exhibit an equilibrium spin-glass phase at low temperatures. At high dilution, well deep in the SG phase, we find spiky distributions of the overlap parameter q that are strongly sample-dependent. For the system sizes studied, the average width of spikes, and the fraction of samples with spikes higher than a certain threshold does not vary appreciably with system size. This is compared with the behaviour found for the Sherrington-Kirkpatrick and the Edwards-Anderson model.

TH.C-P07 - Magnetic control of thermopower in selected manganites

R. Mahendiran [1]

1. National University of Singapore, Singapore

Thermoelectric materials are of great interest because they can directly convert heat into electricity by generating potential difference in response to a temperature gradient. For more than half a century, the field of thermoelectrics has been dominated by semiconductors based p block elements in periodic tables such as Bi, Pb, Te etc. Transition metal oxides were not considered as promising thermoelectric materials until few years ago because majority of them have low mobility. However, the discovery of a large themopower (=100 microvolt/K) and power factor comparable to that of semiconducting Bi_2Te_3 in quasi metallic oxides based on cobalt (example Na_xCoO_2 and $Ca_3Co_4O_9$ etc.) has inspired focused research on thermoelectricity in TMO[1,2]. Oxides thermoelectrics is still an emerging field and much need to be understood. In this talk, I will focus on thermoelectricity in some selected magnetic transition metal oxides. Recently, we have found that thermopower in some of these oxides can be either enhanced or suppressed by external magnetic fields[3,4] In this talk, I will give overview of how electrical resistivity, thermopower and magnetic entropy change in these oxides are intertwined and what we can do to enhance the power factor and figure of merit. Special attention is given to $Pr_{1-x}Sr_xMnO_3$ and $Nd_{1-x}Na_xMnO_3$ system which encompass ferromagnetic metallic/insulating and layered antiferromagnetic quasi metallic/semiconducting phases.

TH.C-P08 - Physical properties of the FeRh alloys: the antiferromagnetic to ferromagnetic transition

J. Kudrnovsky [1], V. Drchal[1], I. Turek[2]

1. Institute of Physics AS CR, Praha, Czech Republic
2. Faculty of Mathematics and Physics, Department of Condensed Matter Physics, Charles University, Praha, Czech Republic

The electronic, magnetic, thermodynamical, and transport properties of FeRh alloys are studied from first principles. We present a unified approach to the phase stability, an estimate of exchange interactions in various magnetic phases, and transport properties including the effect of temperature which are all based on the same electronic structure model.
Emphasis is put on the transition between the ferromagnetic (FM) and antiferromagnetic (AFM) phases. Such a study is motivated by a recent suggestion of FeRh as a room-temperature antiferromagnetic memory resistor [1].
The theory predicts the order-disorder transformation from the hypothetical disordered bcc-phase into ordered B2-phase. Comparison of exchange interactions in the magnetically ordered FM and AFM phases with corresponding spin-disordered counterparts allows to identify relevant interactions which are precursors of magnetically ordered phases.
The most important result is the explanation of a dramatic decrease of the resistivity accompanying the AFM to FM phase transition [2] which is due to the spin-disorder present in the system. The study of the anisotropic magnetoresistance in the AFM phase found recently experimentally [1] is extended also to finite temperatures.

TH.C-P09 - Magnetic properties of the $RAuBi_2$ (R = Ce, Pr, Nd, Gd, Sm) series of intermetallic compounds

C. B. R. Jesus [1], M. M. Piva [1], P. F. S. Rosa [1,2], C. Adriano [1], Z. Fisk [2], P. G. Pagliuso [1]

1. Instituto de Física 'Gleb Wataghin', UNICAMP, Campinas-SP, Brazil
2. University of California, Irvine, United States

In this work we report the physical properties of series of intermetallic compounds $RAuBi_2$ (R = Ce, Pr, Nd, Gd, Sm) studied by means of x-ray powder diffraction, magnetic susceptibility, heat capacity and electrical resistivity measurements. These compounds were grown using the metallic Bi self-flux technique and they crystallize in a tetragonal $ZrCuSi_2$ (P4mmm) structure. Our $RAuBi_2$ single crystals show an antiferromagnetic ordering $T_N \geq 2.3$ K for all measured compounds. The values of T_N show a dramatic breakdown of the De Gennes factor along this series. Using a mean field model including isotropic Ruderman-Kittel-Kasuya-Yoshida (RKKY) magnetic interactions and the tetragonal crystalline electrical field (CEF), we demonstrated that one can qualitatively describe the magnetic properties and the evolution of the ordering temperature along these series. Furthermore, we compare the results present here with the properties of the isoestructural series $RAuBi_2$ [1] and discuss the main effects associated with the chemical substitution at the transition metal (Cu or Au) site.

TH.C-P10 - Magnetic phase diagram of MnSi inferred from ultrasound studies

A. Petrova [1], S. Stishov [1]

1. Institute For High Pressure Physics of RAS, Moscow, Russian Federation

The sound speed and attenuation were measured in the MnSi single crystal in the temperature range of 2-40 K and magnetic fields to 7 Tesla.

The magnetic phase transition in MnSi in zero magnetic field is signified by a quazi discontinuity in the c11 elastic constant, which suggests first order character of the transformation. The quasi discontinuities of c11 initially strongly decreases with magnetic field, practically disappears in the range of ~ 0.1-02/0.3 T, then recovers at ~0.2/0.3-0.45/0.5 T and again vanished at higher magnetic field. Remarkably that the region with almost zero values of in the interval ~0.12-0.2/0.26 T closely corresponds to the extent of skyrmion phase along the magnetic to paramagnetic transition. This implies that the c11 elastic constant is almost continuous through the transition from the skyrmion to paramagnetic phases. The recovery of discontinuities of c11 and the enhanced sound absorption occur at the crossing the phase transition line and the line of minima in c11. The latter is a region of strong spin fluctuations, reflected in maxima of the heat capacity. Despite the fact that this region does not carry features of a real phase transition the existing powerful fluctuations at the minima of c11 make the mentioned crossing point similar to a critical end point, when a second order phase transition meets a first order one.

TH.C-P11 - Anomalous structural, magnetic, optical and electronic properties of $GdCoO_{3-y}$

S. Ovchinnikov [1], Y. Orlov [1], V. Dudnikov [1], N. Kazak [1], K. Shaikhutdinov [1]

1. Kirensky Institute of Physics. Siberian Branch of Russian Academy of Sciences, Russian Federation

The interrelation of temperature induced spin crossover in the perovskite-like rare-earth cobaltates $RCoO_3$ is found by a variety of experimental and theoretical study of structural, magnetic, optical and electronic properties in a wide temperature range 2-1000K. It is found that spin crossover in Co^{+3} induced by lattice expansion at heating self-consistently increases the lattice expansion itself and results in the giant lattice expansion (order of magnitude large than standard anharmonic contribution) at the temperature region of maximal increase of the high spin population. The heat capacity has also the maximum in the same region. The optical transmission spectra have revealed the narrow transmission peak in the infrared region without the usual for semiconductor transparency window. The temperature dependent LDA+GTB electronic structure calculations have revealed the appearance the in-gap states due to high spin population induced by heating and off-stoichiometry. Even the small deviation from stoichiometry $y<0.01$ is enough for the in gap state strongly decrease the semiconductor gap 0.5eV up to 0.1 eV. In solid solutions $La_{1-x}Gd_xCoO_3$ the spin gap variation results from the chemical pressure that is estimated from the Burch-Murnaghan equation of states and verified by high temperature magnetic susceptibility measurements. The spin gap variation allows to control the temperature of maximal lattice dilatation and magnetic susceptibility.

TH.C-P12 - Non-random substitutions and magnetic ordering in $Fe_{7-y}M_yX_8$ (M = Ti, Co; X = S, Se)

N. Baranov [1,2], P. Ibrahim [2], N. Selezneva [2], A. Gubkin [1,2], A. Volegov [2], D. Shishkin [1,2]

1. Istitute of Metal Physics, RAS, Ekaterinburg, Russian Federation
2. Institute of Natural Sciences, Ural Federal University, Ekaterinburg, Russian Federation

A comparative study of four series of pyrrhotite-type chalcogenide compounds $Fe_{7-y}M_yX_8$ (X = S, Se) with substitution of Ti or Co for iron has been performed by means of X-ray and neutron powder diffraction and magnetization measurements. The polycrystalline samples were synthesized by solid state reactions in evacuated quartz tubes. Despite the formation of different superstructures all the synthesized compounds $Fe_{7-y}Ti_yX_8$ and $Fe_{7-y}Co_yX_8$ exhibit a layered crystal structure of the NiAs-type. In $Fe_{7-y}M_yX_8$ compounds having a ferrimagnetic order at y = 0, the substitution of either Ti or Co for iron up to y = 4 is observed to result in a monotonous decrease of the magnetic ordering temperatures, while the resultant magnetization shows a non-monotonous behaviour with a minimum around y = 1.0 - 1.5 except $Fe_{7-y}Co_ySe_8$. The suppression of a magnetically ordered state in $Fe_{7-y}M_yX_8$ with substitutions is ascribed to nearly zero values of magnetic moments on Ti and Co ions, while the non-monotonous changes in the resultant magnetization are explained by the non-random substitution of Ti or Co for Fe in alternating metallic layers. The layer-preferential substitution is confirmed by neutron diffraction measurements. At high Ti concentrations (y > 2) the $Fe_{7-y}Ti_yX_8$ compounds are observed to exhibit unusually high values of the coercive field at low temperatures (Hc = 20 - 24 kOe), which is associated with non-zero orbital moment of Fe ions and crystal field effects.

This work was supported by RFBR (projects No 13-02-00364 and No 13-02-96038) and by the program of the Ural Branch of RAS (project No 15-17-2-22).

TH.C-P13 - Critical exponents of inhomogeneous ferromagnetic $La_{0.8}Sr_{0.2}CoO_3$ single crystal

M. Nandi [1], N. Khan [1], B. Samantaray [1], P. Mandal [1], D. Prabhakaran [2]

1. Saha Institute of Nuclear Physics, 1/AF Bidhannagar, Calcutta, India
2. Department of Physics, Clarendon Laboratory, University of Oxford, Oxford, United Kingdom

The hole-doped cobaltite, $La_{1-x}Sr_xCoO_3$ (LSCO), is a model system to study the magneto-electronic phase separation phenomenon as the system phase separates in nano-sized metallic ferromagnetic (FM) clusters in the back ground of insulating non-FM matrix.[1] With increasing hole doping (x) the FM clusters grow in size and number and percolate at x = 0.18 giving rise long-ranged FM ordering. However, the phase separation extends beyond x = 0.18 and exists up to x = 0.22.[1] The system becomes homogeneous FM[1] above x = 0.22. Here we have determined the critical exponents of the highly inhomogeneous FM x = 0.20 single crystal to find how the presence of phase separation affects the nature of the transition and thereby the universality class of the pure FM LSCO system.

The compound undergoes a second order FM to paramagnetic phase transition at 176 K. The critical exponents (β, γ and δ) characterizing the transition have been estimated by different methods and are listed in Table-I together with the values predicted by theoretical models. The exponents for the present compound are found to be mean-field-like unlike 3D Heisenberg exponents observed for the x = 0.33 compound.[2] Such a large deviation of the exponents from 3D Heisenberg values is attributed to the presence of magneto-electronic inhomogeneity in this compound.[3] The average exchange field originating from the percolating FM clusters in the background of non-FM matrix is responsible for the mean-field-like values of the critical exponents for the $La_{0.8}Sr_{0.2}CoO_3$ single crystal.[3]

Table-I

Material	Methods	β	γ	δ
$La_{0.8}Sr_{0.2}CoO_3$	Modified Arrott plot	0.497(1)	1.25(2)	3.52(5)
$La_{0.8}Sr_{0.2}CoO_3$	Kouvel-Fisher plot	0.488(5)	1.28(2)	3.62(2)
$La_{0.8}Sr_{0.2}CoO_3$	Critical isotherm plot	--	--	3.55(1)
3D Heisenberg	Theory	0.365	1.386	4.8
Mean-field	Theory	0.5	1.0	3.0
3D Ising	Theory	0.325	1.241	4.82

TH.C-P14 - Tuning magnetostructural transformation temperature in antiperovskite compounds

E. T. Dias [1], K. R. Priolkar [1], A. K. Nigam [2]

1. Department of Physics, Goa University, Taleigao Plateau, Goa , India
2. Tata Institute of Fundamental Research, Dr. Homi Bhabha Road, Colaba-Mumbai, India

Magnetic refrigeration based on magnetocaloric effect (MCE) or adiabatic temperature change (ΔT_{ad}) is rapidly becoming an environmentally sound alternative to conventional vapour-cycle refrigerators due to its energy savings potential. Many new materials with large MCE have been discovered as a result of extensive research and a better understanding of this magneto-thermal property.

Mn-based antiperovskite compounds are a group of magnetic materials possessing a wide variety of magnetic structures and magnetic transitions depending on the chemical composition. They also exhibit potentially useful properties such as giant magnetoresistance, large MCE, negative thermal expansion (NTE), magnetostriction, and near zero temperature coefficient of the resistivity.

Mn_3GaC shows a first-order ferromagnetic (FM) to antiferromagnetic (AFM) transition at T~178K accompanied by a large change in entropy (|ΔS|~15J/Kg-K at 2T equivalent to an adiabatic temperature difference of 4K) drawing interest from the point of view of application as a magnetic refrigeration material. When Tin replaces Gallium, the first-order transition temperature is increased to T_C~279K where the compound Mn_3SnC transforms from a paramagnetic (PM) to a non-collinear ferrimagnetic (FI) state with |ΔS|~2.6J/Kg-K at 2T.

Mn_3InC is another antiperovskite compound that exhibits two first-order magnetic transformations at T = 127K from AFM ground state to a FM state and a FM to PM transformation at T~430K. Partially replacing In with Sn critically affects the two transformation temperatures. In this paper, we present a possibility of tuning these magnetic transformation temperatures to around room temperature by adjusting the ratios of Sn and In at the B-site.

TH.C-P15 - Ground-State and magnetocaloric properties of a spin-electron double-tetrahedral chain

L. Galisova [1], J. Strecka [2]

1. Technical University, Kosice, Slovakia
2. Pavol Jozef Šafárik University, Kosice, Slovakia

Ground state and adiabatic demagnetization process of an exactly solvable spin-electron tetrahedral chain composed of localized Ising spins regularly alternating with mobile electrons delocalized over triangular plaquettes are investigated by considering the one-third filling case and the ferromagnetic exchange interaction between mobile electrons and the localized Ising spins. Two types of ground-state degeneracy are discussed: the one arising from chiral degrees of freedom of mobile electrons and the another one appearing owing to a kinetically-driven frustration of the localized Ising spins. It is demonstrated that the investigated system may exhibit an enhanced magnetocaloric effect during the adiabatic demagnetization process manifested through magnified adiabatic cooling rate, which suggests a potential use of the investigated spin-electron system for low-temperature magnetic refrigeration.

TH.C-P16 - Investigation of magnetic and magnetoelastic properties of the unconventional heavy-fermion compound $CeCu_2Ge_2$ (CCG)

5. Jülich Centre for Neutron Science (JCNS) at Heinz Maier-Leibnitz Zentrum (MLZ), Forschungszentrum Jülich GmbH, Garching, Germany

In general, several macroscopic measurements, including spin and lattice degrees of freedom, are necessary to map out the phase diagram of a magnetic compound. This procedure was realized at $CeCu_2Ge_2$ with a ground state strongly influenced by Kondo behaviour. Moreover, the challenging behaviour allows the check, whether a mean field theory succeeds in describing the physics correctly.
$CeCu_2Ge_2$, the counterpart of the heavy-fermion superconductor $CeCu_2Si_2$, exhibits an incommensurate antiferromagnetic ground state with τ_1 = (0.28 0.28 0.54) below the antiferromagnetic ordering temperature T_N = 4.1 K. The magnetism is strongly affected by a screening of the Ce 4f-moments by conduction electrons. The similar energy scales of this Kondo behaviour and magnetic exchange results in a complex magnetic phase diagram with amazing quantum critical phenomena at very-low temperatures. The magnetic properties of $CeCu_2Ge_2$ were studied by magnetization measurements and, using the strong magnetoelastic coupling, by magnetostrictive investigations over a wide temperature range and in fields up to 50 T. Results suggest a refinement of the proposed H-T phase diagram for [100] and [001] direction. Especially, the magnetostriction curves reveal the details clearly, e.g. the temperature dependence of the phase transition at 8 T in fields along [100], which is characterized by second-order type change of the spin-density wave vector to τ_2 = (0.31 0.31 0.54). Going up in field, a new phase emerges at around 12 Tesla, possibly characterized by a disordered transversal residual moment, which disappears at about 26 T.
In order to interpret the bulk measurements and the existing neutron scattering data a mean-field simulation by the McPhase program is in progress. The principal shape of magnetization and susceptibility curves as well as the proposed cycloidal magnetic-structure model is reproduced. The theoretical results demonstrate the great importance of the Kondo effect to $CeCu_2Ge_2$ magnetism.

TH.C-P17 - A new phase in antiferromagnets below the saturation field

Y. Kubo [1], S. Kurihara [1]

1. Department of Physics, Waseda University, Tokyo, Japan

It is known that classical square-lattice Heisenberg antiferromagnets have the N\'eel structure in zero magnetic field, and have a canted structure in fields H and finally saturate at $H_{\rm s}$. In the case of quantum antiferromagnets, however, there are quite strong three-magnon interactions at around $0.75 H_{\rm s}$ [1,2] which lead to a complete softening of a nonlinear spin-wave spectrum at a certain wave vector $K_{\rm c}$ at $H_{\rm c}$ [3]. Moreover, we get an unphysical negative spin-wave spectrum around $K_{\rm c}$ for $H>H_{\rm c}$ [2,4]. We believe that the complete softening at $H_{\rm c}$ strongly indicates the simple canted states become unstable and a new ground state should appear in higher fields [3,4]. The main goal of this study is to clarify what is the new ground state for $H>H_{\rm c}$. We infer from Refs. [3,4] that an incommensurate noncoplanar state, which is characterized by $K_{\rm c}$, appears for $H>H_{\rm c}$. We calculate the free energy in noncoplanar states and canted states, and find that the free energy of the noncoplanar state becomes lower than that of the canted state. Therefore, we see that the incommensurate noncoplanar states appear for $H>H_{\rm c}$.

TH.C-P18 - Magnetic field induced phase transition in $PdCrO_2$

P. Kushwaha [1], N. Nandi [1], C. Geibel [1], A.P. Mackenzie [1,2]

1. Max-Planck Institute, Chemical Physics of Solids, Dresden, Germany
2. Scottish Universities Physics Alliance, School of Physics and Astronomy, University of St. Andrews, St. Andrews, United Kingdom

The delafossite metal $PdCrO_2$, which has a layered structure based on a triangular lattice, is of current interest due to its unconventional transport properties. Previous studies showed highly anisotropic metallic behavior with antiferromagnetic ordering near 38 K. Recent neutron experiments suggested that the ordered state is based on a commensurate co-planar 120° spin structure. Here we report in-plane resistivity (ρ_{ab}) measurements on single crystalline $PdCrO_2$. Zero field resistivity shows an excellent residual resistivity ratio (R_{300K}/R_{2K}) which is in the range of 100 - 200 for all measured crystals. The room temperature resistivity appears to be 6 $\mu\Omega$ cm which is the lowest ever measured in this system. The antiferromagnetic ordering temperature (T_N) is measured to be 38 (±0.1) K. When a moderate magnetic field (≈ 7 Tesla) is applied perpendicular to the ab-plane, ρ_{ab} (T) smoothly increases on decreasing the temperature below 20 K. Further increase in magnetic field enhance this upturn and results in a sharp upward jump at 5 K. Iso-thermal resistivity measurements at 2 K indicate two magnetic transitions at ~2.8 Tesla and ~9.2 Tesla, but no saturation is observed up to the maximum applied field of 14 Tesla, by which field the magnetoresistance has reached 1400%. These results offer insight into the delicate interplay between Cr-derived magnetism and Pd-derived conduction in this fascinating material.

TH.C-P19 - Pressure-induced novel electronic state of $Fe_{70}Ni_{30}$ Invar alloy

G. Oomi [1], R. Saito [2], M. Ohashi [3], T. Nakano [4]

1. Kurume Institute of Technology, Japan
2. Department of Physics,Kyushu University, Japan
3. Faculty of Engineering,Kanazawa University, Japan
4. Faculty of Engineering,Niigata University, Japan

It is well known that the ferromanetic properties of Invar alloys are strongly affected by an application of pressure.Since the pressure coefficient of TC of $Fe_{70}Ni_{30}$ (=390K at ambient pressure) is about -60K/GPa,the ferromagnetism may disappear around 6GPa. In the present work,we made an attempt to measure the electrical resistance under high pressure and magnetic fields in order to investigate the electronic state of $Fe_{70}Ni_{30}$ above &GPa.The magnetoresistance (MR) at high pressure was measured below 9T and 4.2K.It is found that clear T2 terms of the resistance appear at high pressure and the coefficients of this term were enhanced with increasing pressure,indicating an instability of electronic state or a quantum criticall point. On the other hand,the MR below 10GPa is negative same as usual ferromagnets but its sign changes from negative to positive around 12 GPa suggesting a crossover from a loclaized moment regime to paramagnetic or a new magnetic state.

TH.C-P20 - Single crystal growth and characterization of $RNi\,Si_3$ $(R = Gd - Er)$

D. Aristizábal [1], F. R. Arantes [1], F. N. Costa [1], F. F. Ferreira [1], R. A. Ribeiro [1], M. A. Avila [1]

1. CCNH, Universidade Federal Do ABC (UFABC), Santo André, SP, 09210-580 Brazil

We have investigated the structural, magnetic, thermodynamic and transport properties of the new intermetallic series $RNi\,Si_3$ $(R = Gd - Er)$, grown by the Sn-flux method which yields high quality plate-like single crystals. The results of the Rietveld refinement, based on X-ray powder diffraction data, show that these compounds crystallize in a layered orthorhombic structure in the $Cmmm$ space group ($SmNi\,Ge_3$ type) with the main plate surfaces orthogonal to the crystallographic b direction, consistent with the only member previous characterized in this series, $YbNi\,Si_3$ [1]. Temperature dependent magnetization ($2K < T < 300K$) is anisotropic and reveals that the ground states are antiferromagnetic, with rough de Gennes scaling of T_N for the heavy rare-earths. There are also further transitions in the ordered state, indicating changes in the magnetic structure. For $R = Tb, Dy$ and Ho low-temperature magnetic isotherms up to H=90kOe exhibit multiple metamagnetic transitions and alternating reversible/irreversible regions in the ordered state, which are dependent on temperature, magnetic field and crystal orientation. From this complex magnetic behavior we have built tentative magnetic phase diagrams. $HoNi\,Si_3$ presents at least six regions of distinct magnetic structures and is a promising candidate for the realization of the “devil's staircase” [2], involving magnetic frustration and/or long-range exchange interaction. We thank the financial support of FAPESP, CAPES and CNPq.

4. ALBA Synchrotron/CELLS, Cerdanyola del Vallès, 08290, Spain

We report magnetization studies to pressures of 30 GPa combined with synchrotron x-ray powder diffraction (SXRD) studies up to 40 GPa to explore the pressure-induced phase transformations of $Co_xFe_{3-x}O_4$ ($0<x<2$) ferrites. All samples are ferrimagnetic and crystallize with a cubic spinel structure at ambient pressure. Room temperature Fe and Co K-edge x-ray magnetic circular dichroism (XMCD) and magnetization measurements were carried out to investigate the stability of the ferrimagnetic ground state using diamond anvil cells. By increasing pressure, the XMCD signal decrease continuously up to the highest reached pressure by ~50% in Fe_3O_4 (at 25 GPa) and by ~70% in $Co_{1.5}Fe_{1.5}O_4$ (at 16 GPa) and Co_2FeO_4 (at 21 GPa). In $CoFe_2O_4$, the suppression by ~80% of the XMCD signal occurs simultaneously at both Fe and Co K-edges between 24 and 27 GPa. A continuous decrease of the dichroic signal with increasing pressure is observed at the Co K-edge, whereas the Fe K-edge dichroic intensity drops drastically. In $CoFe_2O_4$, bulk magnetization measurements up to 26 GPa confirm the disappearance of ferrimagnetism and indicate an almost linear dependence of the magnetization with the magnetic field in the high pressure phase. All the samples show, coupled to the magnetic changes, structural phase transitions from the cubic spinel structure to an analogous post-spinel phase at around 20 GPa. Spinel and post-spinel phases coexist in a wide pressure range (~20–25 GPa) and the transformation is irreversible. Measurements releasing pressure revealed that the post-spinel phase is stable down to 4 GPa when it decomposes yielding a new phase with poor crystallinity. Later compression does not recover either the spinel or the post-spinel phases. This phase transformation induced by pressure explains the irreversible loss of ferrimagnetic behavior reported in these spinels.

TH.C-P23 - Spin order in $FeCr_2O_4$ observed by mössbauer spectroscopy

S. Nakamura [1,2], A. Fuwa [3]

1. Department of Science and Engineering, Teikyo University, 1-1 Toyosatodai, Utsunomiya, Japan
2. Advanced Research Institute of Science and Engineering, Waseda University, Tokyo, Japan
3. Faculty of Science and Engineering, Waseda University, Tokyo, Japan

A spinel oxide $FeCr_2O_4$ contains of Fe^{2+} ions on the A-site (tetrahedral site). The Jahn-Teller active Fe^{2+} ion causes a successive phase transition from cubic to tetragonal (135 K) and finally to orthorhombic phases (70 K). Neutron powder diffraction revealed a ferrimagnetic order below around 70 K, followed by a spiral magnetic order below 35 K. In this research, we have applied ^{57}Fe Mössbauer spectroscopy to investigate the magnetic structure in detail. A single crystal specimen of (100) platelet was used as an absorber. In order to obtain a single domain state in the low temperature phases, a slight compression along [001] axis was added by attaching epoxy resin on its both edges. Mössbauer spectroscopy was conducted in conventional transmission geometry by using ^{57}Co-in-Rh (25mCi) as γ ray source. The paramagnetic spectrum at room temperature consists of a singlet reflecting the cubic symmetry. The isomer shift is 0.937 mm/s, indicative of high spin Fe^{2+} state. With decreasing temperature, the spectrum splits into a doublet even in the cubic region due to the local and dynamical Jahn-Teller effect. The spectrum at 130 K consists of an asymmetric doublet (I_1:I_2 ~ 3:5) well corresponding to the single domain tetragonal phase. Below 60 K, the magnetically ordered spectrum is observed. The spectrum consists of only one component down to 40 K, which corresponds to the collinear ferrimagnetic order. Since the local structure around the Fe ion is considered to be close to that of the tetragonal phase, the Fe^{2+} spins align presumably along [110] direction. Below 35 K, however, the spectrum consists of distinct two subspectra indicating that the spins align in two different directions. One is still in [110] direction, while the other is approximately in [100] or [010] directions. This spin configuration is not consistent with a simple spiral magnetic structure.

TH.C-P25 - Single crystal growth and characteristics of $Sm_{0.7}Tb_{0.3}FeO_3$ orthoferrite single crystal with spin-reorientation in room temperature

A. Wu [1], B. Wang [1], X. Zhao [1], L. Su [1], S. Cao [2]

1. Shanghai Institute of Ceramics, Chinese Academy of Sciences, China
2. Department of Physics, Shanghai University, China

High quality $Sm_{0.7}Tb_{0.3}FeO_3$ single crystal has been grown by the four-mirror floating zone technique. The magnetic properties of $Sm_{0.7}Tb_{0.3}FeO_3$ single crystal were studied in the temperature range from 3 to 400 K. A clear spin reorientation behavior with the gradual transition of the Fe^{3+} magnetic moment ordering from $\{G_z,F_x\}$-type ordering at low temperatures to $\{G_x,F_z\}$ -type ordering at high temperatures is observed in a range of 330 – 360 K, which significantly lower than that of $SmFeO_3$, while significantly higher than that of $TbFeO_3$. Interestingly, below this transition, with decreasing temperature, the value of M_x increases till 3 K, which is in contrast to a pure $SmFeO_3$. We ascribe this change of behavior to substitution of Sm ions for Tb ones.. At temperatures 30 – 100 K hysteresis curves possess a double-loop shape with with two triangular loops emerging, which is explained by the single domain-wall state of the sample. The shape of hysteresis loop depends on the values of domain wall expulsion field H_{exp} and the domain wall nucleation field $H_{n..}$

TH.C-P26 - Pressure-induced magnetic order in a gapped quantum magnet

A. Mannig [1]

1. ETH Zurich, Laboratory For Solid State Physics, Neutron Scattering And Magnetism Group, Zurich, Switzerland

We present recent muon-spin relaxation and magnetic susceptibility data under applied hydrostatic pressure on the organometallic S=1 quantum magnet $NiCl_2 \cdot 4(SC(NH_2)_2)$.
The material consists of weakly coupled antiferromagnetic chains and has a spin gap resulting from large single-ion anisotropy.
Our muon spin rotation experiments provide local field dependencies on temperature as well as pressure and allow for the mapping of a detailed phase diagram up to 22 kbar. We demonstrate that the compound may be driven through two subsequent pressure-induced transitions into apparently distinct magnetically ordered phases.
Susceptibility-measurements support those results and show the potential of low-pressure transitions to be investigated by various techniques.
With $NiCl_2 \cdot 4(SC(NH_2)_2)$ we add to the very few reported pressure-induced phase transitions in quantum magnets, the recent example being the frustrated quantum spin liquid PHCC [1].

TH.C-P27 - First-order magnetization process as a tool for magnetic-anisotropy description of $U_3Cu_4Ge_4$

D. Gorbunov [1], M.a Henriques [2,3], A. Andreev [2], Y. Skourski [1], M. Richter [4], J. Wosnitza [1]

4. IFW Dresden, Dresden, Germany

Here, we report on high-magnetic-field investigations of a $U_3Cu_4Ge_4$ single crystal. $U_3Cu_4Ge_4$ (orthorhombic crystal structure) is a ferromagnet below 73 K and is characterized by highly localized 5f states as manifested by the spontaneous magnetic moment of 5 μB/f.u. at 2 K. Density-functional calculations point to a ferrimagnetic ground state. As a typical uranium-based intermetallic compound, $U_3Cu_4Ge_4$ displays very strong uniaxial magnetic anisotropy, the anisotropy field between either of two principal crystallographic directions significantly exceeds 100 T. The a axis is the easy magnetization direction. Strong anisotropy is also observed within the (bc) plane. $U_3Cu_4Ge_4$ exhibits strong magnetic hysteresis, the coercive field reaches 0.4 T. The strong magnetic anisotropy is also reflected in the specific heat and electrical resistivity both revealing gapped behavior.
In pulsed magnetic fields at 2 K, $U_3Cu_4Ge_4$ displays a type-II first-order magnetization process (FOMP) along the b axis at 25 T, while the magnetization curve along the c axis is S shaped suggesting a step-wise rotation of the magnetic moments. The critical fields of both field-induced transitions decrease with temperature. The presence of the FOMP is remarkable since it provides a tool for describing the magnetic anisotropy despite its very large value making its direct measurement impossible for $U_3Cu_4Ge_4$. Taking into account anisotropy constants up to the sixth order, we succeeded in describing the magnetization curves measured along the b axis between 2 and 60 K. At 2 K, we obtained the constants: K1 = 17.6, K2 = -33, K3 = 26 MJ/m3. With increasing temperature the constants decrease monotonously and the higher the order of the anisotropy constant, the faster it diminishes with temperature. While the very large magnetic anisotropy of uranium intermetallics is in general hardly accessible to experiment, the present case presents an interesting counter-example.

TH.C-P28 - Substitution in $LiMF_4$: a playground of fundamental interactions

P. Babkevich [1], A. Finco [1], M. Jeong [1], B. Dalla Piazza [1], I. Kovacevic [1], G. Klughertz [1], K. W. Kr[2], D. T. Adroja [3], E. Goremychkin [3], T. Unruh [4], J. Jensen[5], H.M. Ronnow[1]

5. Niels Bohr Institute, Copenhagen, Denmark

Despite its fundamental nature, there exist very few studies on purely dipolar-coupled magnetic systems. Well known examples include LiHoF4 which is an excellent realisation of an Ising system while $LiErF_4$ and $LiYbF_4$ have been found to be XY. The family of compounds, $LiMF_4$, where M = Ho, Er, Yb, Tm, Gd, etc are intriguing to study fundamental interactions. The crystal field environment that the M ions experience plays a crucial role in stabilising magnetism. Through careful analysis of inelastic neutron and susceptibility measurements we are able to explain and predict, in the mean-field approximation, the low-temperature phase diagrams of LiMF4 compounds.

TH.C-P34 - dependence of morin temperature on the size of hematite nanoparticles

J. Kohout [1], T. Kmjeè [1], D Kubaniova [1], L. Kubiekova [1], K. Zavýta [1], P. Brazda [2], E. Santava [2], D. Nizoansky [3], M. Klementova [3], A. Lanèok [3]

3. Institute of Inorganic Chemistry of the ASCR, v.v.i., Husinec, Czech Republic

Bulk hematite (alfa-Fe_20_3) exhibits a spin reorientation transition from antiferromagnetic to weakly ferromagnetic state above TM~264 K, known as Morin transition. TM is decreasing with particle size and for nanoparticles smaller than ~20 nm the Morin transition may even disappear. Nanoparticles of alfa-Fe_20_3 enriched with 57Fe isotope (~95%) were prepared by sol-gel and nanoparticles with natural Fe by hydrothermal methods. The X-ray powder diffraction confirmed alfa-Fe_2O_3 as the main phase. Various particle shapes - spheres, spindles, rhombohedra and small spheres were discerned from TEM pictures with characteristic particle sizes: 126, 42, 26 and 5.6 nm, respectively. The temperature dependence of magnetization after cooling in zero and non-zero magnetic fields was measured in a SQUID magnetometer and TM=255, 215, 187 K respectively, were derived from the rapid increase of magnetization. These data agree with theoretical dependence of TM on the particle size [1]. The small spheres were superparamagnetic, with their magnetization curves fitted by Langevin function taking a lognormal distribution of particle sizes into account, and displayed no Morin transition. The transition was also proved by temperature dependence of Mössbauer spectra of enriched nanoparticles between 4.2 and 300 K. The ratio of the areas of two sextets ascribed to the antiferromagnetic and weakly ferromagnetic phases, gave then their relative concentrations.

The rare earth aluminum borates $RAl_3(BO_3)_4$ have only one magnetic subsystem - a subsystem of rare earth ions. That is why same of these crystals can be a simple model systems for the study of spontaneous and magnetic field induced phase transitions. In this work, the specific heat and ESR were studied in order to determine parameters of interactions between the magnetic ions in the $TbAl_3(BO_3)_4$ crystal.
Investigation of temperature dependence of the specific heat allowed us to determine the magnetic ordering temperature of the rare-earth subsystem of $TbAl_3(BO_3)_4$, $T_c = 0.68$ K. The initial splitting, $\Delta \approx 1.3$ K, and the effective g-factor, $g = 16$, of the lowest quasidoublet of Tb^{3+} ion were determined from the ESR experiments. In the case of antiferromagnetic ordering, in frame of the molecular field theory, the difference between the constants of effective fields of intrasublattice interaction, λ_{11}, and intersublattice interaction λ_{12} can be calculated by using the expression: $(\lambda_{11} - \lambda_{12}) = \Delta/2\ (g_{eff}\ \mu_B)\ 2\tanh\ (\Delta/2T_c)$. In the case of ferromagnetic ordering, $\lambda_{12} = 0$ and λ_{11} is equal to the molecular field constant λ_0. By fitting this expression to the experimental data we obtained $(\lambda_{11} - \lambda_{12})$ or λ_0 equal to 0.03 T^2/K.
Low temperature magnetic ordering and small value of the effective interaction between the magnetic moments of the terbium ions allows us to make the assumption about the dipole-dipole nature of the magnetic ordering in this material.

TH.C-P36 - Towards a simple description of magnetism in heavy rare earth elements: application to magnetic refrigeration.

E. Mendive Tapia [1], J. Staunton [1]

1. The University of Warwick, United Kingdom

Magnetic refrigerants are much more efficient than conventional fridges based on compression/expansion technology and are promising candidates for environmentally friendly refrigerants. Therefore, the development of simple theoretical models for their study has an important value in order to provide qualitative insights into otherwise an incredibly complex research field. Here we employ an ab-initio Disordered Local Moment Theory (DLM) to investigate the magnetic phase diagram of heavy rare earths. We focus on the study of magnetic phase transitions that are characteristic of the common valence electronic structure among them. Gd is used in order to mimic other heavy rare earths due to their chemical similitude. As a preliminary main result, we observe that FAN, distorted AFM, and CONE magnetic phases can be obtained by changing the temperature and/or the strength of an applied magnetic field without including crystal field contributions nor relativistic effects. Investigation of Helifan and other possible new magnetic structures is in process. In the long term, we seek to model the magnetism of the heavy rare earths and nanostructure potential materials exhibiting large caloric responses by scaling the exchange interaction with the Gennes factor and by including anisotropy effects as additional phenomenological terms.

TH.C-P37 - Influence of grain size in the magnetic and magnetocaloric transitions in $La_{0.5}Ca_{0.5}MnO_3$ probed by direct and indirect methods

M. Quintero [1,2], S. Passanante [1,3], I. Irurzun [1,3], D. Goijman [1], G. Polla [1]

3. Departamento de Física, Facultad de Ciencias Exactas y Naturales, UBA, Argentina

The magnetocaloric effect has been revealed as one of the most promising topics in the study of magnetic properties, mainly motivated in the plausible use for magnetic refrigeration applications. During the last years, the increase in the complexity of the systems under study forced a careful revision to the validity of the thermodynamic models used to estimate the effect. A non adequate use can lead to inconsistencies between results obtained by different methods. In this work we used the prototypical manganite $La_{0.5}Ca_{0.5}MnO_3$ as an example of this issue. The influence of grain size in the magnetic properties of this system has been studied more than a decade ago. The presence of long range ordering is suppressed as the grain size decreases, giving place to a metastable state instead of the ground state. The differences obtained using direct and indirect methods are discussed in the framework of domain walls in the ferromagnetic phase of the system.

TH.C-P38 - High temperature magnetic properties and spin-lattice coupling of magnetoelectric epsilon-Fe_2O_3

M. Gich [1], J. Padilla [1], J. Nogués [2,3], J. Kreisel [4,5], A. Roig[1], J. Garcia-Muñoz [1]

5. University of Luxembourg, Luxembourg

Epsilon-Fe_2O_3 is one of the less studied ferrimagnetic iron oxides and it is attracting great interest after the discovery of a huge coercivity (20 kOe)[1] and multiferroicity[2] at room temperature. Its complex structure (with four Fe^{3+} sublattices) favours magnetic frustration and successive magnetic and structural transitions. The collinear ferrimagnetic phase (Tc=500K) is substituted by two different incommensurate magnetic phases on cooling below 150K and 110K respectively [3].
We present magnetic, Raman and neutron measurements questioning the current belief that the magnetic ordering temperature of epsilon-Fe_2O_3 is ~500 K, well below that of other iron oxides such as hematite, magnetite or maghemite. Magnetometry measurements up to 925 K show non-linear behaviour under field and signs of ferrimagnetic order up to temperatures as high as 870 K. The transition to superhard ferrimagnetism upon cooling below 500 K brings about an anomalous evolution of the thermal expansion and selected bands of the Raman spectra. A temperature-dependent neutron diffraction study of these nanoparticles has revealed the presence of magnetic order well above 500 K, in agreement with magnetic measurements. Analysis of neutron data confirmed that the new high temperature ordered phase is also ferrimagnetic, although the net ferromagnetic component is significantly lowered, and it vanishes above 870 K. This temperature is similar to the Curie point in other iron oxides, indicating comparable magnetic coupling strengths.

TH.C-P39 - Charge order in magnetite below the verwey transition studied by combination of ^{57}Fe NMR and mössbauer spectroscopy

J. Kohout, K. Závěta, T. Kmječ, D. Kubániová, B. Sedlák

1. Charles University In Prague, Faculty of Mathematics and Physics, Prague, Czech Republic

Magnetite Fe_3O_4 is a multiferroic mixed-valence transition metal oxide with inverse spinel structure. At high temperatures it is cubic (*Fd3m*) and both NMR and Mössbauer spectroscopy (MS) point to the delocalization of Fe^{2+} and Fe^{3+} ions in the octahedral *B*-sites. At the Verwey temperature (T_V≈120-125 K) magnetite undergoes a first order phase transition: the symmetry is lowered to monoclinic and the electric conductivity drops by more than two orders of magnitude suggesting the electron localization.
According to simple Verwey model, ferric and ferrous ions order in the *B*-sites which was found roughly correct in ab-initio calculation [1]. Senn [2] recently proposed the charge ordering and low-temperature superstructure of Fe_3O_4 from high-energy X-ray diffraction.
Here we present results on the charge order of a high-purity single-crystalline Fe_3O_4 determined by combination of ^{57}Fe NMR and MS. Previous NMR measurements [3-4] found 24 nonequivalent sites for iron cations - 16 octahedral and 8 tetrahedral ones agreeing with the monoclinic *Cc* space group.
The values of hyperfine fields from NMR spectra were used for restricting the number of free parameters when fitting the MS spectra at 4.2 K. After cooling the sample below T_V without and with an external field, the magnetic moments are normal to, and make an angle of ~45° with the plane of the thin platelet, respectively.
The isomer and quadrupole shifts of *B*-sites are split into two groups supporting the idea of charge localization in the MS time window of ~10^{-7} s.
The financial support under the grant GAUK 8313 is gratefully acknowledged.

2. Department of Physics and Astronomy, Unversity of Nebraska-Lincoln, Linclon, Nebraska,United States

3. Lappeenranta University of Technology, Finland

It was found that off-stoichiometric $Ni_{50}Mn_{50-x}In_x$ Heusler alloys are characterized by inhomogeneous structural and magnetic phases and in addition to the field and temperature induced magnetostructural transitions and shape memory effects, they demonstrate exchange bias, giant deformations, kinetic arrest, giant normal (direct) and inverse magnetocaloric effects, large magnetoresistance, giant anomalous Hall effect and other important properties suitable for potential practical applications ([1, 2] and references therein). Since disorder in these alloys plays a key role, even a small addition of fourth element, Z, to Ni-Mn-In alloys can drastically change their properties. We present our last experimental results on structural and magnetic phase transitions, magnetic, magnetocaloric and magneto-optical properties in quaternary Ni-Mn-In-Z (Z =Co, Cu, Al, B, Cr, Si) Heusler alloys with concentration of Ni, In and Z around 50%, 15%, and up to 5%, respectively. Bulk polycrystalline samples were obtained by the arc-melting technique, the monocrystal $Ni_{45}Mn_{36.7}In_{13.3}Co_5$ was grown by the Czochralski method, the thin films were fabricated by pulse laser deposition. The obtained results do not support the correlation between magnetic properties and the number of valence electrons per atom. Magnetic properties depend non-linearly on the fraction of Z element. The adiabatic changes of temperature in magnetic fields up to 1.8 T in the vicinity of martensitic transition reaches -2.0 K at heating the sample but does not exceed -1.0 K and can be even positive in some samples at cooling. Magneto-optical spectra were measured in the geometry of the transverse Kerr effect in the energy range 0.5-4.0 eV and did not reveal the noticeable difference in spectra profiles in martensitic and austenitic states.

TH.C-P41 - Enhanced NMR in entangled nuclear-electronic quantum magnet $LiHoF_4$

I. Kovacevic [1], P. Babkevich [1], M. Jeong [1], G. Boero [1], H. Ronnow [1]

1. Ecole Polytechnique Federale De Lausanne (EPFL), Lausanne, Switzerland

Transverse-field Ising magnet $LiHoF_4$ is known for its electronic quantum criticality which is altered by hyperfine coupling to the nuclear spins. We focus on probing nuclear transitions (NMR) in entangled nuclear-electronic states in $LiHoF_4$ using a vector network analyzer (VNA) in wide frequency range up to 6 GHz and at low temperatures down to 0.15 K. Evolution of the hyperfine levels as a function of field and temperature through quantum and thermal transitions was not only measured experimentally but also simulated within the mean-field approximation. Through this approach we are able to track the evolution of the hyperfine levels as a function of field and temperature through quantum and thermal phase transitions. Our mean-field simulations show that nuclear transition amplitude is enhanced by more than two orders of magnitude due to nuclear-electronic hybridization. We find a quantitative agreement between our experiments and calculations for the resonance positions and relative transition intensities. This allows us to probe the transition energies as well as the wave-functions of $LiHoF_4$. These results bring us a step closer to quantum control of hybrid nuclear-electronic states near quantum phase transition where hybridization is the largest due to avoided level crossing, and at low temperatures where hyperfine interaction is large compared to thermal fluctuations.

TH.C-P42 - Ferromagnetism in partially oxidized CuCl

T. Saerbeck [1], J. Pereiro [2], J. Wampler [3], J. Stanley [3], J. Wingert [3], O. G. Shpyrko [3], I. K. Schuller [3]

1. Institut Laue-Langevin, Grenoble, France
2. School of Physics and Astronomy, Cardiff University, Cardiff, United Kingdom
3. Department of Physics and Center for Advanced Nanoscience, University of California San Diego, La Jolla, United States

We report on the observation of ferromagnetism in bulk CuCl powders partially oxidized in air or humid environments. The phase diagram of copper-halides shows a rich diversity not only in crystalline structure, but also in magnetic and electronic properties. CuCl is reported to be a diamagnetic insulator which is highly susceptible to oxidation. Corrosion products without exception show antiferromagnetic ordering with varying transition temperature and spin structure depending on composition.
In contrast, we observe a distinct ferromagnetic transition and hysteresis with a Tc of 18 K for CuCl partially oxidized in air [1]. The amount of this new ferromagnetic phase is shown to be related to the degree of humidity and exposure time ranging from minutes to several weeks. Magnetic field modulated microwave spectroscopy (MFMMS) and SQUID magnetometry are used to identify magnetic phase transitions and compare them to the antiferromagnetic transitions in other Copper-chloride structures. Through detailed structural investigations and Rietveld analysis, the evolution of the crystallographic structure after different degree of oxidation is determined. No corrosion product of cuprous chloride can account for the observed magnetic properties. In addition, the ferromagnetic state is irreversible with respect to subsequent drying processes, but decays upon prolonged exposure to humidity. This indicates that the magnetic signal originates from an intermediate stable phase in the oxidation process of CuCl.

This work is supported by AFOSR Grant no. FA9550-14-1-0202.

TH.C-P43 - Irreversibility induced by thermal cycles in phase separated manganites

J. Sacanell [1], M. Quintero [1], B. Sievers [1], L. Granja [1], G. Polla [1], P. Levy [1], F. Parisi [1]

1. Departamento de Física de la Materia Condensada, Gerencia de Investigación y Aplicaciones, Comisión Nacional De Energía Atómica, San Martín, Argentina

We have studied the effect of irreversibility induced by repeated thermal cycles on the magnetization of polycrystalline samples of $La_{0.5}Ca_{0.5}MnO_3$ and $La_{0.325}Pr_{0.3}Ca_{0.375}MnO_3$. A decrease of the magnetization at different temperature ranges after cycling is obtained in the temperature range between 300 and 30 K. Both compounds are known to exhibit intrinsic submicrometric coexistence of phases and undergo a sequence of phase transitions related to structural changes. We observed that the changes induced by thermal cycling can be partially inhibited by applying magnetic field and hydrostatic pressure.
Our results suggest that the growth and coexistence of phases with different structures gives rise to microstructural tracks and strain accommodation and produces the observed irreversibility. Irrespective of the actual ground state of each compound, the effect of thermal cycling is towards an increase of the amount of the non ferromagnetic phase in both compounds.
We developed a phenomenological model to describe the observed effect in terms of a growth of one phase against the other through the contact surface between them.

TH.C-P44 - Key role of rutile structure for layered magnetism in chromium compounds

Y. Kondo [1], T. Hotta [1]

1. Department of Physics, Tokyo Metropolitan University, Japan

$CrCl_2$ and CrF_2 with the distorted rutile-type crystal structure exhibit paramagnetism in a room temperature, but at low temperatures, they are known to show different antiferromagnetic (AF) structure. CrF_2 has the simple Néel structure in common with other fluorides, while $CrCl_2$ exhibits peculiar layered AF structure. Our purpose is to unveil the stabilization mechanism of such layered AF structure different from the simple Néel structure.

Since Cr ion is divalent in the halogenation chrome, we find the electron configuration $3d^4$ with one electron in e_g and three electrons in t_{2g} orbitals. We notice that this is just the same electron configuration as Mn^{3+} in manganese oxides. Here we recall that the complicated magnetism in manganese oxide is explained by the competition between the itinerant and localized natures of electrons. Namely, e_g electrons smoothly move in the ferromagnetic t_{2g} spin arrangements with the penalty of magnetic energy, while they are localized for AF t_{2g} spins with the gain of magnetic energy. The situation is well described by the so-called double-exchange model.

In this research, we try to understand the magnetic structure in chromic compounds on the basis of the double-exchange model with orbital degree of freedom. Here we consider a body centered cubic (bcc) lattice without any distortions and the TiO_2 structure (rutile structure) lattice which is obtained from the bcc lattice by pressing it along the c-axis. We find that the layered magnetic structure of $CrCl_2$ never appears as the ground state in the bcc lattice. When we include the distortion along the c-axis, leading to the rutile-type structure, we eventually obtain the layered magnetic structure as the ground state in a wide range of parameters space. In the poster presentation, we report the details of the ground-state phase diagram to explain the appearance of the layered magnetic phase.

TH.C-P45 - Low-temperature specific heat and magnetic ordering in R_2Pd_2In

P. Svoboda [1], S. Maskova [1], L. Havela [1], A. Kolomiets [2]

1. Charles University, Faculty of Math. And Physics, DCMP, Prague, Czech Republic
2. Lviv Polytechnic National Univ., Lviv, Ukraine

The series of isostructural intermetallic compounds R_2Pd_2In (R= La, Pr, Nd, Sm, Gd, Tb, Dy, Ho and Er) crystallizes in the tetragonal Mo_2FeB_2 structure type and orders antiferromagnetically at low temperatures. High quality single crystals of selected R_2Pd_2In have been grown. The zero-field low-temperature specific heat was studied in the temperature region 1.5 - 300 K using relaxation method (PPMS) for all above indicated compounds. Sharp anomalies corresponding to the Néel temperatures were observed in all magnetic compounds together with other anomalies corresponding to the order-to-order changes of magnetic phases. The detailed analysis of the specific heat yielded the magnetic part of the specific heat and magnetic entropy of all studied magnetic compounds.

TH.C-P46 - Magnetic systems at elevated temperatures by relativistic disordered local moments theory

D. Thonig [1], J. Henk [2], O. Eriksson [1]

1. Institute of Physics and Astronomy, Uppsala University, Sweden
2. Martin Luther University Halle-Wittenberg, Germany

The mismatch of experimentally and theoretically observed temperature-dependent magnetic properties, in particular the magnetic moment, the magnon stiffness, and the Curie temperature, requires improvements in first-principles theory. The non-collinear magnetic state at elevated temperatures is described here within a relativistic disordered local moments theory. The coupling between local magnetic moments for a given magnetic configuration is obtained from first-principles calculations, allowing to map the non-collinearity to the spin temperature. Taking into account spin-orbit coupling and a spherical harmonics expansion of the atomistic exchange parameters enables us to account also for higher-order interactions, like Dzyaloshinskii-Moriya or biquadratic exchange.
We introduce to the approach and apply it to bulk ferromagnets as well as to 1-3 ML Fe on Cu(001). In combination with Monte Carlo simulations, our first principles theory is in agreement of the magnetization versus temperature dependence in the entire temperature range of $0 < T < Tc$. The temperature-dependent Heisenberg exchange exhibits a crucial dependence due to the rotation of two magnetic moments, which influences the magnetic ground state obtained from Monte Carlo simulations. Our method makes a significant contribution to a deeper understanding of the complex temperature-dependent exchange mechanisms in magnets.

TH.C-P47 - Possible decoupling of the magnetic field instabilities in the antiferromagnet CeRh2Si2 close to its critical pressure in pulsed magnetic fields.

D. Braithwaite [1], W. Knafo [2], R. Settai [3], D. Aoki [1,4], S. Kurahashi [5], J. Flouquet [1]

1. Univ. Grenoble Alpes and CEA, INAC-SPSMS, Grenoble, France

4. IMR, Tohoku University, Oarai, Ibaraki, Japan
5. Graduate School of Science and Technology, Niigata University, Niigata, Japan

In an Ising antiferromagnet like $CeRh_2Si$ 2, an external magnetic field will destroy the antiferromagnetic order, and induce a polarized paramagnetic state. These two phenomena can occur concomitantly with a 1st order metamagnetic transition. Alternatively antiferromagnetic order can be destroyed at a lower field than the transition to a polarized state, with 2 characteristic fields, HC and HM. In $CeRh_2Si_2$ these two phenomena coincide, implying that HC>HM. However in the paramagnetic compound $CeRu_2Si_2$, doping with Rh induces antiferromagnetic order and a decoupling of HC and HM is found. Pressure is a clean way to tune an antiferromagnetic cerium compound to its critical point. Pressure will increase HM and decrease HC, and perhaps induce this decoupling of the characteristic fields. The experimental verification of this is challenging, requiring measurements under pressure (For $CeRh_2Si_2$ PC is about 1 GPa) with rather high magnetic fields (H>35T). We present a pressure cell optimized for the use in pulsed magnetic fields up to 60T, and pressures up to 4.5 GPa, at temperatures down to 1.5K. Heating effects due to the field pulse are reduced by the use of electrically insulating materials for the elements close to the sample. We report magnetoresistance measurements on a single crystal of $CeRh_2Si_2$. We find a continuous increase of HM with pressure, exceeding 60T at 1.5 GPa. For P<<PC only one anomaly is seen. Close to the critical pressure a broad shoulder develops on the low field side of HM. Normally a rather strong and sharp anomaly would be expected at HC, however the signature could become rather weak and broad due to the reduced value of the sublattice magnetization, and especially the steep slope of HC with pressure. We suggest that this shoulder is likely a sign of the decoupling of the 2 fields, and present the obtained phase diagram.

TH.C-P49 - Necessary conditions for the long-time variation of magnetic structure in frustrated magnets

K. Motoya [1], M. Hagihala [1], M. Matsuda [2]

1. Tokyo University of Science, Japan
2. Oak Ridge National Laboratory, United States

In uniform three-dimensional magnets, we have not expected to observe time variations in magnetic properties within an attainable time scale. Contrary to all expectations, we observed a long-time variation in the magnetic structure of the nondiluted uniform magnet $CeIr_3Si_2$ by means of time-resolved neutron scattering measurements.1,2) Subsequently, similar long-time variations in the magnetic structure were observed in some materials having competing magnetic interactions.3,4) All these compounds exhibit successive magnetic and multistep metamagnetic transitions. However, all materials having these two factors do not necessarily show long-time variation. In order to find necessary conditions we have studied the magnetic property of $Ce(Ir\text{-}Rh)_3Si_2$ system. $CeRh_3Si_2$ shows magnetic transitions at TN=4.72K and Tt=4.48K. In the low temperature phase it shows multi-step metamagnetic transitions. [5] These properties are quite similar to those of $CeIr_3Si_2$. However, our previous neutron scattering and magnetization measurements of $CeRh_3Si_2$ showed no time variation, which is quite different from that of $CeIr_3Si_2$.
In this work, we determined the magnetic phase diagram of the Ce(Ir-Rh)3Si2 system and made time-resolved neutron scattering measurements of some representative compounds. On the bases of time variation behavior of the macroscopic and neutron diffraction measurements, we have found that the presence of spontaneous magnetization in one-side structure is the necessary condition for the presence of long-time variation of magnetic structure in these compounds.

TH.C-P50 - Instability of ferromagnetic Fe nanoclusters produced in amorphous SiO_2 by ion implantation

K. Bharuth-Ram [1], H. Hofsaess [2], K. Zhang [2], H. Masenda [3],

1. Physics Department, Durban University of Technology, South Africa
2. Zweites Physikalisches Institut, University of Goettingen, Germany
3. Physics Department, University of the Witwatersrand,South Africa

A 460 nm thick amorphous SiO_2 layer, formed on a Si (100) surface heated to 1000oC in oxygen atmosphere, was implanted with 57Fe to a fluence of 1 x 1016/cm2 at room temperature and annealed at temperatures up to 1000oC. The implanted and annealed samples were studied by conversion electron Mössbauer spectroscopy (CEMS). The CEM spectra up to an annealing temperature of 800oC showed the presence of a singlet due to dispersed Fe ions and paramagnetic doublets with hyperfine parameters characteristic of Fe^{2+} and Fe^{3+}.
The spectrum after the 1000oC anneal was dominated by a broad ferromagnetic sextet with a hyperfine field of 32 T, showing the formation Fe nanoclusters, in agreement with the observations of Zhang et al. [1] but contrary to those of Nomura et al [2].
A surprising result was that CEMS measurements performed on the annealed sample after a period of 6 months showed the complete disappearance of the ferromagnetic sextet and only the presence of a paramagnetic doublet due to Fe^{2+}.

TH.C-P51 - Pressure effect on the magnetic phase diagram of Nd_2RhIn_8

P. Javorský[1], M. Míšek[2], M. Prachařová[1], J. Kaštil[2], J. Prchal[1], M. Klicpera[1], M. Kratochvílová[1]

1. Charles University in Prague, Faculty of Mathematics and Physics, Department of Condensed Matter Physics, Prague, Czech Republic
2. Institute of Physics ASCR, v.v.i., Praha , Czech Republic

Nd_2RhIn_8 belongs to a large group of structurally related tetragonal compounds which involve several heavy-fermion superconductors based on Ce or Pu. The occurrence of unconventional superconductivity in these compounds is closely connected to magnetic spin fluctuations, and both, the magnetism and superconductivity are believed to arise from the 4f electrons. The studies of isostructural magnetic counterparts are thus essential to investigate the evolution of the f-electron properties in these materials. We focus on Nd_2RhIn_8 which orders antiferromagnetically below T_N = 10.7 K. The Nd magnetic moments are oriented along the tetragonal c axis and the antiferromagnetic order is characterized by the propagation vector (1/2 1/2 1/2). The magnetic phase diagram consists of this ground-state antiferromagnetic phase (AF1) and an additional magnetic phase (AF2) which is formed when applying magnetic field along the c axis prior to transition to the ferromagnetic state.

In this work, we present the pressure effect on the magnetic phase diagram of Nd_2RhIn_8. The magnetization under uniaxial pressure up to 5.3 kbar applied along the tetragonal c axis and the heat capacity under hydrostatic pressure were measured in magnetic fields up to 7 and 14 T, respectively. Both types of measurements reveal an increase of T_N with increasing pressure, the effect is considerably stronger for the uniaxial pressure. We conclude that T_N increases with decreasing c/a. The phase boundary between the ground-state AF1 phase and the AF2 phase shifts to higher magnetic fields with increasing pressure. The ground state phase is thus stabilized by applying pressure. The magnetic phase diagrams in hydrostatic pressures up to 30 kbar are constructed.

TH.C-P52 - Strong anisotropy and multiple phase transitions in the noncollinear incommensurate antiferromagnets $EuRhGe_3$ and $EuIrGe_3$

O. Bednarchuk [1], D. Kaczorowski [1]

1. Institute of Low Temperature and Structure Research, Polish Academy of Sciences, Wroclaw, Poland

$EuRhGe_3$ and $EuIrGe_3$ are representatives of the $EuTGe_3$ (T = Co, Ni, Rh, Pd, Ir, Pt) family that has recently been reported to exhibit nontrivial physical properties in the ordered state with a wide variety of antiferromagnetic (AFM) structures [1-3]. In this contribution, we present the low temperature physical behaviors of two representatives, namely $EuRhGe_3$ and $EuIrGe_3$, which seem to have the most complicated antiferromagnetic arrangements within the series. Single crystals of both phases were grown using In-flux growth technique and studied along the main crystallographic directions by means of electrical transport, heat capacity, thermal expansion, magnetization and magnetic susceptibility measurements. $EuRhGe_3$ and $EuIrGe_3$ were established to order below T_N = 11.3 and 12.3 K, respectively, to a noncollinear AFM structure, incommensurate with the crystal lattice. Some specific features in the temperature variations of the magnetic susceptibility and the specific heat hint at the presence of amplitude modulations of the europium magnetic moments. The AFM order in the Ir-bearing compound was found to undergo an additional spin-reorientation transition at 7.5 K. The magnetic structure of $EuRhGe_3$ is probably of planar AFM type with an "out of *ab*-plane" harmonic component in the propagation wave vector. $EuIrGe_3$ likely orders with more complicated AFM structures which consist of several magnetic domains oriented in a canted noncollinear manner. The application of magnetic field brings about the appearance of a few other magnetic phases along both directions in $EuIrGe_3$, and along the easy *ab*-plane in $EuRhGe_3$. The two materials exhibit metallic conductivity and huge magnetoresistance effect in the AFM states.

TH.C-P53 - Field-induced magnetic phase transitions in Ho_7Rh_3 single crystal

T. Tsutaoka [1], K. Obata [1], A. Sherstobitov [2,3], E. Gerasimov [3], P. Terentev [3], A. Gubkin [2,3], N. Baranov [2,3]

1. Hiroshima University, Hiroshima, Japan

The rare earth compound Ho7Rh3 crystallizes in the Th7Fe3 type hexagonal structure with the space group P63mc in which Ho occupies three non-equivalent sites. Ho7Rh3 enters an antiferromagnetic (AF) state with decreasing temperature below TN = 34 K and shows further magnetic transformation to another magnetic state below 22 K [1, 2]. Unusual negative temperature coefficient of the electrical resistivity E in a wide temperature range above TN was observed in Ho7Rh3 as well as in other R7Rh3 compounds such as Gd7Rh3 or Tb7Rh3.
In this study, we have performed the high-field magnetization (up to 350 kOe) and magnetoresistance (up to 120 kOe) measurements on Ho7Rh3 single crystals grown by the Czochralski method using a tri-arc furnace. At 4.2 K, two field-induced phase transitions were observed up to 100 kOe from the initial AF to the forced ferromagnetic (FF) state; however, the magnetization does not reach saturation even at magnetic fields up to 350 kOe. The metamagnetic transitions along the a-axis are accompanied by the large magnetoresistance effect (~40 %) in the field interval 50 -100 kOe. Meanwhile, along the c-axis, the magnetization gradually increases without saturation with increasing field up to 350 kOe. From analysis of the neutron diffraction data, the magnetic structure of Ho7Rh3 can be described by two propagation vectors with magnetic moments lying parallel to the c-plane. A large suppression of the electrical resistivity by the external magnetic field was observed in the paramagnetic region up to more than 100 K indicating the large magnetic contribution to total resistivity.

This work was supported by the program of the Ural Branch of RAS (Project No 15-17-2-22).

TH.C-P54 - High-field quantum phase transitions induced by weak three dimensionality in triangular-lattice antiferromagnets

D. Yamamoto [1], G. Marmorini [2], I. Danshita [3]

1. Waseda Institute For Advanced Study, Japan
2. RIKEN, Japan
3. Yukawa Institute for Theoretical Physics, Japan

We study the magnetization process of layered triangular-lattice antiferromagnets (TLAFs) by means of a numerical cluster mean-field method with a scaling scheme, motivated by the recent experiments on the spin-1/2 compound $Ba_3CoSb_2O_9$. It has been known that in TLAFs, magnetic field H and quantum or thermal fluctuations stabilize a collinear configuration with two-up and one-down spins on the three sublattices, which forms a one-third magnetization plateau in the magnetization curve. We find that taking into consideration antiferromagnetic interlayer couplings gives rise to several types of extra phase transitions among different coplanar spin configurations. In particular, a first-order transition found at ~0.7 of the saturation field Hs for very small interlayer coupling (less than 10 percent of intralayer coupling) explains the magnetization anomaly observed in the magnetization process of $Ba_3CoSb_2O_9$. This extra quantum phase transition at H~0.7 Hs is expected to occur with even infinitesimally small interlayer coupling and thus can be regarded as another common quantum effect in ideal TLAF compounds, given the unavoidable three dimensionality, in addition to the well-established one-third plateau.

TH.C-P55 - Magnetic properties of quasicrystalline (i-phase) $Ti_{45}Zr_{38}Ni_{17}$ alloy

D. Rusinek [1], J. Przewoznik [1], L. Gondek [1], A. Takasaki [2], A. Hoser [3]

1. AGH University of Science and Technology, Faculty of Physics and Applied Computer Science, Krakow, Poland
2. Department of Engineering Science and Mechanics, Shibaura Institute of Technology, Toyosu, Kotoku, Tokyo, Japan
3. Helmholtz-Zentrum Berlin, Berlin, Germany

Titanium-based amorphous and quasicrystalline alloys have very interesting properties like high strength, high corrosion resistance or hydrogen absorption properties. On the other hand, the magnetic properties of quasicrystalline alloys in Ti-Zr-Ni system were not extensively investigated. The issue of possible magnetic ordering in 3D quasicrystals is one of the very important problems in current magnetism.
Our work is focused on icosahedral $Ti_{45}Zr_{38}Ni_{17}$ alloy. This material was produced at ambient temperature by mechanical alloying using high energy planetary ball mill. The obtained amorphous alloy was heated in order to obtain the icosahedral phase. Crystal structure was examined by in-situ X-ray and neutron diffraction in ambient and non-ambient temperatures. Magnetic susceptibility was by VSM method in temperature range from 2 up to 700 K. Magnetic susceptibility shows behavior typical of Pauli-paramagnet with magnetic susceptibility hardly changing with temperature. Some anomalous behavior at low temperature as well at high temperatures were attributed to a very small amount of ferromagnetic Ni, which remain after mechanical alloying. The above finding was supported by neutron diffraction, that was made at low temperature and under external magnetic field up to 5 T. No signs of magnetic ordering at temperature of 1.7 K were noticed, hinting at absence of localized, ordered magnetic moments. The latter is in concert with isothermal magnetization curve at 2 K, where extremely small value of magnetic moment, less than 0.02 μ_B per Ni atom at magnetic field of 9 T, was evidenced.
Concluding, the quasicrystalline $Ti_{45}Zr_{38}Ni_{17}$ alloy shows no long-range order down to 1.7 K, as expected for materials, in which periodicity is absent.

TH.C-P56 - Dipolar-coupled heisenberg spins system $LiGdF_4$

M. Jeong [1], I. Kovacevic [1], P. Babkevich [1], A. Di Lieto [2], H. Ronnow [1]

1. Laboratory for Quantum Magnetism, ICMP, Ecole Polytechnique, EPFL, Lausanne, Switzerland
2. Dipartimento di Fisica, Università di Pisa, Pisa, Italy

The $LiRF_4$ family is rare systems of purely dipolar-coupled magnets. In particular, $LiGdF_4$ does not possess orbital angular momentum so that the crystal field interaction vanishes. This situation is completely different from other family members such as $LiHoF_4$ and $LiErF_4$ where the crystal field determines the spin symmetry and interaction sign at low temperatures: Ising ferromagnetic and XY antiferromagnetic, respectively. The competition between ferromagnetic and antiferromagnetic characters of dipolar interactions in $LiGdF_4$ may lead new and unconventional low-temperature phases. We investigate this unique dipolar-coupled Heisenberg system with ac susceptibility and muSR measurements. A rich set of phases both as a function of temperature below 0.2 K and a field below 1 T is evidenced by the ac susceptibility. Local probe muSR measurements further show that these low temperature phases are magnetically long-range ordered. This complex phase diagram makes strong contrast to the simple ones of $LiHoF_4$ [1] and $LiErF_4$ [2].

TH.C-P57 - Ferromagnetic resonance of magnetic sublattices in Sc-substituted barium hexaferrite

R. Díaz-Pardo [1], S. Bierlich [2], G. Vazquez-Victorio [1], J. Töpfer [2], R. Valenzuela [1]

1. National University of Mexico, Mexico
2. Ernst-Abbe-Hochschule Jena, Jena, Germany

Sc-substituted hexaferrites have recently raised interest because scandium substitution allows an effective tailoring of anisotropy for many applications. On the other hand, many basic studies [1,2] have revealed that the substitution of Fe^{3+} by diamagnetic Sc^{3+} leads to unusual interactions among the magnetic sublattices in the ferrite. In this work, ferrites with the formula $BaSc_xFe_{12-x}O_{19}$ (x between 0 and 2.0) were prepared by reaction in the solid state at 1300°C for 6 hours. X-ray diffraction patterns confirmed the presence of a single hexagonal phase. Ferromagnetic resonance (FMR) investigation of x = 2 samples at 9.4 GHz in the 100 K - 500 K temperature range exhibited a single, broad resonance at low T (103 K); a progressive splitting into two resonance lines was observed in the 190-430 K, to finally coalesce into a single, narrow resonance line at 473 K, characteristic of a paramagnetic phase (Curie transition is ~ 460 K, as determined by magnetization measurements). These results are interpreted in terms of a substitution of Fe^{3+} by Sc^{3+} in the f sublattices; the presence of a diamagnetic cation produces a splitting of the k sublattice (with which the f sublattices sustain a strong, superexchange interaction) into two distinct sublattices, with different canting angles, and different dependence on temperature. This behavior is shown for all the compositions, exhibiting different temperature ranges and degrees of amplitude, but it is more evident for x = 2. FMR confirms therefore that it is an extremely sensitive investigation tool for complex magnetic materials.

TH.C-P58 - Extremely wide 1/3-magnetization plateau extended to megagauss magnetic fields in a distorted kagome volborthite Cu3V2O7(OH)2-E2H2O

T. Yamashita [1], A. Miyata [1], D. Nakamura [1], H. Ishikawa [1], Y. Okamoto [2], Z. Hiroi [1], S. Takeyama [1]

1. Institute For Solid State Physics, UTokyo, Japan
2. Graduate School of Engineering, Nagoya University, Japan

Volborthite [Cu3V2O7(OH)2-E2H2O] is known as a distorted spin 1/2 kagome frustrated antiferro-magnet. Unique magnetic phase transition called gorbital switchingüh is reported for the first time in single crystals of this material [1]. High magnetic field magnetization curve of single crystal vol-borthite has been already reported in magnetic fields of up to 75 T. A wide 1/3-plateau was observed, starting from 30 T and it still continues up to 75 T, which is close to a limit of maximum magnetic field available by the conventional non-destructive pulse magnet. Magnetic interactions of vol-borthite in low-temperatures has not been clarified yet. The most promising candidate was the J1-J2-Jic model [2] based on density functional theory, which assumes two kinds of nearest-neighbor interac-tion, ferromagnetic J1 and antiferromagnetic inter-chain Jic and with the next-nearest-neighbor J2. The model described well the magnetization curve up to 75 T with the values of interactions J calculated based on the poly-crystal structure, and depicted an end of 1/3-plateau occurred around 115 T. Thus, experimental observation above 100 T has been awaited for the verification of the model. Low-temperature magnetization measurements were conducted in ultra-high pulse magnetic fields of up to 164 T below 20 K. Megagauss magnetic field is generated by the single-turn coil method. Magnetization was obtained both by the magnetic induction method and Faraday rotation technique in magagauss magnetic fields with its pulse width of 6 ƒEs. It was revealed that 1/3-plateau still remained in fields up to 164 T with the giant 1/3 plateau width more than 134 T. This fact shows inadequacy of the J1-J2-Jic model mentioned above, and requests more elaboration of a theoretical model.

Oxygen, which is one of abundant elements, has several unique characteristics. It is well known that the oxygen molecule has a spin-triplet ground state. Competition between magnetic and molecular interactions gave rich varieties of structural, electronic, and magnetic phases under the wide ranges of temperature and pressure [1,2]. The magnetism of solid oxygen is particularly interesting, as the magnetic configuration is sensitive to the relative distance between molecules owing to a short-range feature of the magnetic interaction. In order to analyze such system, the method which can describe accurately both molecular and magnetic interactions has been required. The van der Waals density functional (vdW-DF) method, which is one of promising methods to overcome the problem, has been proposed by Dion et al [3]. The extension of vdW-DF to spin-polarized (magnetic) systems, vdW-DF-GC (GC means spin-polarization-dependent gradient correction), has practically been proposed [4,5]. We used this method to investigate oxygen systems (alpha and delta phases, and molecular systems), and obtained accurate optimized structural parameters in the structures, compared with those obtained using local density and generalized gradient approximations. We found that the structural properties were determined by a delicate balance of magnetic and vdW interactions. Such balance was important not only for the molecular pairs of antiferro- or ferro-magnetic coupling within the a-b plane, but also for the out-of-plane pairs which have a much weak magnetic interaction. In the presentation, we explain the method of vdW-DF-GC and discuss the results of crystal structure and magnetic energy, compared with experimental results.

TH.C-P60 - Magnetic properties of two-dimensional heisenberg antiferromagnet alpha-RbCrF4

Y. Miura [1], H. Manaka [2]

1. Suzuka National College of Technology, Japan
2. Kagoshima University, Japan

Triangular spin tubes alpha-$KCrF_4$ and $CsCrF_4$, which consist of one-dimensional Heisenberg antiferromagnets along the tubes coexisting with geometrically frustrated spin systems in the triangular plane, have been studied extensively[1]. In this study, we further synthesized the series of chromium fluoride alpha-$RbCrF_4$[2] using return to synthetic precursor method. From X-ray powder diffraction measurements at room temperature, $TlAlF_{4\text{-type}}$ crystal structure[3], i.e., the CrF_6 octahedra form a square lattice, was found. Because each plane is separated by Rb ions, two-dimensionality is expected to be good. As a result, alpha-$RbCrF_4$ forms an ideal two-dimensional Heisenberg antiferromagnet with S = 3/2. From magnetic susceptibility measurements above 2 K, antiferromagnetic long-range order appears at 29.3(1) K and the Curie-Weiss temperature is -67(3) K. Below 15 K, using return to synthetic precursor method, we found the intrinsic magnetic ground state.

Chirality plays an important role in the symmetrical properties of nature. In a magnetic substance with a chiral space group, a helimagnetic structure is created by the nearest neighbor (NN) exchange interaction and the Dzyaloshinsky-Moriya (DM) interaction. In particular, the DM interaction is important, because it gives chirality to the magnet. $CrNb_3S_6$ is one of the chiral magnetic substances. On applying the magnetic field perpendicular to the helical axis of $CrNb_3S_6$, the spiral structure winds down periodically, and the magnetic structure with alternate ferromagnetic and spiral domains, the so-called chiral soliton lattice (CSL), emerges [1]. This CSL state is the most characteristic feature of $CrNb_3S_6$. In the present study, we performed electron spin resonance (ESR) measurements in magnetic fields parallel to the helical axis to evaluate the NN exchange constant (J) and the DM constant (D) in $CrNb_3S_6$. We observed some ESR signals below 30 GHz. A nice fitting curve of the ESR mode is obtained by using the equation derived by J. Kishine et al. [2]. From the result, we evaluate the above constants as J/kB=-14.1 K (ferromagnetic) and D/kB=2.24 K. In addition, we observed a linear ESR mode above the saturation field (Hs) with zero energy gap at Hs in $CrNb_3S_6$, while such a mode appears with a finite energy gap at Hs in another chiral magnet MnSi [3].

The cubic CeB_6 is a typical compound in which orbital degrees of freedom play an important role. The G8 ground state of the Ce 4f1 state possesses dipole, quadrupole and octupole degrees of freedom. A phase transition from the paramagnetic phase (phase I) to the Oxy-type antiferroquadrupolar ordered phase (phase II) takes place at TQ = 3.3K, which is followed by another phase transition to the antiferromagnetic phase (phase III) at TN = 2.4K. Accordingly, it is expected that the crystal lattice deforms from cubic to tetragonal below TQ. Actually, dilatometric measurements observed tetragonal deformation more than 3X10^-5 below TN, whereas the tetragonal deformation in phase II was found to be very small.[1] X-ray diffraction (XRD) is a powerful technique that measures the planar spacing d_hkl of the (hkl) plane in a crystal. XRD is particularly advantageous for this type of experiments, because macroscopic measurements observe a value averaged over (tetragonal) domains, while XRD discriminates domains with different planar spacings. A disadvantage of XRD is, however, its rather poor resolution Dd/d (about 10^-5). High-resolution x-ray diffraction (HRXRD) is a sophisticated method that improves Dd/d. By combining a backscattering geometry and a high-resolution monochromator (HRM), one can achieve Dd/d=10^-8. We hence recently utilize HRXRD for detecting tiny lattice deformation.[2] A HRXRD experiment was carried out at BL22XU in SPring-8. The sample was a CeB_6 single crystal grown by a flux method. We observed the (700) reflection. 2theta=179.53 degrees, the photon energy was about 10.5 keV, and HRM was two Si (660) channel-cut crystals. The obtained Dd/d was 4X10^-6 (FWHM). A large tetragonal deformation 7X10^-5 was observed at 1.7 K in phase III, while the tetragonal deformation in phase II was below the detection limit.

Divalent metal molybdates and tungstates with the scheelite type structure constitue a large and important class of materials. The compounds doped with rare earth ions are used solid state lasers, scintillators and components of optoelectronic devices [1]. Our previous studies have showed an existence of new scheelite type solid solutions described as $Cd_{1-3x}RE_{2x}\square_xMoO_4$ for RE = Pr, Nd, Sm-Dy, and $0 < x \leq 0.25$, where $\square$ are cationic vacancies [2].
The main purpose of this study was to investigate the magnetic properties of strongly diluted magnetic molybdate containing 0.001 dysprosium ions. The temperature dependence of magnetic susceptibility recorded both in zero-field-cooled (ZFC) and field-cooled (FC) mode as well as the magnetization isotherm show paramagnetic behaviour with the Curie-Weiss temperature θ = - 6 K, the effective magnetic moment μ_{eff} = 0.394 μ_B/f.u., and the Landé factor g = 0.049 estimated from the Curie constant C = 0.0194 emu·K/mol.
The most spectacular observation here is finding of the transition from paramagnetic to diamagnetic state at the temperature T_{pd} = 137 K and in the magnetic field of 70 kOe. This means that at T_{pd} paramagnetic and diamagnetic components compensated.

TH.C-P66 - Phase transition of mobile potts model for liquid crystals

H. T. Diep [1], A. Bailly-Reyre [1]

1. LPTM, UMR 8089 University of Cergy-Pontoise, CNRS, France

In this paper, we are interested in the phase transition of a mobile Potts model on a lattice with a concentration c: a Potts particle with q states interacting with its neighbors can move from a lattice site to another under the effect of temperature T. This model is interesting for several reasons among which it can describe the melting of a molecular crystal. The model of moving Potts model introduced in this paper is the first in the random category. We consider a simple cubic lattice. The lattice sites are partially filled with q-state Potts spins and each spin can move from a site to an empty nearest site. In this paper, the main results are shown for q=6: the Potts spin at a lattice site can take one of the 6 directions. The model is ferromagnetic J(i,j)=J>0 in this paper. The present model can be called the mobile Potts model to distinguish from the localized Potts model. The mobile Potts model allows to study the order-disorder phase transition associated with the Potts variable while a continuous evaporation of spins at the surface of the system takes place with increasing temperature.
We have performed the simulation by using a Monte-Carlo (MC) Metropolis algorithm. We find a first-order phase transition for high concentration, and second-order phase transition for low concentration down to a certain limit below which there is no more phase transition at a finite temperature. Results for other q at different concentrations will be shown. The mechanism leading to a transition or no transition will be presented.

TH.C-P68 - Spin frustration in the spin-1/2 ising-heisenberg model on triangulated husimi lattices: exact results

C. Ekiz [1], J. Strecka

1. Department of Physics, Faculty of Science, Adnan Menderes University, Aydin, Turkey
2. Institute of Physics, Faculty of Science, P. J. Safárik University, Kosice, Slovakia

The spin-1/2 Ising-Heisenberg model on triangulated Husimi lattices is rigorously solved by combining the generalized star-triangle transformation with the method of exact recursion relations. The model defines a hybrid classical-quantum system consisting of the Ising and Heisenberg spins on recursively built lattices, which interact among themselves either through the Ising or XXZ Heisenberg nearest-neighbour interaction. Exact results for critical frontiers, total and sublattice magnetizations are obtained from a precise mapping relationship with the corresponding spin-1/2 Ising model on a pure Husimi lattice.
The effect of interaction parameters on magnetic properties of the considered model is investigated in particular. The finite-temperature phase diagram in the form of critical temperature versus the interaction ratio dependence was calculated for several values of the coordination number of the underlying Husimi lattice and the exchange anisotropy. It is demonstrated that the phase boundary between the spontaneously ordered and disordered phases essentially depend on the coordination number of the triangulated Husimi lattice. In the limiting Ising case, the critical temperature shows a monotonous decline with increasing a relative strength of the antiferromagnetic Heisenberg interaction. On the contrary, the more general Ising-Heisenberg model exhibits in a highly frustrated region a peculiar spontaneous order for the triangulated Husimi lattices with high enough coordination numbers $q>3$ as well as reentrant phase transitions for particular value of the coordination number $q=3$.

TH.C-P70 - Magnetism of alpha-Sr2MO4 (M = V, Cr) with K_2NiF_4-type structures

H. Sakurai [1]

1. National Institute For Materials Science, Tsukuba, Japan

alpha-Sr2VO4 is expected to have nontrivial spin- and orbital-orderings, or magnetic octapole ordering because the VO6 octahedra are tetragonally distorted with the apical oxygen ions pulled out; the distortion leaves the dyz and dxz orbitals degenerated at the lowest energy level. The compound exhibits successive phase transitions at 101 K and 127 K. Magnetic susceptibility shows a small kink at 127 K and drops at 100 K without magnetic ordering. Below 101 K, a sizable Curie-Weiss term remains, and the Curie constant there is ~1/3 as large as that at the high temperatures. A magnetic ordering appears below 11 K, where only ~13% of theoretical magnetic entropy is released despite no clear sign of short-range ordering in magnetic susceptibility. On the other hand, alpha-Sr2CrO4 has the same distortion of the CrO6 octahedra with 3d^2 electronic configuration for the Cr ions. Recent electronic band structure calculation has revealed that the dxy orbital is energetically lower than the doubly degenerated dyz and dxz orbitals. Thus, also in the Cr compound, orbital degree of freedom remains, although the dxy orbital is occupied by an electron in this case. Magnetic susceptibility and specific heat show successive phase transitions at 112 K and 140 K, which are close to the transition temperatures of the V compound. This suggests that the orbital degeneracy plays an important role in either or both of these transitions. Indeed, at the 140 K transition just a small kink appears in the susceptibility as in the case of the V compound. However, magnetic ordering occurs at 112 K, differently from the 101 K transition of the V compound. The electrons in the dxy orbital may cause the difference in the magnetism between these two compounds. The magnetic susceptibility and specific heat, as well as structural data, will be presented.

TH.C-P71 - Pressure effect on transport properties of $EuNi(Si_1\text{-}xGex)_3$ compounds

K. Uchima [1], Y. Takaesu [1], H. Akamine [2], M. Kakihana [2], K. Tomori [2], A. Teruya [2], M. Hedo [3], T. Nakama [3], K. Yagasaki [3], K. Matsubayashi [4], I. Uwatoko[4]

1. Okinawa Christian Junior College, Japan
2. Graduate School of Science and Engineering, University of the Ryukyus, Japan
3. Faculty of Science, University of the Ryukyus, Japan
4. Institute for Solid State Physics, University of Tokyo, Japan

The compounds of $EuNi(Si_{1-x}Ge_x)_3$ order antiferromagnetically. The Neel temperature T_N decreases monotonously with increasing the Ge concentration x. At the temperature T_C below T_N, $EuNiSi_3$ (x=0) shows an additional magnetic transition into ferromagnetic state. T_C decreases rapidly with increasing x and vanishes at the critical concentration $x \approx 0.3$. For the compound $EuNi(Si_{0.8}Ge_{0.2})_3$ which is a compound near to the boundary between the ferromagnetic and antiferromagnetic ground states in the phase diagram for $EuNi(Si_{1-x}Ge_x)_3$ system, the measurements of the electrical resistivity ρ and thermopower S have been carried out in the temperature range from 2 to 300 K under pressures up to P=1.8 GPa. The anomalies in ρ(T) and S(T) curves are observed at T_C = 16 K and T_N =34 K. Both of T_C and T_N increase linearly with increasing pressure. The temperature variations of ρ and S of $EuNi(Si_{0.8}Ge_{0.2})_3$ at P=1.8 GPa are almost the same as those of $EuNi(Si_{0.9}Ge_{0.1})_3$ (x=0.1) at ambient pressure. The effect of pressure on T_N and T_C is opposite to that of substitution of Si by Ge, i.e., the application of pressure stabilize the ferromagnetic phase. These results indicate that the change of T_N and T_C can be attributed to the change of atomic volume induced by application of high pressure or atomic substitution.

TH.C-P74 - Application of the oguchi method for studies of the hubbard model

T. Balcerzak [1], K. Szalowski [1], M. Jascur [2]

1. Department of Solid State Physics, Faculty of Physics and Applied Informatics, University of Lodz, Lodz, Poland
2. Department of Theoretical Physics and Astrophysics, Faculty of Science, P. J. Safarik University, Kosice, Slovak Republic

Oguchi method in pair approximation has been extended for the investigations of the Hubbard model. The system based on a simple cubic lattice, with half-filling of the band, has been studied. In the frame of the method the grand potential has been derived, from which all thermodynamic properties can be obtained. In particular, for a prototype model of the local electric field, the ground-state and temperature phase diagram have been studied in the whole range of the Hubbard parameter U. The existence of antiferromagnetic phase has been confirmed with the critical temperature maximum value and its location vs. U being in qualitative accordance with Quantum Monte Carlo (QMC) simulations. Moreover, the quantum critical point (QCP) has been found at T=0, separating the antiferromagnetic and paramagnetic phases, and its position has been discussed in the context of existing literature. It can be noted that within our method the accuracy of the Néel temperature calculation improves as U increases. The extensive numerical calculations of the magnetic properties, including spin-spin and charge-charge correlation functions, have been performed and the results are illustrated in figures. It can be concluded, that the extended Oguchi method, going beyond the usual molecular field approximation, can be a potentially useful tool for the studies of magnetic properties of the Hubbard model.

TH.C-P75 - Magnetic phase diagram determination of Ce pnictides by resonant X-ray magnetic scattering

L. Paolasini [1], J. Herrero-Martin [2], H. Walker [3], M. Kohgi [4], K. Kuwahara [4], K Iwasa [5], G. Lapertot [6]

4. Tokyo Metropolitan University, Tokyo, Japan
5. University of Tohoku, Sendai , Japan
6. CEA Grenoble, France

High magnetic field Resonant X-ray scattering experiments were performed to investigate the magnetic phase diagram of CeP and CeSb up to 10 Tesla. Using the Ce L_3 edge resonance, the magnetic interlayer ordering of the Ce can be studied in a great detail, and the results compared to previous neutron [1-2] and x-ray scattering results [3-4]. The energy dependence of resonances are compared in the antiferromagnetic phase at zero field with the huge enhancement found in the field-induced phases, suggesting a strong (f-p) hybridization associated to the main contibution of the Γ_8 ground state. The ferro-paramagnetic phase displays a systematic and continuous reduction of the interlayer paramagnetic modulation as a function of the applied magnetic field, showing similarities with the results of neutrons magnetic scattering experiment under applied pressure and explains the multi-step modulation of magnetic phase diagram determined by resistivity at higher temperatures.

TH.C-P76 - Extreme sensitivity of magneto-structural transitions in Ni2MnGa-based heusler alloys to pulsed high magnetic field

J. Kastil [1], J. Kamarad [1], Z. Arnold [1], Y. Skourski [2], F. Albertini [3]
1. Institute of Physics ASCR, Prague, Czech Republic
2. Hochfeld-Magnetlabor Dresden (HLD), HZDR, Dresden, Germany
3. IMEM CNR, Parma, Italy

The study of Ni_2MnGa-based Heusler alloys is getting a significant attention due to a large variety of their interesting and usable physical properties. Their large magneto-striction that can be induced by relatively small magnetic field is widely used for many years. The diffusion-less magneto-structural transition from martensite (lower symmetry crystal phase M) to austenite (cubic $L2_1$ crystal structure A) is detected in most of the alloys with increasing temperature. The underlying mechanism of a shear deformation of the cubic cell is still not yet completely understood. The band Jan-Teller mechanism was suggested to be the driving force of the transition [1].
The effect of pulsed magnetic field up to 60 T on the transition temperatures T_{M-A}, T_{A-M} and magnetization of the several different samples of Co- and In-substituted Ni_2MnGa-based alloys was studied in wide temperature range. The huge field induced non-linear decrease of T_{M-A} of about 200 K and the accompanied increase of magnetization, up to M_A = 6.3 μ_B/f.u in $Ni_{1.72}Co_{0.28}Mn_{1.25}Ga_{0.75}$ at 2 K, verify an existence of the field induced ferromagnetic state of austenite phase in low temperatures. The observed magnetization of the ground state of both, the martensite and the austenite phases, denotes a different effect of the substitution and the off-stoichiometry on magnetic properties of the phases. The enormous nonlinear shift of transition temperature points to pronounced effect of spin polarization on the Jahn-Teller effect in these samples. The external field of 60 T seems to be high enough to suppress the Jahn–Teller distortion of crystal lattice of some of the studied alloys even at low temperatures.

TH.C-P77 - Magnetic anisotropy in antiferromagnet GdB_6

M. Anisimov [1], V. Glushkov [1], S. Demishev [1]. Shitsevalova [2], A. Levchenko [2], V. Filippov [2], A. Bogach [1], V. Krassnorussky [1], S. Gabani [3], K. Flachbart [3], N. Sluchanko[1]

1. A.M. Prokhorov General Physics Institute of RAS, Moscow, Russian Federation
2. Institute for Problems of Materials Science NASU, Kyev, Ukraine
3. Institute of Experimental Physics, Slovak Academy of Science, Slovakia

In our previous reports [1-2] we have shown that unusual antiferromagnet (AF) GdB_6 (T_{N1}~15.5K, T_{N2}~4.6K) is characterized by the magnetic anisotropy in both AF phases. In order to investigate in details the magnetic anisotropy of GdB_6 we decided to perform the comprehensive study of Hall effect and magnetoresistance (MR) in magnetic fields B<8T oriented along the main crystallographic directions B||<100>, <110>, <111> in the temperature range 2-300K. The data obtained allow to detect the several fundamental results. (*i*) The emergence of the anomalous Hall effect *R^{AHE}_H* in AF II phase in magnetic fields 0.7-1.5T. (*ii*) The appearance of considerable anisotropy of MR at $T<T_{N2}$. The 3D-diagram of the angular distribution of the charge carrier scattering reconstructed from our MR data in AF II state has the form of cross with maximal scattering along the direction B||<110> and four caverns-satellites (along B||<111>), which disappear above 5T. (*iii*) The magnetic H-T phase diagram reconstructed from our data for the main crystallographic directions B||<100>, <110> and <111> contains the several additional transitions (1) at 0.7-1.7T only for the direction B||<111> and (2) at 1.7-5T for B|| <111>, <100>. The results are discussed in terms of the complex scenario including the spin polarons formation in paramagnetic and AF I phases of GdB_6. It was proposed here that the spin polarons along with additional coherent displacement of Gd^{3+} ions from their centrosymmetric positions inside the boron cages (see [3]) are responsible for the anisotropy detected in both AF I and II states of GdB_6.

TH.C-P78 - Spin polarons and magnetic ground state in PrB_6

M.Anisimov [1], V.Glushkov [1], S.Demishev [1], N.Shitsevalova [2], A.Levchenko [2], V.Filippov [2], A. Bogach [1], V. Krassnorussky [1], S.Gabani [3], K.Flachbart [3], N.Sluchanko [1]

1. Prokhorov General Physics Institute, Russian Academy of Sciences, Moscow, Russian Federation
2. *Institute for Problems of Materials Science NASU, Kiev, Ukraine*
3. Institute of Experimental Physics, Slovak Academy of Science, Košice, Slovakia

In current work we present investigation of magnetic, transport and thermal properties of antiferromagnet PrB_6 (T_{N1}~6.7K, T_{N2}~4.6K). The measurements have been performed on high quality single crystals of Pr^NB_6 with various isotope content (N=11, nat.) of boron, and before and after high temperature annealing. In order to investigate the magnetic anisotropy of PrB_6, specific heat, magnetoresistance (MR) have been measured in external magnetic field oriented along main axis B||<100>, <110>, <111>. Based on our measurements, several fundamental results have been obtained. (*i*) Above Neel temperature in the range T_{N1}-21K an unusual low temperature maximum of resistivity was observed in combination with spontaneous magnetization M_{sp}~1.6emu/mol on the initial state (before annealing) of PrB_6 samples. The anomalies detected may be explained in terms of ferromagnetic (FM) fluctuations and itinerant ferromagnetism developed in the presence of n_{vac}~1-2% boron vacancies in the PrB_6 matrix. Moreover, it was found that this FM state is totally destroyed by annealing at T_{an}~1700°C. (*ii*) The performed study of \Delta\rho/\rho(H) allowed us to estimate the magnetic parameters including the local susceptibility \chi_{loc}(T) and the effective magnetic moment \mu_{eff}. The calculated effective magnetic moment depends on the orientation of magnetic field and reaches the maximal values \mu_{eff}=2.5\mu_B for B||<110>, <111> and \mu_{eff}=4\mu_B for B||<100>, whereas the value of inherent moment of Pr^{3+} ions is expected to be \mu(\Gamma_5)=2\mu_B. The results obtained may be attributed to the formation of magnetic clusters which are constructed from magnetic moments of Pr^{3+} ions and spin polarized domains in the conduction band of PrB_6 (5*d*-component of magnetism). These spin polarons of small radius a_{sp}~5Å appear below 21K and are responsible for the itinerant ferromagnetism in PrB_6. Moreover, the anisotropy of PrB_6 may be explained in terms of coexistence of 4f- (local) and 5*d*- (itinerant) components of the magnetic structure of this unusual antiferromagnet.

TH.C-P79 - Thermodynamic properties of the S=1 heisenberg square-lattice antiferromagnet $Ni(pz)_2Br_2$

E. Cizmár [1], K. Ráczová [1], S. A. Zvyagin [2], A. Feher [1]

1. Institute of Physics, Faculty of Science, P.J. Safárik University, Kosice, Slovakia
2. High Magnetic Field Laboratory (HLD-EMFL), Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany

We report thermodynamic, magnetic and electron spin resonance (ESR) studies of the compound $Ni(pz)_2Br_2$ (pz is pyrazine), an S=1 Heisenberg antiferromagnet (AFM) on square lattice. Magnetic susceptibility measured in the temperature range 1.8 - 300 K reveals the presence of a strong single-ion easy-plane anisotropy (D/kB = 7.8 K) and a weak AFM exchange coupling (J/kB = -0.9 K), suggesting that $Ni(pz)_2Br_2$ is in the gapped quantum paramagnetic phase with (anti)excitons as elementary excitations [1]. The preliminary high-frequency ESR experiments on powdered samples indicate the presence of a small zero-field energy gap (~20 GHz). Such observation may suggest that $Ni(pz)_2Br_2$ is in the close vicinity to the quantum critical point (D/J = 5.6), separating the gapped quantum paramagnetic phase and a gapless planar AFM phase. Specific heat studies of $Ni(pz)_2Br_2$ reveal the transition into the AFM long range-ordered state at TN = 1.55 K. Above 6 T the system is in the fully spin-polarized magnetically saturated phase. The analysis of magnetic entropy (calculated from specific heat measured in applied magnetic fields) yields the evidence for inverse magnetocaloric effect in fields up to 5 T (accompanied by decrease of the sample temperature during adiabatic magnetization) followed by the rapid decrease of entropy in the spin-polarized state. The enhanced release of the magnetic entropy in magnetic fields close to the saturation field suggests that this material can be potentially used as a magnetic coolant, with the efficiency comparable (or even better) with that of paramagnetic salts at temperatures below 3 K.

The insulating rare earth (RE) cuprates RE_2CuO_4 crystallizing in the T'-structure turn superconducting upon electron-doping. The undoped parent compounds are characterized by a very strong antiferromagnetic coupling J between the Cu moments within the CuO_2 planes and a very weak coupling J' between adjacent planes that results from the body-centered tetragonal (BCT) structure which cancels out the isotropic Heisenberg interaction of neighboring planes. Therefore this system can be considered as a very good approximation of the S=1/2 two-dimensional (2D) square lattice Heisenberg model which does not possess a magnetic phase transition at finite temperature. The actual process how these quasi-2D systems approach the observed 3D magnetic order has been debated to this day mainly due to the complications caused by the presence of magnetic RE elements. Recently we were able for the first time to synthesize powders of metastable T'-La_2CuO_4 and to investigate it with muon spin rotation (muSR), La-NMR, synchrotron X-ray and neutron scattering. We find that T'-La_2CuO_4 shows a series of magnetic transitions at T = 220, 115, and 40K. NMR proves that below 220K the Cu moments are aligned within the CuO_2 plane due to a strong easy-plane anisotropy while muSR senses only quasi-static order with magnetic fluctuations in the MHz regime. Therefore, the system effectively undergoes a crossover from a 2D-Heisenberg to a 2D-XY behavior below T_CO = 220K. Below 115K the combined muSR and NMR data indicate the onset of static order with a symmetry allowed distribution of relative AFM spin orientations within the CuO_2 planes with respect to the neighboring layers. This physical scenario might be realized due to essentially decoupled layers and an XY anisotropy that is so small compared to the thermal energy that it does not impose a preferred spin direction. A speculative interpretation of the data would be to associate the transition at T_KT = 115K with a Kosterlitz-Thouless transition occuring in the 2D-XY model. Only below T_LRO = 40K, the system locks-in to a special 3D long range ordered non-collinear structure.

TH.C-P81 - Study of the effective magnetic anisotropy in the $MnCr_2O_4$ cubic spinel

D. Tobia [1,2,3], J. Milano [1,2], M.T. Causa [1], E. L. Winkler [1,2]

1. Laboratorio de Resonancias Magnéticas, Centro Atómico Bariloche - CNEA, 8400 S.C. de Bariloche, Argentina
2. Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET), Argentina
3. Instituto De Física "Gleb Wataghin", UNICAMP, Campinas (SP), Brazil

The cubic spinel systems with general formula AB_2O_4, where A, B or both sites are occupied by transition metal ions, have rich phase diagrams due to the correlations between their magnetic, electrical, and structural properties. In the particular case of the chromium spinel $MnCr_2O_4$, the Cr^{3+} ions occupy the octahedral sites in a pyrochlore-like arrangement. As a consequence of this spatial array, this system exhibits magnetic frustration and unusual low temperature magnetic states. At TC=42K the $MnCr_2O_4$ spinel presents long-range ferrimagnetic order; as the temperature decreases below TH=18K, this magnetic phase coexists with a short-range helical order, where the spin rotation axis does not coincide with the helicoidal propagation vector. In this complex scenario, the ferromagnetic resonance (FMR) spectroscopy emerges as a suitable technique because it provides microscopic information related to the exchange and magnetic anisotropy and allows extending the knowledge of the nature of the long-range ferrimagnetic order and the spiral short-range state.[1] Here we present a study of MnCr2O4 polycrystalline magnetic phases through dc magnetization and FMR. We describe the temperature evolution of the system by a phenomenological model that considers the different terms that contribute to the free energy density. Below TC, the FMR spectra were modeled by a cubic magnetocrystalline anisotropy to the second order, with K1 and K2 anisotropy constants that define the easy magnetization axis along the <110> direction. At lower temperatures, the formation of a helicoidal phase was considered by including a uniaxial anisotropy axis along the [1-10] propagation direction, with a Ku anisotropy constant. The values obtained from the fittings at 5K are K1=−2.3x10^4 erg cm-3, K2=6.4x10^4 erg cm-3 and Ku=7.5x10^4 erg cm-3.[2]

4. Institut Laue-Langevin, Grenoble, France

Mn_3GaC among the Mn-based Antipervoskite compounds shows a first order magnetostructural transition from the antiferromagnetic state (AF) to ferromagnetic state (FM) with increasing temperature at Tt = 165 K accompanied with volume change. A thermal hysteresis of 3 K/T occurs at the transition. To decrease the thermal hysteresis, we have substituted 15 % of nitrogen in place of carbon. As a result, long range ferromagnetism disappeared along with the thermal hysteresis. To understand the source of the thermal hysteresis and its relation with ferromagnetism, we have undertaken neutron diffraction and neutron depolarization experiments on the Mn_3GaC and Mn3Ga(C0.85N0.15). According to the results of neutron diffraction experiments for Mn_3GaC, the (332) nuclear reflection shows that at the transition lattice constants associated with both the AF and the FM phase coexist indicating that the system is in a heavily strained state, which can be a cause for the hysteresis. In the neutron depolarization experiments on Mn_3Ga(C0.85N0.15), the flipping ratio does not change when crossing the transition showing the absence of ferromagnetic domains around the first order transition. One factor which leads to narrow hysteresis at magnetostructural transitions is the absence of long-range ferromagnetism in the parent phase of the material.

TH.C-P83 - Magnetization study of cobalt ferrite by mean field approximation

5. Laboratoire de Génie Physique et Environnement, Faculté des Sciences, Université Ibn Tofail, Kénitra, Morocco

Cobalt ferrite ($CoFe_2O_4$) is of interest for magnetoelectric transducer applications [1]. It is ferrimagnetic with an inverse spinel structure, where trivalent Fe^{3+} ions are equally distributed between A and B sites and divalent Co^{2+} ions occupy the B sites [2] and is a hard ferrite [3]. Important factors that may affect the behavior of magnetization are exchange interactions, crystal field (CF), and temperature. So in this work, we study the magnetization of cobalt ferrite with different exchange interactions and crystal fields using the mean field approximation. A variational method based on the Bogoliubov inequality for the Gibbs free energy was used within the mean field theory [4]. The effect of temperature on the magnetization of cobalt ferrite was investigated in the absence and presence of crystal fields. The effect of exchange interactions revealed different behaviors of the magnetization versus the temperature; a pure ferrimagnetic state and a frustrated magnetic behavior were observed for the cobalt ferrite. In addition, the study of the exchange interactions effect on the total magnetization shows that for strong coupling interactions, the total magnetization of the system exhibits a jump at a given temperature. A first order phase transition from ferrimagnetic to ferromagnetic phase was found at low temperature, and a second order transition from ferromagnetic to paramagnetic phase was observed at high temperature. The investigations also revealed that the phase transition temperatures depend on the crystal fields of the octahedral and tetrahedral sites. On the other hand, the magnetization curves shifted to higher temperatures when the exchange interactions values decreased.

TH.C-P84 - Inverse and conventional magnetocaloric effects in Fe_7Se_8 single crystal

I. Radelytskyi [1], R.Szymczak [1], D. Gawryluk [1], R. Puzniak [1], M. Berkowski [1], M.Pekala [2],R. Diduszko [3], J. Fink-Finowicki [1], H.Szymczak [1]

Iron selenide Fe_7Se_8 (3c type) has been extensively studied because of its interesting crystallographic, optical and magnetic properties. This compound is ferrimagnetic metal with high Neel temperature. Its crystal structure is hexagonal and may be derived from the NiAs-type one by introducing ordered Fe vacancies. The main purpose of this paper is to study magnetocaloric effect in this compound. The high quality single crystals of Fe_7Se_8 have been grown applying Bridgman's method. Magnetization and magnetocaloric measurements have been carried out in magnetic fields up to 50 kOe over the temperature range 4.2 to 490 K, together with analysis of the resistivity and the thermoelectric power data. The reorientation spin transition from easy c-axis to easy c-plane has been observed near the temperature T_r = 125 K . It proceeds in an abrupt fashion, as a first-order phase transition. The magnetization curves in the vicinity of this transition were shown to exhibit an S-shape behavior with a clear hysteresis. These first order metamagnetic field induced transitions have been identified above and below T_r. Conventional magnetocaloric effect related to the metamagnetic transitions has been found above T_r while below T_r inverse magnetocaloric effect is clearly seen. The critical fields of the metamagnetic transitions as a function of temperature have been measured and discussed in relation to the mechanism responsible for metamagnetic behavior of the system. The existence of both kinds of magnetocaloric effects is important from the point of view of large rotating field entropy change in Fe_7Se_8 single crystal. A second order phase transition to paramagnetic state has been studied at a Curie temperature T_C = 450 K. The magnetocaloric effect associated with this transition is weaker than those studied near T_r. The giant anisotropy of the magnetocaloric effect is discussed in relation to the magnetic anisotropy of Fe_7Se_8 crystals.

TH.C-P85 - Magnetic properties of Sm_2Fe_{17} single crystal

L. V. B. Diop [1], K. P. Skokov [1], M. D. Kuzæmin [1,2], D. Karpenkov [1], O. Gutfleisch [1]

2. Aix-Marseille Université, IM2NP, Faculté St. Jérôme, Marseille, France

The study of the magnetic properties of the R_2Fe_{17} compounds (where R is a rare-earth element or yttrium) has been of interest for many years. These Fe-rich intermetallic compounds present many interesting magnetic properties. One of them is abnormalities in their ordering temperatures. Their hexagonal or rhombohedral crystallographic structures can be considered as natural multilayer systems: the Fe layers are perpendicular to the c-axis and are accompanied by dumbbell Fe pairs between them. The Fe atoms are located in four inequivalent crystal sites within the unit cell. Despite the extensive investigations devoted to the R_2Fe_{17} compounds, there appear to have been no systematic study of the magnetic anisotropy and magnetic phase transitions in Sm_2Fe_{17}. This may be due to the difficulties associated with growing single crystals. Yet, unambiguous determination of the anisotropy constants requires single crystals. Therefore, we grew a rhombohedral single crystal of Sm_2Fe_{17} and investigated its magnetic properties. The magnetization of the single crystal was measured in various crystallographic directions in static magnetic fields up to 14 T on a commercial Physical Property Measurement System (PPMS14 of Quantum Design). Sm2Fe17 is ferromagnetic below TC = 385 K and presents an easy-plane order. The magnetization curves recorded along the magnetic hard c-axis [001] exhibit a first-order phase transition (FOMP) at low temperatures. We have found, moreover, that the c-axis curves show a finite spontaneous magnetization. Both the magnetic anisotropy field and the critical field of the FOMP transition decrease monotonically with temperature. The obtained results show that there exist both positive and negative exchange interactions for Sm_2Fe_{17}.

TH.C-P86 - Correlating structural and magnetic properties in phase separated manganites

G. Gomez Eslava [1], L. Ghivelder[1], G. Leyva[2], M. Quintero[2], F. Parisi[2]

1. Universidade Federal Do Rio De Janeiro, Brazil
2. Escuela de Ciencia y Tecnologia, Universidad Nacional de General San Martin, Argentina

This work focuses on establishing the influence of structural properties on the magnetic phase separation in manganites. For this purpose, we present results in the family of compounds with general formula $La_{0.225}$ $Pr_{0.4}$ $(Ca_{1-x}Sr_x)_{0.375}$ MnO_3, with emphasis on samples with low Sr content (x=0.00 e 0.05). The samples were characterized by magnetization, specific heat and resistivity measurements. High resolution X-ray diffraction (XPD) measurements allow us to establish a clear correlation between structural parameters and the observed behavior change at approximately x=0.15. Low temperature XPD results show the presence of lattice distortions below 230 K, related with the charge ordering. The growth of the long-range ferromagnetic (FM) phase below 100 K is explained by a decrease in the lattice distortion. It was confirmed, from neutron diffraction measurements, that in the absence of magnetic field a pseudo-CE antiferromagnetic phase is established below 170K. In addition, a decrease in the AFM phase was observed, simultaneously accompanied by a growth in the FM phase, when a magnetic field is applied. Thermal expansion and magnetostriction measurements were made using a capacitive cell. The results confirm the strong correlation between physical and structural properties in the samples. The destruction of monoclinical distortions below 100 K is reflected as the fast contraction of the sample when cooled form 100 K to 50 K. Magnetostriction measurements are in agreement with the meta-magnetic transitions observed by magnetization and NPD techniques, showing that the destruction of the CO state drives the material trough a field-induced contraction process.

TH.C-P87 - Ab initio construction of magnetic phase diagrams in alloys: The case of $Fe_{1-x}Mn_xPt$

B. Pujari [1], P. Larson [1], V. Antropov [2], K. Belashchenko [1]

1. University of Nebraska-Lincoln, United States
2. Ames Laboratory, United States

We develop a first-principles approach to the construction of concentration-temperature magnetic phase diagrams of metallic alloys [1]. The method employs self-consistent total energy calculations based on the coherent potential approximation for partially ordered and noncollinear magnetic states and is able to account for competing interactions and multiple magnetic phases. Application to the $Fe_{1-x}Mn_xPt$ "magnetic chameleon" system yields the sequence of five magnetic phases at T=0 and the c-T magnetic phase diagram in good agreement with experiment. In addition, a new low-temperature phase is predicted at the Mn-rich end. The correct first-order transitions and the Mn-rich phase are only captured if non-Heisenberg terms are included in the magnetic energy, showing the limitations of the conventional approach based on the Heisenberg model Hamiltonian. The wide applicability and predictive power of this approach makes it useful for the design of magnetic materials with desired properties.

TH.C-P88 - Strategies for increasing the Néel temperature of magnetoelectric antiferromagnets

S. Mu [1], A. Wysocki [1], K. Belashchenko [1]

1. University of Nebraska-Lincoln, United States

Magnetoelectric antiferromagnets enable electric control of magnetism, which makes them potentially suitable for nonvolatile memory and other magnetoelectronic device applications. However, progress in device implementation is hampered by the lack of magnetoelectrics that would retain magnetic order at typical computer-core temperatures. Based on first-principles calculations, we developed strategies for increasing the Néel temperature T_N in magnetoelectric Cr_2O_3 and Fe_2TeO_6 antiferromagnets [1,2]. For Cr_2O_3 we find that, although transition-metal substitutions for Cr and N substitution for O are likely to reduce T_N, substitution of O by B is expected to increase it by 5-10% per 1% B substitution for O. Both N and B impurities introduce impurity states mediating strong hybridization and magnetic interaction between the neighboring Cr ions. While for N impurities this leads to magnetic frustration, B substitution enhances the stability of the ground antiferromagnetic state. In Fe_2TeO_6, substitution of larger ions like Zr or Hf for tellurium increases the Fe-O-Fe superexchange angles. The compensating O vacancies tend to form bound complexes with Zr dopants, which do not degrade the electronic band gap. T_N is estimated to increase by 15% at 12.5% substitution of Zr by Te with such compensation. Substitution of N for O is favorable due to the decreased charge-transfer gap. The overall effect for N substitution in the 3– charge state compensated by O vacancies is estimated at 3-4% T_N enhancement per 1% of O substitution by N.

TH.C-P89 - Effect of third element on spin state of europium in its 1-2-2 pnictides: ESR data

Y. Goryunov [1], A. Nateprov [2]

1. E.K.Zavoisky Kazan Physical-Technical Institute, Russian Federation
2. Institute of Applied Physics of Moldovan Academy of Sciences, Moldova

We performed the X band ESR measurements of powder samples $EuCd_2As_2$ with structural type $CaAl_2Si_2$ at temperatures 10-300 K. This structural type, also as structural type $ThCr_2Si_2$, is characterized by alternating single layers of Eu^{2+}, in which ions are located at the nodes of a plane square lattice. As in the past for other 1-2-2 europium compounds with structure type $CaAl_2Si_2$ was observed almost symmetric Lorentzian resonance line. The temperature dependences of the resonance field and linewidth were of the type ~ $(T-T_c)^{-1/2}$, which is indicative of spin fluctuations associated with the phase transition temperature T_c. Also at high temperatures was observed Curie – like temperature dependence of the inverse the ESR intensity with positive temperature Curie Weiss θ_{cw} =16 K, which does not coincide with T_c = T_N ~ 7 K. A comparative analysis of the Eu^{2+} ion g factors deviations for different 1-2-2 pnictides Eu from its value for the free electron, which corresponds to a pure spin state of the ion Eu, was made. It was found that the anion pnictides substitution effect on the g-factor Eu^{2+} is negligible (smaller 0.5%). Lattice constant is proportional to the radius of the anion Pn^{3-} pnictides with accuracy better than 1%. However, the substitution of the transition metal M^{2+} ion leads to a strong increase of the ion Eu^{2+} g - factor despite sameness of configuration of external electronic shells. Obviously, this is related to the size and distribution of the electron density remaining after filling p - orbitals of pnictides due to electrons of the Eu and the transition metal. It should be emphasized that the substitution of Zn^{2+} to Fe^{2+} in EuM_2As_2 changes the behavior of the Eu^{2+} ions layers: of adjacent europium layers are compressed and shifted by half a period along their surfaces and thus doubles the period of the structure of the ions along c -axis. The consequence of this is the metallization of the Eu layers, which is manifested in significant reduction of the g factor to smaller 2.0 and the temperature behavior of the linewidth.

TH.C-P90 - Successive component-separated magnetic transitions on pseudoternary compounds $Ho_{1-x}Gd_xRh_2Si_2$

T. Shigeoka [1], T. Morita [1], T. Fujiwara [1], K. Matsubayashi [2], Y. Uwatoko [2]

1. Yamaguchi University, Japan
2. University of Tokyo, Japan

The ternary compound HoRh2Si2 shows successive component-separated magnetic transitions; the magnetic moments of c- and ab-components independently order at different temperatures, TN1= 29.1 K and TN2=12.1 K, respectively [1]. This behavior may come from some frustration. Complex magnetization processes were observed at low temperatures [2]. This behavior is very interesting. In order to obtain information on the origin of this behavior, magnetic behavior of $Ho_{1-x}Gd_xRh_2Si_2$ has been investigated by measurements of magnetization and magnetic susceptibility. Both transitions TN1 and TN2 increase with increasing x. The partial ordered phase, may be a frustration state, in TN1<T< TN2 is persisted to high concentration x. In $GdRh_2Si_2$, the transition TN1 suddenly disapper; the frustration state goes out. Ho moments play an important rule for an appearance of this pertial ordered phase. Crystal field effects may be also important for this behavior.

Terahertz radiation has emerged as an effective method for the study of spin dynamics in magnetic materials. The frequency range falls within the 0.1-10 meV regime making it comparable to the low-energy terms of the magnetic Hamiltonian and complementary to established methods that probe these interactions such as inelastic neutron scattering. In our recent study [PRB 90:054413 (2014)] we demonstrate how the temperature dependence of an effective anisotropy can be extracted by terahertz spectroscopy of the spin waves in a rare earth orthoferrite NdFeO3. The results suggested a crossing of magnetic anisotropy terms as responsible for the temperature dependent spin reorientation. Here we advance that study, probing the magnetic susceptibility by the spin wave dynamics in the xy plane and along the z axis. Further refinements to the temperature dependent spin wave analysis give insights into the microscopic contributions to the magnetic anisotropy terms. The measurements are also extended to the ErFeO3 compound which experiences different temperature dynamics for the spin reorientation. The results suggest that an interplay between magic dipolar and single ion anisotropies is important in the spin reorientation phenomenon.

TH.C-P92 - Picosecond emergence and control of the photo-induced magnetization across the morin transition in $DyFeO_3$

D. Afanasiev [1], R. Pisarev [2], B. Ivanov [3], T. Rasing [1], A. Kimel [1]

1. Radboud University Nijmegen, Institute for Molecules and Materials, AJ Nijmegen, The Netherlands
2. Ioffe Physical-Technical Institute, Russian Academy of Sciences, St. Petersburg, Russia
3. Institute of Magnetism, National Academy of Sciences, Kiev, Ukraine

The photo-induced phase transitions and dynamics triggered by fs laser pulses is a subject of intense and multidisciplinary research in contemporary science. In magnetism this is an especially intriguing problem since understanding the kinetics of the phase transitions is crucial for achieving the fastest possible magnetic recording and information processing.
Here we show that excitation of antiferromagnetic $DyFeO_3$ in the vicinity of the Morin transition with help of a single 60 fs laser pulse pushes the antiferromagnet from collinear to non-collinear spin state with the net magnetization. Imaging the photo-induced area confirms that emergence of the magnetization proceeds via a depletion of the collinear antiferromagnetic phase and reveals that the initial orientation of its antiferromagnetic vector plays a decisive role in defining the direction of the photo-induced magnetization. The measurements performed for different pump polarizations and applied magnetic fields reveal that the direction of the photo-induced magnetization depends on the polarization of the pump, so that for field below 0.4 kOe a finite fraction of the photo-induced magnetization can be aligned against the external magnetic field.

TH.C-P93 - μSR study on the phase transition from antiferromagnetic Mott-insulator to non-magnetic metal in K-Rb alloy and Rb clusters in sodalite

T. Nakano [1], K. Tanibe [1], L. Manh Kien [1], S. Yoon [2,3], M.Abdel-Jawad [2], F. L. Pratt [4], I.Watanabe [2], Y. Nozue [1]

1. Department of Physics, Osaka University, Japan
2. RIKEN Nishina Center, Japan
3. Department of Physics, The Catholic University of Korea, Republic of Korea
4. ISIS, Rutherford Appleton Laboratory, United Kingdom

Sodalite is a kind of aluminosilicate zeolites where the cages with an inner diameter of 0.7 nm are arrayed in a bcc structure. Na_4^{3+} clusters arrayed in sodalite show antiferromagnetism below the Néel temperature T_N of 48 K. In the cluster, one unpaired s-electron is shared by four Na^+ ions and is confined in the cage. The antiferromagnetic ordering is realized by the exchange interaction between the s-electrons in adjacent clusters. The material is assigned to a Mott insulator. When heavier alkali elements are substituted for Na, T_N systematically increases: 72, 80, and 90-100 K for the clusters with averaged chemical compositions of K_4^{3+}, $(K_3Rb)^{3+}$, and $(K_{1.5}Rb_{2.5})^{3+}$, respectively. However, a recent work has revealed that Rb_4^{3+} does not show antiferromagnetism and shows a metallic behavior. In this work, we investigate the magnetic properties of this system near the insulator-to-metal (I-M) transition in detail by utilizing μSR. The experiments were preformed at the RIKEN-RAL Muon Facility. Zero-field μSR spectra of the K-Rb alloy clusters ($(K_{1.7}Rb_{2.3})^{3+}$) clearly show a muon-spin precession signal with a large amplitude. This evidences that the antiferromagnetic ordering is robust in the major volume of the sample even just before the I-M transition. The internal field at the muon site is estimated to be 166 Oe at 5 K. This value is larger than that in Na_4^{3+} (92 Oe), K_4^{3+} (142 Oe), and $(K_3Rb)^{3+}$ (155 Oe). The systematic increase in the size of s-electron wave function in heavier alkali metals, which has been assigned to the origin of the increase in T_N, may provide stronger Fermi contact interaction between the s-electron and μ^+ stopping near the zeolite framework. On the other hand, Rb_4^{3+} clusters show a very slow relaxation even at 2 K, which confirms the sudden disappearance of antiferromagneic ordering after the I-M transition.

TH.C-P94 - Crystal structure and physical properties of the novel $EuPdSn_2$ compound

I. Čurlík [1,2], F. Gastaldo [3], M. Giovannini [3], M. Reiffers [1,2]

1. Institute of experimental physics, Slovak academy of science, Košice, Slovakia
2. Faculty of Humanities and Natural Sciences, University of Prešov, Prešov, Slovakia
3. Department of Chemistry, University of Genova, Genova, Italy

A new intermetallic compound $EuPdSn_2$ has been synthesized. The pure elements have been weighed in the stoichiometric ratio inside a glove box, in order to avoid Eu oxidation, and closed in a Ta crucible. Afterwards, the compound have been synthesized by induction melting. Its crystal structure was established by X-ray powder diffraction as orthorhombic, space group *Cmcm* (No. 63) with a = 0.4451(4) nm, b = 1.1587(2) nm and c = 0.7455(2) nm. The structure of $EuPdSn_2$ belongs to the $MgCuAl_2$ prototype, a ternary ordered variant of the Re_3B type.
In this work we present the first results of the magnetic properties, electrical resistivity and heat capacity measurements for this compound. The susceptibility dependence χ(T) follows the Curie-Weiss law above 20 K with an effective magnetic moment of $\mu_{eff} = 7.67\mu_B$, which is very close to the theoretical value for Eu^{2+}.
Concerning the magnetic properties, an antiferromagnetic transition is observed at T_N = 13 K. All the other measurements fit well with this scenario. The magnetization dependencies $M(B)$ measured at various constant temperatures show a magnetic saturation below T_N. The values of electrical resistivity ρ(T) at low temperatures below T_N increase in absolute values with the applied magnetic field due to the Lorentz force. The residual resistivity ratio RRR = 28 demonstrates the very good quality of this polycrystalline sample.

TH.C-P96 - Magnetic properties and negative magnetocaloric effect in Mn(Ru-Rh)As

D. Szymański [1], J. Tobola [2], W. Chajec [1], R. Zach [1], S.Haj-Khlifa [3], D. Fruchart [3], E. K. Hlil [3]

1. Institute of Physics, CUT, Cracow, Poland
2. AGH University of Science and Technology, Faculty of Physics and Applied Computer Science, Cracow, Poland
3. Institut Néel, CNRS, Grenoble, France

We report on magnetic properties and magnetocaloric effect (MCE) of $MnRu_{1-x}Rh_xAs$ system (SG: Fe_2P-type), which exhibits complex magnetic behaviours [1,2,3]. While the Rh content is less than 0.2, the compounds order ferromagnetically (F) with a Curie temperature (T_C), which decreases vs. x. For x>0.8, magnetic ordering is more complex and the system evidences magnetoelastic phase transitions between the antiferromagnetic (AF) and (F+AF) ordered state and the (F+AF) and paramagnetic (P) one. Based on previously analyzed XRD measurements in 80–550K temperature range [4], in this work we mainly focus on the MCE properties. The negative MCE was not yet reported for the samples with 0.8<x<1 composition range to our best knowledge. The experimental investigations of magnetic entropy changes (x=0.9, x=0.95) is analyzed by using Maxwell relation and Clausius-Clapeyron equation. Both approaches are compared and critically discussed, as previously presented for parent MnRhAs compound [2]. Moreover, magnetic properties of $MnRu_{1-x}Rh_xAs$ are analyzed in view of electronic structure calculations using KKR and KKR-CPA methods for ordered compounds (x=0 and x=1) and disordered alloys (0<x<1), respectively.

TH.C-P97 - Neutron depolarisation imaging of the ferromagnetic quantum phase transition in $ZrZn_2$

P. Schmakat [1,2], M. Halder [2], G. Brandl [1,2], M. Schulz [1], S. Hayden [3], R. Georgii [1], P. Böni [2], C. Pfleiderer [2]

1. Technische Universität München, FRM II, Germany
2. Technische Universität München, E21, Germany
3. University of Bristol, Bristol, United Kingdom

When a polarised neutron beam traverses a ferromagnetic material, the orientation and strength of the polarisation changes sensitively as a function of the ferromagnetic moment and the size of the ferromagnetic domains. We have developed an experimental set up that allows to perform neutron depolarisation imaging as a function of magnetic field. In a study of the ferromagnetic quantum phase transition in the weak itinerant ferromagnet ZrZn2 under pressure we find, that a peculiar field dependence of the neutron depolarisation survives on the paramagnetic side of the temperature versus pressure phase diagram. This provides putative evidence for the emergence of complex magnetic textures.

TH.C-P98 - Correlation between electrical properties and antiferromagnetic ordering in brownmillerite-type $Ca_2Fe_2O_5$

I. Kagomiya [1], Y. Hirota [1], K. Kakimoto [1], A. Fuwa [2], S. Nakamura [3,4]

1. Department of Materials Science and Engineering, Nagoya Institute of Technology, Nagoya, Japan
2. Faculty of Science and Engineering, Waseda University, Japan
3. Department of Science and Engineering, Utsunomiya, Japan
4. Advanced Research Institute of Science and Engineering, Waseda University, Japan

The brownmillerite Ca2Fe2O5 possesses antiferromagnetic transition at TN = ~700 K, which is relatively higher among magnetic iron oxides. Some studies have been reported that the Ca2Fe2O5 shows iron charge disproportionation (Fe^{3+} <-> Fe^{4+} + Fe^{2+}) in the particulartemperatures.[1] We suppose that the charge disproportionation simultaneously contributes to electrical- and magnetic-properties. As a result, the correlation between electrical properties and antiferromagnetic ordering is expected in the Ca2Fe2O5. Although there are many reported studies about electrical- or magnetic-properties of the Ca2Fe2O5, studies and discussion about the correlation between them have been still rare. With the point of view, we try to investigate whether the correlation is present or not in the Ca2Fe2O5. The polycrystalline Ca2Fe2O5 was prepared by a conventional solid state reaction method. Magnetization of the Ca2Fe2O5 was investigated by a SQUID magnetometer with oven in the temperature range of 300 - 800 K. In addition, Mössbauer spectroscopy was investigated to confirm magnetic structure and iron valence of the prepared Ca2Fe2O5. The electrical conductivity was investigated in the temperature range of 300 - 800 K by a four-point measurement technique. It was found that activation energies estimated from Arrhenius plot of the electrical conductivity changed around TN. The activation energy was 0.26 (0.48) eV at higher (lower) temperatures than TN. The fact means that the electrical transport mechanism modified at the magnetic transition. From the activation energy value and the reported study[1], we suppose that the transport mechanism modified from charge transfer based on the iron charge disproportionation to polaron hole hopping at higher temperatures than TN. It suggests that the magnetic ordering of the Ca2Fe2O5 is closely related to presence of the charge disproportionation, because the charge transfer makes the super-exchange interaction.

TH.C-P99 - The uniaxial pressure effect on the magnetic phase transitions in spin-lattice coupled system $CuFeO_2$

H. Tamatsukuri [1], S. Mitsuda [1], T. Nakajima [2], S. Aoki [1], S. Hosaka [1], K. Prokes [3], K. Kiefer [3]

1. Tokyo University of Science
2. RIKEN Center for Emergent Matter Science (CEMS)
3. Helmholtz-Centre Berlin for Materials and Energy

The triangular lattice antiferromagnet $CuFeO_2$ is a strong spin-lattice coupled system, whose magnetic phase transitions are accompanied by crystal lattice distortions to relieve the geometrical spin frustration. In previous study, by the magnetic susceptibility and neutron diffraction measurements under uniaxial pressure (p) up to 100 MPa along a direction of supporting the spontaneous lattice distortions, we investigated how applied p modify the magnetic phase transition [1]. Although they observed a rise of the magnetic phase transition temperature, applied p up to 100 MPa is too small to investigate the p variation of q0, which is a magnetic modulation wave number at the magnetic phase transition temperature and should reflect ratios of coupling constants. In this study, we have achieved the application of p up to 600 MPa, and have performed the similar experiments. As a result, we have revealed that the value of q0 is not changed even by applied p of 600 MPa, suggesting that coupling constants are almost invariable for applied p. In contrast, the phase transition temperature drastically increases with increasing p. This result indicates that, despite the invariable q0 for applied p, the value of Jmax(q0), which is a Fourier transformed maximum value of coupling constant determining the magnetic phase transition temperature within the mean field approximation, is changed. Unlike the case in geometrically frustrated but non spin-lattice coupled system $CoNb_2O_6$, in which coupling constants are easily modified by applied p [2], our results suggest that applied p does not directly affect the coupling constants, and thus spin-lattice coupled term in Hamiltonian may be essential for determining the magnetic phase transition temperature in $CuFeO_2$.

TH.C-P100 - Quantum phase transitions and staggered dimer order in the J1 – J1' – J2 frustrated anisotropic exchange antiferromagnetic Heisenberg model

S. Rufo [1], J.R. de Sousa [2,3], J.A. Plascak [1,4,5]

1. Universidade Federal De Minas Gerais, Brazil
2. Universidade Federal Do Amazonas, Brazil
3. National Institute of Science and Technology for Complex Systems, Brazil
4. Center for Simulational Physics, University of Georgia, United states
5. Universidade Federal da Paraíba, Brazil

The magnetic properties of the spin-1/2 J1 – J1' – J2 Heisenberg antiferromagnetic model with anisotropic exchange interactions is studied on a square lattice. This model is an extension of the prototypical J1 – J1' – J2 model (when J1 = J1') and also presents the same kind of frustration at low temperatures. The directions of the exchange interactions are: J1 along of the x axis, J1' along of the y axis and J2 along the diagonal direction on a square lattice. The results have been obtained by using a variational method based on a trial vector for the ground state. The zero temperature phase diagram depends on the values of the interactions J1, J1', J2 as well as on the exchange anisotropies, where the latter ones allow the Hamiltonian to vary between the classical Ising and the quantum isotropic Heisenberg models. The system presents a Néel ordered phase, a collinear antiferromagnetic phase and a disordered quantum phase between them. An interesting result points out that these exchange anisotropies play an important role regarding not only the order of the transitions between the Néel and the quantum disordered phases, but also the area of existence of the quantum disordered phase as well. We have also computed the dimerization parameter and the staggered dimer order has founded and analyzed, disagreeing with the spin-liquid picture for the intermediate phase. In addition, we can present also our results analyses about for a particular quase-one dimensional case, i.e. with no frustration parameter. We found for this case that an infinitesimal interchain coupling paramenter J1' is sufficient to stabilize a long-range order, different from some works that forecast a finite value for this coupling. That last result was published in Phys.Rev. E 88, 34101 (2013).

TH.C-P103 - Low Temperature Magnetic Properties of a New Quasi-one-dimensional Organic Magnet alpha-2-Cl-4-F-V

Y. Kono [1], S. Kittaka [1], T. Sakakibara [1], H. Yamaguchi [2], Y. Hosokoshi [2]

Recently, several verdazyl radical crystals have been synthesized and found to consist of unconventional quasi-one-dimensional magnetic lattices [1,2]. They are molecular-based crystals, and each of molecules possesses the verdazyl radical, which has an S = 1/2 quantum spin. Chemical modification of the verdazyl radical molecule easily enables tuning of the intermolecular interactions, and it is thus useful for realizing quasi-one-dimensional quantum spin systems which have unique magnetic properties. In this study, we present low-temperature magnetic properties of a new verdazyl radical crystal alpha-2-Cl-4-F-V. The molecular orbital calculations of the material predicted the strongest one-dimensional antiferromagnetic interaction and three main interchain interactions between the S = 1/2 quantum spins. DC magnetization and heat capacity measurements have been performed at temperatures between 0.1 K and 2 K in several magnetic fields up to 7 T. The magnetization curve at 0.1 K shows gapless behavior like conventional one-dimensional quantum spin systems and saturates at about 5 T. A peak is observed in the temperature dependence of the heat capacity at 0 T, indicating that a three-dimensional ordering occurs at about 0.2 K. On the other hand, the temperature dependence of the magnetization in several magnetic fields shows a similar anomaly appearing in many of gapped spin systems, such as quantum spin ladders, differing from ordinary three-dimensional orderings. This behavior is attributed to the highly frustrated character of the interchain interactions predicted by the molecular orbital calculations.

TH.C-P104 - Effect of pressure on magnetic and transport properties in the lightly electron-doped manganite compound Sr-substituted $CaMn_{0.95}Sb_{0.05}O_3$

T. Aoyagi [1], M. Matsukawa [1], H. Takahashi [1], H.Taniguchi [1], S. Kobayashi [1], S. Nimori [2], R. Suryanarayanan [3]

3. University Paris-Sud, Paris, France

We report on the effect of pressure of magnetic and transport properties in the lightly electron-doped manganite compound $(Ca_{1-x}Sr_x)Mn_{0.95}Sb_{0.05}O_3$ with a fixed carrier content, to better understand magnetization reversal of this system. In a weak magnetic-field-cooled measurement, diamagnetic magnetization is observed for $x<0.15$, which changes to positive values for $x\geq0.15$. However, with the application of pressure to the x=0.16 sand x=0.17 samples, the magnetization reverses sign and diamagnetism is restored. We present a magnetic phase diagram as a function of Sr content, under ambient and hydrostatic pressures. The ac magnetic susceptibility measurement indicates the existence of magnetic frustration for the Sr-substituted samples. The low temperature negative magnetization of this system has been discussed on the basis of the local lattice distortion of MnO_6 octahedra associated with the orbital-spin coupling.

2. Experimentalphysik, Duisburg-Essen University, Duisburg, Germany
3. ThyssenKrupp Electrical Steel, Gelsenkirchen, Germany
4. Institut Laue-Langevin, Grenoble, France

$La_{0.5}Pr_{0.5}Mn_2Si_2$ undergoes an antiferromagnetic-ferromagnetic transition at about 250 K. This transition can also be induced by an external magnetic field leading to a metamagnetic transition. This leads to a large change in the configurational entropy, which is useful for magnetic cooling and studying the magneto-caloric effect. We investigated the details of the spin configuration as the magnetic ordering progresses from AF to FM by neutron-diffraction techniques under magnetic fields up to 5 T and by using spectral refining methods.

TH.C-P107 - Exotic spin structures and phase transitions in a complex magnetoelectric CuB_2O_4 as evidenced by optical linear dichroism studies

K. Boldyrev [1], M. Popova [1], R. Pisarev [2], L. Bezmaternykh [3]

3. Kirensky Institute of Physics, Siberian Branch of the Russian Academy of Sciences, Krasnoyarsk, Russian Federation

Copper metaborate CuB_2O_4 has a complex crystal structure (SG I42d, Z=12), in which magnetic Cu^{2+} ions (S=1/2) in the unit cell occupy two different crystallographic positions. This compound exhibits a unique combination of magnetic, magnetoelectric, linear and nonlinear optical properties. To mention some of them, Cu(4b) and Cu(8d) magnetic subsystems order magnetically at different temperatures, 21 K and ~ 8 K, respectively. Multiple frustrated and nonfrustrated antisymmetric exchange interactions within and between the 4b and 8d magnetic subsystems result in a rich complex magnetic phase diagram. Recent studies of electronic absorption spectra of CuB_2O_4 revealed narrow zero-phonon (ZP) exciton lines for all transitions between the crystal-field-split 3d-states of Cu^{2+} ions [1].
In this work we report on a large sublattice-sensitive optical linear dichroism (LD) on ZP exciton lines which arises below the temperature of the antiferromagnetic ordering in the crystallographically isotropic (xy)-plane of CuB_2O_4 [2]. We elucidate the nature of the LD attributing it to the magnetic Davydov splitting. Using this dichroism we have discovered a splitting of the phase transition at ~ 8 K into two transitions with external magnetic field dependent temperatures. Our LD data are against a simple spin helix magnetic structure reported earlier and suggest elliptical helicoidal spin structure with a temperature-dependent direction of the long axis of the spin ellipse.
To summarize, on the example of CuB_2O_4 we show that the discovered LD can be used as a new efficient method for revealing hidden features of magnetic structures and phase transitions in complex multi-sublattice multiferroics and magnetics. This work was supported by the RFBR Grant No 15-02-04222a and the President of the Russian Federation (Grant No MK-3521-2015.2).

TH.C-P108 - Stabilizing the ferromagnetic ordering of Co nano-assemblies on graphene by dipolar interaction

C. Kuo [1], Y. Chang [1], Y. Chan [1], S. Wu [1], T. Wu [1], C. Huang [1], D. Wei [2]

1. Department of Physics, National Sun Yat-Sen University, China

2. National Synchrotron Radiation Research Center, Taiwan

Magnetic nano-structures may demonstrate novel electronic and magnetic properties over their material counterparts of thin films and bulk system. This is meaningful concerning the fact that micro-fabrication technology nowadays steps to nano-scale. Their integration with carbon-based materials further indicates the application in biomedics and spintronics, where the stabilization of magnetization is one of the major issues. In nano-particles, dipolar interaction is thought to dominate exchange interaction and withstand elevating temperature, so as to serve magnetic coupling. However, the capacity of magnetic anisotropy against thermal fluctuation, that is, the stability of magnetic ordering needs to be investigated.
In this work, the evolution of magnetic ordering in graphene-under-layered cobalt assemblies is reported. The quality preparation of graphene and the 3D-growth of cobalt assemblies are determined by scanning tunneling microscopy (STM). Moreover, by using x-ray magnetic circular dichroism (XMCD), the magnetic properties of cobalt assemblies are characterized. It is pointed out that for the magnetic ordering in cobalt assemblies, the coupling of cobalt particles is crucial in competing with thermal fluctuation while the magnetic anisotropy of single particle will not beat it. To confirm the mechanism for magnetic coupling, an evaluation in the framework of magnetic dipolar interaction through nano-particles is given. Accordingly, up to cobalt of 15 ML, where 'ML' stands for the equivalent monolayer of cobalt in Co/Pt(111) thin films, a phase change from superparamagnetic to ferromagnetic ordering is expected at room temperature (RT). The idea is consistent with the subsequent deposition up to 25 ML cobalt in experiments. This reveals the capability of engineering the stability of magnetization, for instance, to the onset of ferromagnetic ordering. As the magneto-static effect, dipolar interaction is insensitive to interface roughness such as some angstroms. This is about to support the advantages of magnetic nano-particles related devices.

TH.C-P109 - Thermodynamic properties of $NdCu_4Au$

A. Bashir [1], M. Tchokonté [1], D. Britz [2], A. Strydom [2]

1. University of The Western Cape, South Africa
2. University of Johannesburg, South Africa

The studies of magnetic susceptibility, $\chi(T)$, magnetization, $\sigma(\mu_0 H)$, and specific heat, $C_p(T)$, of the new antiferromagnetic (AFM) $NdCu_4Au$ compound are reported. The room temperature X-ray diffraction analysis indicates a cubic $MgCu_4Sn$ – type crystal structure with space group *F-43m* (No. 216) for the $NdCu_4Au$. The field cooled (FC) and Zero-field cooled (ZFC) dc $\chi(T)$ data show a coincide which suggest no evidence of an inhomogeneous magnetic ground state in this compopund as a result of spin – glass – like state. The low temperature $\chi(T)$ data shows an AFM - like anomaly associated with a Néel temperature T_N = 3.9 In the paramagnetic, $\chi(T)$ data follows the Curies – Weiss law with an effective magnetic moment μ_{eff} = 3.42(2) μ_B and a paramagnetic Weiss temperature θ_p = −6.96(6) K. The value obtained for μ_{eff} is close to the value of 3.62 μ_B expected for the free Nd^{3+} - ion. $\sigma(\mu_0 H)$ data shows a linear behaviour up to 7 T in the paramagnetic region at T = 10 K and deviation from linearity above 2.5 T in the ordering region at T = 2 K characteristic of metamagnetic behaviour. $C_p(T)$ data confirm AFM phase transition at T_N = 3.5 K close to 3.9 K observed in $\chi(T)$ result. The 4f – electron specific heat shows a Schottky – type anomaly around 25 K with energy splitting Δ_1 = 14.5(4) K and Δ_2 = 63(1) K of the Nd^{3+} (J = 9/2) multiplet, that are associated with the first and second excited state of the Nd^{3+} - ion. The 4f – electron entropy reaches the value of Rln2 close to the T_N at 4.2 K and saturates at the value of Rln(2J+1) at T = 70 K.

TH.C-P110 - Magnetic characterization of $YbMn_2Sb_2$ single crystals

J. Munevar [1], F. P. Vieira[1], M. A. Avila[1], R. A. Ribeiro[1]

1. CCNH, Universidade Federal do ABC (UFABC), Santo Andre, Brazil

We report the growth of high quality single crystals of the ternary intermetallic compound YbMn2Sb2 by the Sn-flux method, and the subsequent structural and magnetic characterization. X-ray diffraction measurements in powdered samples confirmed the trigonal structure; lattice parameters, atomic positions and atom distances as previously reported [1], where atoms of Yb separate layers of MnSb. The magnetic properties were studied via heat capacity between 2 and 300 K and magnetization measurements from 2 to 700 K. Susceptibility measurements as a function of temperature with external field perpendicular to the c axis show that the YbMn2Sb2 orders ferromagnetically around 580 K. Furthermore, it can be seen that the compound exhibits reduced susceptibility below 120 K, possibly caused by a spin flop process resultant of an antiferromagnetic reordering [1,2]. To observe the nature of the antiferromagnetic transition we measured the heat capacity, in which a peak is observed around 120 K. A Sommerfeld coefficient γ= 2.2 mJ/mol.K^2 is estimated, which indicates no heavy fermion behavior. Possible contributions to the magnetic state coming from Yb are also discussed. We thank the financial support of FAPESP, CAPES and CNPq.

TH.C-P111 - Electromagnetic waves emitted from spiral magnetic at phase transition

D. Kuzmin [1], I. Bychkov [1], A. Kamantsev [2], V. Koledov [2], V. Shavrov [2]

1. Chelyabinsk State University, Russian Federation
2. Kotelnikov Institute of Radio-engeneering and Electronics of RAS, Russian Federation

In present work we have investigated electromagnetic waves radiation from magnetics with spin spiral ordering at phase transition to ferromagnetic state. The study cover some typical situations: fast change of the state, slow change with the linear time dependence of the spiral angle, and periodical process. It has been shown the possibility of two types emittion. The first one is non-stationary terahertz radiation picosecond pulse, the second one is stationary radiation with the frequency of external field. The results of the work may be useful for both terahertz and microwave devices.

The work was supported by grants of RFBR ## 13-07-00462, 15-07-99654, and particularly by RScF # 14-22-00279

TH.C-P112 - Modeling of first order phase transitions kinetics in systems with coupled order parameters

I. Bychkov [1], D. Kuzmin [1], A. Kamantsev [2], V. Koledov [2], V. Shavrov [2]

1. Chelyabinsk State University, Russian Federation
2. Kotelnikov Institute of Radio-engeneering and Electronics of RAS, Russian Federation

We present common 1D model of first order phase transition based on coupled solution of order parameters evolution and heat transfer equations. Such a model may be used for simulation of phase transitions in multiferroics or magnetostructural phase transitions, for example. First order phase transition process have been described by Landau-Khalatnikov-like equation with the thermodynamic potential of 2-3-4 type. Time and space distributions of the order parameters and temperature have been obtained for different heat regimes. Position and speed evolution of the interphase boundary have been calculated.

TH.C-P114 - Effect of Cu-substitution on Magnetic State of Mn2NiGa Heusler alloy

M. Vagadia [1], A.K. Nigam [1]

1. Tata Institute of Fundamental Research, Mumbai, India

Effect of Cu substitution at Ni site in Mn2NiGa shape memory alloy, prepared by arc-melting, has been studied. Temperature dependent magnetization measurement suggests existence of martensitic phase transition near room temperature in Mn2NiGa alloy. Magnetization isotherms measured at different temperatures near transition temperature show the occurrence of magnetocaloric effect associated with magneto-structural transformation. The maximum value of magnetic entropy change is ~ 12 J/Kg-K at 5T applied magnetic field. On the other hand, substitution of 10% Cu at Ni - site results in complete suppression of martensitic phase where the magnetization shows ferromagnetic behavior in the temperature range of 5 - 350K. Magnetoresistance (MR) measurement as a function of applied magnetic field shows slight asymmetry in MR about the direction of magnetic field in both the samples under study.

TH.C-P115 - Low-temperature properties of transition-metal and rare-earth diborides

G. Benka [1], A. Bauer [1], A. Regnat [1], C. Pfleiderer [1]

1. Technische Universität München - Lehrstuhl Für Topologie Korrelierter Systeme, Germany

The class of hexagonal C32 diborides MB_2 (space group P6/mmm), where M is a transition-metal or rare-earth element, crystallize in a rather simple layered yet closest-packed hexagonal crystal structure. Still, these compounds display a wide range of magnetic and eletronic properties.
Examples include ferromagnetism[1], antiferromagnetism[2] and superconductivity[3]. Taken together, tuning the C32 diborides via compositional tuning and/or by applying pressure, allows for an investigation of quantum phase transitions or changes of the Fermi surfaces topology in a simple, crystallographically unchanged environment. Additionally, the hexagonal structure may give rise to geometrical frustration.
However, presumably due to the very high melting temperatures of the C32 diborides and the resulting lack of high-quality samples, the electronic and magnetic properties of most of these compounds have not been explored in detail so far. We report a comprehensive study of high-purity polycrystals and single crystals of MB_2 (M = Cr, Mn, Nb, V, Zr, Dy, Er, Gd, Ho, Pr, Tb, Tm, Y, Yb).
All samples were prepared from 99% boron-11 enriched boron. A thorough metallurgical characterization is followed by first investigations of the low-temperature properties by means of magnetization, ac suscetipility, specific heat, and electrical transport.
As a result, our study establishes a sound basis for future experiments in this fascinating class of materials.

TH.C-P116 - CuMnSb: between local and itinerant antiferromagnetism

P. Jorba Cabré [1], A. Bauer [1], A. Regnat [1], G. Brandl [1], B. Roessli [2], A. Senyshyn [3], M. Meven [3], S. Gottlieb-Schönmeyer [1], K. Hradil [4], Peter Böni [1], C. Pfleiderer[1]

1. Technical University of Munich - Physik Depertment, Munich, Germany
2. Laboratory of neutron scattering, PSI. Switzerland
3. Heinz Maier-Leibnitz Zentrum (MLZ), Munich, Germany
4. Universität Wien, X-ray center, Wien, Austria

At room temperature, CuMnSb crystalizes in the cubic $C1_b$ half-Heusler structure. Other than most isostructural siblings, which order ferromagnetically at temperatures of a few hundred Kelvin, CuMnSb exhibits antiferromagnetism with a relatively low Neel temperature (≈ 55 K). We have successfully grown the first single crystals from optically float-zoned polycrystalline feed rods. After a detailed metallurgical characterization, we have collected magnetization, specific heat, electrical resistivity, Hall effect, thermal conductivity, as well as both elastic and inelastic neutron scattering data. Curiously, CuMnSb combines typical properties of local-moment and itinerant magnets in a rather unique manner. While the commensurate magnetic structure with ordered moments that correspond to the fluctuating moments is typical for local-moment magnetism, the high stability of the order in magnetic fields, and the metallic behavior of the sample, are a strong arguments in favor of itinerant magnetism. A comparably high Curie-Weiss temperature alludes to the presence of disorder-induced geometric frustration. At a lower temperature ($T^* \approx 35$ K) a second transition has been observed, corresponding to a slight reorientation of the spins of about 10° from the [111] direction. The inelastic neutron experiment revealed an interesting spin wave dispersion with a 3 meV gap closing at T_N, and an unusual broadening that could be explained by magnetic fluctuations or by anti-site disorder. Furthermore, inelastic neutron scattering under pressure, has reveal an unexpected change in the magnetic order.

TH.C-P118 - High pressure phase diagram of the singlet-ground-state magnet $CsFeCl_3$

N. Kurita [1], H. Tanaka [1]

1. Tokyo Institute of Technology, Tokyo, Japan

$CsFeCl_3$ is a hexagonal ABX3-type compound where Fe^{2+} ions with an effective S=1 form ferromagnetic spin chains along the c-axis and antiferromagnetic (AF) triangular lattices in the c-plane. Owing to the single-ion anisotropy D, the ground state becomes a spin singlet with a finite gap for the first excited state. In $CsFeCl_3$, the D-term overcomes the exchange interactions and hence no magnetic ordering is observed in zero field. Application of magnetic field along the c-axis suppresses the excitation gap and, above the critical field Hc~4T, an antiferromagnetically ordered state appears [1]. With applying pressure, the antiferromagnetic (AF) phase is extended toward both higher temperature and lower field regimes [2]. For further understanding of the AF phase in $CsFeCl_3$, we have performed magnetization measurements in the low temperature range down to 0.5 K at ambient pressure, and down to 1.8 K at several pressures up to 1.5 GPa. In the magnetization process at 0.5 K, an anomaly at 3.8 T associated with the AF transition is clearly observed, as compared to the previous result measured at 1.8 K. Together with temperature dependence of magnetic susceptibility under several fields, a more detailed field-temperature phase diagram of $CsFeCl_3$ is obtained at ambient pressure. With increasing pressure, Hc monotonically decreases. At high pressures exceeding the critical pressure of Pc~0.9 GPa, an anomaly associated with the AF transition is observable in a nearly zero field.

4. Karlsruher Institute for Technology, IAM-WK, Eggenstein-Leopoldshafen, Germany
5. Brookhaven National Laboratory, Department of Physics, Upton, United States

Cr_{1-x}Fe_{x} shows reentrant spin glass behaviour below a doping dependent freezing temperature T_{f}. In contrast to a classical spin glass, the transition at T_{f} separates the spin glass state from a magnetically ordered rather than a disordered state. For low concentrations x the ordered state is antiferromagnetic and changes first to paramagnetic and subsequently to ferromagnetic state with increasing x [1, 2].
We report a study of the spin relaxation process in Cr_{1-x}Fe_{x} by means of high resolution neutron spin echo, magnetisation measurements and neutron depolarisation imaging for a wide range of concentrations x. This allows us to compare the relaxation process depending on the particular state at high temperatures. Our measurements provide an unprecedented combination of microscopic information on the spin dynamics and spin freezing on multiple length and time scales.

4. Department of Engineering Physics, Electronics and Mechanics, Graduate School of Engineering, Nagoya Institute of Technology, Nagoya, Japan

As well known, the Yb-based intermetallic compounds can induce a magnetically ordered state from a nonmagentic state due to the hole-electron analogy of Yb magnetic 4f13 electrons by applying pressure. YbNi3Al9 displays typical characteristics of a heavy-fermion antiferromagnet with a Neel temperature of TN = 3.4 K and an enhanced electronic specific heat coefficient of 100 mJ/(mol K2), reflecting a competition between the Kondo effect and the crystalline electric field (CEF) effect [1]. The crystal structure is identified as the trigonal ErNi3Al9-type with chiral space group R32. Recent reports on the physical properties of YbNi3X9 (X = Al, Ga) single crystals revealed deferent ground states under pressure at low temperatures [2]. In this paper, we report neutron diffraction studies of YbNi3Al9 that show q = (0, 0, 0.8) spiral antiferromagnetic ordering below TN, with a magnetic moment 1.2(2) uB per Yb that is orientated within the ab plane. We also present magnetic properties at ambient pressure.

TH.C-P122 - in MnSi

I. I. Lobanova [1,2], V. Glushkov [1,2], N. Sluchanko [2], S. Demishev [1,2]

1. Moscow Institute of Physics And Technology (State University), Moscow, Russian Federation
2. Prokhorov General Physics Institute of RAS, Moscow, Russian Federation

Non-centrosymmetric B20 helical magnet MnSi attracts attention of scientific community due to pressure-induced quantum criticality [1], skyrmion lattice formed below Tc~30 K [2] and topological Hall effect observed in this non-trivial spin texture [3]. However, the features of the spin-polarized (SP) state, into which the helical one collapses at B>0.6 T, are not well understood up to now. It was recently shown that the vertical phase boundary between the SP and paramagnetic (P) states as well as the universal scaling of magnetoresistance as squared magnetization in P phase of MnSi can be explained in terms of Heisenberg type localized moments rather than within itinerant magnetism model generally applied to this system [4]. To shed more light on the charge carriers scattering the anisotropy of transverse magnetoresistance (TMR) has been studied at 2-60 K by measuring bar-shaped single crystal in magnetic field B<6T applied perpendicular to <110> axis. The explicit difference between temperature and field dependences of TMR for B||<001> and B||<110> has been detected in both SP and P phases. In moderate magnetic field B<2 T the TMR anisotropy was found to change the sign at TC, while at higher fields the transition region broadens falling into the range from 23 K to 40 K at B= 6 T. No distinct anomaly was observed for B||<111>, which corresponds to the pitch vector of magnetic helix formed in the ground state of MnSi. The results are discussed in terms of phase separated state formed in MnSi in vicinity of the SP-P phase transition.

3. Hochfeld-Magnetlabor Dresden, Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany

Among the rare-earth R, transition metal T, intermetallics, the Co Laves phases are particularly interesting because of the magnetism of the 3d band in these systems is strongly influenced by the R sublattice magnetization. If the R bears a magnetic moment, the f-d exchange results in a ferro- (light R) or ferrimagnetic (heavy R) coupling between the Co and the R magnetization sublattices. High magnetic fields force ferrimagnetic RCo2 to gradually change the antiparallel alignment between the R and the Co moments towards a ferromagnetic phase. In particular, for ErCo2 a transition at 52 T has been reported, which was identified as Itinerant Electron Metamagnetism (IIEM) [1]. On the other hand, in ferromagnetic systems (as PrCo2) no field induced transition has been detected. The local interactions can be modified by substituting Er by Pr, changing the internal exchange fields to give rise to spin flipping transitions. In this work we have systematically measured the low-temperature high-field magnetization of ErxPr(1−x)Co2 at 4, 10, and 40 K at the Dresden High Magnetic Field Laboratory. Er substitution ErxPr(1−x)Co2 by Pr sets the condition for the system to undergo a field induced phase transition, ranging between 22 T (x=0.1) and 50 T (x=0.9). A clear jump in magnetization is observed in every diluted system. The modification on the internal exchange fields with increasing x plays the major role in modifying the critical field.

5. National Institute for Materials Science, Tsukuba, Japan

The clathrate compound $Pr_3Pd_{20}Ge_6$ is an interesting compound showing rattling motions of praseodymium (Pr) atoms, quadrupole order of 4f electrons, and hyperfine-enhanced nuclear magnetism. This compound has a $Cr_{23}C_6$-type cubic structure, where the Pr ions are located at two different crystallographic sites. The ground states at the 4a and 8c sites are a Γ_5 triplet and a non-Kramers Γ_3 doublet, respectively. Magnetic ordering and quadrupole ordering in $Pr_3Pd_{20}Ge_6$ have been studied by ultrasound and ac-susceptibility measurements [1, 2]. In the present study, we have performed thermal-expansion and magnetostriction measurements on single-crystalline sample of $Pr_3Pd_{20}Ge_6$ along [001] and [110] axes. The thermal expansion and magnetostriction were measured by a capacitance method in the temperature range of 2 and 30 K under the magnetic fields up to 8 T. We observed a difference of the magnetostriction between [001] and [110] axes. This lattice distortion was discussed in terms of CEF effects and symmetry strains.

TH.C-P127 - Synthesis and characterization of compositionally graded Fe-Rh films

N. B. Doan [1], Y. Dusch [1], G. Diguet [1], N. Dempsey [1], L. Ranno [1]

1. CNRS - Institut NEEL, Grenoble, France

The chemically ordered near-equiatomic FeRh phase that exhibits an abrupt antiferromagnetic to ferromagnetic transition close to 350 K is of interest from both the viewpoint of fundamental physics and for potential applications. The latter interest is based on the fact that the magneto-structural phase transition gives rise to magneto-caloric, magneto-resistive and magneto-strictive effects. It was already shown that phase change characteristics, and thus the material's functional properties, depend on the chemical composition and degree of chemical order. Very recent studies have revealed that the transition characteristics can also be tuned through strain, controlled through epitaxial growth on single crystalline substrates with a particular lattice parameter or through the use of piezoelectric substrates. Here, we report on a study compositionally graded FeRh films deposited onto both Si and PNM-PT substrates by magnetron sputtering of composite targets. The interest of such compositionally graded films lies in the fact that both magnetic and structural properties can be studied as a function of film composition, all other deposition and annealing parameters being constant, and that the interface between ferromagnetic and antiferromagnetic zones can be studied. The film composition, as measured by EDX, was shown to vary linearly across the substrate at a rate of 5.4 at%Rh/cm. We will report on temperature and field dependent magnetization and resistivity measurements made on samples of different composition, using a VSM-SQUID and transport rig, respectively. We will then report on how the application of voltage to the piezoelectric substrate influences the phase change characteristics.

This work was funded by the EC FP 7/2007-2013 programme under grant agreement n° 310748 (DRREAM).

TH.C-P128 - Critical exponents and hall effect in iron- and cobalt-based metallic glasses

A. Rosales-Rivera [1], J. Hernandez-Parra [1], J. Lopez-Tabares [1], J. Hincapie-Bedoya [1], A. Velasquez-Salazar [1], D. Gomez-Montoya [1], J. Chavarria-Rubio [1], F. Daniel Saccone[2]

1. Laboratorio De Magnetismo Y Materiales Avanzados, Universidad Nacional De Colombia, Sede Manizales, Colombia
2. Laboratorio de Sólidos Amorfos, INTECIN, FIUBA-CONICET, Buenos Aires, Argentina

In this work, we investigate the universality class and the Hall effect of three different metallic glasses, namely Fe70Nb10B20, (Fe50Co50)75Si5B20, and Co70Nb10B20. In so doing, we determined the critical exponents for the zero-field magnetization (β) and critical isotherm (δ) and critical temperatures from magnetization measurements. These metallic glasses were prepared as amorphous alloy ribbons by means of the melt spinning technique. The magnetization as a function of temperature of each sample was measured in the range 300-950 K using a vibrating sample magnetometer (VSM-VersaLab by Quantum Design) at fixed external magnetic fields (H). The Hall effect measurements were carried out at room temperature for applied dc magnetic field and dc electrical current varied in the range -10 < H < 10 kOe and 10 < Idc < 50 mA, respectively.
The present study shows that the magnetic features of Fe70Nb10B20 and (Fe50Co50)75Si5B20 are distinct in some aspects from the corresponding ones found in the soft magnetic metallic glass but less localized Co70Nb10B2. In fact, the universality class of the first two metallic glasses seems to correspond to the Ising model (Ô = 0.332), while that in the latter seems to be more near with the Heisenberg model (β = 0.371). The possible mechanisms leading to such universality classes including the spin-orbit interaction, shape anisotropies, direct exchange and itinerant exchange are analyzed. The Hall effect experiments indicate that the extraordinary Hall contribution decreases more rapidly on Co70Nb10B2 as compared to (Fe50Co50)75Si5B20 and Fe70Nb10B20.

TH.D-P01 - Full potential calculation of magnetic properties of $TbFe_2$

M. Imaizumi [1], C. Soufen [1]

1. Universiade Paulista Julio De Mesquita Filho –Unesp, Sao Paulo, Brazil

Rare-earth metals named group of lanthanides combine with Fe 3d transition metals to form a series of RFe_2 cubic phase Laves intermetallic compounds and it was thoroughly investigated during last years. These materials crystallize in the MgCu2 (Fd m) Laves phase and exhibit a number of interesting magnetic applications. In this structure the equivalent atom to Mg atom, the Rare- Earth atom, occupies equivalent sites with cubic point symmetry. Most of these intermetallic compounds are ferromagnetic. Then ab initio calculation has been performed on magnetic properties of intermetallic compound. The Khon - Sham equations were solved by applying the full potential linearized augmented plane wave (FPLAPW) method with spin orbit coupling(LS). In this approach the local density approximation (LDA) was substituted for (LDA+U) as exchange - correlation potential due to the strong electron - electron interaction. These calculations provide the total energy as function of volume, the total and partial densities of states and spin magnetic moment. From total energy the equilibrium lattice parameter and total energy in equilibrium volume were calculated. The spin magnetic moment was calculated from the difference between the majority and the minority total density of states below the Fermi energy. The spin magnetic moment calculated was 6.70 μB while the experimental value was 6.30 μB. Our results are in according to the values reported in the literature.

TH.D-P02 - High-field magnetoelasticity of Tm_2Co_{17}

A. V. Andreev [1], Y. Skourski [2], A. A. Zvyagin [3], S.Yasin [2], S. Zherlitsyn [2]

1. Institute of Physics, Academy of Sciences, Prague, Czech Republic
2. Dresden High Magnetic Field Laboratory, Helmholtz-Zentrum Dresden-Rossendorf Dresden, Germany
3. B.I. Verkin Institute for Low Temperature Physics and Engineering of the National Academy of Sciences of Ukraine, Kharkov, Ukraine

Er_2Co_{17} and Tm_2Co_{17} (hexagonal structure) are ferrimagnets which exhibit a field-induced transition at 40 T field applied along the c axis. In spite of the similar magnetic properties, the transition in Er_2Co_{17} and Tm_2Co_{17} looks different. In Er_2Co_{17} it is clearly of the first order and corresponds to sharp rotation of the Er sublattice. In the case of Tm_2Co_{17}, the transition is attributed to a direct ferri-to-ferromagnetic transformation in a way of paramagnetic remagnetization of the Tm sublattice which is very unusual. The explanation looks reasonable but it would be useful to confirm this by different behavior of other properties at the transition. The transition in Er_2Co_{17} is accompanied by sharp anomalies in the sound velocity and magnetostriction. If the transition in Tm_2Co_{17} has indeed a different origin, it should be seen in the magnetoelastic effects accompanying the transition.
We measured sound velocity and magnetostriction in pulsed fields up to 65 T applied along the c axis of Tm_2Co_{17} single crystal grown in triarc furnace by Czochraski method. Similar to Er_2Co_{17}, the transition in Tm_2Co_{17} is accompanied by clear anomalies in the sound velocity. The observed 0.3% jump of the sound velocity at the transition is negative in Tm_2Co_{17}, whereas it is positive in Er2Co17. The magnetostriction at the transition also differs very much from that in Er_2Co_{17}. In Tm_2Co_{17}, the transition is accompanied by a smooth minimum of 0.15*10-4 in longitudinal magnetostriction whereas in Er_2Co_{17}7 by a very sharp expansion of much larger magnitude (1.2*10-4). In the transverse mode, the effect in Tm_2Co_{17} looks as very broad minimum of low amplitude (<0.1*10-4) whereas in Er_2Co_{17} as very sharp and large shrinkage (2.6*10-4). Thus, both the magnetoacoustics and magnetostriction are rather different in Tm_2Co_{17} and Er_2Co_{17}. This supports our idea about different nature of the field-induced transitions in these compounds.

TH.D-P03 - Ferromagnetism in UCoAl induced by Os doping

A. V. Andreev [1], K. Shirasaki [2], J. Sebek [1], D. I. Gorbunov [1,3], S. Danis [4], T. Yamamura[2]

1. Institute of Physics, Academy of Sciences, Prague, Czech Republic
2. Institute for Materials Research, Tohoku University, Katahira 2-1-1, Sendai, Japan
3. Dresden High Magnetic Field Laboratory (HLD), Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany
4. Department of Condensed Matter Physics, Charles University, Prague, Czech Republic

UCoAl (hexagonal crystal structure) exhibits a metamagnetic transition from the paramagnetic ground state to the forced ferromagnetic state in a uniquely low transition field of 0.7 T applied along the c axis. A magnetic moment at the transition is induced on U but the state of the 5f electrons depends very drastically on the interaction with ligands. When Co is substituted by Fe, Ru, Rh, Ir, the critical field of the transition rapidly decreases and already few % doping stabilizes ferromagnetism. Opposite, Ni, Pd, Pt stabilize paramagnetism.
In the present work we studied influence of Os on the magnetism of UCoAl. The homogeneity range in the UCo1-xOsxAl system is limited to x = 0.2 with a small lattice expansion in the basal plane. Magnetization measurements performed on single crystals show that compounds with x = 0.02, 0.05, 0.10 are ferromagnets with easy c axis. The spontaneous magnetic moment Ms increases from 0.40 mB per formula unit at x = 0.02 to 0.53 mB at x = 0.10, which is almost twice larger than the magnetic moment induced at the metamagnetic transition in UCoAl. All the compounds exhibit huge magnetic anisotropy characteristic for UCoAl. Extrapolation of the a-axis magnetization curves to crossing with M = Ms gives anisotropy field Ha as 120-130 T. But this method does not take into account that the easy-axis magnetization is not saturated in the maximum applied field and grows even faster that the hard-axis one. So, the real Ha as a field of crossing of the easy- and hard-axis curves is considerably larger that these already huge values. Similarly to Ms, the Curie temperature increases with x and reaches 48 K for x = 0.10. Thus, Os stabilizes ferromagnetism in UCoAl considerably stronger than Rh and Ir and slightly stronger than Fe and Ru.

TH.D-P04 - Single crystal study of layered U_nRhIn_{3n+2} materials: case of the novel U_2RhIn_8 compound

A. Bartha [1], M. Kratochvílová [1], M. Dušek [2], M. Diviš [1], J.Custers [1], V. Sechovský [1]
1. Department of Condensed Matter Physics, Charles University, Praha, Czech Republic
2. Department of Structure Analysis, Institute of Physics ASCR, Praha, Czech Republic

We report on the single crystal properties of the novel U_2RhIn_8 compound studied in the context of parent $URhIn_5$ [1] and UIn_3 [2] systems. The compounds were prepared by In self-flux method. U_2RhIn_8 adopts the Ho_2CoGa_8-type structure with lattice parameters a = 4.6056(6) Å and c = 11.9911(15) Å. The behavior of U_2RhIn_8 strongly resembles that of related $URhIn_5$ with respect to magnetization, specific heat and resistivity showing strong magnetocrystalline anisotropy. U_2RhIn_8 orders antiferromagnetically below T_N = 117 K and exhibits slightly enhanced Sommerfeld coefficient γ = 47 $mJ.mol^{-1}.K^{-2}$. T_N increases with increasing c/a ratio within the UIn_3 – $UrhIn_5$ – U_2RhIn_8 series contrasting with the behavior of the cerium counterparts. Magnetic field leaves the value of Néel temperature for both $URhIn_5$ and U_2RhIn_8 unaffected up to 9 T. On the other hand, T_N increases with applying hydrostatic pressure up to T_N = 126 K at 3.2 GPa. The character of uranium 5f electron states of U_2RhIn_8 was studied by first principles calculations based on the density functional theory combined with Hubbard model.

5. Indian Institute of Technology Bombay, Mumbai, India

We have study the effect of external pressure on the magneto thermal properties and magnetization relaxation measurements across the ferromagnetic to antiferromagnetic transition of polycrystalline compounds Nd_7Pd_3. We observed three transition temperatures Tt, Tc and TN at 15 K, 34K and 39K respectively. The ordering temperature Tc and TN of the Nd7Pd3 are found to strong dependent on pressure (dTc/dP=-1.9K/bar and dTN/dP=-0.31K/bar) whereas insensitive with Tt. Large magnetic entropy change has been also observed near Tc and its sensitive with pressure also. The transition is incomplete at low temperatures with the stretched exponential relaxation behavior dominating over the power law, which is indicative of glassy dynamics or the arrest of the kinetics of the phase transition. In the intermediate temperature regime, the magnetic relaxation can be explained as a combination of both the power law and stretched exponential. We will discuss in details in full paper.

TH.D-P07 - Control of magnetic properties in alpha-Dy_2S_3 single crystal by using magnetic field

S. Ebisu [1], K. Fuji [1], Guoqing [1], Y. Shibayama [1]

1. Muroran Institute of Technology, Japan

Control of magnetic properties has been attempted in alpha-Dy_2S_3 single crystal by using magnetic field. alpha-Dy_2S_3possesses orthorhombic crystal structure having two crystallographically inequivalent Dy sites and shows successive antiferromagnetic transitions at TN1 = 11.4 K and TN2 = 6.4 K associated with various steep responses in physical properties. Such features are considered to originate from existence of metastable magnetic phases. A metastable phase induced by cooling in strong magnetic field of 18 T had been found in our previous work. In the present study, we have attempted to induce new magnetic phases by using the magnetic field of 7 T. Rotating magnetic field direction in the ac-plane of alpha-Dy_2S_3single crystal, which is actually performed by rotation of the sample in rigid magnetic field, brings about an anomalous increase of the magnetization up to 8.4 muB/Dy-atom at 6.0 K in the magnetic field of 7 T along the a-axis. The a-direction magnetization at the same condition in the stable phase is 5.4 muB/Dy-atom. This metastable phase induced by the rotation of the magnetic field persists until 1.3 T in the process of decreasing the magnetic field. The values of the magnetization below 1.3 T are consistent with those in the stable phase. The magnetization of this metastable phase has the same magnitude as the one of the metastable phase induced by strong-field cooling at 18 T; therefore, these metastable phases are inferred to be the same. Moreover, a certain process that combines the rotating of the magnetic field with cooling the sample in the magnetic field gives rise to exchange of the features of the magnetization curves for the a- and c-direction. Consequently, the easy magnetization axis in the ac-plane switches to the c-axis after this process from the a-axis in normal situation.

TH.D-P08 - Magnetic properties of double doped UH_3 -based hydrides

M. Paukov [1], I. Tkach [1], D. Drozdenko [1], P. Minárik [1], D. Kriegner [1], Z. Matej [1], S. Masková [1], L. Havela [1]

1. Charles University, Prague, Czech Republic

Interaction with hydrogen is an important issue related to application of uranium and its alloys. Any contact of α-U with H leads to formation of the stable allotropic form β-UH_3, a dark pyrophoric powder, formed via the metastable α-UH_3. *Bcc* U-Mo and U-Zr alloys form different types of hydrides, although both are based on UH_3. While the U-Mo alloys lead to amorphous structure based on β-UH_3 (grain size 1 nm), the U-Zr alloys lead to crystalline hydrides of the α-UH_3 type, which could be therefore synthesized first time without the β-UH_3 admixture. Surprisingly their magnetic properties are very similar and both groups exhibit first an increase of Curie temperature with the concentration of dopants. Thus T_C can exceed T = 200 K in the Mo case. Provided the amorphous structure guaranteed by Mo, it can accept other types of dopants in addition. We tested for Ti, Fe, and Zr and investigated variations of magnetic properties. We assumed that the amorphous structure must be more accepting diverse sizes of dopant atoms. Our investigation of magnetic properties of such double doped hydrides shows ferromagnetic ordering with parameters only weakly depending on the dopants. The addition of Zr enhances T_C more than addition of Ti, addition of Fe broadens the transition and enhances magnetization per U atom.

TH.D-P09 - Hexanuclear lanthanide clusters exhibiting magnetic chilling and relaxation properties

J. Tong [1], X. Xu [1], G. Luo [1]

1. Xiangyang Noncommissioned officers School, China

Polynuclear lanthanide complexes are intensively studied because of the fascinating magnetic properties, including magnetocaloric effect (MCE) and single-molecule magnetism (SMM).[1-4] And studying clusters with similar structures has considerable significance to improve our knowledge of the structure¨Cmagnetic property correlation of the LnIII complexes. In our effort to synthesize polynuclear lanthanide complexes, we have employed the homologous ligands H2ppo and H2Meppo, which potentially show various coordination modes that can form new polynuclear complexes. And gives rise to four analogous hexanuclear lanthanide complexes with the same skeleton, include two GdIII6 complexes and two DyIII6 complexes. Magnetic studies have revealed large magnetocaloric effect in the two weak antiferromagnetic GdIII6 complexes and SMM behaviors in the two ferromagnetic DyIII6 complexes. The differences in the nature of magnetic couplings between two GdIII6 complexes and two DyIII6 complexes are likely affected by the easy axes through the ligand fields and the slightly differences in structures through employed homologous ligands.

TH.D-P11 - Metamagnetic transition in $TmCo_4Al$

A.V. Andreev[1], O. Isnard[2,3], Y. Skourski[2], D.I. Gorbunov[1,4]

1. Institute of Physics, Academy of Sciences, Prague,Czech Republic
2. Université Grenoble Alpes, Institut NÉEL, Grenoble, France
3. CNRS, Institut NÉEL, Grenoble, France
4.Dresden High Magnetic Field Laboratory, Helmholtz-Zentrum Dresden-Rossendorf Dresden, Germany

The high-field (up to 60 T) magnetization was studied on single crystal intermetallic compound $TmCo_4Al$ having hexagonal crystal structure of $CaCu_5$ type. Single crystal was grown by a modified Czochralski method in triarc furnace.
$TmCo_4Al$ is a ferrimagnet with Curie temperature T_C=490 K and spontaneous magnetic moment M_s = 2.1 m_B per formula unit (at 4.2 K) directed along the *c* axis. The Tm sublattice dominates at low temperatures but weakens with increasing temperature faster than the Co sublattice, so above the compensation point T_{comp} = 87 K the total moment is along the Co sublattice.
It was found that the compound exhibits sharp metamagnetic transition with critical field of 29 T (at 4.2 K) applied along the *c* axis which corresponds to rotation of the Co sublattice. Magnetic moment of the Co sublattice (in assumption of collinear antiparallel arrangement of the Tm and Co sublattices in the ground state) can be determined from the difference between 7 m_B (moment of Tm^{3+} ion) and total M_s as 5 m_B. Therefore, the observed magnetic moment 12 m_B after the metamagnetic transition corresponds to the forced ferromagnetic arrangement of the sublattices ($M = M_{Tm}+M_{Co}$) and no more transitions should be expected in higher fields. The critical field of the transition decreases with increasing temperature and becomes zero at T_{comp}. Above T_{comp} where the Tm sublattice is antiparallel to the field direction, no transition is observed. However, the *c*-axis susceptibility *dM/dH* is much larger than below T_{comp}. It points to a continuous rotation of the Tm sublattice toward the magnetic field, in contrast to the first-order process when the Co sublattice rotates.
The high-field behavior of $TmCo_4Al$ is discussed in comparison with results on other intermetallics of Tm with 3d-metal recently studied on the single crystals (Tm_2Co_{17}, Tm_2Fe_{17}, $TmFe_5Al_7$).

TH.D-P12 - *I-V* characteristics in $CdMoO_4:Nd^{3+}$ single crystal

B. Sawicki [1], E. Tomaszewicz [2], M. Berkowski [3], H. Duda [1], T. Groñ [1]

1. Institute of Physics, University of Silesia, Katowice, Poland
2.Department of Inorganic and Analytical Chemistry, West Pomeranian University of Technology, Szczecin, Poland
3. Institute of Physics, Polish Academy of Sciences, Warszawa, Poland

Scheelite-type ABO_4 molybdates and tungstates form important group of materials widely used in several technical applications. They have been used as solid state scintillators and laser host materials. Doped with rare earth ions they have been applied as diode pumped solid-state lasers with very high stability of emission of nano- or femtosecond pulses.
Single crystal of new cadmium and neodymium molybdate $CdMoO_4:Nd^{3+}$ ($Cd_{0.958}Nd_{0.028}\square_{0.014}MoO_4$) has been successfully grown by the Czochralski method. The X-ray diffraction analysis confirmed that this solid solution crystallizes in the scheelite type structure with the space group $I4_1/a$ [1]. Our previous studies showed paramagnetic behaviour of $CdMoO_4:Nd^{3+}$ single crystal [2].
The main purpose of this study was to investigate the *I-V* characteristics using a KEITHLEY 6517B Electrometer/High Resistance Meter. The *I-V* characteristics, measured at 300 and 400 K showed a non-symmetric and non-linear behavior (back to back diode-like). Larger values of current in the forward direction was observed at 300 K and crystallographic plane *a* than at 400 K and crystallographic plane *c*.
This work was supported by Ministry of Scientific Research and Information Technology (Poland) and funded from science resources: No. 1S-0300-500-1-05-06 and No. DS-518-10-020-3101.

TH.D-P13 - Magnetic properties of $NdPd_5Al_2$

J. Zubác [1], K.Vlaskova [1], P. Javorsky [1]

1. Charles University, Faculty of Mathematics And Physics, Prague, Czech Republic

Antiferromagnetic $NdPd_5Al_2$ belongs to a large family of structurally related ternary tetragonal intermetallics which includes RT5X2, RTX_5 and R_2TX_8 compounds (R represents rare earth element or actinide, T is a transition metal and X is a p-metal). Several of these compounds are considered as archetypal unconventional heavy-fermion superconductors. We report on magnetic and physical properties of $NdPd_5Al_2$ as their non-superconducting magnetic analogue.

$NdPd_5Al_2$ crystallizes in the $ZrNi_2Al_5$-type structure with lattice parameters a= 4.147 Å and c= 14.875 Å. The magnetic phase transition occurs at TN=1.3K. The antiferromagnetic ordering survives in magnetic fields applied perpendicular to c-axis up to 3 T; in higher fields the compound is already in the field-induced ferromagnetic state. The compound exhibits a distinct magnetocrystalline anisotropy due to the crystal field effects with c-axis as easy magnetization direction. Specific heat analysis indicates the first excited crystal field level around 40 K. The presented study is focused particularly on explanation of magnetic properties in terms of crystal field interactions and comparison to other relevant materials with similar structure.

TH.D-P15 - Searching for superconductivity in $NpAl_2$: a study of low temperature ground state properties

J. Griveau [1], E. Colineau [1], L. Martel [1], R. Eloirdi [1], R. Caciuffo [1]

1. European Commission, Joint Research Centre (JRC), Institute for Transuranium Elements (ITU), Karlsruhe, Germany

We report the results of an extensive study of the ground state properties of $NpAl_2$, a compound in which 5f electrons are considered to be well localized and that represents a reference system for ferromagnetism in actinides. Considerations on its bulk properties (ordering temperature T_C, *5f* effective paramagnetic moment and T_C decrease with pressure) point to a strong analogy with the non-conventional superconductor UGe_2, raising questions about the possible occurrence of superconductivity at low temperature and/or under compression. Low temperature magnetic, electrical transport, and thermodynamic measurements under an external magnetic field (up to 14 T) will be reported for the first time, together with results of ^{27}Al NMR spectroscopy measurements in the paramagnetic state.
Precise dc magnetisation data confirm ferromagnetic ordering (T_C ~ 56 K) but also indicate that thermal treatments change the ferromagnetic characteristics of the material (from weak to moderate magnet), whilst ac magnetic susceptibility shows the presence of an anomaly at ~ 21 K not reported before. Thermal treatments also modify the anomaly of the heat capacity curve associated with magnetic order. An enhanced electronic contribution g_e ~80 mJ mol^{-1} K^{-2} clearly indicates the presence of electronic carriers. The electrical resistivity curves (RRR>15), very similar to those measured for UGe_2, exhibit a slight maximum above T_C. Finally, the variable offset cumulative spectra (VOCS), acquired in the paramagnetic state by NMR spectroscopy, show a high sensitivity of the ^{27}Al nuclei spectral parameters (Knight shift and line broadening) to ferromagnetic fluctuations, even at room temperature.
This work reveals a partial delocalised nature of the 5f carriers in $NpAl_2$, whose bulk properties appear to be similar to those of UGe_2.

TH.D-P17 - 5d-3d antiferromagnetic spin coupling of Tm and Lu adatoms with Fe monoatomic islands on W(110) probed by spin-polarized tunneling microscopy

D. Coffey [1,2], J. L. Diez-Ferrer [1], D. Serrate [1,2], M. Ciria [2,3] C. de la Fuente [2,3], J. I. Arnaudas [1,2]

1. Lab. de Microscopías Avanzadas - Inst. de Nanociencia de Aragón, Univ. de Zaragoza, Zaragoza, Spain

3. Instituto de Ciencia de Materiales de Aragón, CSIC-Univ. de Zaragoza, Zaragoza, Spain

In Rare Earth-Transition Metal (RE-TM) compounds the RE-TM magnetic interaction proceeds via an indirect mechanism in which the 5d electrons act as the intermediary.[1] Intra-atomic exchange ferromagnetically couples the 4f and 5d spins of the RE and the interatomic direct 5d-3d exchange, associated with the hybridization of the pure TM-3d and RE-5d bands,[2] produces the final coupling between the RE and the TM spin moments. When the 5d band is less than half full and the 3d band is more than half full, the case of RE-(ferromagnetic TM) compounds, the 5d-3d exchange is antiferromagnetic and the RE and TM spins couple antiparallel. Here, we report on an extreme situation, where only adatoms of RE are adsorbed on a TM ferromagnetic monolayer. We have investigated with scanning tunneling microscopy and spectroscopy Thulium and Lutetium adatoms, deposited on iron monolayer islands, with in-plane magnetization,[3] pseudomorphically grown on a clean W(110) substrate under ultra-high vacuum conditions, at low temperature. The spin polarized differential conductance images obtained with an Fe covered tungsten tip and taken both at constant height and at constant current, show that Tm and Lu present a contrast opposite to the one shown by the respective Fe islands beneath. A possible dependence on the spin polarization shown by the adatom on the energy and vertical distance to the tip [4] has been discarded by performing the measurements at different bias and heights without appreciable modification of the reversed contrast observed between the adatom and the island. These results, combined with first-principles calculations indicate that the Lu and Tm 5d moments lie in plane and couple antiferromagnetically with their underlying iron islands, in agreement with the Campbell model even at the single atom limit.

TH.D-P18 - Optical and magneto-optical interactions in Co doped CeO2 thin films prepared by pulsed laser deposition

M. Zahradnik [1], M. Kucera [1], R. Antos [1], M. Veis [1], J. Mistrik [2], L. Bi [3], H. Kim [3], G. F. Dionne [3], C. A. Ross [3]

Magnetically doped CeO_2 is a dilute magnetic semiconductor with high Curie temperature and excellent silicon compatibility [1, 2]. These properties make it a promising material for applications in integrated non-reciprocal photonic devices. Knowledge of complete permittivity tensor is necessary to enhance the non-reciprocal effect and to optimize the device functionality. Here we investigate magnetically doped thin films of $Ce_{1-x}Co_xO_{2-\delta}$ prepared by pulsed laser deposition on MgO (x = 0.05 and 0.10) and oxidized Si (x = 0.20) substrates. The samples grew as polycrystalline films with thickness ranges from 262 to 753 nm and out-of-plane easy axis. A systematic study was performed by combination of spectroscopic ellipsometry and magneto-optical (MO) Faraday and Kerr spectroscopy. Both diagonal and off-diagonal permittivity tensor components were obtained and verified by theoretical calculations confronted with experimental data. Diagonal spectra obtained from spectroscopic ellipsometry revealed two optical transitions between oxygen and cerium states. off-diagonal spectra fitted from MO Faraday spectra revealed two paramagnetic transitions involving cobalt ions. Proper spectral dependence of the permittivity tensor was confirmed by MO Kerr spectroscopy. Calculated MO Kerr effect showed excellent agreement with the experimental data. Measurements performed at temperature of liquid nitrogen excluded temperature dependence of MO Faraday effect and therefore confirmed proposed theoretical model. An essential influence of cobalt doping on the resulting ferromagnetic properties of CeO_2 was observed.

TH.D-P19 - Deviations from Matthiessen rule and resistivity saturation effects in rare-earth metals revealed in first principles calculations

J. Glasbrenner [1], B. Pujari [1], K. Belashchenko [1]

1. University of Nebraska-Lincoln, United States

According to earlier first-principles calculations [1], the spin-disorder contribution to the resistivity of rare-earth metals in the paramagnetic state is strongly underestimated if Matthiessen's rule is assumed to hold. To understand this discrepancy, the resistivity of paramagnetic Gd (and Fe for comparison) is here [2] evaluated by taking into account both spin and phonon disorder. Calculations are performed using the supercell approach within the linear muffin-tin orbital method. Phonon disorder is modeled by introducing random displacements of the atomic nuclei, and the results are compared with the case of fictitious Anderson disorder. In both cases the resistivity shows a nonlinear dependence on the square of the disorder potential, which is interpreted as a resistivity saturation effect. This effect is much stronger in Gd than in Fe. The non-linearity makes the phonon and spin-disorder contributions to the resistivity non-additive, and the standard procedure of extracting the spin-disorder resistivity by extrapolation from high temperatures becomes ambiguous. An "apparent" spin-disorder resistivity obtained through such extrapolation is in much better agreement with experiment compared to the results obtained by considering only spin disorder. By analyzing the spectral function of the paramagnetic Gd in the presence of Anderson disorder, the resistivity saturation is explained by the collapse of a large area of the Fermi surface due to the disorder-induced mixing between the electronic and hole sheets.

TH.D-P20 - Crystal field effects in polymorphic compound $TbIr_2Si_2$

T. Shigeoka [1], Y. Kurata [1], T. Nakata [1], T. Fujiwara [1], K. Matubayashi [2], Y. Uwatoko [2]

1. Yamaguchi University, Japan
2. University of Tokyo, Japan

The tetragonal ternary compound $TbIr_2Si_2$ exhibits polymorphism; it has two different crystallographic structures: the $ThCr_2Si_2$-type structure (I4/mmm, centrosymmetry: I phase) and the $CaBe_2Ge_2$-type one (P4/nmm, non-centrosymmetry: P phase) without changing chemical composition [1]. So this compound is suitable to study how physical properties are influenced by crystallographic symmetry. We succeeded to grow both $TbIr_2Si_2$ (P and I phase) single crystals and performed magnetic measurements. The compounds of both phases exhibit antiferromagnetic orderings while the magnetic behavior changes drastically depending on the symmetry. The $TbIr_2Si_2$ (I) has the high magnetic ordering temperature of TN=80 K and a strong magnetic anisotropy with the easy direction of the c-axis. It has two magnetic transitions at 9.5 K and 2.5 K besides TN. On the other hand, the $TbIr_2Si_2$ (P) has comparatively low ordering temperature of TN2=12 K and another transition temperature of TN1=5 K, and exhibits relatively weak magnetic anisotropy with the easy direction in the ab-plane. In the both compounds, anomalies, which suggest the existence of component-separated magnetic transitions, are observed on the temperature dependence of magnetic susceptibility, indicating a frustration. It is noticeable that the ab-component of magnetic moment orders at higher temperature for the P-phase compound, which is contrast to usual behavior; the c-component orders at higher temperature usually as the behavior of the I-phase compound. We think this novel behavior has been never known so far, and expect that the P-phase compound has a novel magnetic order. Crystal field effects was estimated from magnetization processes and magnetic susceptibility. Difference of magnetic anisotropy between both compounds is explain by crystal field effects.

TH.D-P21 - Non-equilibrium behavior of the magnetization in the helimagnetic phases of the rare earth alloys R_{1-x}Y_{x} (R = Gd, Tb, Dy)

T. Yamazaki [1], J. Ishiyama [1], Y. Noya [1], M. Kurihara [1], H. Yaguchi [1]

1. Department of Physics, Faculty of Science And Technology, Tokyo University of Science, Japan

The magnetic alloy system Gd_{1-x}Y_{x} shows a para-helimagnetic phase transition at a Néel temperature, T_{N} and a heli-ferromagnetic phase transition at a Curie temperature, T_{C} in the Y-concentration range of 0.3 < x < 0.4. In our previous study, we measured AC- and DC-magnetization of Gd_{0.62}Y_{0.38} in low magnetic field, and observed non-equilibrium behavior of the magnetization along the a^{*}-axis in the helimagnetic phase. Features associated with the observed behavior are itemized as follows: (i) difference between the zero-field-cooled (ZFC) magnetization and the field-cooled (FC) magnetization, (ii) enhancement of the imaginary part of the AC-susceptibility, (iii) strong nonlinearity of the magnetization around T_{N}. The features (i)~(iii) are similar to those observed commonly in spin-glass systems. This similarity suggests that a novel non-equilibrium state such as a helical-glass state, which is theoretically proposed near ferromagnetic quantum critical points, is realized in the helimagnetic phase of Gd_{0.62}Y_{0.38}.

In order to search such glass-like behavior in analogous materials, we have investigated the magnetic properties of polycrystalline samples of Tb, Dy, their magnetically diluted alloy systems Tb_{1-x}Y_{x} (x = 0.14, 0.28) and Dy_{1-x}Y_{x} (x = 0.03, 0.50). Clear differences between the ZFC and FC magnetizations were observed in all of these materials, although the difference observed in Dy and Dy_{1-x}Y_{x} was rather small. The non-linearity of the magnetization is observed only in Tb and Tb_{0.86}Y_{0.14}. This suggests that the non-equilibrium behavior observed in these materials relates to the strength of the ferromagnetic interaction.

TH.D-P22 - Charge density wave stabilization in LaSb$_2$ by Ce ion substitution

$CeSb_2$ is a well-known layered compound having several magnetic transitions at low temperatures. On the other hand, $LaSb_2$ is known as a two dimensional metal that shares the same layered structure. However, a linear magnetoresistance is observed on this last system, which has been associated to some sort of charge ordering.
In this work the observation of a Charge Density Wave (CDW) order in the $La_{1-x}Ce_xSb_2$ family compound is reported. Crystals of several compositions x ($0 < x < 1$) have been grown using flux method. Variation of the lattice parameters with x has been found. A previously unnoticed kink in the resistivity of $LaSb_2$ at temperatures higher than room temperature has been also found. A charge modulations superposed to the atomic lattice has been observed by Scanning Tunneling Microscopy experiments. Our results show that a CDW is present in the superconductor $LaSb_2$, which is stabilized in presence of substitutional disorder at a finite x. The CDW onset temperature is observed decreasing with increasing x and competing with magnetism from Ce. The magnetic phase diagram is made from the specific heat anomalies and shows magnetic transitions for $x > 0.4$.

TH.D-P23 - Magnetic phase diagram of non-kramers Γ_3 doublet system $prpb_3$by specific heat measurements

Y. Sato [1], Y. Inagaki [1], T. Kawae [1], T. Onimaru [2], H. Suzuki [3]

2. Department of Quantum Matter, Hiroshima University, Japan
3. National Institute for Material Science, Ibaraki, Japan

Multipolar ordering in the magnetic fields has been intensively studied during the last two decades. Especially, many studies on CeB_6, which is the typical example to show anomalous multipolar ordered phases, have been devoted experimentally and theoretically and clarified that the field-induced multipoles have a key role on the multipolar ordered phase in the magnetic fields[1]. To reveal the concrete role, we focus on a non-Kramers Γ_3 doublet system in Pr-compounds because the Γ_3 doublet, which carries O_2^0-type and O_2^2-type quadrupoles, is the one of the simplest multipolar-degenerate system.
A $PrPb_3$ has a Γ_3 doublet as a ground state and is well known to show the antiferro qudrupolar ordering at T_Q = 0.4 K[2]. We measured the specific heat of the single crystal of $PrPb_3$ in the magnetic fields up to H = 8 T along [100], [110], and [111] crystalline directions. The obtained magnetic phase diagram in H ||[100] shows the appearance of a new high-field phase above H = 5 T[3]. In addition, the high-field phase are also observed in H ||[110] above H = 6 T, which is consistent with the previous report by magnetization measurements[4]. In the case of H ||[100] and [110], the type and symmetry of the field-inducible multipoles is different between O_2^0-type and O_2^2-type quadrupole[1]. Therefore, these results indicate that the phase transition from O_2^0-type quadrupolar ordered phase to O_2^2-type one is induced due to the difference of the field-inducible multipole between each ordered phase.
On the other hand, the specific heats in H ||[111] show no evidence that ordered phase exists at least above H = 6 T. The result can be understood by reflecting the feature that the field-inducible mulipoles have the same symmetry between each quadrupoles in H ||[111][1].

TH.D-P24 - Magnetic properties of $CePtIn_4$

K. Uhlirova [1], P. Proschek [1], J. Prokleska [1]

1. Charles University In Prague, Faculty of Mathematics And Physics, Department of Condensed Matter Physics, Praha , Czech Republic

We report on single crystals growth and magnetic properties of $CePtIn_4$, a new indium rich Ce-Pt-In compound. Single crystals of $CePtIn_4$ were grown by indium flux method. The compound was characterized by microprobe analysis and x-ray diffraction. It adopts $YNiAl_4$ –type crystal structure similar to other recently published compounds $CeNiIn_4$ and $EuNiIn_4$ [1-3]. Specific heat, magnetization and electrical resistivity measurement have shown an antiferromagnetic transition at T_{N1} = 2.3 K and another transition at 0.9 K is visible in specific heat data. This behavior resembles the properties of iso-structural $CeNiIn_4$ and $EuNiIn_4$ with antiferromagnetic order below T_{N1} = 1.4 K and 13 K, respectively, and second order-to order magnetic transitions at lower temperatures [1-3]. However, compare to these compounds, $CePtIn_4$ has very low Sommerfeld coefficient γ = 3 mJ $mol^{-1}K^{-2}$. The magnetic part of entropy calculated from the specific heat data reaches value of Rln2 showing localized character of the Ce^{3+} moments. Magnetization isotherms at 1.8 K show on metamagnetic transition at field of 1T applied along the *b*-axis while magnetization measured along *a*- and *c*-axis show linear dependence up to field of 7 T. This behavior is consistent with specific heat measurements in magnetic field applied along the principal crystallographic directions; the Néel temperature quickly decreases when magnetic field is applied along the *b*-axis while in the other directions it is almost intact.

4. Physics Department, Nuclear Research Center Negev, Beer-Sheva, Israel
5. Institute of Physics, Academy of Sciences of The Czech Republic,Prague, Czech Republic

We report the results of a study carried out on a neptunium-transition-metal binary compound Np_2Ni_{17}, which has been synthesized and characterized by means of: Powder X-Ray Diffraction, SQUID magnetometry, ^{237}Np Mössbauer spectroscopy and specific heat. Np_2Ni_{17} is a derived crystallographic structure of $NpNi_5$ [1] and is the Nickel analogue of Np_2Co_{17} [2]. Np_2Ni_{17} crystallized in the Th_2Ni_{17} hexagonal structure ($P6_3/mmc$ no. 194) with a room temperature lattice parameters a = 8.28215(7) and c = 8.04029(8) Å, containing two non-equivalent Np sites. Np_2Ni_{17} exhibits an antiferromagnetic order below T_N ~ 17.5 K. Mössbauer spectra in the ordered state show two ordered Np sites, one with a huge ordered moment (μ_{Np} ~ 2.25 μ_B) and the other carry hardly any ordered moment at all (μ_{Np} ~ 0.2 μ_B). C_P measurements confirm the onset of an antiferromagnetic order while revealing a complex low temperature behaviour, with both electronic and magnetic Shcottky anomalies that are present.

TH.E-P01 - Ab initio theory of the gilbert damping in random alloys: the torque-correlation formulation

I. Turek [1], J. Kudrnovsky [2], V. Drchal [2]

1. Institute of Physics of Materials, Acad. Sci. Czech Rep., Brno, Czech Republic
2. Institute of Physics, Acad. Sci. Czech Rep., Praha, Czech Republic

We present a formulation of the Gilbert damping tensor within the fully relativistic linear muffin-tin orbital (LMTO) method for substitutionally disordered ferromagnetic alloys. We show that the true, but random spin-torque operators in the original torque-correlation formula [1] can be replaced by non-random effective spin-torque operators, which simplifies the configurational averaging in the coherent-potential approximation (CPA) considerably.
The resulting Kubo-Greenwood formula for the Gilbert damping tensor represents thus an obvious analogy of the LMTO formula for the conductivity tensor containing non-random effective velocity operators [2]. Particular attention is paid to the related vertex corrections indispensable for an internal consistency of the theory. We prove a special Ward identity which yields several important properties of the Gilbert damping tensor: (i) its vanishing in the non-relativistic limit, (ii) its vanishing in the non-magnetic limit, and (iii) its transverse nature, i.e., the only non-zero components of the tensor are appropriate for the dynamics of small deviations of the magnetization direction from the equilibrium orientation.
The developed theory, implemented in the atomic-sphere approximation, is applied to fcc Ni-Fe and bcc Fe-V alloys. The calculated results show that the coherent part of the Gilbert damping constant is always positive, in contrast to recent results for Fe-rich Fe-V alloys based on the random spin-torque operators [1].

TH.E-P02 - Relativistic effects on electron transport in magnetic alloys

V. Drchal [1], J. Kudrnovsky [1], I. Turek [2]

1. Institute of Physics, AS CR, Prague, Czech Republic
2. Institute of Physics of Materials, AS CR, Prague, Czech Republic

We study relativistic effects on electron transport in spin-polarized metals and random alloys on ab initio level using the fully relativistic tight-binding linear muffin-tin-orbital method.
We employ Kubo linear-response approach adapted to disordered multisublattice systems in which the chemical disorder is described in terms of the coherent potential approximation (CPA). The CPA vertex corrections are included. We calculate both the Fermi surface and Fermi sea terms of the full conductivity tensor. We find that in cubic ferromagnetic 3d transition metals (Fe, Co, Ni) and their random binary alloys (Ni-Fe, Fe-Si) the Fermi sea term is small in comparison with the Fermi surface term, however, in more complicated structures, such as hexagonal cobalt and selected Co-based Heusler alloys, it becomes important. High values of the anisotropic magnetoresistance (AMR), found for Ni-rich alloys, are explained by a negligible disorder in the majority spin channel while a change of the sign of the anomalous Hall effect on alloying is a band-filling effect without a direct relation to the high AMR. We also study the effect of the structural long-range order and thermal spin disorder on the transport properties of partially ordered Fe-Pt alloys [2]. The main result is that all components of the resistivity tensor increase with disorder, but anomalous Hall resistivity increases much faster than the longitudinal resistivity. We find an overall good agreement between the theory and experimental data.

TH.E-P03 - Modulation of the amplitude of spin transfer torque in double barrier magnetic tunnel junctions

C. Baraduc [1], P. Clément [1], P. Coelho [1], C. Ducruet [2], L. Vila [3], M. Chshiev [1], B. Dieny [1]

1. Spintec, Grenoble, France
2. Crocus Technology, santa Clara, United States
3. SP2M/NM - CEA Grenoble, France

Double barrier magnetic tunnel junction are of particular interest concerning spin transfer torque issues. In such structures, it has been shown that spin transfer torque (STT) exerted on the magnetization of the central free layer can be enhanced [1], correlatively yielding a decrease of the critical current for STT magnetization switching [2,3], which may lead to low consumption devices. Here we show that spin transfer torque may be either enhanced or reduced depending of the magnetic configuration of the top and bottom electrodes. When their magnetizations are antiparallel, STT amplitude will be maximum, yielding an easy switching. On the contrary, if they are parallel, STT amplitude will decrease so much that the probability of switching, even at high voltages, is almost zero. Thus reading a MRAM could be performed at higher voltage with no risk of writing and consequently at higher speed. This effect could pave the way towards more reliable and faster magnetic memories. Results obtained on double junctions with reference layers composed of two pinned synthetic antiferromagnet will be presented. Both in-plane (Slonczewski's) and out-of-plane (field-like) torques are studied. Since these two torques add and subtract differently, specific effects can be observed in these dual junctions. In particular, we demonstrated magnetization switching by pure field-like torque.

TH.E-P04 - The study of the spin proximity effect from a solution of the modified boltzmann transport equations

V. Zayets [1]

1. Spintronics Research Center, AIST, Japan

The spin proximity effect describes the fact that at a contact between two conductors, the spin accumulation diffuses from the conductor with a higher spin polarization to the conductor with a smaller spin polarization. For example, in the vicinity of a contact between a ferromagnetic and non-magnetic metals, in the ferromagnetic metal the equilibrium spin accumulation becomes smaller than in the bulk and the electron gas in the non-magnetic metal becomes spin-polarized. The spin proximity effect and the spin injection were studied using a solution of the modified Boltzmann transport equations [1,2]. It was found that the origin of the spin proximity effect is the spin diffusion. In contrast, the origin of the spin injection is the spin drift. It was shown that the spin injection only modifies the distribution of the spin accumulation across the contact, which was initially established due to the spin proximity effect. It was demonstrated that the electrons with energies below and above the Fermi energy contributes differently into the these effects. In the case of the spin injection, the contributions are of the opposite signs. In the case of the spin proximity effect, the contributions are of the same sign. The reason of this difference is that the electrons and the holes are drifted in the opposite directions, but they diffuses in the same direction. As result, the spin injection in a metal is not efficient, but the spin proximity effect is substantial. In a metal significant drift current is required in order to modify the distribution of the spin accumulation across a contact enough so that the spin injection can be detected.
The physical mechanism of an enlargement of spin accumulation due to the ordinary Hall effect was described.

TH.E-P05 - Resonant magnetoresistance in asymmetrical double-barrier magnetic tunnel junction

N. Useinov [1], L. Tagirov [1]

1. Kazan Federal University, Russian Federation

High tunneling magnetoresistance (TMR) is now well known in single magnetic tunnel junctions (SMTJs). Besides single-barrier, the double-barrier MTJs (DMTJs) have also been extensively studied for the novel physical phenomena and potential applications in spintronic devices [1]. In our work the resonant tunneling is studied theoretically for the asymmetrical DMTJ with a bias voltage. In this nanostructure the magnetization of the middle ferromagnetic metal layer can be aligned parallel (P) or antiparallel (AP) with respect to the fixed magnetizations of the external ferromagnetic electrodes. Analytical expression for the transmission coefficient of the DMTJ is received

$$T_{2b,s}^{\mathrm{P(AP)}} = 1\Big/\left[T_{1,s}^{-1}T_{2,s}^{-1} + \left(T_{1,s}^{-1}-1\right)\left(T_{2,s}^{-1}-1\right) + 2\sqrt{T_{1,s}^{-1}\left(T_{1,s}^{-1}-1\right)}\sqrt{T_{2,s}^{-1}\left(T_{2,s}^{-1}-1\right)}\cos\Phi_{V,s}\right],$$

which is expressed through the single-barrier transmission coefficients $T_{1,s}$ and $T_{2,s}$ taking into account the voltage drop on each barrier and spin degrees of freedom of the electron. Here, $\Phi_{V,s}$ is the characteristic phase under the applied bias. The theoretical model of the spin-polarized conduction and TMR in planar nanocontacts with different ferromagnetic metals is developed [2]. The dependences of the transmission coefficient and TMR on the applied voltage under resonant conditions, $\cos\Phi_{V,s} = -1$, are shown in Fig. 1 and Fig. 2. The parameters used in the calculations of the curves correspond to article [2].

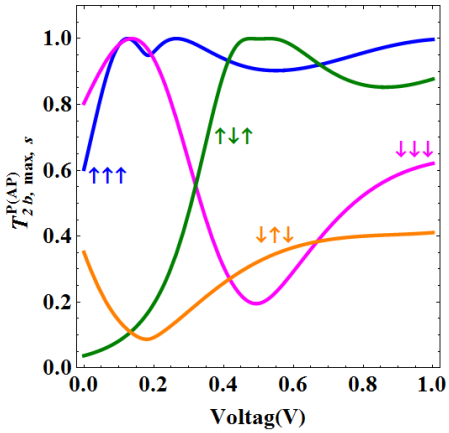

Fig. 1 Transmission coefficient vs bias in the asymmetrical DMTJ for four spin conduction channel is denoted by arrows.

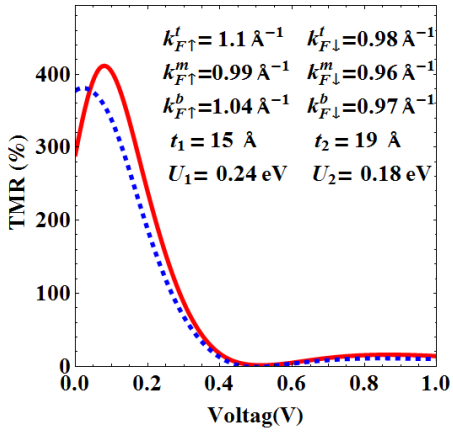

Fig. 2 TMR in the case of resonant (solid line) and non-resonant (dot line) tunnelling of electrons through the DMTJ.

TH.E-P06 - Spin-pumping using the $Ni_{80}Fe_{20}$ thin film annealed in a magnetic field

H. Shimogiku [1], N. Hanayama [2], Y. Teki [3], H. Tsujimoto [1], E. Shikoh [1]

1. Graduate School of Engineering, Osaka City University, Japan
2. Faculty of Engineering, Osaka City University, Japan
3. Graduate School of Science, Osaka City University, Japan

The spin current by the spin-pumping with the ferromagnetic resonance (FMR) is enhanced by improving the ferromagnetic material as the spin injector. In this study, a Ni80Fe20 thin film, which is easily formed, was focused and the magnetic property of the Ni80Fe20 was controlled by annealing in a magnetic field.
A $Ni_{80}Fe_{20}$ (25)/Pd (10 nm in thick) bilayer sample was prepared on a SiO2/Si substrate by using an electron-beam deposition under the vacuum of 10-6 Pa. After the depositions, the sample was annealed in the external magnetic field of 30 mT under the vacuum of 10-3 Pa. The maximum temperature in the annealing was set to be 673 K, and the temperature was gradually lowered. When the FMR of the A $Ni_{80}Fe_{20}$ of the sample was excited, a spin current was generated in the Pd layer by the spin-pumping. Then, the spin current was converted to a charge current by the inverse spin-Hall effect (ISHE) in the Pd layer, and detected as the electromotive force.
The output voltage due to the ISHE of the annealed sample was 2.60 uV when the static magnetic field direction in the annealing was parallel to that under the FMR, while that of the non-annealed sample was 1.94 uV. That is, the output voltage became 1.3 times larger by using the annealing than that without the annealing. The output voltage due to the ISHE in the Pd and the static and dynamic magnetic properties of the A $Ni_{80}Fe_{20}$ film were dependent on the applied magnetic field direction in the annealing. The results indicated that the spin current generation efficiency by the spin-pumping was increased by using the A $Ni_{80}Fe_{20}$ annealed after the film making, without using the other special techniques like an epitaxial growth in the film making process [1].

The development of metallic lateral spin valves is being hampered by their low output signal. Indeed, the obtained giant magneto-resistance (GMR) is smaller than 1% and non-local measurement are used to detect such low spin signals. Nonetheless those devices are already very useful for the investigations of several basic sciences, such as spincaloritronics, spinorbitronics and all spin logics. There are several strategies to increase the output signal, such as confinement effect [1], the reduction of the spin back flow by the insertion of tunnel barriers [2] as well as innovative designs [3]. In combination of a material study and a careful design of the structures we achieved GMR signals at room temperature of 6% and we target 50 % at the 25 nm node. Indeed, the decrease of the device size is automatically associated to an increase of the output signal, due to an increase of the spin resistances as well as the decrease of the spin relaxation within the non-magnetic spin channel (bridging the spin injector and spin detector). We could thus envisioning signals comparable to that of multilayered pillars. Notably, the use of CoFe as ferromagnetic material allowed the increase by a factor of height of the spin signal compared to Py, the most commonly used material. These results are, for instance, an important step toward the use of lateral devices as reading elements in hard disk drives.

Spintronics is a rapidly growing field that aims at using and manipulating not only the charge, but also the spin of the electron. Sophisticated applications such as hard-disk read heads and MRAMs have been introduced in the last two decades. Further progress could be achieved with pure spin currents, which are an essential ingredient in an envisioned spin-only circuit that would integrate logics and memory. One of the most robust experimental approaches to create pure spin currents is by using lateral spin valves (LSV) in a non-local geometry [1]. However, electrical manipulation of pure spin currents (via spin-orbit coupling, as proposed by Datta and Das) has a fundamental limitation, because the best spin-transport materials are those showing the lowest spin-orbit.
We propose and demonstrate an alternative way of modulating pure spin currents based on magnetic, instead of electric, gating, by taking advantage of the spin-mixing conductance concept. To that end, Co/Cu LSVs have been fabricated on top of a ferromagnetic insulator (YIG). A modulation of the pure spin current is observed as a function of the relative orientation between the magnetization of YIG and the polarization of the spin current. Such modulation is explained by solving the spin-diffusion equation and considering the spin-mixing conductance (G_r) at the Cu/YIG interface. The accuracy between the measured data and the expected modulation provides an effective way of studying the interface. From our results, $G_r \sim 4\times10^{11}\Omega^{-1}m^{-2}$ is obtained. An increase of this value will enhance the efficiency of the magnetic gating. This can be achieved by carefully tuning the fabrication parameters. Our experiment paves the way for novel manners of spin manipulation, bringing closer pure spin currents and logic circuits [2].

TH.E-P10 - Spin current transport in a Nb/Cu/NiFe tri-layer structure

K. Ohnishi [1,2], Y. Ono [1], M. Sakamoto [1], T. Kimura [1,2]

1. Dept. of Physics, Kyushu University, Japan
2. Research Center for Quantum Nano-Spin Sciences, Kyushu University, Japan

The ferromagnet/superconductor hybrid structure has attracted the attention because the Cooper pair in the ferromagnet is expected to show unique transports such as 0-pi transition in a Josephson junction and spin triplet supercurrent. These spin-dependent superconducting phenomena can be induced also in the nonmagnetic metal under the spin injection because the spin accumulation induced in the normal metal is similarly treated as a conduction electron state in a ferromagnet. However, the experimental study in these systems has not been performed sufficiently because of the influence of the charge current such as Joule heating and Oersted field.
In this report, we investigated spin current transport in a nanopillar-based lateral spin valve structure consisting of Permalloy(Py)/Cu/Nb trilayer, which strongly suppress the aforementioned current-induce effects.
The spin transport properties have been evaluated by measuring the nonlocal spin valve signal, namely spin signal. The spin signal below 30 K is almost constant when the Nb is in the normal metal state. When the Nb becomes superconductor below 6.8 K, the spin signal increases with decreasing the temperature. This indicates that the spin-current absorption is strongly suppressed at the Cu/Nb interface because the spin current cannot enter into the superconducting energy gap.
From this result, we can estimate the temperature dependence of the superconducting gap magnitude at the Nb/Cu interface. Moreover, around 2.3 K, we observe the superconducting proximity effect in the Cu layer. This indicates that the spin-polarized electrons and Cooper pairs coexist in the Cu layer around 2.3 K.
This is an important step for the observation of the spin dependent superconducting phenomena.

TH.E-P11 - Study of the ferromagnetic resonance properties in epitaxial FePt samples

A. Conca [1], S. Keller [1], L. Mihalceanu [1], J. Greser [1], E. Papaioannou [1], B. Hillebrands [1]

1. Fachbereich Physik And Landesforschungszentrum OPTIMAS, Technische Universität Kaiserslautern, Germany

Metallic FM/Pt bilayers show a large increase in magnetic damping due to the presence of spin pumping, and large inverse spin Hall voltages (ISHE) are observed. In the past, most of the research has focused on polycrystalline films [1-4]. However, the study of such effects in epitaxial films can provide further insight into their nature. Here, we present studies on epitaxial Fe/Pt bilayers grown by molecular beam epitaxy. Several samples with a Fe layer with a fixed thickness of 12 nm and varying Pt thickness were studied. Additional reference samples with no Pt, capped with MgO or Al have been also measured to estimate the properties in absence of spin pumping.
A ferromagnetic resonance setup is used to measure the dependence of the Gilbert damping parameter, the effective magnetization and other parameters on the Pt thickness. The anisotropic properties are studied by the study of the coercive field Hc with a rotational MOKE setup and by the angular dependence of the resonant field. Measurements of the generated ISHE voltages are also presented and discussed in relation to the FMR data.
An increase of the damping with Pt thickness is already observed for the thinnest studied Pt thickness in comparison to the reference samples. The angular dependence of Hc shows typical sharp features originated in domain nucleation and formation of metastable domain configurations. These are not present in the angular dependence of HFMR which shows a much smoother dependence. Both show the cubic anisotropy expected for Fe although a superposed uniaxial anisotropy is observed.

The spin Hall effect (SHE) [1] allows for a reciprocal conversion between charge and spin currents using the spin orbit coupling which can be at the core of several promising spintronics devices. The spin orbit interaction is used to produce a transverse flow of spin or charge in response to a longitudinal excitation, these are the direct or inverse SHE. The spin Hall angle (SHA), the ratio of longitudinal and transverse electronic conductivities, is the characterizing parameter of this conversion. So far, large SHA have been reported in transition metals like Pt, Pd, W, Beta-Ta and in a few alloys with large spin orbit coupling impurities: CuIr, CuBi or CuPb [2].
In this presentation we will report on our study of the SHE induced in Au using resonant scattering on W impurities [3] by using the Non-local probe configuration in Lateral Spin Valves (LSVs). These nano-devices consist of two ferromagnetic electrodes (F) connected by a non magnetic wire (N) allowing for the injection and for the detection of pure spin currents in order to study the direct and inverse SHE by insertion of an additional spin absorbent Au1-xWx nano-wire. We will demonstrate that a correct analysis requires going further on the 1D model in order to extract the correct spin diffusion length and consequently the spin Hall angle. We will discuss the critical limit where the correction are important in the frame work of resistor model and supported by our experimental data as a function of the absorbent Au1-xWx nano-wire width.

TH.E-P15 - Spin-orbit torque measurement by magneto-optical Kerr effect with circularly polarized light

S. Yun [1], J. Moon [1], H. Whang [1], S. Choe [1]

1. Department of Physics, Seoul National University, Seoul, Republic of Korea

Spin-orbit torque (SOT) from the interface between ferromagnet and heavy metal layers has drawn much interest due to the high efficiency in magnetization switching and domain wall motion [1, 2]. To investigate the SOT, a technique [3, 4] based on the electrical harmonic measurement of the anomalous Hall effect was proposed and extensively utilized to quantify the effective fields caused by the SOT. However, it was recently found that in the electrical measurement, a number of large artifacts exist such as the planar Hall effect, the Nernst effect and so on [5, 6] and therefore, the analysis becomes difficult and complicated. To avoid such artifacts, an optical harmonic method [7] based on the polar magneto-optical Kerr effect (p-MOKE) was recently proposed, but the p-MOKE effect also has a similar planar effect that is proportional to sin2Ñ§, where Ñ§ is the angle between the directions of the magnetization and the light polarization. Here, we propose that such planar effect can be systematically removed by use of a circularly polarized light, since Ñ§ rotates in the optical frequency and thus the planar effect becomes averaged out. Therefore, it is possible to quantify the pure out-of-plane component of the magnetization. The present method is applied to 5-nm Ta/1.8-nm Pd/0.3-nm Co/2.5-nm Pt samples to measure the longitudinal and transverse components of the SOT-induced effective field. The validity of the present results is confirmed in comparison to the results obtained by the electrical method with correction of the electric artifacts.

There has been considerable attention paid to the spin current transport in a magnetic insulator. A representative structure for this study is the magnetic/nonmagnetic hybrid structures based on YIG, where the spin current is generated by the spin pumping and the spin Seebeck effects quantitative analysis. However, the use of such spin currents makes it difficult to analyze the experimental results quantitatively.
On the other hand, nonlocal spin injection based on a lateral spin valve structure provide the reliable and quantitative information about the spin current. Since a lateral spin valve can be prepared without severe regulations, the method can be extended to the system with other magnetic insulators.
Here, we investigate the spin current transport in a magnetic insulator NiO by using a lateral spin valve structure.
The sample used for the present study consists of a CoFeAl/Cu lateral spin valve fabricated on a NiO film. Here, the interface between Cu and NiO is well cleaned by the low voltage Ar ion milling. We surely confirmed that the NiO film is real electrical insulator.
The spin transport in the NiO film has been evaluated from the nonlocal spin valve measurements. We found that the nonlocal spin valve signal with the NiO film show a strong reduction from that without NiO film although the electrical resistance of the Cu channel did not show a significant change.
This indicates that the NiO film is a strong spin absorber. We also found that the background voltage and the spin signal depends on the relative angle between the direction of the accumulated spin in the Cu channel and the magnetization direction of the NiO.

TH.E-P18 - Temperature dependence of inverse rashba-edelstein effect at metallic interface

A. Nomura [1], T. Tashiro [1], K. Ando [1]

1. Keio University, Japan

We report temperature evolution of spin-charge conversion through the inverse Rashba-Edelstein effect (IREE) in a metallic heterostructure. Conversion between spin and charge through spin-orbit coupling is an essential function in spin-based technologies. The spin-charge conversion can be realized in solids through the spin-orbit interaction, which couples the spin of an electron to its momentum. Spin-charge conversion has been demonstrated by the inverse spin Hall effect (ISHE), arising from spin-dependent scattering of electrons by impurities in heavy metals. Most recently, the novel way of spin-charge conversion is experimentally demonstrated: the IREE [1], arising from the broken space-inversion symmetry at metallic interfaces. The IREE at a metallic interface have attracted attention recently, however, the phenomenon has not yet been understood clearly. Here, we studies that spin-charge conversion at the interface between Ag and Bi by using spin pumping. We use spin pumping to inject a spin current from a Ni20Fe80 layer into three different films: a Ag/Bi film, a Ag film and a Bi film and we detect the resulting charge current. Because the current of a Ni20Fe80/Ag/Bi film is much larger than a Ni20Fe80/Ag film and aNi20Fe80/Bi film, spin-charge conversion in a Ni20Fe80/Ag/Bi film is asserted to be originated from Rashba spin-orbit coupling in a Ag/Bi heterojunction. Through measuring temperature dependence of spin-charge conversion in a Ni20Fe80/Ag/Bi with measured values of the temperature-dependent parameters, such as electrical resistivity, microwave absorption intensity, damping constant, and saturation magnetization, we revealed that spin-charge conversion in a Ni20Fe80/Ag/Bi film is almost independent of temperature. This finding provides a crucial piece of information for understanding the physics of spin currents and spin-orbit coupling in metallic heterostructures, promising substantial advances in spintronics and spin-orbitronics.

TH.E-P19 - Theoretical analysis on the anomalous hall conductivity of disordered Fe50Co50 alloys; effects of electron lifetime depending on the magnetic quantum number

K. Hyodo [1], A. Sakuma [1]

1. Dept. of Appl. Phys., Tohoku University, Japan

The mechanism of the anomalous Hall effect in the real metals is one of the important topics in both fundamental and applied viewpoints. In the intrinsic mechanism, the effective magnetic field which drives the anomalous Hall conductivity (σ_{xy}) originates from the Berry phase of the wave function of electrons[1]. Especially, in transition metals, this Berry phase is attributed to the difference of the magnetic quantum numbers of electrons[2], which indicates that the sign of the effective field and thenσxy are opposite between the hopping from the state having magnetic quantum number m to –m and from –m to m. In no scattering systems, finite σ_{xy} is obtained from the energy polarization between ±m states caused by the diagonal term of the spin-orbit interaction (SOI).
In this study, we focus on the finite scattering systems andσ_{xy} originated from the difference of lifetime between +m and -m states, which occurs from the m-dependent mixing induced by the spin-flip term in SOI. We calculated σ_{xy} of the chemically disordered $Fe_{50}Co_{50}$ alloys using the first-principles technique. The random alignment of atoms was considered by coherent potential approximation (CPA). The obtained result indicates that σ_{xy} from the spin-flip term of SOI is enhanced with increasing the chemical disorder. We confirmed that this effect is mainly due to the difference of spin-flip scattering rate between +m and –m states in the majority spin state, which is induced by the chemical disorder.

TH.E-P20 - Spin hall magnetoresistance in absence of proximity effects in $Pt/CoFe_2O_4$ bilayers

M. Valvidares Suarez [1], P. Gargiani [1], K. Ollefs [2], F. Wilhelm [2], E. Pellegrin [1], A. Rogalev [2], N. Dix [3], F. Sánchez [3], J. Fontcuberta [3]

1. ALBA Synchrotron Light Facility, Cerdanyola del Vallés, Catalonia, Spain
2. ESRF-The European Synchrotron, Grenoble, France
3. Institut de Ciència de Materials de Barcelona (ICMAB-CSIC), Bellaterra, Catalonia, Spain

Magnetoresistance has been observed in some non-magnetic metals (NM) in intimate contact with ferromagnetic insulators. Whereas magnetic proximity effects may induce the formation of magnetic moment in the metallic layer, thus allowing to account for the observed magnetoresistance, an alternative scenario, relying on the spin Hall effect and inverse spin Hall effect, has also been invoked. Indeed, experiments in NM/YIG and NM/AB_2O_4 where YIG and AB2O4 stand for ferromagnetic garnet and ferrites respectively can be well described within the framework of the Spin Hall effect. Still, disclosing the presence of induced moments in the NM layer is a crucial aspect to be addressed. So far this issue has been addressed in Pt/YIG bilayers with somehow contradictory findings [1, 2], that may indicate a critical role of interfaces on the observed behavior [3]. Here, we face this problem, by reporting on the magnetic properties of Pt(8 nm)/$CoFe_2O_4$ (30 nm) bilayers, grown in-situ, on SrTiO3(111) substrates. We have recently shown that these bilayers display a significant magnetoresistance that we attributed to spin Hall magnetoresistance (SMR) [3]. Here, we use X-ray magnetic circular dichroism (XMCD) experiments at the Pt M3 (2645 eV) and L3,2 (11564 eV) edges, performed respectively at BL29 and ID12 x-ray beamlines at the ALBA and European Synchrotron Facilities, to set an upper limit for any magnetic moment at Pt of about 0.001 μb/Pt atom, averaged over all Pt thickness. This observation suggests that in $Pt/CoFe_2O_4$, the observed SMR magnetoresistance is best described as resulting from a spin accumulation in the Pt layer, controlled by the magnetization direction of the neighboring $CoFe_2O_4$ layer and denies a significant magnetic proximity effect on Pt.

TH.E-P22 - Unidirectional spin hall magnetoresistance in ferromagnet/normal metal bilayers

C. Onur Avci [1], K. Garello [1], A. Ghosh [1], M. Gabureac [1], S. F. Alvarado [1], P. Gambardella [1]

1. Department of Materials, ETH Zürich, Zürich, Switzerland

Magnetoresistance is generally invariant under magnetic field and current reversal due to the Onsager reciprocity[1]. However this is not always not true in noncentrosymetric conductors where nonlinear terms can give rise to current dependence that is quadratic in the applied voltage and linear in the magnetization. We demonstrate that such conditions are realized in simple bilayer metal films where the spin-orbit interaction and spin-dependent scattering couple the current-induced spin accumulation to the electrical conductivity. We show that the longitudinal resistance of Ta/Co and Pt/Co bilayers changes when reversing the polarity of the current or the sign of the magnetization. Accordingly, we observe a decrease (increase) of the longitudinal resistance when the SHE-induced spin accumulation at the FM/NM interface is antiparallel (parallel) to the majority spin direction in the FM. This magnetoresistance effect scales linearly with current density and has opposite sign in Ta and Pt, which we associate to the modification of the interface scattering potential, induced by the spin Hall effect in these materials. The thickness and spacer layer dependence of this effect underline the substantial role of the spin Hall effect and the interfacial spin accumulation. We furthermore develop a model showing that this unidirectional spin Hall magnetoresistance[2] is consistent with the current-in-plane giant magnetoresistance theories[3,4] when the second magnetic layer is removed and the spin accumulation due to the spin Hall effect is taken into account. Our results suggest a new route to altering the electric properties of metal films by control of the magnetization.

TH.F.P27 - Vortex domain wall trapping via asymmetric notches

M. Voto [1], L. López Díaz [1], L. Torres Rincón [1]

1. University of Salamanca, Spain

Domain walls in in-plane magnetized strips above certain cross sectional area are naturally found to have a vortex configuration (VDW) [1]. The behaviour and the potential landscape of a propagating VDW interacting with a geometrical pinning site have been studied extensively [1,2] and shown to be asymmetric with respect to the propagation direction. In particular, a VDW approaching a notch finds its equilibrium before the notch rather than at its centre. This causes a weak pinning of the wall for an anti-parallel applied field; a relevant difference compared to the potential well found for transverse domain walls [1]. It would be convenient for certain applications and experiments [3] that a VDW could be pinned at a notch by applying a low field so that it remains strongly pinned when the field is reversed. With this goal in mind, we have investigated the trapping of a VDW in a permalloy nanostrip of 300x30 nm^2 cross-section by means of systematic micro-magnetic simulations. Tailoring notches on both edges of the strip, we design a pinning site that enhances the asymmetric energy landscape of the VDW, determining energy barriers of different heights for a propagating VDW depending on which side the notch is approached. The potential well created this way is accessed at 12-14 mT and not escaped until up to 26 mT in both directions. This pinning site acts like a valve for VDWs and can be exploited in applications that require asymmetric propagation of Dws such as shift registers and GMR sensors in which precise propagation direction for field driven DWs is required.

TH.F-P01 - Field and current driven magnetic domain wall motion in disordered A_1-FePt nanowires

P. Ho [1], J. Zhang [1], J. Currivan [1,2], D. Bono [1], C. Ross [1]

1. Massachusetts Institute of Technology, United States
2. Harvard University, United States

Domain wall (DW) in magnetic nanowires has technological potential in DW logic and racetrack memory devices. While an understanding of permalloy domain dynamics is well established, there are limited studies on other in-plane anisotropy ferromagnetic film. In particular, there are no reports on chemically disordered A1-structure FePt, with a larger magnetocrystalline anisotropy K_1 of magnitude 6×10^5 erg cm^{-3}. The larger anisotropy of A_1-FePt promotes thermal stability against superparamagnetism, and its spin-orbit coupling and spin polarization also differ from other transition metal alloys. An understanding of the DW dynamics in in-plane anisotropy A_1-FePt provides a useful complement to existing knowledge of DW dynamics in soft transition metal alloys and hard $L1_0$-FePt. In this work, the A_1-FePt DW structure, behaviour and dynamics under the influence of a field, pulsed current and field-assisted pulsed current were studied. Arc-shaped A_1-FePt nanowires of linewidth 375 nm with 2 µm diameter injection pads were patterned. Upon an applied H_y = 10 kOe saturation field transverse to the nanowire, a 180˚ vortex DW was introduced. Translational propagation of the DW was observed at H_x = 40 to 80 Oe applied parallel to the wire, while complete propagation to the end of the arc occurred at H_x = 100 Oe. DW displacement was observed with low pulsed current densities of $2.5 – 5.0 \times 10^{11}$ A m^{-2} but DW velocities were small, with values of 7×10^{-4} m s^{-1} at 5×10^{11} A m^{-2} and 1.8×10^{-2} m s^{-1} at 2×10^{12} A m^{-2}. The strong spin orbit scattering and poor spin polarization limited efficient spin transfer driven DW motion. A field-assisted spin transfer torque, combination of 5.0×10^{11} A m^{-2} current and a field of H_x = 60 Oe, drove the domain wall 1.8 µm to the end of the arc at a faster velocity.

TH.F-P03 - Simulation of the field-driven magnetic domain wall motion under the dzyaloshinskii-moriya interaction

K. Yamada [1], Y. Nakatani [1]

1. University of Electro-Communications, Tokyo, Japan

The Dzyaloshinskii-Moriya interaction (DMI) has been a great attention in the magnetic domain wall (DW) motion[1-3]. It has been reported by the theoretical analysis that the DMI produces an effective chiral field that stabilizes Néel type walls, leading to efficient coherent motion much faster than the DW velocity of several hundred at the Walker field [1,2]. In these reports, they have studied the DW motion around the Walker field, however they have not discussed the DW motion in a high field region in which it is moved with the precessional motion. In the region, the DW velocity is affected by fluctuations of DW shape [4], and the vertical Bloch lines are nucleated and moved on the DW. In this report, we perform micromagnetic simulations and investigate the field-driven DW motion under the DMI, in particularly, in the high field region where is much higher than the Walker field.
The two-dimensional micromagnetic model is used in simulations. Nanowire structures have 1.2 nm thickness, infinite length and various widths (w) from 50 to 200 nm. The nanowire is divided by a rectangular prism with dimensions of 2.0×2.0×2.5 nm^3. Typical material parameters for perpendicular magnetized Co/Ni multilayer film are used. A magnetic field (H_z) is applied in the wire thickness direction, and its range is from 0 to 1.5 kOe. The DW velocity over the Walker field is not only changed by the value of DMI but also by w. The breakdowns of the DW velocity occur several times in the wires of w = 100 and 200 nm.

TH.F-P04 - Effect of electric current on domain wall dynamics in nanocrystalline FeCoMoB microwire

P. Klein [1], A. Jimenez [2], G. Badini-Confalonieri [2], M. Vazquez [2], R. Varga [1]

1. Institute of Physics, Faculty of Science, UPJS, Kosice, Slovakia
2. Instituto de Ciencia de Materiales de Madrid, CSIC, Madrid, Spain

Propagation of domain wall in thin wires is used in modern spintronics to transfer or store information. Particularly, operation speed of such devices strongly depends on the domain wall velocity. Therefore, domain wall velocity is a crucial parameter for correct work of such applications.
Glass-coated microwires with positive magnetostriction are characterized by peculiar magnetization process that runs through the single domain wall propagation. Moreover, the domain wall velocity in such wire is very fast (over 10km/s [1]). Therefore, they are ideal materials for study the single domain wall dynamics on macroscopic scale [1]. However, very few attempts have been devoted to study the effect of electric current on domain wall dynamics in bistable microwires with exception [2].
In the given contribution we have studied effect of electric current on domain wall dynamics in nanocrystalline FeCoMoB microwires. The FeCoMoB microwires were annealed by classical way in furnace above crystallization temperature at 500 oC for 1 hour in order to obtain homogeneous nanocrystalline state of metallic core. The domain wall dynamics was studied by classical Sixtus-Tonks method. Moreover, electrical current flowing through microwire was applied to produce circular magnetic field. It has been found, that electric current in one direction enhances domain wall velocity (although it dereases its mobility) while exactly opposite effect was observed in second direction of flowing electric current.

TH.F-P05 - Evidence for chiral magnetic domain-wall in ferrimagnetic GdFeCo wires

Magnetic domain-wall (DW) dynamics has been intensively investigated due to the fundamental interests as well as technological applications such as memory and logic devices. To date, ferromagnets have been mainly examined for magnetic DW motion. However, recent studies [1] have shown that ferrimagnets can be an alternative platform due to the unique properties of ferrimagnets. Ferrimagnets have two magnetic sub-lattices the magnetizations of which are aligned in the opposite direction. Their small net magnetization and a large magnetic anisotropy may respectively lead to a low critical current density for DW motion and a high thermal stability. In this presentation, we report an evidence for the chiral magnetic DW structure in ferrimagnetic GdFeCo wires. We measure a field-driven DW velocity in GdFeCo (30 nm)/ Pt (5 nm) wires by a real time DW detection technique [2]. The DW velocity increases with increasing out-of-plane magnetic field (Hz). At a threshold field, the DW velocity abruptly decreases and gradually increases again. This feature can be attributed to the change of DW dynamics from the steady motion to the precessional motion, which is known as the Walker breakdown. We next check the in-plane field dependence of the DW velocity for Hz = 20 mT. The DW velocity is found to exhibit a minimum at a finite in-plane field (Hm). Moreover, the sign of Hm is reversed when we change the DW structure from up-down DW to down-up DW. This result suggests that a chiral magnetic DW structure is formed in ferrimagnetic GdFeCo wires.

The vertical Bloch line (VBL), a topological defect inside a magnetic domain-wall (DW), is known to play an essential role in the two dimensional DW dynamics. A nucleation and a propagation of VBL retard the DW motion. Recently, novel type of antisymmetric exchange interaction, namely the Dzyaloshinskii-Moriya interaction (DMI), has been found to play a crucial role in the formation and the dynamics of topological objects such as magnetic soliton, vortex, and skyrmion. It thus raises an intriguing question how the DMI affects the dynamics of VBLs and DW.
We prepared two types of Co/Ni films having symmetric and asymmetric layer structures, respectively. Since the DMI is expected to exist only in asymmetric layer structure, we can elucidate the effect of DMI on the DW dynamics by comparing two different samples. An electrical time-of-flight measurement technique was employed to investigate a field-driven DW dynamics. We observed a distinct difference in the DW velocity between symmetric and asymmetric samples. The DW velocity for asymmetric Co/Ni sample was found to be 5 times larger than that for symmetric Co/Ni sample, implying that a new energy dissipation channel is opened in asymmetric Co/Ni sample. Micromagnetic simulation reveals that the DMI induces the annihilation of VBLs, resulting in the emission of spin waves. This emission of spin waves is found to be a new energy dissipation channel, which boosts up the DW velocity.

Spintronics is an emerging research field that bridges magnetism and electronics, offering multiple applications such as magnetic memories, logic devices, etc. The operation of these different devices is often based on different physical phenomenon. The device function is strongly linked to the type of excitation (electric or magnetic) as well as to the precise material parameters. We propose a new approach where the shape is used as a new parameter that defines the device behavior. Similarly to the paper origami, the objects are made of the same material, but since they have different shape they operate as different magnetic devices. This possibility is based on current induced non-collinear domain wall (DW) motion in Pt/Co/AlOx trilayers. Here, non-collinearity is defined with respect to the direction of the current flow and to that of DW motion. In all the previous experiments reported in literature, the current induced DW motion was studied in magnetic nanowires by applying current along the wire that defines the direction of the DW motion. In our experiment, the current is applied at different angles between +75 and -75 with respect to the direction of the DW motion. We observed that the DW moves in a selective way through different directions in the two dimensions. Using these observations, we could design different two dimensional shapes where the DW motion could be manipulated according to the device requirements. This led to the realization of new kinds of reversible and irreversible magnetic switches differentiated only by shape.

TH.F-P08 - Domain walls in thin film magnets/TI junctions

Y. Ferreiros [1], F. Buijnsters [2]

1. Instituto De Ciencias De Materiales De Madrid (ICMM), Madrid, Spain
2. Institute for Molecules and Materials, Radboud University Nijmegen, The Netherlands

The spin-transfer torque generated by the surface states of a 3D TI has recently been measured to be larger than for any other spin-transfer torque source measured so far, which encourages the applicability of thin film magnet/TI junctions for spintronic based devices. We analytically compute the effective action for the magnetization in this system with an out-of-plane domain wall (DW) configuration, at finite density and in the presence of an external electric field. We show that an electronic chiral state appears bounded to the DW carrying 1D equilibrium (finite density) and out of equilibrium (non zero electric field) dissipationless currents. We show that in addition the chiral state generates an in-plane hard axis anisotropy term in the effective action, in the direction perpendicular to the DW. We also address whether a Dzyaloshinskii-Moriya (DM) type of interaction appears, concluding that it is not the case. However we show that the 1D equilibrium current gives a term that resembles the interfacial DM interaction, but with the important difference that it is a first order term in the magnetization.
The equilibrium profile of the DW is computed as a function of the chemical potential, qualitatively reproducing the behavior of recent numerical results, and the physical explanation of the effect is shown to lie in the competition of the chiral 1D current and the induced hard axis anisotropy. We also study the motion of the DW via an external current, and show that the threshold for Walker breakdown (WB) is increased and determined by the exchange interaction. Furthermore this threshold can be further increased by both doping the TI and applying an external electric field. Having an analytic control of the Hamiltonian settles the basis for future investigations, for example addressing magnonic propagation and the appearance of a magnonic torque on the DW.

TH.F-P09 - Ultrafast dynamics of current induced motion of magnetic domain wall in permalloy sublayer in bilayer niobium-permalloy structure.

L.S. Uspenskaya [1], S.V. Egorov [1]

1. Institute of Solid State Physics RAS, Moscow, Russian Federation

The electrical current switching of the magnetic state of ferromagnetic layer in hybrid ferromagnet-superconductor structures opens a new possibility to control the properties of the hybrids supposed to be used in cryoelectronics [1]. Herewith we report the results of study of the dynamic properties of magnetic domain walls in 40 nanometer thick permalloy tapes grown on niobium sublayer at their motion exited by magnetic and electric fields. The study was performed by magnetooptic visualization technique by means of yttrium iron-garnet films in temperature range 6 K - 300 K [2]. We found that on cooling from room to liquid helium temperature the coercivity of the walls shifted under the magnetic field pulses increases following thermoactivated law, and the mobility of the walls decreases according to power law like T^(-1/4). Nevertheless, the mobility of the walls shifted under the current pulses increases with temperature decrease following T^(1/3) dependence. The domain wall under the current excitation moves faster that under the field. The maximum velocity of the wall becomes as large as 1000 m/s at 10 K, and 4000 m/s at 6 K. The result looks absolutely surprising taking into account that the niobium transition into superconducting state takes place at Tc = 8.5 K, which means that main current flow occurs not in the permalloy but in the niobium layer at T<Tc.

The manipulation of pure spin currents in nanostructures generates an increasing interest, being notably the basis of two emerging research fields: The spincaloritronics [1], where the spin currents are generated by thermal gradients and the spin-orbitronics [2], where such currents are manipulated by means of the spin-orbit coupling as the spin-Hall or the Rashba effects. These spin currents can also be created by means of non-local injection in lateral spin valves (LSV), which is an attractive tool for studying spin transport properties in non-magnetic materials. Moreover, the absorption of pure spin current by a ferromagnetic element is associated to a spin transfer that can induce magnetic oscillations [4] or even lead to magnetic switching [5]. In the other hand, the manipulation of magnetic Domain Walls (Dws) in nano-structures by means of spin currents has been the subject of intense research over the last decade [6,7]. In this presentation, we report on the possibility to create switchable pure spin current sources, controlled by magnetic domain walls [8]. When the domain wall is located at a given point of the magnetic circuit, a pure spin current is injected into a nonmagnetic wire. Using the reciprocal measurement configuration, we demonstrate that the proposed device can also be used as a pure spin current detector. Thanks to its simple geometry, this device can be easily implemented in spintronics applications; in particular, a single current source can be used both to induce the domain wall motion and to generate the spin signal. Finally these DW based detector can be combined to build a AND logic function

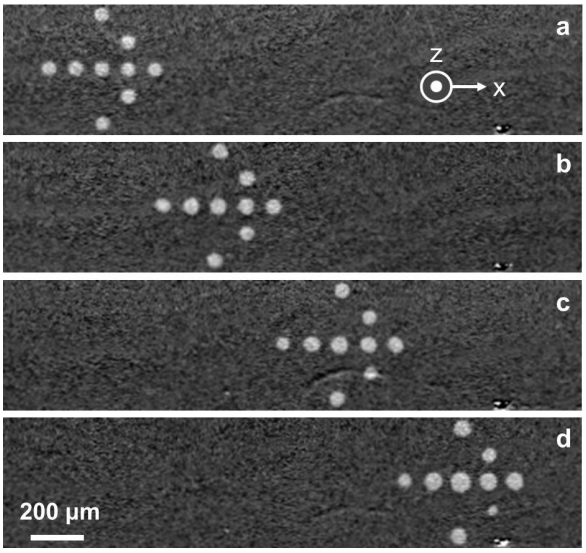
Up to now, there have been suggested many concepts of the unidirectional coherent magnetic domain walls (DWs) motion for next-generation promising memory and logic devices [1-3]. Such concepts based on DWs can be demonstrated by either by injecting large electric currents into nanowires [1] or by using the DW tension induced by sophisticated structural modulation [2, 3]. However these schemes require either a high threshold [1] or highly sophisticated nanofabrication processes [2, 3]. Here, we demonstrate a new scheme for unidirectional DW motion without any current injection or structural modulation. This scheme utilizes asymmetry domain expansion with respect to magnetic fields [4] induced by the Dzyaloshinskii-Moriya interaction. Due to this asymmetry, an alternating magnetic field results in a coherent motion of the DWs. Figure 1 show a proof-of-principle experiment. An arbitrary 5x5 array pattern of bubbles (Fig. 1a) is initially created on the film using the thermomagnetic writing method [5]. Under the alternating magnetic pulses, all bubbles exhibit coherent unidirectional motion, as shown by the sequential images (Figs. 1b-d and see Ref. [5]) captured during the pulses. Interestingly, the bubble-array pattern, called bubblecade, is exactly maintained even after traveling more than 1 mm (Fig. 1d). The observation of the coherent unidirectional bubbles motion can possibly replace the mechanical motion of the magnetic media, enabling a new device prototype ùmagnetic bubblecade memoryùwith two-dimensional data-storage capability.



TH.F-P12 - Magnetization dynamics of iron garnet crystals in oscillating magnetic field

L. Pamyatnykh [1], L. Agafonov [1], D. Mekhonoshin [1], S. Pamyatnykh [1], M. Lysov [1], G. Shmatov [1]

1. Ural Federal University, Russian Federation

Dynamic remagnetization mechanism was investigated based on (111) iron garnet (TbErGd)3(FeAl)5O12 sample plate. Dependencies of stripe domains drift speed and domain walls oscillations parameters in an alternating magnetic field applied perpendicular to the sample plate were established. Parameters of the sample: saturation magnetization Ms = 40 Gs, constant of uniaxial magnetic anisotropy Ku = 5500 erg/cm3, magnetocrystalline anisotropy constant K1 = -3400 erg/cm3, orthorhombic anisotropy constant Kp = 3200 erg/cm3. Dynamic domain structure (DDS) was revealed using magnetooptic Faraday effect and was captured using stroboscopic technique by high speed digital camera at the rates up to 1200 fps. A solid-state pulsed laser with a wavelength of 527 nm and a pulse duration of 25 ns synchronized with the alternating magnetic field was used for illumination. This allowed to obtain a series of DDS images in a successive phases of the magnetic field. The drift velocity of stripe domains, amplitude of oscillations and peak velocity of oscillations of domain walls were measured in a frequency range 25-1200 Hz for amplitudes up to 500 Oe. It was established that the character of dependencies of amplitude of oscillations and of peak velocity of oscillations of domain walls on amplitude of alternating magnetic field qualitatively changes for amplitudes that correspond to the drift of domain walls. Numerical modeling of motion of stripe domain structure with the parameters of the real sample was performed based on the model of coupled harmonic oscillators that takes dynamic attenuation into account. The results of numerical modeling are compared to the experimental results.

TH.F-P13 - Dimensional crossover in stochastic behavior of magnetic domain-wall creep motion

T. Taniguchi [1], K. Kim [1], T. Tono [1], T. Moriyama [1], T. Ono [1]

1. Institute For Chemical Research, Kyoto University, Japan

It has been recently reported that the spin Hall torque (SHT) can drive a magnetic domain wall (DW) in asymmetric layer structures involving a strong Dzyaloshinskii-Moriya interaction (DMI) [1]. In order to utilize this DW driving mechanism, it is crucial to understand the microscopic DW behavior under SHT and DMI. Since a DW can be considered as an elastic string-like object, a DW generally has a roughness in two dimensional space due to the pinning sites in wires.
In this presentation, we demonstrate the crossover from two dimensional to one dimensional characteristics of the DW motion in Co/Ni nanowires with DMI. A DW can propagate with two driving forces; a magnetic field or a current invoking SHT. We compare the distributions of DW velocity in creep regime for two driving force in a different wire widths (w). While the distribution for current-driven case is about 3 times larger than that for field-driven case when $w \gtrsim 1$ mm, both driving forces show similar velocity distributions when $w \lesssim 500$ nm. The difference in the distribution for wider wires can be attributed to the difference in the DW roughness for two driving forces [2]. On the other hand, when w is reduced to w_{opt}, below which DW moves collectively [3], the difference in the DW roughness disappears and the two driving forces have the same distributions. Our findings suggest that the effective magnetic field induced by SHT is equivalent to the external field in one dimensional wires, though it is not in two dimensional wires.

TH.F-P14 - Head-to-head domain wall structures in wide permalloy strips

V. Estevez [1], L. Laurson [1]

1. Aalto University, Aalto, Finland

We analyze the equilibrium micromagnetic domain wall structures encountered in Permalloy strips of a wide range of thicknesses and widths, with strip widths up to several micrometers. By performing an extensive set of micromagnetic simulations, we show that the equilibrium phase diagram of the domain wall structures exhibits in addition to the previously found structures (symmetric and asymmetric transverse walls, vortex wall) also double vortex and triple vortex domain walls for large enough strip widths and thicknesses. Also several metastable domain wall structures are found for wide and/or thick strips. We discuss the details of the relaxation process from random magnetization initial states towards the stable domain wall structure and show that our results are robust with respect to changes of, e.g., the magnitude of the Gilbert damping constant and details of the initial conditions. Phys. Rev. B 91, 054407 (2015)

TH.F-P15 - Non-uniform internal degrees of freedom in field-driven extended domain walls in perpendicular media

T. Herranen [1], L. Laurson[1]

1. COMP Centre of Excellence and Helsinki Institute of Physics, Department of Applied Physics, Aalto University, Aalto, Finland

Domain walls (DW) in nanostrips with perpendicular magnetic anisotropy (PMA) driven by a magnetic field along the easy axis experience a Walker breakdown (WB) [1] at the Walker field $B = B_W$. In nanostrips, the in-plane magnetization of the DW rotates uniformly around the z-axis for $B > B_W$. In this work we perform micromagnetic simulations on a wide granular CoPtCr strip with 1.2 µm width and 20 nm thickness. The disorder is generated by adding a random 10 % variation in the anisotropy magnitude in each grain. The grains are generated by Voronoi tessellation, and have an average diameter of 11.9 nm. We show that a DW in such wide strips also experiences the velocity drop related to the WB. Unlike in nanostrips, the internal magnetization of the DW in wide strips breaks into non-uniform in-plane magnetic structures for $B > B_W$. These non-uniformities are nucleated either at the sample boundaries, or due to disorder.

Analysis of the non-uniform in-plane magnetization shows that it can be described as a set of domains separated by internal domain walls. With a magnetic field pulse on a DW pinned by two notches we can generate configurations with e.g. a 180° internal DW, similar to the transverse walls in nanostrips with in-plane magnetization. These internal DW structures are stable in room temperature. The study of the field-driven dynamics of the internal DWs shows that they do not experience a WB due to the topological restrictions originating from the surrounding $\pm\hat{z}$ domains.

TH.F-P16 - Influence of asymmetric geometry on domain wall chirality detected in Y-shaped nanowires

W. Kwak [1], J. Kwon [1], B. Cho [1]

1. School of Materials Science and Engineering, Gwangju Institute of Science and Technology, Republic of Korea

The control of domain wall motion in a magnetic nano-strip has received considerable attention over recent decades because many applications of spintronic devices are based on domain wall motion, including spin logic devices and race-track memory. Recently, many research groups have reported that domain wall propagation is dependent on the chirality of the domain wall in artificial structures. Domain wall chirality is generally set up by applied magnetic field, and is important for controlling the domain wall motion. However, the magnetic field used to stabilize the chirality produces an inevitable drawback for high density devices. Here, we found that the asymmetric geometry in which a nucleation pad is attached at the lower edge of a nanowire has preference for the chirality of transverse walls when the walls are injected from a nucleation pad into a magnetic nanowire. Chiralities of the injected wall were confirmed by chirality dependent propagation in a Y-shaped magnetic nanowire having a spin-valve structure. Domain wall position was detected through magnetoresistance (MR) measurement during reversal of the permalloy free layer. As a result, in this geometry, clockwise transverse walls can be stably formed in a relatively lower transverse field range than is possible with counter-clockwise walls. This is due to the tendency in which one edge defect having higher magnetostatic energy does not like to encounter a pinning site, which offers selectivity for chirality. Object oriented micromagnetic framework (OOMMF) was implemented for the investigation of domain wall nucleation in the suggested geometry and supported the experimental results. Our findings emphasize the importance of the placement of parts related to domain wall nucleation so as to control domain wall structures.

TH.F-P17 - Manipulation of domain wall motion in Ta-CoFeB-MgO ultrathin films by making use of sub-nanometer steps modulation

A. Digiacomo [1], R. Mantovan [1], N. Vernier [2], T. Devolder [2], K. Garcia [2], G. Tallarida [1], M. Fanciulli[1,3], B. Ocker [4], L. Baldi [5], M. Mariani [5], D. Ravelosona[2]

4. Singulus Technology AG, Kahl am Main, Germany
5. Micron Semiconductor Italia S.r.l., Agrate Brianza, Italy

Control of magnetic domain wall (DW) motion in nanowires has attracted great interest due to the possibility to develop high density non-volatile memory and logic circuits such as racetrack memory. Within the challenge of finding optimal strategies to target ultimate scaling, the use of ultrathin CoFeB layers showing perpendicular magnetic anisotropy (PMA) is particularly attracting. In this contribution we present a possible strategy for fabricating artificial pinning sites in order to manipulate DW motion in ultrathin (1 nm) CoFeB layers. Sub-nanometer steps modulation are synthesized at the surface of SiO2-Si3N4 substrates, on top of which Ta/CoFeB/MgO stacks showing PMA are deposited by magnetron sputtering. The DWs dynamics in the ultrathin CoFeB layers is studied by Kerr microscopy. The propagation velocities for DWs moving "across" the steps are about two orders of magnitude lower than the velocities of DWs moving "along" the steps. Reported results demonstrate that appropriate engineering of the substrate is an efficient way to manipulate DWs in Ta/CoFeB/MgO structures. The proposed method is compatible with nanoscale dimensions and large-scale mass production, which open new opportunities for the modulation of DW motion in ultra-high density spintronics devices.

TH.F-P19 - Enhancement of spin-orbit torque and Dzyaloshinskii-Moriya interaction in Co films sandwiched by various 3d, 4d, and 5d transition metals

C. Cho [1], S. Yun [1], H. Whang [1], D. Kim [1], D. Kim [1], J. Moon [1], S. Je [1], Y. Oh [2], B. Park[2], S. Choe [1]

1. Seoul National University, Republic of Korea
2. KAIST, DAEJEON, Republic of Korea

Current-induced domain-wall motion has been intensively studied over the last decades due to its promising application toward high-density and low-energy-consumption memory and logic devices. Recently, it has been found that the efficiency of the domain-wall motion can be largely enhanced by the spin-orbit torque (SOT) [1] combined with the Dzyaloshinskii-Moria interaction (DMI) [2]. In presence of the DMI caused by a broken symmetry in heavy-meatal/ferromagnetic interfaces [3], the Neel-type domain-wall structure is stabilized, which then results in the domain-wall motion driven by the SOT via the spin Hall current from non-ferromagnetic heavy metals [4]. It is therefore radical to analyze the sign and magnitude of the DMI and SOT to understand their physical origin as well as to achieve memory and logic devices. In this study, we investigate the DMI and SOT of various metallic ferromagnetic films, of which the structures are Ta(5 nm)/Pt(2.5 nm)/Co(0.6 nm)/X(1.5 nm) films with various choice of X by Ti(3d), Cu(3d), Ru(4d), Pd(4d), Ta(5d), W(5d), Au(5d), and Mg. The sign and magnitude of the DMI are then measured from the asymmetric domain-wall expansion [3] as shown by Fig. 1. Figure 1 shows the asymmetric domain-wall expansion image (inset) and the domain-wall speed v with respect to the in-plane magnetic field Hx, from which the magnitude of the DMI-induced effective field HDMI is determined by observing the inversion symmetry axis. The figure clearly shows that HDMI is sensitive to the composition of X. The SOT is then measured by the w-2w measurement method [5], as exemplified by Fig. 2 for the sample with the choice of X by Ta. The tendency of SOT and DMI will be provided a designing rule for engineering new spintronics devices.

The theory of avalanches of pinned interfaces provide a series of predictions about the statistical properties of the magnetization processes in soft magnetic materials. The analysis of magnetic avalanches (Barkhausen jumps) has showed the occurrence of scaling laws with critical exponents which are well predicted by interface depinning models. For instance, polycristalline bulk magnetic materials are well described by the so called ABBM model, which assumes to have a single domain wall moving in a random media with spatial Brownian properties. This model actually belongs to a more general class of mean-field (MF) models, which show universal properties, independent of the specific properties of a material. From this model, the average shapes of temporal avalanches is predicted to be a inverted parabola, as experimental verified in Permalloy thin films. Other materials have shown properties that go beyond the MF prediction, with different sets of critical exponents. Anyway, all these results have shown a good correspondence between models and experimental results, but failed to give a quantitative description of the magnetization dynamics. Recent advances in the theory of interfaces in random media had shed a new light in this respect, both in and beyond mean-field. In this paper, we have analyzed a large set of experimental avalanches, and compare them with new theoretical predictions. For instance, the average shape of temporal avalanches are compared with the prediction without free parameters. In addition, the average shape at fixed size is perfectly described by non-MF models, even discriminating between the small differences compared to the MF one. Good agreement is also found in presence of eddy currents in materials when MF occurs. All these results are able to offer for the first time a full quantitative comparison of the scaling properties magnetization dynamics.

TH.F-P21 - Improvement of current induced domain wall motion in TbFeCo wire on plastic substrates

A.Tsukasa [1], T. Atsushi [1], A. Hiroyuki [1]

1. Toyota Technological Institute, Japan

Recently, much attention has been paid to current induced domain wall (DW) motion due to its advantage applications [1, 2]. In most reports of the current induced DW motion, Silicon substrate is often used to set magnetic wire on. To its application as a memory, the cutting cost is necessary. If it is possible to replace by an inexpensive plastic substrate it would reduce much the memory cost. It is expected that plastic substrate can be a good candidate in this case. However, there are few reports of the current driven DW motion with plastic substrate. In this study, TbFeCo/Pt wires are fabricated on plastic substrates and Si substrates by using photolithography techniques and DC sputtering.

DWs were moved along the direction of the current due to Spin Hall Effect from Pt capping layer. The threshold current densities J_{th} for DW motion are 1.34×10^{10} [A/m^2] and 5.30×10^{10} [A/m^2] for the wires on the plastic and Si substrate, respectively. It suggested that the current induced DW motion in TbFeCo on plastic substrates is improved effectively. The threshold current density of the plastic substrate was much smaller than that of Si substrate.

TH.F-P22 - Current induced domain wall motion along current direction in Pt/GdFeCo(110nm)/SiO_2/Si sub. magnetic nanowire

Y. Kurokawa [1], M. Kawamoto [1], H. Awano [1]

1. Toyota Technological Institute, Japan

Manipulating magnetic domain wall (DW) using electric current is paid attention from the viewpoint of device application such as new type of magnetic memories. Recently, a number of experimental investigations for current induced DW motion in perpendicular magnetized magnetic wire have been reported. In our previous study, we reported that amorphous TbFeCo wire has low critical current density (Jc) because of low saturation magnetization (Ms) of that. In this study, we observe current induced DW motion of amorphous GdFeCo wire which also has low Ms.
The GdFeCo wires are fabricated by electron beam lithography and magnetron sputtering. To avoid the ambient oxidization, the wires are capped by a 2 nm thick Pt layer.
The current induced DW motion in GdFeCo wires are observed by Kerr microscope. Almost all the Ms of the GdFeCo wires are lower than 100 emu/cc. The Jc of the GdFeCo wire whose thickness is 110 nm is 7.5x10^10 A/m^2. That is almost same value of the Jc of the TbFeCo and is also much lower than that of the FeNi (~10^12 A/m^2). Surprisingly, the direction of current induced DW motion in the GdFeCo wire is current direction. Generally, this result indicates that the DW driving force is due to spin hall effect and dzyaloshinsky-moriya interaction from the Pt interface. However, this result also indicates that these effects probably do not act only on the Pt layer interface.
This work was financially supported by the Ministry of Education, Culture, Sports, Science and Technology, Japan-Supported Program for Strategic Research Foundation at Private University (2014-2019) and KAKENHI No.26630137 (2014-2016).

TH.F-P23 - Analytical modeling of magnetic domain wall motion under applied fields and currents

S. Ali Nasseri [1], B. Sarma [1], G. Durin [1,2], C. Serpico [1,3]

1. ISI Foundation, Torino, Italy
2. Istituo Nazionele di Ricerca Metrologica (INRIM), Torino, Italy

Manipulating domain walls within nanostructures has many applications in the development of spintronic logic and storage devices [1]. Such applications have led to increased interest within the scientific community in developing models which can qualitatively or quantitatively describe the domain wall motion under applied fields and currents. The main analytical model for analyzing the motion of magnetic domain walls is the 1-D model for rigid traverse walls [2]. This model qualitatively describes the motion of the domain wall, while it fails to match experimental and numerical results quantitatively. Many researchers in recent years have introduced new interactions such as spin transfer torques in the 1-D model with the aim of reaching a more general model [3]. Experimentalists have also used this model to describe the motion of different domain walls, including vortex walls. It seems that in many of such attempts, formalisms are not followed accurately and the main assumptions of the model (such as the bloch wall profile used in developing the model) are underestimated. Taking into account such flaws, the authors embarked on analytically deriving the equations of motion for a generalized domain wall under fields and currents.
In this paper, we reformulate the method to derive the equations of motion for a magnetic domain wall in nanostructures in terms of collective variable. The proposed formulation is based on the D'Alembert's principle which may be viewed as an extension of the Lagrangian formulation in presence of conservative and nonconservative forces. This formalism is then applied to analyze the motion of a rigid titled transverse domain wall and the results are compared with micromagnetic simulations to assess the accuracy of the analytical model.

We have investigated the current-driven domain wall motion in cylindrical nanostructures comprised of a pair of nanotube and nanowire segments. Under certain values of external magnetic fields, it is possible to pin a vortex domain wall in the transition zone between the wire and tube segments. We explored the behavior of this domain wall under the action of an electron flow applied in the opposite direction to the magnetic field. Thus, for a fixed magnetic field, it is possible to release a domain wall pinned simply by increasing the intensity of the current density, or conversely, for a fixed current density, it is possible to release the domain wall simply decreasing the magnetic external field. When the domain wall remains pinned due to the competition between the current density and the magnetic external field, it exhibits a oscillation frequency close to 8 GHz. The amplitude of the oscillations increases with the current density and decreases over time. On the other hand, when the domain wall is released and propagated through the tube segment, this shows the standard separation between a steady and a precessional regime. The ability to pin and release a domain wall by varying the geometric parameters, the current density or the magnetic field, transform these wire-tube nanostructures in an interesting alternative as an on/off switch nano-transistor.

TH.F-P25 - Electric-current-induced dynamics of bubble domains in TbFeCo wires of various compositions with different cap layers

M. Tanaka [1], H. Kanazawa [1], S. Sumitomo [1], S. Honda [2], K. Mibu [1], H. Awano [3]

1. Nagoya Institute of Technology, Japan
2. University of Tsukuba, Japan
3. Toyota Technological Institute, Japan

Electric-current-induced dynamics of domain walls in magnetic wires is paid attention because of the potential for new spintronics devices. Some researchers have reported that the reverse or transverse forces with respect to the electron flow are induced in the current-induced dynamics of the domain walls by the spin Hall effect or Rashba effect. Bubble domains, whose domain walls do not reach the wire edges, allow us to estimate these forces from a different aspect. In this presentation, we show the current-induced forces for bubble domains in perpendicular magnetized ferrimagnetic TbFeCo wires with various saturation magnetizations with different cap layers.
TbFeCo wires with different saturation magnetizations of about 10 nm in thickness with cap Pt and Ta layers of 2 nm were fabricated on thermally oxidized Si substrates using electron-beam lithography, sputtering and a lift-off method. The width of the wires was designed to be about 10~40 um. The magnetizations of the TbFeCo wires were set to be transition-metal-dominant and rare-earth-dominant sides. Bubble domains were induced in the wires using laser annealing under an external magnetic field. The current-induced dynamics of bubble domains was observed by polar Kerr microscopy at room temperature.
It was found that the bubble domains in the TbFeCo wires with relatively low saturation magnetizations collapsed, whereas those with relatively high saturation magnetizations grew, under a current flow. A bubble domain in the TbFeCo wire with the Pt cap layer grew to an electric current direction with a tilted angle. The tilt direction of the bubble-domain' growth in the TbFeCo wires with the transition-metal-dominant and rare-earth-dominant magnetizations are opposite each other. We discuss the composition- and the cap-layer-dependence of electric current induced dynamics of the bubble domains.

TH.F-P26 - Investigation of vortex domain wall motion in permalloy nanowire with nano-constriction

V. Parakkat [1], Anil P.S. Kumar [1]

1. IISc, Bangalore, India

We have investigated the magnetic field induced reversal, in permalloy nanowire (430nm wide) attached to a nucleation pad (5micron) at one end, using localized electrical probes. The nano structure was fabricated by liftoff, of 15nm thick film grown (on SiO2) using pulsed laser ablation. Here we utilize the anisotropic magnetoresistance of permalloy to electrically track domain wall(DW) injection from the pad, its pinning at a geometrical constriction(280nm deep) and depinning. We studied the statistics of various events in the reversal processes and observed two well defined depinning field values corresponding to vortex domain walls of different chiralities. The nucleation of DW in the nucleation pad is highly stochastic. But we could control this by applying transverse component of magnetic field which helped in tuning the probability distribution of the injection of DWs of different chiralities. Hence, we used this technique to inject DW preferentially into the NW to study its interaction with a “lambda” shaped notch.

The minor hysteresis loop measurements provided us with direct proof of the chirality dependence of the potential landscape seen by the vortex DWs at the notch and is well supported by the simulation data. We observed that there is a large difference in the values of depinning field required to move DW to left side of the notch and to the right, thus demonstrating the asymmetric nature of potential barrier at the notch, which depends on chirality of the DWs.

The pinning probability was higher for clockwise vortex DW since the potential barrier seen by it at the notch is higher compared to counter-clockwise vortex DW; this implies that a careful discretion is required for the selection of the type of DW to be used in DW based devices.

TH.F-P28 - DeltaE effect and magnetomechanical damping in the re-entrant spin glass state of ferromagnetic bulk metallic glasses

J. Torrens-Serra [1], F. Solivelles [1], S. Kustov [1]

1. Universitat De Les Illes Balears, Palma de Mallorca, Spain

Ferromagnetic bulk metallic glasses are classical materials, exhibiting the re-entrant spin glass transition. The latter implies a strong decline of domain wall (DW) mobility. In the present work, the acoustic technique has been employed to follow the effect of polarizing field on the dynamics of DWs below and above the re-entrant spin glass (RSG) transition temperatures in several ferromagnetic Fe-based bulk metallic glasses (BMG). Experimentally, the dependences of deltaE effect, linear (micro- and macroeddy) and non-linear (hysteretic) magnetomechanical internal friction components at a frequency close to 90 kHz versus polarizing field have been studied between 15 and 300 K for a series of Fe-Cr-Mo-C-B BMGs with the Curie temperature from 73 to 310 K.

Above the RSG freezing temperatures, all three magnetomechanical damping components show a classical pattern: a monotonous decrease of the microeddy and hysteretic terms and a maximum in the macroeddy damping component versus magnetic field. DeltaE effect clearly shows the contributions of micro- and macroeddy relaxations.

In the RSG state, the non-linear, hysteretic damping component demonstrates an intense maximum versus field close to the position of the macroeddy current damping maximum. The formation of the maximum of non-linear damping with increasing field is concomitant with the strong variation of the functional form of the strain amplitude dependence of damping, which shows a classical Rayleigh behaviour above this “critical” field. These observations indicate that the polarizing field provokes RSG “melting”, which is clearly detected by means of the acoustic technique.

TH.F-P29 - Walker breakdown of domain wall motion driven by spin waves in perpendicular magnetic anisotropy nanostrip

L. Chang [1], S. Lee [1]

1. Institute of Physics, Academia Sinica, Taiwan

In this report, we numerically and analytically investigate the SW induced DW motion in a nanostrip with perpendicular magnetic anisotropy by means of micromagnetic simulation (OOMMF). We find the Walker breakdown in all cases of spin wave driven DW motion, as in the field driven and charge current driven DW motions. The nanostrip dimension is 4000 × w × t nm^3. The strip width w and thickness t varies from 20 to 80 nm and 2 to 10 nm, respectively. A DW at the center is subjected to a SW source 500 nm apart on the left with amplitude H_0 in the transverse direction and frequency f. When a SW approaches the DW, fluctuation of magnetization appears on the DW region, which gives rise to an effective field $\boldsymbol{H}_{eff}$ acting on the DW. The effective field exerts a torque to rotate the DW magnetization, resulting in the DW motion. The directions of the SW induce DW motion and the transmission coefficient for the propagating SW across the DW are depending on the in-plane tilt angle of the wall magnetization. The DW velocities versus amplitude of the SW for different types of DW will be presented. The oscillatory amplitude and frequency of the DW motion is analyzed. This study provided new perspectives for the control and manipulation of DW in a nanostrip.

Th.G-P01 - Reversible control of ferromagnetism in Fe_3O_4 via lithium insertion/extraction

G. Wei [1], Y. Chen [1], S. Xiao [1]

1. School of Physics, Shandong University, China

Transition metal oxides have been extensively studied as anode materials for high-performance lithium ion batteries. It is notable that the redox states of these materials can be controlled by the electrochemical potential of the electrode. A revisable control of magnetism can be achieved if the charge/discharge voltage range is carefully set, because the variation of valence states of transition metal may change the exchange coupling between the d orbital electrons. With the rapid development of battery manufacturing technology, this brilliant feature makes it a new approach to achieve room-temperature magnetic control using electrochemistry method. We fabricated a miniature lithium-battery sealed in a glass tube using Fe_3O_4 as the anode. XRD and CV curves were combined to determine the suitable discharge potential limit that would allow maximum lithium insertion but avoid structural damage to the magnetic electrode. Ex situ XRD indicates when the cell is discharged to 0.8V, the patterns of the cathode are the same as those of Fe_3O_4, indicating that the cathode maintains inverse spinel structure. However, at 0.7V, some characteristic peaks of the spine disappear and the new pattern can be assigned to Lix Fe_3O_4. An in situ magnetic measurement of Fe_3O_4 during the inserting/ extracting of Li ions was conducted in the reversible range from 3.0 to 0.8 V. A highly reversible variation in magnetic response was observed with respect to the lithium insertion/extraction process. The cycle time is only 10 min and can be further improved with a higher current. The obvious magnetic variation, fast magnetic response speed as well as uncomplicated fabrication process make this LIB styled device a promising candidate for future practical applications.

Th.G-P02 - Computer simulation of domain wall motion induced by a slope electric field

S. Murayama [1], K. Yamada [1], Y. Nakatani [1]

1. University of Electro-Communications, Tokyo, Japan

Recently, the domain wall (DW) motion device has attracted a great deal of attention, because it will be a candidate for a nonvolatile information storage, which has a potential for reducing consumption power. In recent years, as a new method for reducing the power, the electric field-driven DW motion method has been proposed [1-3]. In this study, we perform the micromagnetic simulations, and investigate the DW motion by using a slope electric field (SEF). Since the anisotropy field in the magnetic nanowire can be changed at each position in this approach [4,5], it lead to change the DW energy at each position, and accordingly, the DW moves only by this electric field.

The size of the magnetic nanowire is 60 nm of width, 3.9 nm of height, and infinite length. The nanowire is divided by a rectangular prism with dimensions of 3.0×2.0×3.9 nm^3. Typical material parameters for Co/Ni multilayer film [6]. The effect of the SEF is realized by decreasing the K_u linearly with respect to the magnetic nanowire, and the reduction rate of the K_u is defined as ΔK_u.

The maximum velocity is 1100 cm/s at ΔK_u = 170 erg/cm^3/nm, and the DW moves to right which is the direction to decrease K_u (x > 100 nm). The DW moves with the steady motion up to ΔK_u = 170 erg/cm^3/nm, and the v is proportional to ΔK_u. Above ΔK_u = 170 erg/cm^3/nm, the DW moves with the precessional motion, and the v is decreased. These phenomena are the similar with the Walker breakdown.

In magnetic recording medium, information can be written by switching a magnetization direction of a magnetic material. Up to now, the switching has been realized by applying a magnetic field and/or an electric current. Domain wall (DW) displacement induced by an electric current is one of the most promising techniques. For practical applications, precise control of the DW position and its speed are desired. We have been investigating an electric field effect on magnetism using electric field-effect devises consisting of a gate electrode, an insulator layer and a ferromagnetic material. Recently, we reported that the velocity of domain wall motion induced by magnetic field can be widely modulated just by applying an electric field. In this work, we have investigated the current induced DW motion under an electric field in the absence of external magnetic field in a perpendicularly magnetized MgO/Co/Pt system. We observed the domain wall motion by means of a magneto-optical Kerr effect (MOKE) microscope through a transparent gate electrode. In this system, there is a strong Dzyaloshinsky-Moriya interaction at the interface between the Co and Pt layers due to spin orbit interaction and structural asymmetry, and the DW moves in the same direction as electric current via spin-Hall torque. The observed DW motion in this experiment was in thermally activated creep regime. The DW creep velocity decreased with increasing the gate voltage, i.e., increasing the electron density at the surface of the Co layer.

Th.G-P04 - First-principles density functional study on magnetic-anisotropy-energy non-linear variation by electric field in double Fe/MgO interfaces

D. Yoshikawa [1], M. Obata [1], S. Haraguchi [1], Y. Taguchi [1], T. Oda [1,2]

2. Institute of Science and Engineering, Kanazawa University, Japan

Controlling of the magnetic anisotropy energy (MAE) by electric field (EF) is one of the most interesting techniques for exploitation in magnetic random access memory (MRAM). The magnetization direction reversal, required for writing information, has been accomplished with the technique of spin-transfer torque (STT) effect, however there has been still the fatal problem, heating problem. The control of MAE by EF can solve this problem, because the reduction of energy barrier for magnetization reversal suppresses the heat. One of the most important problems in the technology is to find the magnetic material which shows an EF-sensitive MAE. To this aim, the mechanism for a large MAE variation by EF should be understood. In this context, we have investigated electronic structures and MAEs of double Fe/MgO interfaces [2,3]. We have carried out the first-principles density functional computation for the slab models MgO/Fe/MgO and Fe/MgO/Fe, using fully relativistic ultrasoft pseudopotentials, planewave basis, and generalized gradient approximation (GGA). We estimated the MAEs in the MgO/Fe/MgO with respect to the EF. The variation ratios of MAEs with respect to the EF were obtained to be in good agreement with the experimental data [4]. We found that there was a remarkable correlation between the MAE variation and number of electrons on the interface Fe atom [3]. We calculated the orbital-angular-dependent partial density of states (PDOS) of the interface Fe atom, and found that there were very interesting features around the Fermi energy. In the presentation, we discuss dependence on the number of layers and a possible origin of MAE non-linear variations.

4. CREST, Japan Science Technology, Japan

Voltage control of magnetism in ferromagnetic thin-films has attracted much attention as the ultimate technology for low-power operation of spintronic devices. In particular, the voltage induced magnetic anisotropy change in ferromagnetic metals [1,2] is promising since the control is applicable for magnetic tunnel junction devices. As a mechanism of the anisotropy change, changes in the electronic occupation state of *d*-orbital and in the band structure by the electric-field-induced accumulated charge at the ferromagnet/insulator interface are plausible, which may lead to a change in the interfacial perpendicular magnetic anisotropy through the spin-orbit interaction. However, no experimental evidence to prove this mechanism has been reported. In the present study, the electric-field effect on the magnetic properties of $L1_0$-FePt ultrathin layer was investigated by x-ray magnetic circular dichroism (XMCD) spectroscopy at the Pt L edges.
An MgO(100)substrate/MgO(3 nm)/Cr(20 nm)/Pd(50 nm)/[Fe(1.4Å)/Pt(2.0Å)]2/MgO(5 nm) multilayer was fabricated by molecular beam epitaxy. The FePt layer was prepared by alternate deposition of pure Fe and Pt. The film was coated with a polyimide (1500 nm) layer in the air immediately taken out of vacuum. Magnetization hysteresis loops demonstrated perpendicular magnetic anisotropy of the $L1_0$-FePt layer increased at a negative bias voltage, which induces charge depletion at the FePt/MgO interface. The XMCD measurement under voltage application was performed at BL39XU of SPring-8 synchrotron radiation facility. Our sum rule analysis showed that the effective spin magnetic moment (m_{spin} - $7m_T$) in Pt increases about 10% under negative bias voltage, which would be correlated to the voltage induced magnetic anisotropy change in FePt.

Magnetic tunnel junctions (MTJs) are very important for applications in field sensors, magnetic random access memories and spin logics. Recently there are a lot of efforts aiming at electric-field control of magnetism in MTJs to manipulate their electronic transport property, which could lead to ultralow-energy-consumption devices. So far two methods have been demonstrated for the electric-field control of electronic transport property in MTJs. One is the MTJ with a ferroelectric or multiferroic barrier, which works at low temperatures. Another one employs an electric field to switch the magnetic moment of ultrathin ferromagnetic layer of MTJ with voltages close to the breakdown voltage of the junctions and the assistance of a magnetic field. Therefore, electric-field modulation of tunneling magnetoresistance (TMR) at room temperature without a magnetic field is highly desired. One promising way is to employ the strain-mediated coupling in ferromagnetic/piezoelectric structure, in which remarkable electric-field controls of magnetism have been widely achieved at room temperature. Though MTJs/piezoelectric has been predicted by theory, experiment work is still lacking. We fabricated the key structure of MTJs CoFeB/AlOx/CoFeB on Pb(Mg1/3Nb2/3)0.7Ti0.3O3 (PMN-PT) ferroelectric single crystal. Electric fields can result in a piezostrain in PMN-PT, which transfers to the ferromagnetic film leading to change in magnetic anisotropy. We demonstrate a reversible, continuous magnetization rotation and manipulation of TMR at room temperature by electric fields without the assistance of a magnetic field. This work provides a new approach to manipulate the spin state and TMR of MTJs via electric fields, and should be significant for electric-field controlled spintronics.

Th.G-P07 - Underlayer material dependence of perpendicular magnetic anisotropy in CoFeB/MgO tuned by electric fields

W. Skowronski [1,2], T. Nozaki [2], Y. Shiota [2], S. Tamaru [2], K. Yakushiji [2], H. Kubota [2], A. Fukushima[2], S.Yuasa [2], Y. Suzuki [2]

Magnetic multilayer systems with perpendicular magnetic anisotropy (PMA) are suitable for the next generation magnetic random access memories (MRAM) due to their increased thermal stability and better scalability than in-plane magnetized systems [1]. In addition, magnetization of ultra-thin ferromagnets can be switched by ultra-fast electric-field pulses [2], or controlled in magnetic tunnel junctions (MTJs) used as magnetic field sensors [3] or radio frequency detectors [4].
We present studies on the PMA energy of thin CoFeB films deposited on metallic underlayers: Pd, Pt, Ta, Ir, W, CuN, Zr and Nb. In selected multilayer systems, we have measured CoFeB magnetic moment and the saturation field thickness dependence in order to calculate the magnetic dead layer and the PMA energy. We have repeated this investigation after annealing multilayers at various temperature up to 450°C.
The multilayer system with Ir underlayer exhibit very high interface PMA energy of 1.9 mJ/m2 stable up to 300°C. By using W buffer smaller PMA of 1.2 mJ/m2 is measured, however, the thermal stability is confirmed up to 450°C. In addition, we fabricated MTJ structure of CoFeB (0.88 nm)/MgO(2.5 nm)/CoFeB(5 nm) in order to investigate an influence of the electric field on PMA. We measured change of the anisotropy energy per applied electric field of up to 100 fJ/Vm. In order to prove the repeatability and high operation speed we have measured voltage induced ferromagnetic resonance up to 30 GHz in patterned MTJ driven by radio frequency stimuli, tuned by the static electric fields.

Th.G-P08 - Electric-Field modulation of magnetic anisotropy in the system under magnetic proximity effect

Y. Hibino [1], T. Koyama [1], A. Obinata [1], K. Miwa [2], S. Ono [2], D. Chiba [1]

1. The University of Tokyo, Tokyo, Japan
2. Central Research Institute of Electric Power Industry, Japan

Electric field control of magnetism in ferromagnetic materials (FMs) using a capacitor structure has attracted a great deal of attention in the research field of spintronics [1]. Recently, the electric field manipulation of magnetism has been focused not only to the FMs but also the non-magnetic material Pt [2] and Pd. Pt and Pd is known to be an exchange-enhanced paramagnetic material, which the Stoner criterion for ferromagnetism satisfies due to the large peak in the density of states near the Fermi surface. In addition, It has been reported that the magnetic moment of Pd and Pt is induced at the interface adjacent to the FMs (magnetic proximity effect) [3]. We focused on this induced magnetic moment in Pd and manipulated its magnetism especially the perpendicular magnetic anisotropy (PMA).
We have studied the electric field effect on the PMA of perpendicular magnetized Pd/Co/Pt system. By applying electric field to the Pd layer using ionic liquid, the PMA of the whole system significantly changed up to 0.12 mJ/m^2 even though the Pd is non-magnetic material in ordinary. One of the possible origin of the effect is the relative change in electron occupation state of 4d orbit in the spin polarized Pd due to the proximity effect. This result indicates that the electric field effect is valid even in the ferromagnetic system created by the proximity effect.

Th.G-P09 - Strain mediated voltage control of metal-insulator transition in VO_2 / PMN-PT heterostructures

A. Petraru [1], R. Soni [1], H. Kohlstedt [1]

1. Nanoelektronik, Technische Fakultõt Der Christian-Albrechts-Universitõt, Zu Kiel, Germany

Vanadium oxide (VO_2) is a correlated electron material that exhibits a first-order metal-insulator phase transition (MIT) accompanied by a drastically change in electrical resistivity of up to five orders of magnitude as well a large change in infrared transmission. These properties make VO_2 potentially useful for electrical, optical and electro-optical switches and sensing applications. The transition temperature can be controlled in a relatively wide range by doping or by strain. In this work we focus on controlling the transition temperature of VO_2 in form of epitaxial thin films via strain. Thus, we choose 0.72Pb(Mg1/3Nb2/3)-0.28PbTiO3 (PMN-PT) piezoelectric crystalline substrates for this propose. Due to their huge piezoelectric coefficients in the order of 2500 pm/V, the PMN-PT substrates are used to impose additional amount of biaxial strain to the VO_2 films, by applying an external bias to the substrates. The films were deposited using pulsed laser deposition method, starting from a V2O5 ceramic target. By employing X-Ray diffraction measurements, the lattice parameters of the PMN-PT substrates and VO_2 films were measured as a function of applied bias to the substrate. We show that a reversible biaxial in-plane strain of 0.1 ± 0.01% at an electric field of E = 10 kV/cm is achieved by applying the E field perpendicular to the substrate plane. The strain is partly transferred to the epitaxial VO_2 film on top and acts in the (110) plane of the rutile phase of the VO_2 films. We investigate the influence of the biaxial strain on the transition temperature and on the conductive properties of the VO_2 films. Additionally, the influence of the surface charge modifications at the interface VO_2 / PMN-PT (ferroelectric) on the conductive properties of the vanadium dioxide films is investigated.

Th.G-P10 - Electric field effect on induced magnetic moment in Pd

A. Obinata [1], D. Hayakawa [1], Y. Hibino [1], T. Koyama [1], K. Miwa [2], S. Ono [2], D. Chiba [1]

1. The University of Tokyo, Japan
2. Central Research Institute of Electric Power Industry, Japan

Recently, electric field control of magnetism in ultra-thin ferromagnetic metals has attracted attention in the research field of spintronics*1,*2. Electrical modulation of electron density at the surface of them plays a main role for achieving it. On the other hand, it is known that the magnetic moment is induced in Pd layer by contacting it with that of a ferromagnetic transition metal element such as Co *3 (the ferromagnetic proximity effect). We aimed to control this proximity-induced magnetic moment in Pd by applying gate electric field. For the observation of the change in the magnetic moment under gating, we deposited MgO/Pd(1.7 nm)/Co(tCo)/Pt(4.1)/Ta from the surface side on an intrinsic Si substrate by rf sputtering. The magnetic moment was confirmed to be induced in whole Pd layer at 10 K for the present Pd thickness. We fabricated an electric double layer capacitor structure with an ionic liquid as a gate insulator*2. A gate voltage VG was applied between the bottom Pd and the top nonmagnetic Au electrode through the ionic liquid. By applying an electric field to the ferromagnetic surface of this Pd layer, a clear change in the magnetic moment below Curie temperature, which was directory measured using SQUID magnetometer, was observed. This indicates that the induced magnetic moment in non-magnetic metals by the proximity effect are electrically tunable.

Th.G-P11 - Correlation between resistive switching behavior and ferromagnetism in pure ZnO thin films

Y. Hu [1], S. Li [2]

1. Department of Applied Physics, National University of Kaohsiung, China
2. Institute of Electro-Optical Science and Engineering, National Cheng Kung University, China

In the past decade, zinc oxide (ZnO) doped with minute amounts of transition metal elements has been intensively investigated as a promising diluted magnetic semiconductor for possible spintronic applications. However, room temperature ferromagnetism (RT-FM) in pure or nonmagnetic-element-doped ZnO films has been frequently reported, implying that the magnetic moments arise solely from native defects. Meanwhile, the resistive switching properties that are very common in a variety of oxide thin films have also been ascribed to native defects. In this work, we prepared Ti/ZnO/Ti multilayer films by using a magnetron sputtering method with different O2/Ar gas ratios. All of the samples were deposited on c-plane sapphire substrates at RT. Bipolar resistive switching (RS) behavior were observed in the sample grown without O2 gas. An introduction of O2 gas during film growth increases the set voltage and finally destroys the RS behavior. Photoluminescence results show that the intensity of the emission due to oxygen vacancies decreases with an increase in O2/Ar gas ratio during film growth. In particular, we measured the M-H curves of the sample grown without O2 gas in initial, high resistance (HR), and low resistance (LR) states. The pure ZnO sample with the best bipolar RS behavior is ferromagnetic in all of the states, and the saturation magnetization of the sample in LR and initial states is the largest (~1.8 emu/cm3) and smallest (~0.4 emu/cm3), respectively.
These results clearly demonstrate that the bipolar RS behavior in pure ZnO film is due to the existence of oxygen vacancies, and a voltage-controlled ferromagnetism in oxide thin film may be achieved for potential magneto-electrical device applications in the near future.

Th.G-P12 - Magnetoresistance in amorphous alloys and thin ferromagnetic films

J. Zapata Farfan [1], H. Montiel Sánchez [1], G. Alvarez Lucio [2]

1. Universidad Nacional Autónoma De México, Centro De Ciencias Aplicadas Y Desarrollo Tecnológico, Circuito Exterior S/N, Ciudad Universitaria, Delegación Coyoacán, México
2. Instituto Politécnico Nacional, Escuela Superior de Física y Matemáticas, México D.F. México

The phenomenon of Anisotropic Magnetoresistance (AMR) was measured in amorphous alloys and thin ferromagnetic films with the same composition. Measurements were carried out with the four probe technique, by means of a sample holder specially designed for the experimental setup, according to the electromagnet that is used, since there are no commercial devices. Ferromagnetic samples were introduced into a magnetic field with a mechanical system capable of rotating 180 degrees with the aim of detecting the angle for the highest variation of electrical resistance and make a characterization obtaining the percentage of AMR change and the easy or hard axis, according to AMR theory. All samples were swept in magnetic field between -1 to 1 T and in current in a range from 1 fA to 0.1 A in order to determine AMR, This phenomenon was first observed in Gold and Nickel to validate the system, finally it was observed a maximum electrical resistance change when the magnetic field orientation is perpendicular to the easy axis of the ferromagnetic materials and it is associated with intrinsic magnetic properties of the material. It is necessary to mention that we carried out all the instrumentation for the AMR technique.

Jennyfer Zapata want to thank the National Council for Science and Technology of Mexico (CONACYT) for the financial support.

Th.G-P13 - Voltage controlled optical and magnetic properties in ferromagnetic nanostructures studied by optical spectroscopies

L. Ohnoutek [1], L. Beran [1], R. Antos [1], M. Veis [1], A. Jun Tan [2], U. Bauer [2], G. S. D. Beach [2]

1. Charles University in Prague, Faculty of Mathematics and Physics, Prague, Czech Republic
2. Department of Materials Science and Engineering, Massachusetts Institute of Technology, Cambridge, Massachusetts, United States

Control of magnetization in ferromagnetic nanostructures via electric field is essential for development of novel spintronic devices. Recently, Bauer et al [1,2] reported switching of magnetic properties by electrically modulated interfacial chemistry at Co/metal-oxide interface. Detailed studies of this interface are necessary to fully understand the mechanisms responsible for magnetization changes. Magneto-optical (MO) spectroscopy and spectroscopic ellipsometry are highly sensible and non-destructive methods, which can probe magnetic and optical properties of nanostructures with depth sensitivity and provide the opportunity to study the voltage induced interface effects responsible for the changes in magnetic anisotropy as well as in optical properties of ferromagnetic nanostructures. The investigated Ta(4 nm)/Pt(3 nm)/Co(0.9 nm)/GdOx(4 nm) films were prepared by dc magnetron sputtering at room temperature under 3 mTorr Ar with a background pressure of ~1x10-7 Torr, on thermally-oxidized Si(100) substrates. The gadolinium oxide (GdOx) layer was sputtered from a metal Gd target at an oxygen partial pressure ~5x10-5 Torr. Gate electrodes of Au(5 nm) were deposited through a shadow mask. Measurements of MO Kerr rotation and ellipticity were carried out on magnetically saturated samples in polar and longitudinal configuration. The spectral range of the experiments was from 1.2 to 5.5 eV. Spectroscopic ellipsometry experiments employed Muller matrix ellipsometer Woolam RC2. The spectra were acquired for as deposited sample and for samples modified by applied voltage up to 8 V. Both spectroscopic ellipsometry as well as MO spectroscopy clearly showed changes in optical and MO properties of studied nanostructures with applied voltage. Comparison of the experimental results with theoretical models revealed the voltage induced changes at Gd/GdOx interface.

3. Central Research Institute of Electric Power Industry, Japan

Electric field-induced modulation of magnetic properties such as coercivity[1] , magnetic anisotropy[2, 3], and Curie temperature TC[4, 5] in metallic magnets opens up a new paradigm of spintronic devices for achieving ultra-low power consumption. Recently, it has been found that an electric double layer capacitor (EDLC) provides much larger charge accumulation than a solid capacitor due to the extremely large capacitance [1, 5]. In this presentation, we demonstrate electrical modulation of blocking temperature TB in superparamagnetic Ni/Cu system by using EDLC. A Ni(1.5 nm)/Cu(1.0 nm) layer with a Ta(2.6 nm) buffer layer was deposited on a GaAs (001) substrate by rf sputtering. The Ni layer was covered with a 2-nm-thick MgO layer to protect it against oxidization. We made a capacitor structure which is composed of the Ni layer as a bottom electrode, an Au thin film as a gate electrode, and an polymer film containing ionic liquid (TMPA+-TFSI-) sandwiched between them. When a gate voltage VG is applied, the electric double layer is formed across the MgO layer, and the electric field is applied to the surface of the Ni layer. To determine the TB under the application of VG, we measured the zero-field-cooling magnetization using a superconducting quantum interference device [5]. TB was observed to increase with VG, and the amount of the change was about 8.6 K for VG = ü}2 V. We ascribe the change in TB to the electric-field-induced change in magnetic anisotropy.

Th.G-P15 - Direct imaging of reversible electric control of magnetic domains in $La_2/3Sr_1/3MnO_3$

M. Foerster [1], D. Pesquera [2], B. Casals [2], F. Sanchez [2], G. Herranz [2], L. Aballe [1], J. Fontcuberta[2]

Electric control of magnetic devices is a current research activity of major interest. In this direction, electric control of magnetic anisotropy via magnetoelastic coupling in magnetic films grown on piezoactuators, appears as a simple and potentially convenient strategy. However, a critical issue is the deterministic selection of the magnetization direction through strain-induced flop of the magnetization to orthogonal directions. Here we address this problem by observing the magnetic domain evolution of $La_2/3Sr_1/3MnO_3$ (LSMO) thin films grown on piezoelectric PMN-PT (001) substrates. We have used photoemission electron microscopy with X-ray magnetic circular dichroism contrast (XMCD-PEEM) to monitor in-situ the domain reconfiguration upon applying a voltage bias to the piezo substrate. Out of plane electrical fields were applied to the substrate using the LSMO as top electrode and a silver paint bottom electrode. Starting from a pre-poled state, the magnetic domain pattern in the XMCD image reflects an effective uniaxial anisotropy (twofold) of the film. Upon reversing the poling voltage applied at the piezo substrate, we observe changes in the domain pattern that indicate a biaxial (fourfold) anisotropy upon passing the substrate coercive field. Interestingly, when returning to the original poling, not only the uniaxial anisotropy is restored, but also the new domain configuration is almost identical to the previous one, i.e. the same distribution of north and south domains, which is not expected from the axial (i.e. not directional) nature of an electrically induced magnetic anisotropy mediated by strain.

Th.G-P17 - Distinguishing spin-torque from electrical modification of anisotropy in voltage-induced ferromagnetic resonance

C. Gonzalez [1], C. Garcia [1]

1. Departamento de Fisica, Universidad Tecnica Federico Santa Maria, Valparaiso, Chile

During the last years, there has been an increasingly interest in the possibility control of magnetic dynamics by electric fields. Some recent experiments [1,2] in magnetic tunnel junction (MTJ) nanopillars have been demonstrated that the electric field can modify the magnetic perpendicular anisotropy on such devices, leading to voltage-induced ferromagnetic resonance. However, it has also been showed that there should be an important contribution of spin torque in such MTJ's response [1]. In this work, we present an analytic model to predict the magnitude and the lineshape of the voltage-induced ferromagnetic resonance, which permits distinguish the electric field and spin torque contributions to the magnetization dynamics. Our results are in good agreement with a recently published work in CoFeB/MgO/CoFeB MTJs [2]

Th.G-P19 - Electrical writing of magnetic and resistive multistates in CoFe films deposited onto $Pb[ZrxTi_1\text{-}x]O_3$

V. Iurchuk [1], B. Doudin [1], J. Bran [1], Bohdan Kundys [1]

1. Institut de Physique et Chimie des Matériaux de Strasbourg, France

Ever increasing miniaturization requirements stimulate large research efforts to find alternative to magnetic field methods to control magnetization in magnetoresistive memories. Use of electric field induced deformation energy of piezoelectric elements is a promising way of magnetization control. The reversible electromagnetic coupling with electric fields applied to a whole substrate was demonstrated to result in 'two states' operation [1]. However the technologically important surface electric field control, multistate operation and ability to erase the written states with electric fields have not been proven till recently [2,3]. In this work we describe the subcoercive and surface operation to write and erase remnant magnetic and resistive states in CoFe overlayer deposited on ferroelectric $Pb[ZrxTi_1\text{-}x]O_3$. Magneto- and electroresistance responses are further explored as the functions of CoFe thickness. The simplest resistance strain gage-like structure is realized as a multistate memory cell demonstrating both resistive memory (RRAM) and magnetoresistive memory (MRAM) functionalities in a single device.

Nowadays electronic devices are dissipating more and more power. Hence, the use of the heat currents generated in adjacent electronic circuits for running devices (without other source of energy) is a promising strategy in terms of energy efficiency. Since 2008, a large number of publications have reported a surprising magneto-voltaic signal measured on a ferromagnetic electrode in response to a thermal excitation. In our presentation we will show that the observed magneto-voltaic signal can be accounted by anomalous (also called magnon hall) and planar Righi-Leduc effects. The Righi-Leduc effect refers to the thermal analogue of the Hall effect, for which the electric current is replaced by the heat current and the generated electric field by the temperature gradient. In both cases, the magnetic field generates a transverse force that deviates the carriers (electron, phonon, magnon) in the direction perpendicular to the current. In a ferromagnet, the magnetization plays the role of the magnetic field, and the corresponding effects are respectively called anomalous Hall and anomalous Righi-Leduc (ARL). Furthermore, a second transverse contribution due to the anisotropy, the planar Hall effect, is superimposed to the anomalous Hall effect has also a thermal counterpart named planar Righi-Leduc effect (PRL) [1]. We will report experimental evidences of those thermal counterparts in ferromagnets that are either electrical conductor (NiFe) or insulator (YIG). Varying the measurement geometry we demonstrate that the recorded magneto-voltaic signals follow the symmetry associated to ARL and PRL. Moreover their signs and amplitudes are strongly dependent on the capping layer nature. This fact is well explained by considering the presence of thermocouples in the used multilayer.

Th.H-P02 - Spin-dependent Peltier effect in a lateral spin-valve device with epitaxial Heusler-compound electrodes

K. Yamasaki [1], S. Oki [1], S. Yamada [1], T. Kanashima [1], K. Hamaya [1,2]

1. Osaka University, Japan
2. Osaka University and JST-CREST, Japan

In the field of spin caloritronics, the spin-dependent Peltier effect was experimentally detected in nanopilar spin-valve structures [1]. If giant pure spin currents are injected from a ferromagnetic material into a nonmagnetic one, one can detect the spin-dependent Peltier effect even in a lateral spin-valve (LSV) structure [2]. So far, we have developed a technique for generating giant pure spin currents at room temperature by using epitaxial Co-based Heusler-compound Co_2FeSi (CFS) films [3]. Here, we demonstrate the spin-dependent Peltier effect in a LSV with the epitaxial CFS electrodes.
We first confirmed the generation of giant pure spin currents in LSVs [3]. By using the same LSV and a second-harmonic ac lock-in technique, we observed thermally induced spin injection, so called spin-dependent Seebeck effect [4], at room temperature and obtained the spin-dependent Seebeck coefficient of ~ -15.8 μV/K. By changing terminal configuration and a thermocouple electrode in the same LSV, we detected clear spin Peltier signals under spin-injection conditions and the spin-dependent Peltier coefficient of ~ -4.74 mV was obtained. This study is the first observation of the spin-dependent Peltier effect in the LSV structure.
This work was partly supported by CREST from JST and by Grant-in-Aid for Scientific Research on Innovative Areas “Nano Spin Conversion Science” (Grant No. 26103003).

Th.H-P03 - Observation of spin-dependent peltier effect using anomalous nernst effect

T. Nomura [1], G. Uematsu [1], S. Hu [2], T. Kimura [1,2]

1. Department of Physics, Kyushu University, Japan
2. Research Center for Quantum Nano-Spin Science, Kyushu University, Japan

Recent development in understanding the interplay between heat and spin produces unique heat-utilizing application based on spins. A representative and fascinating phenomenon is thermal spin injection, in which excess heat can be used to produce spin current through the spin-dependent Seebeck coefficient. Recently, we have found that CoFeAl show the excellent property for the thermal spin injection because of the large spin-dependent Seebeck coefficient. According to the reciprocal relationship, a large spin-dependent Peltier coefficient will be expected at the CoFeAl/nonmagnetic-metal interface. However, because of the difficulty of the heat manipulation, it was difficult to detect the signal related to the Peltier effect. Here, we demonstrate that the spin-dependent Peltier effect can be observed by using the anomalous Nernst effect.
The sample used for the present study is a conventional lateral spin valve structure consisting of two CoFeAl wires bridged by a Cu wire. Here, the heat current induced by the spin-dependent Peltier effect at one CoFeAl/Cu interface was detected as the Anomalous Nernst voltage at the other CoFeAl/Cu interface. It should be noted that, under the electrical spin injection, the voltage due to the spin-dependent Peltier effect shows the field dependence similar to the spin valve signal under the electrical spin injection. Therefore, the spin current was created by the thermal spin injection. The field dependence of the voltage under the thermal spin injection shows a clear asymmetric behavior supporting the existence of the spin-dependent Peltier effect.

Th.H-P04 - Spin-thermoelectric voltage in the ste element using LPE YIG films grown on GGG substrates

Y. Li [1], Y. Kono [2], K. Mizunuma [2], Y. Saiga [2], M. Imamura [1]

1. Fukuoka Institute of Technology, Japan
2. DENSO CORPORATION Research Laboratories, Japan

The voltage generated when a temperature gradient dT is applied to the element fabricated with an ultrathin platinum layer coated on an yttrium iron garnet magnetic plate is called a spin-thermoelectric (STE) voltage, and the voltage has been considered to be due to the spin Seebeck effect based on spin currents driven by a temperature gradient. We present the results of measurements on the STE voltage of a device composed of 4-10micro-m-thick YIG films grown on a 10x10x0.5mm3 gadolinium gallium garnet substrate by using liquid phase epitaxy and the Pt- coating layer applied to the YIG film surface by sputtering. Crystallinity was evaluated by an x-ray diffraction, and it was confirmed that the films were grown with high crystallinity on the GGG substrate showing the very sharp (111) diffraction spectra of 20,000 counts at 2theta=51.5ó¬. Magnetic characteristics of the films were measured by using VSM. The in-plain saturation field to the film surface was a small value of 25 Oe and the Hc value was ~1 Oe. The STE measurements were made at the probe distance of 5mm for the temperature difference dT of 30 °C. The thickness of Pt-coating was 1.4 nm. The STE voltage values of 9.3-12.2 micro-V/K observed in the elements using the 4-10micro-m-thick LPE YIG films are almost equal to the values measured for 0.5mm-thick YIG bulk plate crystals. These good results in the STE voltage measurements are considered to show that the LPE YIG films used in this SSE experiment have good crystallinity. We have studied the Pt-coating thickness dependence of the spin-Seebeck voltage in the Pt-YIG configuration for 0.5mm-thick bulk YIG plates in detail. The electric current density in the Pt-coating is discussed as well as the dependence of STE voltage on the Pt-coating thickness.

Since the discovery of the spin Seebeck effect (SSE) [1] much attention has been devoted to the study of the interaction between heat, spin and charge in magnetic systems. The SSE refers to the generation of a spin voltage upon the application of a thermal gradient, which is detected by means of the inverse spin Hall effect (ISHE). Unlike the conventional Seebeck effect which requires the presence of electronic carriers, the SSE has also been observed in insulating magnetic materials, opening the possibility to explore magnetic oxides as potential candidates for thermoelectric applications. Therefore the study of the thermomagnetic transport properties in this type of materials is of interest in order to gain insight in the spin-heat interaction. Here, we report optimization of the SSE in Fe_3O_4/Pt thin film heterostructures at room temperature by variation of several degrees of freedom of the structures. It has been previously shown that in this system the measured voltage is highly dominated by the SSE [2] and that the anomalous Nernst effect of magnetite [3] accounts for less than 1%. Our results further show that the SSE is characterized by a diffusive spin transport behavior and that the spin pumping across the Fe3O4/Pt is strongly affected by the interface parameters.

Th.H-P06 - Magnetic field induced spin wave energy focusing

N. Perez [1], L. Lopez-Diaz [1]

1. University of Salamanca, Salamanca, Spain

The capacity of spin waves to transport both energy and angular momentum as they propagate is at the heart of the emerging fields of spin caloritronics [1] and magnon spintronics [2]. To successfully translate fundamental research in these fields to technology it is crucial to be able to manipulate the flow and delivery of energy carried by spin waves in a controllable and flexible way over different length scales. An et al [3] took a first step in this direction, showing that magnetostatic surface spin waves (MSSW) allow for non-reciprocal unidirectional propagation and for remote heating at the sample edge towards which they propagate. In our work, we study these local temperature variations induced by spin wave propagation by means of a model that couples non-uniform magnetization dynamics and heat flow. We show that the remote heating reported by An et al [3] is due to geometry-induced gradual reduction of the effective field (the sample is cut at the edges, and the reduced width produces an increase of the demagnetizing field). We demonstrate that the same effect can be achieved by a reduction in the external field instead of a constriction at the edge and, furthermore, that both the location and the amount of energy to be delivered to the lattice can be controlled accurately this way. With our proposed system, up to 40\% of the magnetic energy pumped by an antenna could be delivered to a small area several millimeters away, opening the door to promising spintronic and spin caloritronic devices.

Th.H-P07 - Longitudinal spin seebeck effect in Bi-substituted neodymium iron garnet on GGG substrate prepared by MOD method

H. Asada [1], A. Kuwahara [1], K. Sueyasu [1], T. Ishibashi [2], Q. Liu [2], G. Lou [2], K. Kishimoto[1], T. Koyanagi [1]

1. Yamaguchi University, Japan
2. Nagaoka University of Technology, Japan

Spin-thermoelectric coating based on a longitudinal spin-Seebeck effect (LSSE) has been demonstrated using $Y_2BiFe_5O_{12}$ formed by a metal-organic decomposition (MOD) method which is one of the most attractive techniques for preparation of large-area films at low cost[1]. In order to find out the material with large thermo-spin conversion efficiency, the systematic study for various materials is quite important. In this paper, we investigate the LSSE in Bi-substituted Neodymium Iron Garnet (Bi:NIG) prepared by MOD method and examine the dependence of thermoelectric voltage on Bi composition. Nd^{3+} has similar ionic radius (99 pm) with Bi^{3+} (102 pm) which is effective to maintain the good crystallinity when Nd is substituted by Bi. $Nd_{3-x}Bi_xFe_5O_{12}$ films (x=0-1) with a thickness of approximately 200 nm were prepared on (001)-oriented GGG substrates by MOD method. After annealing (700 °C for 13 h in air), a Pt layer with a thickness of 10 nm and a size of 7x1 mm^2 was deposited by sputtering. The 008 diffraction peaks of Bi:NIG are observed and other phase does not be observed in the XRD patterns in all films, indicating the highly oriented Bi:NIG films are obtained. The electric voltage caused by LSSE in the Bi:NIG/Pt samples are measured by applying a temperature different of 10 K perpendicular to the film plane. By reversing the applied magnetic field, the LSSE signals of the samples indicate the clear hysteresis reflecting the M-H loop. It is clarified that the LSSE voltage increases with increasing Bi in this composition range. The amplitude of the LSSE voltage for x=1 is approximately two times larger than that for x=0. Magnetic properties of Bi:NIG films are also discussed.

The interaction between heat and spin currents has been a very active field of study and highly boosted recently since the discovery of the Spin Seebeck effect (SSE). The mechanism and control of spin injection, detection and, in general, the optimization of SSE signal is still in progress. Here we present experimental results in agreement with the magnonic bulk thermal current model but in contrast to interface based models used for metals and semiconductors.
Fe_3O_4 epitaxial thin films with different thickness were deposited on a magnesium oxide substrate by means of pulsed laser deposition (PLD) in an ultrahigh-vacuum chamber. The quality and properties of the films were checked by X-ray diffraction, X-ray reflectivity, magnetization and resistivity vs temperature and transmission electron microscopy. Anomalous Nernst effect (ANE) and SSE measurements were performed to careful study the characteristic dependence of thermomagnetic signal on the thickness of the magnetite. The experimental data is in agreement with reported models[1,2] where the bulk spin current is calculated macroscopically with the Boltzmann equation for the magnon flow. Following this model the estimation of the magnon diffusion length in magnetite thin films is 40 ± 10 nm.

Structuring of materials is the most general approach to control wave properties in a solid body. Spin waves – eigen excitations of the electrons' spin system – are of special importance nowadays due to the large potential for applications (e.g. processing[1], filtering[2,3] or short-time storage[4] of data). While all these applications rely on pre-defined constant structures, a dynamic variation of the structures opens access to novel physical phenomena and to novel applications.
Here, we present an approach for the realization of fully-tunable two-dimensional magnetic materials. By using laser light of 532 nm wavelength and a spatial light modulator, we reconstruct computer generated holograms[5] on a 5 micrometer thick, ferrimagnetic Yttrium Iron Garnet (YIG) spin-wave waveguide. The absorbed light creates local temperature patterns (thermal landscapes) in the magnetic medium. A black absorber (including carbon black nanoparticles) painted on top of YIG increases the absorption and, thus, the contrast of the thermal landscape due to the approximately one order of magnitude smaller thermal conductivity compared to YIG. An acousto-optical modulator controls the temporal heating. The local change in temperature results in landscapes of the saturation magnetization and in the control of spin-wave characteristics. The proposed fully-reconfigurable magnetic material is demonstrated on the example of one- and two-dimensional thermal landscapes, e.g., magnonic crystals – artificial periodic magnetic lattices.

Spin Seebeck effect is the mechanism of thermal spin injection from a ferromagnet into an attached paramagnetic metal [Uchida et al., Nature 455, 778 (2008)]. We have theoretically investigated the spin Seebeck effect in compensated ferrimagnets [Ohnuma et al., Phys. Rev. B 87, 014423 (2013)] and predicted that the sign of the spin Seebeck signal changes at the compensation temperature, which is recently confirmed by an experiment [Geprags et al., arXiv : 1405.4971 (2014)]. Interestingly, the experiment found another sign change at a lower temperature. Here we explain its origin by taking account of sublattice dependence of the exchange coupling at the ferrimagnet/paramagnet interface.

Th.H-P11 - Comprehensive study of nickel - zinc ferrites as an opportunity for spincaloritronic applications

J. Arboleda [1], O. Arnache [1], C. Ostos [2]

1. Grupo de Estado Sólido, Universidad de Antioquia, A. A. 1226, Medellín, Colombia
2. Grupo de Materiales Abosrbentes y Catalísis, Universidad de Antioquia, A. A. 1226, Medellín, Colombia

Current developments in spincaloritronics, especially the so mentioned Longitudinal Spin Seebeck effect (LSSE), have encouraged a particular interest in the search for insulating materials with some magnetic order (ferro/ferri). Spinel mixed oxides ferrites, such as Ni-Zn ferrite oxides (NZFO), are displayed as suitable candidates for this type of edge applications. We have prepared a series of polycrystalline NZFO whose composition is Ni1-xZnxFe2O4, with different concentrations of Ni and Zn (x = 0, 0.3, 0.4, 0.5, 0.7, 1) via solid state reaction. A pretty full study using several complementary techniques (XRD, XPS, SEM, EDS, XRF, VSM, Mössbauer spectroscopy, and DC transport measurements) show a very interesting structural, magnetic and electric behavior depending of Zn concentration. Crystal structure goes from inverse spinel (Ni-ferrite, x=0) to normal spinel (Zn-ferrite, x=1) with a fairly accurate elemental composition. Intermediate concentrations exhibit mixed spinel structure. Likewise, magnetic order change from ferromagnetic to antiferromagnetic. We suggest a Yafet-Kittel magnetic ordering in the mixed ferrites, based on magnetic measurements. Further, high electrical resistivity was observed in all samples, which is desirable for LSSE measurements free for artifacts signals such as ANE. Therefore, our results show that the NZFO have physical properties with promising characteristics for differents types of applications, in particular, they could be good candidates for the active field of spincaloritronic.

Th.H-P12 - Enhancement of spin-injection-induced electrical voltage using thermally excited CoFeAl film

G. Uematsu [1], T. Nomura [1], M. Kawakita [1], K. Okabe [1], S. Hu [2], T. Kimura [1,2]

1. Department of Physics, Kyushu University, Japan
2. Research Center for Quantum Nano-Spin Science, Kyushu University, Japan

Enhancing the efficiency of generation of the spin current is imperative and a primary issue for the practical application of spin-based electronics, seamless device integration with the conventional complementary metal-oxide semiconductor technology is another important milestone for developing spin-based nanoelectronics. Thermal spin injection, which is a recently discovered unique characteristic of spin current, may be an innovative method for simplifying device integration without the need for electricity. Recently, we have found that CoFeAl has an excellent property for the thermal spin injection because of its unique band structure. In this paper, we focus on increasing the electrical voltage due to the thermal spin injection in a submicron-scaled lateral spin valve structure and sub-millimeter-scaled spin Hall device.
In the lateral spin valve structure, we have developed a multi-terminal ferromagnetic voltage probes.
By properly choosing the voltage probes with the optimized magnetization configuration, we have observed a large spin valve signal around 2 micro Volt by the thermal spin injection with suppressing the spurious signal induced by the anomalous Nernst effect.
In the spin Hall device, we have prepared the CoFeAl/Pt bilayer film with 200 micron in width and 600 micron in length. By creating the temperature gradient, we have observed a giant spin Hall signal over a few hundred micro volts. We have also confirmed that the voltage can be enhanced by the series connection of several spin Hall devices. This demonstration strongly enhances the potential of the CoFeAl as the material for spin-caloritronic devices.

Th.H-P13 - Utilization of antiferromagnetic electrodes in magneto-thermoelectric device for large area application

D. Kim [1], K. Lee [1], B. Park [1]

Magneto-thermoelectric (MTE) effect, a voltage generation due to temperature gradient in ferromagnet(FM)/non-magnet(NM) bilayers, has attracted interests because of its potential application for energy conversion well as the spin current source. The signal of the MTE strongly depends on the NM materials in which thermally-injected spin current is converted to voltage via inverse spin Hall effect (ISHE). Thus, the NM material with a large ISHE is essentially required to achieve a substantial MTE voltage. Recently, the ISHE has been reported in antiferromagnet (AFM) materials and its magnitude is comparable to those of Ta or Pt. Moreover, the AFM can be utilized for the control of magnetization reversal of the adjacent FM via exchange coupling. In this study, we investigated the MTE in the AFM IrMn/FM CoFeB structures, where the thermal voltage is generated by laser-induced vertical thermal gradient. We observed that the MTE voltage was gradually increased with IrMn thickness (tIrMn) up to 10nm and slowly decreased for larger tIrMn. The exchange bias between AFM and FM was developed when tIrMn is thicker than 13nm. We fabricated a pair of wires of an AFM/FM bilayer, of which one ends are connected each other. The tIrMn is controlled to be 10nm for one wires and 20nm for the other. As one with thicker tIrMn only shows an exchange bias, we can control the relative magnetic configuration of the wires. In the antiparallel configuration, the MTE signals from each wire are opposite sign so they are added, while they are the same sign thus subtractive in parallel alignment. Furthermore, the MTE voltage could be proportionally enhanced to the number of pairs formed in magnetic thermopile. Our results demonstrate that the employment of the AFM with a large ISHE and exchange biasing can be utilized in large area application of the MTE devices.

Th.H-P14 - Longitudinal spin-seebeck effect in cobalt-ferrite epitaxial thin films with different preferential axes

T. Niizeki [1], T. Kikkawa [1], K. Uchida [1], M. Oka [1], K. Z. Suzuki [1], H. Yanagihara [1], E. Kita [1], E. Saitoh [1]

One of the most attractive outputs from "insulator spintronics" [1] is recently-proposed thermoelectric (TE) generation using magnetic insulators (MIs) as TE power sources since it has potential advantages in versatility, costs, and ubiquitousness compared with conventional semiconductor-based TE devices [2]. This epoch-making MI-based TE generation is initiated by a heat-mediated pure-spin-current creation in MIs, called spin-Seebeck effect (SSE) [3, 4], and then followed by the electric conversion via the inverse spin-Hall effect (ISHE) [5, 6] in a paramagnetic metal such as Pt adjacent to the MI. Although the SSE has been demonstrated in soft MIs so far [3, 4, 7-9], SSE in hard MIs [10,11] is recently attracting much attention from the viewpoint of both physics and application. In this study, we focused on cobalt ferrite (CFO), an exceptionally hard magnetic spinel ferrite, as an anisotropy tunable SSE material and experimentally demonstrated the longitudinal SSE (LSSE) in a bilayer of Pt/CFO grown on different substrates. Epitaxially-strained CFO thin films were prepared on $MgAl_2O_4$ (MAO)(110) and MgO(001) substrates by reactive rf sputtering technique. The CFO(110)/MAO(110) exhibited an in-plane uniaxial anisotropy whereas CFO(001)/MgO(001) showed a perpendicular anisotropy. Thermally generated spin voltages in those CFO films were measured via the ISHE in the polycrystalline Pt deposited on the top. External-magnetic-field (H) dependence of the LSSE voltage (V_{LSSE}) with H || [001] in Pt/CFO/MAO sample exhibited a magnetic hysteresis loop with a high squareness and a large coercivity, whereas that in Pt/CFO/MgO showed a nearly closed loop, reflecting the magnetic anisotropies induced by the different epitaxial strain. The magnitude of V_{LSSE} has a linear relationship with the temperature difference (ΔT), giving the relatively large $V_{LSSE}/\Delta T$ of about 3 μV/K for CFO(110) which was kept even at zero external field. The temperature dependence of V_{LSSE} measured for various preferential axes will also be presented.

Th.H-P15 - Spin-thermoelectric transport in quantum spin hall systems beyond linear response

S. Hwang [1], R. Lopez [1], M. Lee [2], D. Sanchez [1]

1. Institut De Fisica Interdisciplinaria I Sistemes Complexos IFISC (CSIC-UIB), Palma de Mallorca, Spain
2. Department of Applied Physics, College of Applied Science, Kyung Hee University, Yongin, Republic of Korea

Spin-polarized transport is studied in a quantum spin Hall antidot system with a two-terminal setup [1]. Helical nature of the conducting edge states makes the screening potential at the dot region become spin dependent even without external magnetic fields nor ferromagnetic contacts. Therefore, the electric and heat currents due to voltage or temperature biases become spin polarized, where the degree of polarization can be tuned by dot energy level or the background temperature. We show that this spin-filter effect arises in the nonlinear transport regime only and has a purely interaction origin. Furthermore, our results show that a pure spin current can be generated by thermoelectric means: with a thermal bias applied, the created thermovoltage induces a spin-polarized electric current (spin Seebeck effect) for vanishingly small charge current. Analogously, pure spin heat can flow in response to a voltage shift even if the total thermal flux vanishes.

Th.H-P16 - Thermal and thermal gradient effects on microwave power spectral density of MgO based MTJ nanopillars

T. Böhnert [1], S. Serrano-Guisan [1], M. Tarequzzaman [1], J. D. Costa [1], E. Paz [1], R. Ferreira [1], P. P. Freitas [1]

1. INL - International Iberian Nanotechnology Laboratory, Braga, Portugal

Theoretical studies predict that temperature gradients can be an efficient method to generate magnetic excitations (TSTTs). A deep comprehension of such heat-driven magnetization dynamics phenomena is specially required in magnetic tunnel junction (MTJ) systems as it can provide a mean to overcome scalability limitations in magnetoresistive memory (MRAM) elements as well as to explore the contribution of heat dissipation on current-induced spin torque nano-oscillators (STNOs). Here we explore the influence of temperature and thermal gradient effects on magnetization dynamics on MgO/CoFeB based MTJ nanopillars with RA of ~ 3 uOhmm2. For this, high-frequency voltage noise measurements [2] (up to 20 GHz) were carried out in a temperature variable probe station enabling to compare current-biased microwave magnetization dynamics at different temperatures (Tps up to 125C) and bias voltages below the voltage breakdown (|V_bias |<400 mV). At low Tps (~ 25 C) the power spectral density is similar for both current polarities. But an increase in Tps leads to an increase of the spectral linewidth for Vbias > 0. Note that for opposite bias voltages (Vbias < 0) almost no modification on the linewidth has been observed, whereas the total emitted power (Pout) is increased by a factor of 4. As a general trend the ferromagnetic resonance f always decreases with Tps as a signature of the reduction of the coercivity field (and therefore the overall effective magnetic field) with temperature. In order to quantify the contribution of possible TSTTs on such effects, calibration of the effective temperature and thermal gradients developed across the MTJ nanostructure and temperature dependent resistance measurements of the bottom contact line will be addressed.

Th.H-P17 - Non-equilibrium thermodynamics of the longitudinal spin seebeck effect

V. Basso [1], E. Ferraro [1], A. Sola [1], A. Magni [1], M. Kuepferling [1], M. Pasquale [1]

1. Istituto Nazionale di Ricerca Metrologica, Torino, Italy

The longitudinal spin Seebeck effect (LSSE), measured in ferrimagnetic insulators, is the consequence of the transport properties of out-of equilibrium magnons which are at the same time responsible for heat and spin currents [1]. While the microscopic physics has been already investigated in detail, the thermodynamic aspects need further investigation [2,3]. In particular we aim to define a spin Seebeck coefficient ε_M, relating the magnetization current to the associated thermodynamic driving in insulators. Here we employ non-equilibrium thermodynamics to state the problem with currents and forces. As the magnetization current can be absorbed and generated inside the material, we need to state a continuity equation for the non conserved magnetization. Here we choose the simple form $dM/dt + \nabla \cdot j_M = (1/\tau)\,(H - H_{eq}(M))$, where M is the magnetization, j_M is the magnetization current, H is the magnetic field, $H_{eq}(M)$ the magnetic equation of state at equilibrium and τ is a relaxation time associated with the damping processes. We find that gradient of $(H-H_{eq})$ takes the role of the thermodynamic driving force. The theory permits to predict the LSSE effect for different thickness and type of sensing layer. In particular we apply this theory to the LSSE experiment of Ref.[4] in which a thermally generated spin current in a ferrimagnetic insulator (YIG) diffuses into a paramagnetic metal (Pt) where is revealed by the inverse spin Hall effect (ISHE). The part of the YIG spin current which is actually injected into Pt depends on the thicknesses of the layers and on materials dependent parameters: the damping and the correlation length. Once these values are estimated, by using literature values for YIG and Pt, the comparison with LSSE experiments, gives an estimate of the value of the intrinsic spin Seebeck coefficient.

Th.H-P18 - Microwave-induced spin currents in ferromagnetic-insulator|normal-metal bilayer system

V. Vasyuchka [1], M.Agrawal [1], A.Serga [1], V. Lauer [1], E. Papaioannou [1], B. Hillebrands [1]

1. Department of Physics and State Research Center OPTIMAS, University of Kaiserslautern, Kaiserslautern, Germany

The generation of a pure spin current in ferromagnet|normal metal systems recently has attracted a great attention. The spin Seebeck effect is one route to generate spin current by applying a heat current to ferromagnets. In particular, the longitudinal spin Seebeck (LSSE) effect is of much importance due to its technologically promising applications. Keeping the future application in focus, a comparative study of the spin current direction (flow) for different spin-current-generation processes like spin pumping and spin Seebeck effect is very crucial. In previous studies, the direction of the spin current in these processes has been determined by combining the FMR technique with additional dc/ac or Peltier based heating techniques.

Here, we demonstrate microwaves as a simple-and-controlled heating technique to generate a thermal gradient in ferromagnetic insulator|normal metal systems to study the static and temporal dynamics of the LSSE. Experiments were conducted using a bilayer of a magnetic insulator, Yttrium Iron Garnet (YIG) 6.7µm-thick film, and a normal metal, 10nm-thick Platinum (Pt). The static dc measurements provide crucial information about the direction of the spin current flow. The experiment demonstrates that in the LSSE a spin current flows from the normal metal (hot) towards the ferromagnet (cold), while in the spin pumping case, the flow is opposite. The temporal dynamics of the LSSE experiment manifests the sub-microsecond timescale of the effect which is slower than the spin pumping process. The thermal magnon diffusion model can explain the outcomes of the experiment and leads to conclude that the timescale of the effect relies the evolution of the vertical thermal gradient in the vicinity of the ferromagnet|normal metal interface. From our experiment, a typical magnon diffusion length of 500 nm is estimated for the YIG|Pt system.

Th.H-P19 - Effect of strontium deficiency on structural, magnetic and magnetocaloric properties of $La_{0.65}Eu_{0.05}Sr_{0.3-x}MnO_3$ (0≤ x ≤0.15) manganite

R. Bellouz[1], A. Dinia[2], M. Oumezzine[1], K. Hlil[3], G. Schemerber[2], M. Oumezzine[1]

1. Laboratoire de Physico-chimie des Matériaux, Département de Physique, Faculté des Sciences de Monastir,Université de Monastir, Tunisia
2. Institut de Physique et Chimie des Matériaux de Strasbourg (IPCMS) UMR 7504 CNRS-Université de Strasbourg, Strasbourg Cedex 2, France
3. Institut Néel, CNRS-Université J. Fourier, Grenoble, France

We have investigated the effect of nominal strontium deficiency on the structure, magnetic and magnetocaloric properties of $La_{0.65}Eu_{0.05}Sr_{0.3-x}\square_xMnO_3$ (x=0.05, 0.1 and 0.15). The samples were synthesized using the Pechini sol-gel method. X-ray diffraction analysis shows that the compounds crystallize in the rhombohedral structure with the R-3C space group. Raman spectra at room temperature reveal gradual change in phonon modes, which increased with increasing nominal strontium deficiency. Magnetization as a function of temperature shows that these compounds exhibit a paramagnetic to ferromagnetic phase transition with decreasing temperature. Arrott plot analyses and a universal curve method were applied to study the order of the magnetic transition in this system. The maximum of magnetic entropy change in a magnetic field of 5T is found to be 5.44, 5.15 and 4.96 J kg−1 K−1 for x=0, 0.10 and 0.15 respectively. The relative cooling power (RCP) of $La_{0.65}Eu_{0.05}Sr_{0.3-x}\square_xMnO_3$ series is nearly 69% of pure Gd, which will be an interesting system for application in room temperature refrigeration.

Th.H-P20 - Spin-dependent thermoelectric transport in T-shaped double-quantum-dot systems

Ionel Tifrea [1], Y, Alexander Gauf [1] N, Mircea Crisan [2]

1. California State University Fullerton, United States
2. 'Babes-Bolyai' University, Cluj-Napoca, Romania

We investigate the thermoelectric properties of a T-shaped double quantum dot system connected to two ferromagnetic electrodes whose magnetic moments are oriented at an angle θ with respect to each other. The system is modeled using a generalized Anderson Hamiltonian that accounts for finite on-site Coulomb interaction in each of the system's component quantum dots. The system's electrical conduction (G) and the fundamental thermoelectric parameters such as the Seebeck coefficient (S) and the thermal conductivity (κ), along with the system's thermoelectric figure of merit (ZT) are numerically estimated based on a Green's function formalism that includes contributions up to the Hartree-Fock level. Our results account for finite onsite Coulomb interaction terms in both component quantum dots and discuss various ways leading to an enhanced thermoelectric figure of merit for the system. We demonstrate that the presence of Fano resonances in the Coulomb blockade regime is responsible for a strong violation of the Wiedemann-Franz law and a considerable enhancement of the system's figure of merit (ZT).

Th.I-P01 - Transient exchange Interaction in a helical antiferromagnet

K. Dumesnil [1], M.C. Langner [2], S. Roy [3], A.F. Kemper [4], Y.D. Chuang [3], S.K. Mishra [3], R.B. Versteeg [3], Y Zhu [2], M.P. Hertlein [3], T.E. Glover [3], R.W. Schoenlein[2]

4. Computational Science Division, Lawrence Berkeley National Laboratory, United States

The ultrafast dynamics of the uniform ferromagnetic phase in transition metals and lanthanides currently drive a strong interest to unravel the various mechanisms responsible for the demagnetization process. However, the dynamics in non-collinear phases, as observed in many lanthanides, are yet unexplored, while transiently altering the conduction electron distribution can have a profound influence on the long-range magnetic structure. In this study, time-resolved resonant x-ray scattering experiments (Ultrafast optical pump/x-ray probe) have been performed in the Dy metal to explore the dynamic response of the helical order to injection of unpolarized spins. Those measurements reveal the coupling mechanisms between the constituent spin systems, by observing the dynamics of the core spins in response to excitation of the conducting electrons responsible for the RKKY indirect exchange interaction. A reduction in the amplitude of the helical order parameter and a shift in the helical wave vector q on disparate time-scales, strongly dependent on both the pump fluence and sample temperature, have been observed. Notably, the dynamics in the helical antiferromagnetic phase (HAF) of Dy are significantly slower than those observed in the ferromagnetic (FM) phase of other Lanthanide metals. These anomalous dynamics are attributed to the relationship between the wave vector of the electronic excitation k and the wave vector of the core magnetic ordering q. In the FM phase, the electronic excitation at k = 0 is closely coupled to the magnetic ordering at q = 0. In the HAF phase, the core spin helix is concomitant with a nesting of the Fermi surface (FS). Initial ultrafast scattering of spins from the k = 0 excitation does not directly change the energy-minimizing configuration of the system, and the helical dynamics are driven by changes to the shape of the FS and subsequent changes to the electron distribution through scattering events.

Th.I-P02 - Antiferromagnetic writing and reading of an optical polarization state

T. Satoh [1,2,3], R. Lida [2], T. Higuchi [4], M. Fiebig [5], T. Shimura [2]

1. Department of Physics, Kyushu University, Japan
2. Institute of Industrial Science, The University of Tokyo, Japan
3. PRESTO, Japan Science and Technology Agency, Japan
4. Lehrstuhl für Laserphysik, Friedrich-Alexander-Universität Erlangen-Nürnberg, Germany
5. Department of Materials, ETH Zurich, Switzerland

The interaction between light and magnetism is considered a key to fast, energy-efficient data-storage technologies. Ultrafast optical magnetization control is a step in this direction. Yet, its premise remains a binary one: Light in either of two polarization states generates (writes) or adopts (reads) a magnetic bit carrying positive or negative magnetization. The fundamental limitation to just two states is overcome by employing all three degrees of freedom of optical polarization as an information carrier and representing this, in principle, arbitrary optical polarization state magnetically. Here we demonstrate this principle by using a three-sublattice antiferromagnet, hexagonal YMnO3, for encoding the optical polarization state. Two in-plane modes and an out-of-plane mode are triggered by linearly and circularly polarized light pulses via the inverse Cotton-Mouton effect and the inverse Faraday effect, and detected by circularly and linearly polarized ones via the Cotton-Mouton effect and the Faraday effect, respectively. The control and detection represent a bijection of quantum information from polarization of pump pulse to magnetic oscillation and toward polarization of probe pulse. Also, the two-dimensional vector control of magnetic oscillation of YMnO3 was realized by a pair of optical pulses with different polarizations.

Th.I-P03 - Ho on Pt(111) as a single-atom memory bit: a quantum master equation analysis

C. Karlewski [1,2], M. Marthaler [1], T. Märkl [3], T. Balashov [3], W. Wulfhekel [2,3], G. Schön [1,2]

3. Karlsruher Institute of Technology, PI, Germany

Due to underlying symmetries the two degenerate angular-momentum ground states of a single holmium atom (with J=8) on a Pt(111) surface have exceptionally long lifetimes, as observed in recent scanning tunneling microscopy studies. This opens perspectives for the application as a single-atom memory bit. For control and read-out the atom is coupled to electronic contacts. Hence the spin dynamics of the system is governed by a quantum master equation. In general it cannot be reduced to a classical master equation in the basis of the unperturbed crystal-field Hamiltonian. Rather, depending on parameters and control fields, `environment induced superselection' principles choose the appropriate set of basis states, which in turn determines the specific relaxation channels and lifetimes. Our results suggest that in ideal situations the lifetimes should be even longer than observed in the experiment. We, therefore, investigate the influence of various perturbations. We also study the initialization process of the state of the Ho atom by applied voltage pulses and conclude that fast, high fidelity writing into the memory, on a 100ns timescale, should be possible. [arXiv:1502.02527]

Th.I-P04 - Power dependence of the inverse spin-Hall effect in Py/Pt microstructures

L. Feiler [1], K. Sentker [1], N. Kuhlmann [1], G. Meier [1,2.3]

3. Max-Planck Institute for the Structure and Dynamics of Matter, Hamburg, Germany

The inverse spin-Hall effect (ISHE) has lately been of strong interest due to potential spintronic applications such as read-heads for magnetic hard disc drives. We study laterally microstructured permalloy (Ni80Fe20)/platinum bilayers [1] that could fulfill such technological needs. The samples consist of a 30 nm thick and 2 µm Î 8 µm large permalloy microelement with a 15 nm thick platinum strip on top, positioned over the signal lead of a coplanar wave-guide. The permalloy element is driven at ferromagnetic resonance by an Oersted field, generated by the waveguide. Due to this excitation spin pumping [2] occurs at the permalloy/platinum interface and a spin current is injected into the platinum layer. This spin current is detected as a voltage via the inverse spin-Hall effect [1]. To simultaneously track the magnetization dynamics of the permalloy we also probe the broadband ferromagnetic resonance (FMR) transmission with a vector-network analyzer. We observed that the voltage peak height at resonance does depend on the excitation field strength. Below 0.5 mT this dependency is linear and the peak has a Lorentzian profile that becomes slightly asymmetric, as reported by Mosendz et al. [3]. For higher field strengths we measure an abrupt nonlinear increase of the voltage and thenceforth the peaks feature a broader shape. As dominating contributions from anisotropic magnetoresistance and foldover effects have been ruled out in Ref. [3] and [4]. We assume that the pronounced occurrence of spin wave and edge modes might explain strongly enlarged ISHE voltages.

Inverse magnetostriction is the effect by which magnetization can be changed upon application of a strain. It is particularly relevant to magnetic data storage technologies as a possible route towards induction-free data manipulation[1]. The strain modulation may be created by applying a radio frequency (rf) voltage to interdigitated transducers (IDTs), which generate surface acoustic waves (SAW). We recently demonstrated the ferromagnetic resonance (FMR) induced by a 549 MHz SAW on a 50nm layer of (Ga,Mn)(As,P)[2]. This magnetic semiconductor is an interesting system since the magnetostrictive coefficients vary strongly with temperature (up to Curie temperature Tc~90K), and the magnetic anisotropy can be made arbitrarily weak by epitaxial growth. It is therefore an excellent test-bench to develop and validate theoretical models, and ultimately guide material engineering for all-acoustic magnetization switching We suggest 2 possible routes for SAW-assisted out-of-plane magnetized layer switching [3]. In the first one, the field is applied in the plane of the layer and advantage is taken of the SAW-FMR effect. Numerical simulations then evidence a wide range of fields and SAW amplitudes triggering highly non-linear precessional behavior that can eventually lead to irreversible magnetization switching. In the second configuration, the field is applied anti-parallel to the magnetization, and the SAW is expected to reduce either the domain-wall energy, or switching barriers. Experiments on a 50nm thick layer of (Ga,Mn)(As,P) in this configuration have evidenced a spectacular reduction of the coercive field of up to 68% in the presence of a SAW, and at all temperatures up to Tc. For rf voltages applied slightly out of the IDTs' resonance frequency, no reduction at all is observed confirming the specific action of the SAW.

Th.I-P06 - Enhanced magnetocrystalline anisotropy in an epitaxial array of cobalt nanowires: a ferromagnetic resonance study

I. Camara [1], V. Pierron-Bohnes [1], Y. Henry [1], C. Achkar [2], N. Liakakos [2], T. Blon [2], K. Soulantica [2], M. Respaud [2], M. Bailleul [1]

Arrays of ferromagnetic nanowires are of considerable interest for many applications including magnetic recording, permanent magnets and microwave devices. Traditionally, the nanowires are fabricated by electrodeposition in porous membranes, which results in arrays of polycrystalline objects with relatively large diameters (10nm or above) and moderate densities (a few %). Recently, we developed a new method of epitaxial solution growth allowing us to produce single crystalline Co nanowires with 6 nm diameter arranged in ultradense hexagonal arrays [1]. Here, we report on the determination of the room-temperature magnetocristalline anisotropy of such nanowires.

The measurements were performed using the technique of broadband ferromagnetic resonance. The nanowire array was placed on a coplanar waveguide and its microwave absorption was measured as a function of the microwave frequency and of the external magnetic field, directed either parallel or perpendicular to the nanowires. We observe unusually large resonance frequencies (40 GHz at remanence) and resonance fields (2.3T hard-axis saturation field) which we attribute to an enhanced magnetocristalline anisotropy. By modelling the dipolar interaction in the array, we could indeed reproduce the resonance positions assuming a uniaxial anisotropy with first and second order constants K_1=750 kJ/m^3 and K_2=150 kJ/m^3, two values that are about 50% larger than those of bulk cobalt. This spectacular enhancement of magnetocristalline anisotropy, which was also confirmed through independent high field magnetic torque measurements, is attributed to a sizeable surface contribution.

3. PRESTO, Japan Science and Technology Agency, Tokyo, Japan

We report about our study crystals of rare-earth Gd-Bi-doped iron garnets with and without Yb ions with compensation temperatures T=96K and T=218K and Curie temperatures T=594K and T=538K respectively.Ultrafast magnetization precession, induced via the inverse Faraday effect [1], was detected by time-resolved magneto-optical spectroscopy method [2]. The amplitude and frequency of the precession were studied as a function of the external magnetic field, polarization and temperature within 80-600 K range. Two separate types of oscillations were detected: magnetic field dependent mode with a frequency about few GHz caused by backward volume spin waves excitations and magnetic field independent mode with a sub-THz frequency. Strong decrease of frequencies of these modes was observed close to the compensation and Curie temperatures.The origin of the high-frequency mode could be explained by excitation of the exchange resonance between rare-earth and transition metal sublattices in garnets. Temperature dependences of the experimental data are in good agreement with proposed theoretical model. Obtained results could be important for non-thermal control of the magnetic orderingin dielectrics by polarized laser pulses. The work was supported by SYMPHONY project operated within the Foundation for Polish Science Team Program co-financed by the EU European Regional Development Fund, OPIE2007-2013.

Th.I-P09 - Stroboscopic ferromagnetic resonance detection depending on laser power

S. Yoon [1,2], R. D. McMichael [1]

1. Center for Nanoscale Science and Technology, National Institute of Standards and Technology, Gaithersburg, United States
2. Maryland Nanocenter, University of Maryland, College Park, United States

In this presentation, we introduce a new ferromagnetic resonance (FMR) detection method using stroboscopic magneto-optical Kerr effect (MOKE). FMR is a useful method for investigating the magnetic properties of various thin films and spintronic devices. Therefore, many FMR analysis methods have been developed and improved. In particular, the availability of fast laser pulses and the non-contact nature of optical measurements have made optical approaches attractive for fast dynamic measurements. In our method, magnetization precession in a magnetized permalloy film is driven by microwave fields on a coplanar waveguide. Linearly polarized 1550 nm light is amplitude-modulated by an electro-optical modulator with the same frequency as the microwaves (1 to 10 GHz) and focused on the sample surface. The polarization of the reflected light changes depending on the phase of the spin precession. The intensity-weighted average polarization depends on the relative phase of the microwave signal and light intensity and also on the complex magnetic susceptibility. Laser powers above 10 mW induce resonance shifts that we attribute to heating. We will discuss the details of our new stroboscopic FMR measurement and the effect of laser power on magnetic properties.

Th.I-P10 - Spin wave mode identification in magnetic semiconductors

C. Gourdon [1], S. Shihab [1], H. Riahi [2], L. Thevenard [1], H. von Bardeleben [1], A. Lemaître[3]

1. Institut Des Nanosciences De Paris-UPMC Paris06 -CNRS, UMR7588, 4 Place Jussieu, Paris, France

3. Laboratoire de Photonique et Nanostructures, CNRS, UPR 20, Marcoussis, France

Ultrafast magnetization dynamics triggered by laser pulses and detected by pump-probe experiments gives access to fast demagnetization, carrier cooling and trapping and magnetization precession times on a fs to ns time scale. This magneto-optical technique is applied both in highly absorbing materials like metals and weakly absorbing ones like ferromagnetic semiconductors. Several perpendicular standing spin waves modes (PSSW) may be excited in thin layers by laser pulses and detected through magneto-optical effects. Ferromagnetic resonance (FMR) also provides access to the frequency of those PSSWs. However the conditions for excitation and detection of the PSSW are different for the two techniques, especially in weakly absorbing materials. This is clearly revealed in GaMnAsP ferromagnetic semiconductors where two or more spin waves modes can be optically detected [1,2] whereas only one by FMR in some layers. However the spatial profile (k-number) of the PSSWs, which is of major importance for the determination of the exchange constant from the mode frequency and k-number spacing [2], is difficult to determine. We report on this mode assignment through a systematic study of optically generated and detected PSSWs in the ferromagnetic semiconductor GaMnAsP as a function of layer thickness and phosphorus alloying, for in-plane and out-of-plane magnetized samples. The assignment of the mode k-number is obtained through a detailed comparison of the mode frequencies optically detected and those obtained from FMR, when available, as well as those inferred from the exchange constant determined by domain pattern analysis. We further develop a comprehensive semi-analytical model to justify the optical observation of particular PSSWs.

We employed simultaneous detection of THz emission and transient magneto-optical Kerr effect (MOKE) to study ultrafast laser-induced magnetization dynamics in multisublattice magnets NdFeCo and GdFeCo amorphous alloys with in-plane magnetic anisotropy. A pure Co film was used as a reference sample. An excellent agreement between the dynamics revealed with the help of these two techniques is obtained for Co, while for GdFeCo a satisfactory quantitative agreement was observed. In contrast, for NdFeCo the THz emission reveals faster dynamics than the magneto-optical response. Note that in the multisublattice alloys, the dynamics measured with the MOKE is associated with the dynamics of the FeCo sublattice. This means that the observed mismatch for NdFeCo reveals that the Nd-sublattice exhibits MOKE-invisible and faster magnetization dynamics compared to the FeCo sublattice. Analyzing the similarities and differences of GdFeCo and NdFeCo alloys makes it clear that the orbital magnetization of Nd plays a significant role in the ultrafast demagnetization process.

Th.I-P12 - Simulation of ultrafast spin dynamics in DyCo5

A. Donges [1], S. Khmelevskyi [2], D. Hinzke [1], L. Szunyogh [2], U. Nowak [1]

1. University of Konstanz, Germany

In search of new magnetic recording materials, allowing faster manipulation than today's hard disks, ferrimagnetic transition-metal-rare-earth compounds are of great interest. In this class of materials the so called thermally induced magnetization switching (TIMS) was discovered [1]. Here, the magnetization can be switched solely by a fs-laser-pulse without applying an external magnetic field.
Our focus is on monocrystaline ferrimagnetic DyCo5 featuring extraordinary properties, such as high magnetocrystaline anisotropy and high Curie-temperature, making it a promising candidate for data storage materials. These properties are not found in commonly used materials for studies on TIMS such as GdFeCo. Furthermore, in DyCo5 the magnetization undergoes a reorientation-transition from the in-plane to the out-of-plane direction in a temperature range between approx. 320 K and 370 K [2].
This reorientation-transition will play a crucial role for ultrafast laser excitation.
We studied both, equilibrium and dynamic magnetic properties of DyCo5 using an atomistic Heisenberg spin model, where the Heisenberg exchange parameters were calculated via the Korringa-Kohn-Rostoker-method. We perform Langevin dynamics simulations, i. e. solving the stochastic Landau-Lifshitz-Gilbert equation numerically. In our model, the laser excitation is taken into account via the two-temperature-model.
Our simulations show that in the high temperature phase, TIMS is in principle possible. However, ferromagnetic-resonance-experiments suggest a very high Gilbert-damping for DyCo5 [3], which we find to be a limiting factor concerning TIMS. In the low temperature phase our finding is, that TIMS is generally prohibited, where in response to laser excitation a transient multi-domain-state appears on the time scale of the thermal relaxation time.

2. Institut Jean Lamour, UMR CNRS 7198, Université de Lorraine, Vandoeuvre, France
3. Unité Mixte de Physique CNRS/Thales, UMR CNRS 137, Palaiseau, France

Even in the absence of external magnetic fields magnetostrictive materials are characterized by built-in strains in the range of 0.001-1% of lattice constant [1]. Here we further explore the ultrafast magneto-acoustics in Terfenol [2] to show that femtosecond laser demagnetization of Terfenol leads to the generation of picoseconds acoustic shear pulses. Assuming a simple model of ultrafast demagnetization in high-fluence regime, when the final lattice temperature exceeds the Curie point and the length of magnetization vector drops to zero on a sub-picosecond time scale [3], we show how the ultrafast “release” of the built-in strain generates ultrashort acoustic pulses. Depending on the initial orientation of magnetization, not only longitudinal but also shear acoustic pulses can be generated by this novel physical mechanism. We also report the first experimental observations demonstrating the generation of picosecond shear acoustic pulses from single-crystal Terfenol samples. We analyze different configurations under external magnetic fields leading to the optimum conditions for the generation of shear acoustic pulses.

Th.I-P14 - Temperature study of ultrafast photomagnetic effect in YIG:Co garnet films

K. Szerenos [1], A. Maziewski [1], A. Stupakiewicz [1]

1. Laboratory of Magnetism, Faculty of Physics, University of Bialystok, Poland

Light-induced ultrafast magnetization dynamics in Co-doped yttrium iron garnet thin films (system similar as one in [1]) were studied. Experiments were performed by means of time-resolved magneto-optical pump-probe technique using Faraday geometry . A non-thermal effect was used to induce the magnetization precession, based on photoinduced magnetic anisotropy under linear polarization of pump beam laser pulses [2]. Ultrafast magnetization dynamics were studied as a function of the external magnetic field, pump beam polarization, pump beam wavelength and temperature within 300-500 K range. The dependencies of magnetization precession amplitude, frequency, decay time and Gilbert damping parameter were investigated. Decreases of both frequency and amplitude of precession were observed near the Curie temperature in investigated garnets. The experimental results are in well agreement with simulations of ferromagnetic resonance mode frequency considering in the effective field of both magnetocrystalline and photoinduced anisotropy terms. The possibility of non-thermal control of the magnetization in ferrimagnets using linear polarization of femtosecond laser pulses is demonstrated.

Th.I-P15 - Magnetization dynamics of a dipolar chain at finite temperature

D. Laroze [1,2], O. Suarez [1], R. Stamps [2]

1. University of Glasgow, United Kingdom
2. Universidad de Tarapaca, Chile

Avalanche dynamics is studied for chains of dipolar coupled magnetic particles. We find that transient and highly nonlinear dynamics within the initial stages of a cascading reversal can drive formation of patterned domain structures that can persist until steady state is reached. We numerical integrate set of coupled Landau-Lifshitz-Bloch equations that take temperature into account. A perturbative method allows us to perform a separation of time scales such that we can compute time evolution over very long timescales. We examine in particular pattern formation produced through competition between long range dipolar coupling, that can be controlled by particle spacing, and magnetic anisotropies that can be controlled by particle shape and size.

Th.I-P16 - Time-resolved ferromagnetic resonance in ultrathin perpendicularly magnetized films: efficient nonlinear high order harmonics generation

A. Capua [1], S. Yang [1], T. Phung [1], A. Fantini [1], N. Kaminski [1], J. Woo Joeng [1], C. Rettner [1], W. Kim[2], S. Park [2], S. Parkin [1], Y. Ferrante[1]

2. Samsung Electronics Co., Ltd, Suwon, Republic of Korea

Using a phase locked microwave RF source with a Ti:Sapphire 70 fs pulsed laser which serves as a magneto-optical Kerr effect (MOKE) probe, we study the ferromagnetic resonance of perpendicularly magnetized ultra-thin (11Å)CoFeB and (3Å)Co/(7Å)Ni/(1.5Å)Co magnetic layers in the time domain. When the system is operated at high external magnetic field compared to the crystalline anisotropy field we extract the Gilbert damping parameter in three ways; from measurement of the phase response; the magnetization amplitude spectrum and from measurement of the absorption spectrum. We show that the damping values agree well with measured values obtained from a time resolved pump-probe MOKE measurement (TR-MOKE). At low external magnetic fields which are comparable to the anisotropy field, however, the system becomes highly non-linear and higher harmonics of the basic RF frequency are efficiently generated. Additionally, we show that while in the high field regime the phase response shifts by π at the low field regime the phase response is almost zero resulting in a pure amplitude response. This behavior is due to phase compensation of two competing effects: precession about the external field and about the anisotropy field. This operation point imposes unique properties on the magnetic susceptibility.

TH.I-P17 - High-field high-repetition-rate THz sources for studying ultra-fast magnetization dynamics

S. Kovalev [1], B. Green [1], T. Golz [2], A. Fisher [3], I. Radu [4], J. Seok Lee [5], A. Deac [1], T. Kampfrath [6], N. Stojanovic [2], M. Gensch [1]

6. Fritz Haber Institute, Berlin, Germany

THz field-driven magnetization dynamics has been in the focus of several recent highlight experiments that proof that the transient magnetic field in ps - long high field THz pulses can couple directly to the spin system and give rise to long-lived coherent excitations. In this contribution we discuss how the recent arrival of a new class of, so called, super-radiant THz sources, will allow to probe the triggered spin dynamics with unprecedented sensitivity in a frequency range from 0.1 to 3 THz. It is furthermore discussed if these high-field high-repetition rate THz sources can be utilized to employ more specific probe techniques such as e.g. time-resolved (TR) Raman/Brilliouin scattering,TR ARPES measurements or spin-current measurements.

Th.I-P18 - Nonequilibrium fluctuations in nanomagnets

G. Bertotti [1], E. Ferraro [1], C. Serpico [2]

1. Istituto Nazionale Di Ricerca Metrologica, Torino, Italy
2. Universitá Federico II, Napoli, Italy

Magnetization dynamics in nanomagnets are dominated by two competing features: (i) the dynamics are stochastic in nature, due to the strong fluctuations caused by the interaction with the thermal bath; (ii) in typical operations relevant to magnetic recording and spintronics applications (fast magnetization switching, high-frequency precession), the system is driven far from thermodynamic equilibrium. Such fluctuation-dominated nonequilibrium processes are governed by characteristic relations for the work and the entropy production [1,2], relations that are broadly referred to in the literature as fluctuation theorems. In this paper, we derive a fluctuation theorem for the case of stochastic magnetization dynamics in a uniformly magnetized nanomagnet. By using the path-integral form of the solutions of the Fokker-Planck equation for the dynamics under time-varying external magnetic field, we express the statistical weights of magnetization paths in terms of a specific action integral. The values of the action associated with a path and its time-reversed conjugate path are connected with the heat exchanged by the system with the thermal bath along that path. Connections of these results with known fluctuation theorems are derived, together with implications of the found fluctuation relation on the characterization of nanoscale magnetization processes. Numerical simulations are carried out in order to test the conditions under which the exponential averaging characterizing Jarzynski's and Crook's equalities [1,2] becomes relevant and leads to deviations from usual thermodynamic work relations.

Th.I-P19 - Magnetization dynamics in low-symmetry iron garnet film induced by femtosecond laser pulses

A. Kalashnikova [1], L. Shelukhin [1], V. Pavlov [1], P. Usachev [1], R. Pisarev [1]

1. Ioffe Physical-Technical Institute, St Petersburg, Russian Federation

Thin films of iron garnets with generic formulae Y3Fe5O12 (YIG) are the model media for developing principles of dielectrics-based spintronics [1] owing to their exceptionally narrow FMR line, high domain walls mobility, and composition-controlled magnetic anisotropy. The possibility to tune and control the magnetic anisotropy of YIG films on a subpicosecond time scale via excitation by ultrashort laser pulses can extend their functionality and link two rapidly developing areas of femtomagnetism [2] and magnonics [1].
We report on experimental magneto-optical pump-probe study of laser-induced picosecond and nanosecond magnetization dynamics in 10 micron thick rare-earth substituted iron garnet (YPrLuBi)3(FeGa)5O12 film grown on a low-symmetry Gd3Ga5O12 substrate of the (210) orientation. Owing to the complex magnetic anisotropy of such films dominated by the growth-induced contributions, they provide a possibility for detecting changes of anisotropy constants induced by femtosecond laser pulses.
We demonstrate that femtosecond laser pulses induce the magnetization precession in the studied film and distinguish two distinct excitation mechanisms. The first one shows dependence on pump pulse circular polarization, and thus can be identified as the ultrafast inverse Faraday effect [3]. The second mechanism appears to be dominating at low external magnetic field and depends on its sign. Thorough analysis of field and polarization dependencies shows that the magnetization precession is excited due to laser-induced change of the anisotropy parameters occurring at the picosecond time scale. Phenomenological analysis of these processes allowed us to separate relative contributions from laser-induced changes of different anisotropy parameters.

The amorphous rare earth - transition metal (RE-TM) alloy GdFeCo has been extensively studied in the recent past. This is mainly due to the intriguing phenomenon of all optical magnetic switching (AOS) that was first demonstrated in this material. AOS is thought to be strongly linked to the ferrimagnetic order of GdFeCo. A main characteristic of ferrimagnetism is the magnetization compensation temperature at which the magnetizations of the antiferromagnetically coupled RE and TM magnetic sublattices cancel each other out and the coercive field should diverge. The exact mechanism of AOS is still under discussion and many open questions concerning the compensation temperature and sublattice behavior remain due to insufficient data at fields > 1.5 T. We recently build a time resolved magneto optical Kerr effect (TR-MOKE) setup for high magnetic fields with which we investigated amorphous Gd24Fe66.5Co9.5 below, across and above the magnetization compensation temperature in fields up to 30 T. These fields allow us to closely map the static magnetic behavior of the system crossing the compensation temperature. Furthermore, using static and time resolved MOKE we find that at applied magnetic fields beyond 2 T, a significant change in the MOKE signal occurs that indicates a field induced magnetic transition. This transition can be observed below and above the compensation temperature and seems to limit the divergence of the coercive field at the compensation temperature. Furthermore, the magnetization dynamics significantly change after this field induced transition occurs. At temperatures above the compensation temperature , the (TR-)MOKE signal even changes sign upon crossing the transition field at ~2.6 T.

TH.I-P24 - Laser-induced spin precessional dynamics in FeCo/MnGa bilayers with different interfacial exchange couplings

Q. Ma [1], S. Iihama [2], X. Zhang [1], T. Miyazaki [1], S. Mizukami [1]

1. WPI-AIMR, Tohoku University, Japan
2. Department of Applied Physics, Tohoku University, Japan

Magnetic bilayers consisting of a soft magnetic layer and hard magnetic layer with a perpendicular magnetic anisotropy (PMA) have attracted much attention because those are well suited not only for magnetic storage media but also for various spin-transfer-torque applications. However, there are few reports on spin precessional dynamics in coupled bilayers with a large perpendicular magnetic anisotropy. Here we report the effect of ferromagnetic (F) and antiferromagnetic (AF) interfacial coupling on spin precessional dynamics in the L10-MnGa/FeCo bilayers which show the F (AF) coupling for the case of Fe-rich (Co-rich) composition [1]. The epitaxial L10-MnGa (30 nm)/FexCo1-x (1.5 nm) bilayers (x=0.9, 0.1) were grown using magnetron sputtering. Polar magneto-optical Kerr effect was measured in time domain using all-optical pump-probe method (TRMOKE) with various direction of the external magnetic field direction [2]. Both the bilayers show similar dependences of precession frequency on the field direction. However, the dependences of precession amplitude on the field directions are quite different. The F-coupled bilayer shows the large precession amplitude when the field is applied near in-plane, whereas the precession disappears at certain field angle. On the other hand, the precession amplitude in the AF-coupled bilayer is monotonically changed by varying the field angle. The data for the both samples are well explained by the macro-spin model described by the Landau-Lifshitz equation taking into account of the interfacial exchange coupling and magnetic anisotropy modulated by ultrashort pulse laser [3].

This work is partially supported by Grand-in-Aid for KAKENHI for Young Researcher (A) (No. 24686001) and for Innovative Area (Nano Spin Conversion Science) (No. 26103004).

TH.I-P25 - Microwave assisted magnetization reversal under circularly polarized field in thin exchange-coupled multilayer media

M. LoBue [1], A. Pasko [1], C. Serpico [2], F. Mazaleyrat [1], R. Tayade

1. SATIE - CNRS - ENS de Cachan, France
2. Dipartimento di Ingegneria Elettrica, Università di Napoli Federico II, Napoli, Italy

Microwave assisted magnetization switching (MAS) is one of the most intensely studied techniques aimed to reduce the reversal field in ultra high-density magnetic recording [1, 2, 3]. The key idea is to induce magnetization reversal by controlling the large amplitude magnetization precession excited by the application of a microwave AC magnetic field. Many authors have shown that an important reduction of the switching field, characteristic of single phase high-anisotropy materials, can be obtained by using exchange coupled multilayer media [4]. In a recent work we showed that in a soft-hard exchange coupled bilayer, with perpendicular anisotropy, zero-field switching condition is achievable under application of an in-plane circularly polarized microwave filed [5]. In the previous study we showed that for thick layers (i.e. layers with thickness greater than the domain wall width of the materials) the system behave as two coupled uniform modes (i.e. P-modes [3]) and the switching process can be described using a simplified macro-spin approach. Here, using a finite difference element code to solve Landau-Lifshitz equation, we study the response of a bilayer within the very same planar geometry changing the thickness of the layers to explore under which conditions stable P-modes are still dominating the dynamics in very thin systems. The appearance of quasi periodic modes (i.e. Q-modes [3]) is studied and its influence on the stability of the system is discussed.

TH.I-P27 - Microwave linewidth broadening of FeCuNbSiB ferromagnetic films: effect of annealing

M. J. P. Alves [1], D. E. Gonzalez-Chavez [1], F. Bohn [2], R. L. Sommer [1]

1. Centro Brasileiro De Pesquisas Fisicas - CBPF/MCTI, Brazil
2. DFTE, Universidade Federal do Rio Grande do Norte – UFRN, Brazail

We systematically investigate the annealing effects on the microwave linewidth broadening of FeCuNbSiB ferromagnetic films with thickness of 100 nm, using broadband ferromagnetic resonance and grazing incidence x-ray diffraction. The samples were annealed for 1h at several temperatures up to 400 ^{o}C. We correlate the non-uniform residual stress obtained from x-ray measurements with the ferromagnetic resonance linewidth due to effective field inhomogeneities measured from broadband FMR. We also estimate the annealing temperature effect on the Gilbert and two-magnon scattering contributions to the total FMR linewidth. In all samples we found the Gilbert damping constant is around 0.003, which is smaller than the values reported for traditional materials as NiFe and CoFeB. We show that the effective field inhomogeneities constitute the main contribution to the microwave linewidth, while this contribution is related to the non-uniform residual stress in the films which is reduced by thermal annealing. Besides we found that the two-magnon scattering contribution for the linewidth is small but not negligible for all studied samples.

Th.I-P28 - Emergence of coherent magnetization reversal at dynamic regime: a detailed vectorial-resolved angular-dependent study.

J. Camarero [1,2], T. Pérez [1], J. F. Cuñado [1,2], A. Maldonado [1], P. Perna [2], F. Ajejas [1], S. L. de las Heras [2], M. Niño [2], D. Cabrera [2], R. Guerrero [2]

1. Universidad Autonoma de Madrid, Madrid, Spain
2. IMDEA Nanoscience, Madrid, Spain

Systematic measurements performed as a function of the applied magnetic field sweep rate (dH/dt) support the scenario of nucleation-dominated reversal in the high dynamic regime and wall propagation-dominated reversal in the low dynamic regime [1-3]. However, studies on the angular dependence of the magnetization reversal dynamics are still lacking.
We present a detailed study on the angular dependence of the magnetization reversal dynamics in a model system with well-defined in-plane uniaxial magnetic anisotropy. Time-resolved vectorial-Kerr magnetometry measurements have been performed at room temperature over a broad range of applied magnetic field sweep rates (dH/dt), from 10-4 to 10+4 T/s, and for the whole angular range of applied magnetic field orientations (a_H) relative to the anisotropy axis direction. Although the angular dependence of the magnetization reversal mechanisms is preserved, thermal activated dynamical effects are observed such as increasing transition fields and widening irreversible transitions in both magnetization components when dH/dt is increased. The angular dependence of the remanence magnetization in both magnetization components does not depend on dH/dt. In contrast, thermal activated dynamical effects are found during irreversible processes and depend on a_H. Around the easy-axis directions, magnetic domain wall displacement and domain nucleation regimes govern the magnetization reversal at low and high sweep rates, respectively. Both dynamical effects are reduced as we move away from the easy-axes, vanishing along the hard-axis direction. The crossover between the two regimes increases as a_H increases. At the hard-axis direction, rotation processes govern the magnetization reversal independently of dH/dt. Remarkable, the magnetic properties become closer to the predicted ones by the coherent rotation model in the high dynamic regime, i.e., where nucleation processes are more relevant. This results in a gradual transition from a pinned to a coherent rotation like angular dependent behavior as dH/dt increases.

Th.I-P29 - Frequency and field linewidth conversion of FMR spectra only valid for samples with neglegible extrinsic linewidth contribution

Y. Wei [1], P. Svedlindh [1]

1. Uppsala University, Uppsala, Sweden

Both frequency-swept and field-swept ferromagnetic resonance measurements have been carried out for a number of different samples to analyze the correlation between the experimentally measured frequency and field linewidths. We managed to fabricate FeCo thin films with almost zero extrinsic linewidth contribution, with intermediate extrinsic linewidth contribution and with significant extrinsic linewidth contribution by varying growth temperature and substrate material.
Contrary to the belief commonly held by many researchers, our experimental results indicate that the widely used conversion relation based on the derivative of the resonance condition (Kittel formula) is only valid for samples almost without extrinsic contributions to the linewidth (zero-frequency field linewidth $\Delta H0 \approx 0$). Furthermore, a close examination of the literature reveals that previously reported results support our findings, with successful conversions related to samples with negligible extrinsic contributions and unsuccessful conversions related to samples with significant extrinsic contributions to the linewidth. A linewidth contribution ratio k_w that is defined as the ratio between the zero-frequency intercept and the slope of the field linewidth versus frequency curve is introduced to estimate the validity of linewidth conversion. It is suggested that a value of k_w smaller than about 10 GHz would yield a reasonable conversion. The findings are of great significance in providing guidance for FMR linewidth measurements and data analysis.

TH.J-P02 - Switching of the magnetic vortex core in a pac-man disk

T. Sato [1], K. Yamada [1], Y. Nakatani [1]

1. University of Electro-Communications, Tokyo, Japan

The magnetic vortex structure [1] observed in a ferromagnetic circular disk has been intensively studied recently because its binary state can be used for high-density and non-volatile storage media. To realize a vortex core memory, the controlling of the core polarity and the reducing energy of the core switching are key issues. In order to solve these issues, we focus on utilizing a Pac-man (PM)-shaped disk [2,3]. The PM disk has an open slot extending from the center to the circumference, as a result, the core can be annihilated and nucleated using that part. In this work, we report micromagnetic simulations and investigated the vortex core switching using an in-plane nanosecond field and current pulses in order to study the switching mechanisms and switching conditions in the PM disk.
A three-dimensional micromagnetic model was used in the simulation. The PM disk was divided by a rectangular prism with dimensions of 2x2x2.5 nm^3. The diameter and the thickness of the PM disk were 200 nm and 40 nm, respectively. The notch depth and notch angle of the PM disk are 80 nm and 25 degree, respectively. Typical material parameters for Permalloy were used.
The minimum core switching field (current density) is reduced by 72% (75 %) compared to that of a circular disk with the same diameter and thickness. In the case of field, the core switches irregularly with respect to both the field pulse amplitude and duration. On the other hand, in the case of current, the core polarity can be controlled by the direction of applying the current [4,5].

Vortices in patterned magnetic elements exhibit interesting dynamic behaviour that can be exploited for data storage and as oscillators. An essential requirement is reliable control over the vortex core polarization. It has so far been shown that the vortex core polarization can be reversed through the interaction of the vortex with magnetic fields [1], electric currents [2], or spin waves [3] in single-material structures [4]. Using scanning transmission X-ray microscopy we demonstrate a new vortex core reversal mechanism [5] in heterogeneous multilayer structures [6]. Layering and mutual imprinting of a Co/Pd multilayer with out-of-plane magnetization and a permalloy (Py) layer with in-plane magnetization results in a magnetically asymmetric heterogeneous structure, in which the vortex core in the in-plane Py film coexists with an out-of-plane maze domain pattern in the Co/Pd multilayer. We excite the vortex with an alternating magnetic field and the core polarization is determined from the sense of gyration. Simultaneously, the vortex core is displaced across domain boundaries in the Co/Pd using a static external magnetic field. We find that the sense of gyration of the vortex changes as it crosses a domain boundary of the Co/Pd multilayer, indicating the reversal of the core polarization. Micromagnetic simulations reveal a complex switching process triggered by the interaction of the vortex core with an underlying domain wall. This interaction results in the formation of a region in which the out-of-plane magnetization in the vortex core is quenched and dissolved by the propagation of two dynamically generated magnetic singularities (Bloch points). This process demonstrates the complex magnetization dynamics that can occur in heterogeneous structures and provides a new means to control the vortex core magnetization.

TH.J-P04 - Engineering 1D potential barrier for fast guided skyrmion motion

W. Gan [1], I. Purnama [1], H. Tung Fook [1], M. Ramu [1], W. Siang Lew [1]

1. Nanyang Technological University, Simgapore

Magnetic skyrmion, which is a topologically stable field configuration, has recently been observed in chiral ferromagnets. This potentially draws a step closer to the creation of skyrmion-based non-volatile magnetic memory. However, a long-standing fundamental issue that will hamper the progress of the "Skyrmion memory" is that the current-driven skyrmion does not follow the direction of conduction electron due to the presence of the Magnus force. The skyrmion deviates from a straight path and annihilates at the film edges eventually. In this work, we show that it is possible to counter the Magnus force and prevent it from annihilating by introducing a spatially non-uniform potential distribution along the nanowire. A few methods to implement the potential was investigated, including geometrical construction, material parameter tuning and layer coupling. Although the size of the skyrmion is usually defined by the nanowire width and its material parameters, here we demonstrate that the skyrmion can be compressed to as small as 4 nm by altering the width of the potential barrier. This greatly enhances the packing density of skyrmions on a nanowire. The skyrmion compression causes the skyrmion to be warped into an elliptical shape which is more susceptible to spin transfer torque from an applied current. Therefore, the speed of the current-driven skyrmion motion can be increased significantly by tuning the lateral dimension of the potential barrier. Lastly, we demonstrate that our proposed solution can also be imposed on curved nanotracks with steep bends to guide the skyrmion motion.

TH.J-P05 - Skyrmion pinning dymanics in nanostructures for diode and symmetric operations

H. Tung Fook [1], W. Liang Gan [1], I. Purnama [1], M. Ramu [1], W. Siang Lew [1]

1. Nanyang Technological University, Singapore

Magnetic skyrmions are stable spin configurations originating from chiral interactions. There is significant scientific interest in the creation of a skyrmion-based memory device due to the high stability of skyrmions at small sizes. However, skyrmions are highly resistant to the conventional pinning used in domain-wall memory devices as they are known to skirt around the pinning sites in the magnetic film that they reside on. This poses a significant problem as the skyrmion's position becomes less predictable. In this work, we investigate the pinning effect of several geometrical structures by micromagnetic simulations. Instead of removing material to form pinning notches, our proposed structures have a patterned top layer to act as pinning “anti-notches”. It was found that a single anti-notch on one side of the track acts as a diode due to the Magnus force which causes skyrmions to drift from the direction of electron flow. The threshold current required to overcome the pinning varies with notch depth and notch angle.

Our results show that anti-notches with larger depth increases the pinning strength but pinning material smaller than 5 nm in size have almost no impact on pinning. Skyrmions driven towards the pinning site are compressed at the anti-notch and the compression is higher at wider notch angles, making the skyrmion more susceptible to spin transfer torque. The depinning current peaks at certain notch angle due to skyrmion compression and repulsion by the anti-notch. Furthermore, skyrmions pinned at the anti-notch require a higher current to depin compared to skyrmions approaching at higher speeds.

To achieve reversible 2-way operation for memory device applications, we propose a symmetric anti-notch design on both sides of the nanowire. Kerbs at both longitudinal edges of the nanowire counteracts the Magnus force and restricts the skyrmion's motion to within the centre region of the nanowire.

TH.J-P06 - Skyrmion stability on curved surfaces

2. Universidad de Santiago de Chile, Chile

During the last decade a strong interest has focused on the properties of topological structures on curved surfaces based on the fact that the surface's shape determines the physical properties of several systems. As examples, one can cite the ordering of nematic liquid crystals on a curved substrate and the local density of states of a conical graphene sheet. In the same hand, curvature is important to describe the physical properties of magnetic nanostructures. In some recent works, it was shown that toroidal nanorings can support a vortex-like magnetization for smaller sizes than cylindrical nanorings. Skyrmions were first described in nuclear physics, when Skyrme showed that topologically stable field configurations for interacting pions can occur as particle-like solutions. However, these topological structures do not appear only in particle Physics. In last two decades, skyrmions have been studied in several condensed matter systems, e.g., nematic liquid crystals, Bose-Einstein condensates, and magnetic systems. In particular, regarding magnetic systems, skyrmions are chiral spin structures with a whirling configuration which appear like a magnetization groundstate due to the competition among Exchange, anisotropy, Zeeman and Dzialoshinsky-Moriya interactions. Here we study the stability and energetics associated to topological skyrmions appearing as excitations coming from the interplay between the Heisenberg model and external magnetic fields on rotationally symmetric curved surfaces. We show that the presence of cylindrically radial and azimuthal fields coupled to the surface curvature destabilizes skyrmions which are predicted to appear when there are no magnetic fields. Weak fields shift the minima of the Heisenberg model (HM) in such way that the mapping of the spin sphere vector field is not completely done and the skyrmion-like excitation has not topological stability. On the other hand, a strong magnetic field yields stable 2π skyrmions, which has their widths diminished by the magnetic field strength.

TH.J-P07 - Spin-current induced magnetization patterns in nanomagnets

We study formation of stable periodical magnetization structures in planar ferromagnetic nanosamples under the action of a transversal spin-polarized current via Slonczewski-Berger mechanism. The influence of the spin-current, whose polarization is directed along the normal to the ferromagnetic plane, leads to formation of various periodical magnetization patterns just below the saturation current. A square vortex-antivortex lattice is formed in two-dimensional films [1,2], a one-dimensional domain structure is formed in a wire [3] and various intermediate vortex-antivortex structures are formed in a stripe [4]. We developed a linear theory of instability of the saturated state for thin films under the influence of spin-polarized current and proposed a mechanism of current-induced vortex-antivortex superlattice formation. In the case of a thin nanowire with square cross-section we found that periodical domain walls structure appears for small thicknesses, for large thicknesses the periodical structure is absent and the saturation process is characterized by a hysteresis. For the case of nanostripes we also demonstrated that the dependence of the saturation current on the stripe width is nonmonotonic one. Also we found a variety of stable regular structures which appear in the process of the nanostripe saturation and studied the influence of Oersted field on them. All theoretical results are verified by micromagnetic simulations.

In the last few years, more attention has been focusing on topologically nontrivial magnetic structures, such as magnetic vortices in soft ferromagnetic nanodiscs and skyrmion lattices in chiral magnetic thin films. Another interesting example is magnetic bubble domains. A magnetic bubble carries an integer topological number Ns, the so-called skyrmion number, whose absolute value, unlike skyrmions with Ns being either +1 or -1, varies depending on the magnetic profile on the circumference of the bubble.
We theoretically study the relation between the dynamics of magnetic bubbles with different Ns and the electron transport, by investigating the effects of spin-transfer torque and spinmotive force, via which the magnetic and electronic channels interact with each other. We find that the current-driven dynamics of a bubble significantly depends on Ns. It turns out that the transverse motion with respect to the applied current is strongly suppressed as Ns increases.
Next, we demonstrate that the motion of bubble driven by magnetic field gradient induces a spin current and an accompanying electric voltage, i.e., spinmotive force[1]. The spin current along the bubble motion has its origin in the non-adiabaticity of the electron spin dynamics. We show that the measurement of the corresponding electric voltage may allow us to determine the phenomenological parameter β that describes the dissipative dynamics of the magnetization and plays an important role in its current-driven motion.

The investigation of propagating spin waves is a key topic of magnetism research [1]. For the excitation of spin waves with short wavelengths, it was typically necessary to either use transducers with sizes on the order of the desired wavelengths (striplines or point-contacts) or to generate those spin waves parametrically by a double-frequency spatially uniform microwave signal [2]. Only recently, a novel mechanism for the local excitation of spin waves has been discovered, which overcomes the wavelength limit given by the minimum patterning size. This method utilizes the translation of natural topological defects, namely the gyration of magnetic vortex cores [3].
In the present contribution we will show that in a stacked vortex pair system with uniaxial magnetic anisotropy, spin waves of different symmetries and dimensionalities can be excited. The response of this system was imaged by means of time-resolved scanning transmission x-ray microscopy. For excitation frequencies above ~500 MHz, circularly spiraling spin waves occur in the same way as previously reported [3]. At the same time, however, additional plane waves are generated along the 180° domain walls that arise from the uniaxial anisotropy. Such generated waves propagate subsequently to the edge of the sample with the wave fronts remaining parallel to the walls. Interestingly, even an interference of both distinct two-dimensional spin wave symmetries (plane vs. circular spiral) can be imaged in the vicinity of the cores. When the excitation frequency is set to below ~500 MHz, a transition from the two-dimensional to a one-dimensional spin wave dynamics is observed. While the uniform domains remain almost free from detectable magnetic oscillations, high amplitude propagating spin waves become evident within the sharp 180° domain walls, originating from the central vortex cores.

Spin-transfer torque reveals the potential of spintronic devices for a new generation of electronic components showing multiple functionalities, notably for microwave applications. Within this palette of new applications, spin transfer nano-oscillators (STNOs) are anticipated as being the most promising one [1]. However their usual highly nonlinear behavior has been demonstrated to be responsible of a linewidth enhancement [2], detrimental for applications. By considering a double vortex based STNO, we highlight how the tunable behavior of coupled modes provides a mean to successfully handle the properties of spin-transfer nano-oscillators.
Here we investigate the spin transfer dynamics in a hybrid Magnetic Tunnel Junction with two vortices that are coupled by dipolar interaction. Depending on the relative configurations of the two vortices (core polarities or chiralities), different coupled modes are excited by spin transfer torque. Interestingly the intrinsic microwave properties of these excited modes (frequencies, spectral coherence and localizations of the modes) strongly depends on the core polarity configuration i.e. parallel (P) or antiparallel (AP). The strong impact of coupled modes on the non-linear behavior allows to combine large output emitted power (up to a few hundred nanowatts) and high quality factors (Q > 1000) at zero field, because of the vanishing the non-linearities in AP configuration [3].

This confirms the potential of coupled modes in order to increase the spectral coherence and the tunability of spin transfer nano-oscillators based on coupled vortices. Such a level of control on the nonlinear behavior reinforces our choice to exploit the microwave properties of collective modes for applications in advanced spintronics devices for integrated telecommunication concerns.

TH.J-P11 - Advanced dzyaloshinskii-moriya interaction meter based on angular dependence of asymmetric magnetic domain-wall motion

D. Kim [1], S. Yoo [1,2], D. Kim [1], B. Min [2], S. Choe [1]

1. Department of Physics And Astronomy, Seoul National University, Republic of Korea
2. Spin Convergence Research Center, Korea Institute of Science and Technology, Republic of Korea

Recently, much attention has focused on the Dzyaloshinskii-Moriya interaction (DMI) in ferromagnetic systems for magnetic-skyrmion-racetrack memory. In order to form a skyrmion state, it is needed to have the large DMI value D about 3.5 mJ/m^2 which can be converted into the DMI-induced magnetic field H_DMI=636 mT, where DW width is 5 nm and saturated magnetization is 1.1äe10^6 A/m. Recently, the measuring DMI technique based on asymmetric DW motion has been proposed. In this technique, H_DMI can be directly quantified by observing the shift Hshift of the symmetric axis in the DW speed v(H_x) measurement with respect to the in-plane magnetic field H_x. However, in material with skyrmion state where H_DMI is too large (>600 mT), it cannot be applicable due to limitation of the maximum strength H_max of the applied in-plane magnetic field. In this study, we propose an advanced technique to overcome such field-strength limit. The core idea is to utilize the dependence of Hshift on the tilting angle of the DWs with respect to the direction of the in-plane magnetic field. We perform that the Hshift measurements for the tilted DWs with various tilting angles (0óX, 30óX, 60óX, and 90óX) for Pt/Co/Pt film and then find that H_shift is very sensitive to tilting angle, following a simple relation H_shift =H_DMI cos(theta). Therefore, with a large angle, H_shift becomes much reduced possibly less than H_max. The present idea can be also demonstrated to other films (Pt/Co/AlOx and Pt/Co/MgO), where H_DMI is even much larger than the field-strength limit of equipment, and thus enables the development of an advanced DMI meter based on asymmetric DW motion.

TH.J-P12 - Vortex core reversal by excitation of a higher vortex gyromode (flexure mode)

G. Dieterle [1], A. Gangwar [1,2], M. Noske [1], J. Förster [1], M. Weigand [1], I. Bykova [1], H. Stoll [1], C. H. Back [2], G. Schütz [1]

2. University of Regensburg, Department of Physics, Regensburg, Germany

Magnetic vortex core reversal by excitation of the fundamental gyromode G0 [1] or azimuthal spin waves [2] have been published before. Here we focus on higher order gyromodes, also called flexure modes, which are characterized by a strong z-dependence of their gyration radius [3,4]: one node in z-direction for G1, two nodes for G2 etc. For thinner samples these higher order gyromodes do not exist because their formation costs too much exchange energy. However, in our samples which are thick enough, Permalloy disks, 80 nm thick, 250 nm or 500 nm in diameter, vortex core switching mediated by the first order gyromode G1 could be demonstrated experimentally. Measurements have been performed by scanning transmission X-ray microscopy at the MAXYMUS endstation at the BESSY II synchrotron as well as with a table-top MOKE microscope, where a sophisticated lock-in technique was developed in order to detect the switching of the tiny vortex core, about 20 nm in diameter. Furthermore we imaged the first order gyromode mode G1 using time-resolved X-ray microscopy by exciting this mode with rotating magnetic fields with sub-switching threshold amplitudes. The time-resolved movies taken experimentally are in good agreement with our micromagnetic simulations.
In addition, hybridization will be discussed of both higher order gyromodes, G1 and G2, with azimuthal spin waves. In particular, by studying the second order gyromode G2 by micromagnetic simulations we found that this mode does not exist as a separate mode but forms, together with the first order azimuthal spin wave [2] of the same sense of rotation, one single highly hybridized mode.

TH.J-P13 - Spin polarised current induced vortex core expulsion in magnetic tunnel junctions

A. Jenkins [1], R. LeBrun [1], E. Grimaldi [1], P. Bortolotti [1], S. Tsunegi [1], H. Kubota [2], K. Yakushiji [2], A. Fukushima [2], S. Yuasa [2], V. Cros [1]

Spin torque nano-oscillators (STNOs) have raised considerable recent experimental interest, with potential applications including radio frequency and low energy communication devices. Our vortex-based STNO consists of a magnetic tunnel junction, where the free layer has the magnetic vortex ground state. The vortex core can be resonantly excited by a radio frequency current, I_{rf}, if the frequency of the current matches the frequency of the gyrotropic mode of the vortex.
An exciting potential functionality for STNOs is as a high frequency detector, where an rf current is applied to the STNO, resulting in a spin-torque diode induced d.c. voltage due to the mixing of the resistance and the current oscillations. A magnetic vortex has the potential to provide a high precision zero field detector, which operates at a lower frequency range (100 MHz - 2 GHz) than the standard uniform modes previously investigated.
For relatively low I_{rf} (300μA), the vortex shows resonant behaviour when excited by an rf current, but when I_{rf} is increased a large jump in the generated voltage is observed. This jump is associated with the core of the vortex being expelled from the disk, which has been confirmed with micromagnetic simulations. A new type of detector is proposed, based on core expulsion, displaying promising high sensitivity, large generated voltage.
Unlike the classical rectification voltage associated to the resonant mode, the magnitude of the voltage jump associated with the expulsion of the vortex core is independent of I_{rf}. The jump in voltage is actually associated with a resistance change owing to the TMR difference between the vortex state and the uniform state relative to the uniform polariser. The voltage response associated with the expulsion of the vortex core has a maximum 'effective' sensitivity, $\Delta V/P_{rf}$, of 40,000 V/W.

TH.J-P14 - Real time measurements of vortex core expulsion in magnetic tunnel junctions

A. Jenkins [1], R. LeBrun [1], E. Grimaldi [1], P. Bortolotti [1], S. Tsunegi [1], H. Kubota [2], K. Yakushiji [2], A. Fukushima [2], S. Yuasa [2], V. Cros [1]

1. Unité Mixte de Physique CNRS/Thales and Université Paris Sud, Palaiseau, France
2. Institute of Advanced Industrial Science and Technology (AIST), Spintronics Research Center, Ibaraki, Japan

Spin torque nano-oscillators are a recent field of much experimental interest, owing the impressive variety of potential applications, ranging from bio-inspired neural networks to magnetic read heads, and from high frequency current sources to frequency detectors. For the latter of these potential applications, the frequency detector, the manipulation of the resistance state via high frequency currents is of significant interest, an effect which can be achieved via the resonant expulsion of the vortex core. A magnetic tunnel junction with a free layer which has a magnetic vortex at remanence is excited by both high frequency and dc currents, Irf and Idc, respectively. When the excitation radius of the magnetic vortex core is greater than the radius of the disk, the vortex is expelled, where the final magnetisation state (static uniform magnetisation state either parallel or antiparallel to the polariser) is determined by a small in-plane magnetic field.
We have observed that as Irf approaches the critical rf current necessary to observe the expulsion, Irfcrit, there is a finite probability of core expulsion, where the vortex is stochastically expelled but returns after a certain time. The dwell time in the expelled state depends upon of the magnitude and frequency of Irf. In the absence of the in-plane magnetic field, there is an equal probability for the final state to be in either the parallel or antiparallel state, and is found experimentally that the core, and the resultant magnetisation state stochastically switches between parallel and antiparallel as a function of time.

TH.J-P15 - Time-resolved holographic imaging of magnetic vortex dynamics

3. Diamond Light Source Ltd, United Kingdom

X-ray Holography with extended reference by autocorrelation linear differential operation (HERALDO) holds great promise for imaging magnetic materials at the nano-scale. In particular it has been demonstrated recently that in-plane magnetised thin films can be imaged with much greater ease and stability than similar techniques such as Fourier Transform Holography (FTH). Here we report our first experiments on using the HERALDO technique to obtain time-resolved measurements. As an object of study we used magnetic vortex structures formed in 2µm x 2µm permalloy magnetic elements. Experiments were performed at ESRF using 16 bunch mode x-ray filling pattern. The aim of the experiments was to excite the vortex core gyration with a magnetic pulse and image different phases of gyration in a stroboscopic regime. The RF excitation of the vortex core was achieved with a CPW antennae integrated directly on top of the magnetic elements. By using different delay times between the pump and the probe allowed us to image the dynamics of the core within the sample at different stages of time from the point of excitation. Our results coincided with our predicted simulations for gyration time and amplitude. We aim to further develop this technique to be used on other, more exotic dynamic magnetic structures.

TH.J-P18 - Effect of the dzyaloshinskii-moriya interaction on the in-plane magnetization of submicronic structures

M. Cubukcu [1], J. Sampaio [1], A. Khvalkovskiy [2], M. Kuteifan [3], D. Apalkov [2], V. Lomakin[3], V. Cros [1], N. Reyren [1]

3. Department of Electrical and Computer Engineering, University of California at San Diego, La Jolla, United States

The Dzyaloshinskii-Moriya interaction (DMI) is known to be a direct manifestation of spin-orbit coupling (SOC) in systems with broken inversion symmetry. A large DMI can be generated at the interface, which breaks the symmetry, between a material having a large SOC (e.g. Pt or Ta) and a thin ferromagnetic layer. The DMI competes with the exchange interaction and can lead to new phenomena. We will present both micromagnetic simulations and experiments showing such competition in submicronic structures with in-plane magnetization. For example, our numerical results in elliptical structures show that for small volume and large aspect ratio, a strong DMI-associated energy is taking over the shape anisotropy, and that the magnetization is aligning along the minor axis of the ellipses: As the DMI energy increases and exceeds the energy associated to the shape anisotropy, the magnetization axis switches from the major axis to the minor one. This is due to the amount of tilted spins on the edges that is increased in this configuration, effectively reducing the DMI energy. Simulations were performed to study this phenomenon as a function of the geometry and the magnetic material parameters. We then fabricated nanostructures (e.g. ellipses) made of CoFeB/Pt ultrathin bilayers using e-beam lithography. Finally, these structures are characterized by Magnetic Force microscopic measurement to verify the numerical predictions.

Skyrmions are small size stable topological structures with very good mobility that have been considered for the use in future magnetic devices in the emergent field known as "Skyrmionics" [1]. The existence of such structures is usually associated to the presence of the Dzyaloshinskii-Moriya interaction (DMI) in magnets lacking inversion symmetry or thin films with translational symmetry breaking across the interface and spin-orbit interaction in the substrate. Skyrmions are characterized by a topological charge, the skyrmion number (Sk = +1 or -1). Several methods have been proposed to generate isolated skyrmions in magnetic thin films with DMI, based on micromagnetic simulation [2]. An unequivocal, general-purpose way to generate isolated skyrmions in magnetic films without stringent requirements of applied current, DMI and magnetic anisotropy is still lacking. In the present work we show that by judiciously tailoring the perpendicular magnetic anisotropy (PMA) it is possible to stabilize a skyrmion without DMI. The occurrence of skyrmion in Co/Pt multilayers has already been observed by photoelectron emission microscopy (PEEM) at room temperature [3]. Since the PMA can be tailored just by changing the Co thin film thickness, the skyrmions appear only in a particular range of Co thickness. Using an exhaustive analysis of micromagnetic simulations of Co films with the appropriate geometries and several values of PMA, we describe the magnetic configuration of disks, strips and squares. Our results show the limits of applicability of these non-DMI skyrmions in suitable ranges of perpendicular anisotropy, e.g., PMA in the range of 1.1 MJ to 1.4 MJ for a disk with a diameter of 2000 nm. The winding numbers are calculated in all structures and confirm the occurrence of these isolated, stable, axially symmetric skyrmions. Dynamic properties of these non-DMI skyrmions in strips, such as the propagation velocity as a function of spin polarized current density and applied external fields will be presented.

TH.J-P22 - Theoretical study on spin torque diode effect of a high-magetoresistance tunnel junction having a vortex free-layer and an in-plane polarized reference layer

H. Tsukahara [1], H. Imamura [2]

1. High Energy Accelerator Research Organization, Tsukuba, Japan
2. National Institute of advanced industrial science and technology, Japan

Spin torque (ST) induced dynamics of a magnetic vortex core has attracted much attention because of its potential applications as microwave oscillators[1]. The vortex-based ST oscillator (STO) exhibits comparatively narrow line-width compared with other kinds of STOs such as single-domain nano-pillars and point-contacts. ST diode (STD) is another important application of STO and it was recently demonstrated that the readiofrequency detection sensitivity of the MgO-based magnetic tunnel junction (MTJ) exceeded that of the semiconductor diode detector at a certain condition[2]. Since the out-of-plane component of ST is necessary to induce the self-oscillation of a vortex core, most studies of vortex based STO utilize the perpendicular magnetic filed or perpendicularly polarized reference layer (RL). However it was shown that the in-plane current flowing through the free layer (FL) could induce the self-oscillation of a vortex core[3].
In this study we theoretically analyze the STD effect of a high-magnetoresistance tunnel junction having a vortex FL and in-plane polarized RL. The tunnel resistance and therefore the tunneling current have strong in-plane inhomogeneity because of the curing magnetic structure of the magnetic vortex in the FL. The in-plane inhomogeneity of the tunneling current produces the in-plane current flowing in the FL. By solving the Thiele equation incorporated with the ST term due to the in-plane current we show that the in-plane ac current generated by the inhomogeneity of the tunneling ac current produces the steady oscillation of the vortex core and therefore the STD voltage. The threshold current amplitude of 10 nm thick circular CoFe FL with a diameter of 200 nm and magnetoresistance ratio of 200% is obtained as 0.055 mA

TH.J-P23 - B20 FeGe thin films elaboration for skyrmions observation

C. Bouard [1,2], P. Warin [1, 2], M. Jamet [1,2], A. Marty [1,2]

1. CEA, INAC-SP2M, Grenoble, France
2. Univ. Grenoble Alpes, INAC-SP2M, Grenoble, France

For a few years skyrmion has become a subject of interest. This topologically protected spin structure is a promising candidate for high density storage. Lack of inversion symmetry is a crucial condition for skyrmions formation. B20 chiral ferromagnets meet this condition and have a narrow skyrmion phase. FeGe is one of those, with the highest Néel temperature. Moreover working with thin films enables to decrease the magnetic field required to the skyrmion phase. We investigated two ways of fabrication. The first one is the solid phase epitaxy of iron on germanium. The second one is the deposition of FeGe on Si (111) substrate by sputtering. We used X-ray diffraction, AFM and SEM to characterize our samples. Firstly we deposited 10 nm of iron on Ge (111) substrate by molecular beam epitaxy, followed by an annealing at various temperatures. We observed that Fe diffuses above 400 °C. The B20 phase appears at 800 °C. Yet B20 FeGe is not predominant. We also noticed strange patterns at the surface of our samples. Secondly we deposited 50 nm of FeGe on Si (111) substrate by sputtering. Si (111) is ideal since it has a lattice parameter very close to the B20-FeGe. When the substrate is not sufficiently heated during the growth, we have a polycrystalline monoclinic phase. Above 400 °C, we obtain the B20 phase. But we observe a demixing, iron diffusing in silicon. The layers are also incredibly rough. Next step is finding a good protocol by varying deposition parameters.

TH.J-P24 - Temperature dependence of the ferromagnetic resonance at the spin reorientation transition of Mn_2RhSn thin films

C. Bennati [1,2], A. Caprile [2], O. Meshcheriakova [3], C. Felser [3], G. Ghigo [1], M. Coisson [2], M. Pasquale [2]

1. Department of Applied Science and Technology, Politecnico di Torino, Turin, Italy

3. Max-Planck-Institut für Chemische Physik fester Stoffe, Dresden, Germany

Recent experimental and theoretical studies, which demonstrate a complex non collinear magnetic behavior in Mn_2RhSn [1], indicate the realistic possibility of engineering the skyrmion states in this and in similar Heusler systems. In geometrically constrained systems, the skyrmion phase persists within a wider field-temperature regime [2].
In this work we correlate the magnetization dynamics and the static magnetic properties of a Heusler thin film of Mn_2RhSn grown on MgO(001) substrate by magnetron co-sputtering of the constituents. A low temperature vector network analyzer ferromagnetic resonance (VNA-FMR) setup is used to detect the behavior of the resonance frequency peak when the temperature is varied from 8 K to 150 K. The hysteresis loops are measured with a vibrating sample magnetometer (VSM) in the same temperature interval. In both techniques, the in plane (ip)/out of plane (oop) components of magnetization are investigated, while biasing the sample with a constant external magnetic field parallel/perpendicular to the surface. From static magnetic measurements, it is found that the oop component does not change in the whole temperature range 8 - 150 K, while a significant variation in the saturation magnetization of the ip component is observed.
The FMR measurements reveal a critical temperature region where a phase transition is inferred from the behavior of the ip and oop magnetization. A minimum in the oop FMR frequency is observed at 85 K, thus the aforementioned phenomenology is interpreted as connected to the spin reorientation transition, predicted for this alloy [1]. Being this spin reorientation process accompanied by a canted state, the inset of skyrmions state is favored in the temperature range around 85 K. Moreover, applying the Kittel equations for magnetization dynamics, it has been possible to reconstruct the evolution of the value of the anisotropy field Hk with temperature.

TH.J-P25 - Observation of spin transfer torques in the transverse magnetic susceptiblity of the Skyrmion lattice phase of MnSi

F. Rucker [1], A. Bauer [1], C. Schnarr [1], A. Chacón [1], P. Köhler [1], C. Pfleiderer [1]

1. Lehrstuhl für Topologie korrelierter Systeme, Technische Universität München, Garching, Germany

In the skyrmion lattice phase of MnSi the observation of sizeable spin transfer torques [1-3] in small angle neutron scattering and the Hall resistivity for current densities already five orders of magnitude smaller as compared to conventional magnetic materials promises easy experimental access to the precise qualitative and quantitative form of the Landau Lifshitz Gilbert equation. We report measurements of the transverse magnetic susceptibility in the skyrmion lattice phase of MnSi. As our main result we find a distinct increase of the transverse susceptibility with increasing current density around the critical current density jc. We discuss the broader implications of our experimental findings, which provide, for the first time, a direct link between a thermodynamic property and the effects of spin transfer torques in skyrmion lattices.

TH.J-P27 - Movement of non-collinear magnetic textures driven by temperature gradients

R. Yanes Diaz [1], D. Hinzke [1], U. Nowak [1]

1. Universität Konstanz, Konstanz, Germany

Recently, Dzyaloshinskii-Moriya (DM) interaction has attracted attention in magnetism due to the fact that it can lead to the formation of skyrmions as well as spin spirals [1] with promising applications in spintronics [2,3]. Furthermore, temperature gradients can cause magnonic spin currents and with that spin transfer torques leading to a movement of a domain wall [4,5]. In this work, we combine both topics to analyse the dynamics of two dimensional non-collinear magnetic textures subject to a temperature gradient.
Numerical calculations of the dynamics of a spin spiral (SS), skyrmion lattices, and isolated skyrmions are carried out within an atomistic spin model using Langevin dynamics. Our results show that the SS moves towards the hotter area driven by the temperature gradient. The SS velocity depends on the sign of the temperature gradient due to chirality o the spiral.
In the case of Skyrmions, first we calculate the magnetic phase diagram and determine the isolated skyrmions and skyrmions lattice phases using Monte Carlo simulations. Later, we study the dynamics of these two phases observing here a clear difference between the movements of isolated skyrmions and skyrmions lattice. While in the isolated skyrmion case the motion is determine by the temperature gradient and the Magnus force, in the lattice case the interaction between skyrmions plays a fundamental role.

TH.J-P28 - Emergent electrodynamics in $Mn_{1-x}Fe_xSi$

C.Schnarr [1], F. Rucker [1], C. Franz [1], R. Ritz [1], A. Bauer [1], C. Pfleiderer [1]

1. Technische Universität München - Lehrstuhl Für Topologie Korrelierter Systeme, Germany

The emergent electrodynamics of the skyrmion lattice phase in chiral magnets comprise of an emergent magnetic field of one flux quantum per skyrmion that gives rise to an emergent electric field, when the skyrmion lattice moves under the application of spin currents exceeding a critical current density j_c [1,2]. We report a study of the emergent electrodynamics in $Mn_{1-x}Fe_xSi$, where we exploit a well understood increase of the topological Hall resistivity by an order of magnitude with increasing Fe concentration [3]. On the one hand, this allows us to track j_c for increasing emergent magnetic field in the presence of increasing disorder. On the other hand, we observe evidence for emergent electric fields even in the magnetoresistance, reflecting, in combination with the emergent electric field in the Hall signal, the direction of motion of the skyrmion lattice.

TH.J-P29 - Resonant perpendicular magnetic field induced interlayer-coupled vortex and other metastable state excitations

C. Teng [1], L. Chang[2], S. Lee[2]

1. Academia Sinica, Taiwan
2. National Chengchi University, Taipei, Taiwan

We report experimental detection of interlayer-coupled magnetic vortex core and different stable excitation states in out-of-plane magnetic field that oscillates at the eigenfrequencies of permalloy(Py)/Cu/Py trilayer disks. The samples are Ta(10)/Py(10)/Cu(3)/Py(25) (thickness in nm) disks with 2µgm diameter, patterned via electron-beam lithography on top or in the gap of ground-signal-ground (GSG) coplanar waveguides. In-plane or out-of-plane high-frequency magnetic field can be generated by a radio frequency signal generator. We show that by using a sequence of an in-plane resonant field (H_t) and a resonant out-of-plane field(H_r), different ferromagnetic (FM) layer resonant states can be controlled in a systematic way. The two FM layers were in resonance under specific fields H_t and H_r, where the thick FM layer was in the magnetic vortex state configuration and the thin FM layer was in other stable states. When the thin FM layer is excited, the inverse spin Hall effect (ISHE) induced in the adjacent Ta layer generated dc voltage difference across the sample. We observed several peaks between 5 GHz and 7 GHz (figure 1), which were sensitive to the field. Good agreements between the experimental results and those from micro-magnetic simulations were found. Despite the complex behaviors, the interlayer-coupled state can be clearly measured at several different frequencies, thus can be useful for designing magnetic devices base on multiple magnetic resonant states.

TH.J-P30 - Antiferromagnetic Skyrmions

O. Tretiakov [1], J. Barker [1]

1. Institute For Materials Research, Tohoku University, Japan

Manipulating small spin textures, which can serve as bits of information, by electric current is one of the main challenges in the field of spintronics. Ferromagnetic skyrmions attracted recently a lot of attention because they are small in size and can avoid pinning, while moved by electric current, better than other topological objects such as domain walls. Meanwhile, ferromagnetic skyrmions still have disadvantages such as the presence of stray fields and transverse dynamics, making them harder to employ for spintronic applications. In this work, we propose a novel topological object: antiferromagnetic (AFM) skyrmion. This topological texture has no stray fields and we show that its dynamics is faster compared to its ferromagnetic analogue. We find the dependence of AFM skyrmion radius on the strength of Dzyaloshinskii-Moriya interaction coming from relativistic spin-orbit effects and temperature. More importantly, we show that due to unusual topology the AFM skyrmions do not have a transverse to the current component of velocity and thus can be perfect candidates for spintronic applications.

TH.J-P31 - Skyrmion interactions with domain walls in perpendicular magnetized materials

F. Garcia-Sanchez [1], J. Kim [1], A. Vansteenkiste [2], B. Van Waeyenberge [2]

1. Institut d'Electronique Fondamentale, Univ. Paris-Sud, Orsay, France and UMR 8622, CNRS, Orsay, France
2. Department of Solid State Sciences, Ghent University, Ghent, Belgium

Skyrmions are spin configurations that possess topological charge. Due to their robustness they have been proposed as information carriers in future magnetic memory devices [1]. Key to implementing such memories are operations like the controlled creation or destruction of skyrmions. In this work we report micromagnetic simulations of the interaction between domain walls and skyrmions. We show that several of those operations can be achieved by means of a moving domain wall. It has been reported that the Dzyaloshinskii-Moriya interaction, necessary to stabilize skyrmions, gives rise to Neel walls and increased Walker fields in perpendicularly magnetized wires [2]. We show that the Walker breakdown in these materials consists of the creation of inhomogeneities along the wall. If skyrmions are stable for the corresponding applied field, then the moving domain wall periodically nucleates skyrmions. Moreover, the speed of field-driven domain walls is affected by the presence of skyrmions, which do not move under homogeneous fields. The domain wall acts as a field gradient and produces a drift in the skyrmions, where the drift component parallel to the domain wall is larger due to the gyrotropic motion of skyrmions. When the speed of the domain wall exceeds that of the drift then the skyrmion is annihilated. This behaviour presents practical features for a skyrmion memory like the creation of a skyrmion reservoir or a memory eraser. These results show the connection between different types of topological defects in magnetic materials.

TH.J-P32 - Time-dependence of the topological unwinding of skyrmions in chiral magnets

A. Chacon [1], A. Bauer [1], M. Halder [1], J. Kindervater [1], F. Rucker [1], S. Mühlbauer [2], C. Pfleiderer [1]

1. Technische Universität München, Germany
2. Heinz Meier-Leibnitz Zentrum (MLZ), Germany

Cubic chiral helimagnets with space group P213 share a common magnetic phase diagram comprising a helical, a conical, a field-polarized, and a paramagnetic state. In addition, these materials give rise to a regular arrangement of topologically non-trivial spin whirls, the so-called skyrmion lattice [1]. Usually, in the bulk chiral magnets the latter is stabilized only in a small phase pocket in finite fields close to the helimagnetic ordering temperature. In Fe1-xCoxSi, however, the skyrmion lattice may be made to exist down to the lowest temperatures, when field cooling through the skyrmion lattice phase [2]. The resulting metastable state may then decay into different topologically trivial states, subject to the detailed temperature and field history. As each skyrmion is associated with an emergent flux of precisely one flux quantum, its unwinding is accomplished through a topological defect that acts effectively as a sink of magnetic flux, i.e., a magnetic monopole [3]. A detailed understanding of the underlying processes, besides their implications for fundamental solid state research, may pave the way for spintronic applications exploiting the creation and deleting of single skyrmions in various compounds or heterostructures [4, 5]. Here, we report a comprehensive study of single-crystal Fe0.5Co0.5Si by means of small-angle neutron scattering, magnetization, and ac susceptibility measurements. All data have been collected as a function of temperature, magnetic field, cooling history, and, in particular, time. Depending on the details of the field and temperature history, we observe evidence for distinctively different processes of the topological unwinding.

Understanding the detailed effects of local inhomogeneity, intrinsic to most thin film materials used in nanomagnetic technology, becomes increasingly important as device dimensions shrink. Spatial inhomogeneity on the nanoscale can affect both static and dynamic magnetic responses [1]. Focused ion beam patterning is an elegant way to artificially-impose magnetic inhomogeneity on a very local scale. The strength and lateral dimension of the sites are tailored by varying the beam dose.
A quantitative understanding of magnetic pinning has been gained through studies of the quasi-static (Barkhausen) response of a magnetic vortex core interacting with the local energetic landscape [2,3]. An extension of nanomechanical torque magnetometry, with the capability of measuring simultaneously the DC moment and AC susceptibility [4], enables us to characterize the modifications both of statics and dynamics, arising from the presence of engineered pinning sites.
Experimental results for a Permalloy disk will be discussed, and compared to numerical micromagnetic simulations.

Control of parameters of the magnetic vortex state in the disks is interesting and actual problem. In our previous studies we have showed that in a nanostructure consisting of big and small disks of permalloy, separated by a nonmagnetic Cu layer, the motion direction of the vortex core is dependent on the orientation of the applied magnetic field [1-3]. In this paper we experimentally show the effect of single-domain state in a small disk on the precession of the vortex core in a large disk. Diameter of the small and big disks are 200 and 600 nm, respectively. The disk thickness is 35 nm and the thickness of the copper layer between the disks is 3 nm. Disk-on-disk nanostructures have been fabricated on a Cr/Au waveguide. As reference samples we have used arrays consisting of single Py nanodisks with the diameter of 600 nm. Measurements of dynamic properties of the vortex have been done in a reflection mode using the vector network analyzer (VNA). The measured resonance frequency in single Py disks with diameter of 600 nm at zero field is 452 MHz, and the linewidth is 15 MHz. In the disk-on-disk nanostructure the linewidth increases up to 65 MHz, which is caused by an interaction between the small and big disks. We have showed that the change in orientation of the static in-plane magnetic field leads to a modification of a spin-wave spectrum of the nanostructure. Using micromagnetic simulations, we have analyzed the motion dynamics of the magnetic vortex in the disk-on-disk nanostructure. A good agreement between the calculated and experimentally measured data has been found.

Magnetic chirality is the key ingredient to stabilize skyrmion textures and lattices, which combine fascinating properties with the potential of becoming the spintronic devices of the future. These new states of matter are generated by the anti-symmetric zyaloshinskii-Moriya interaction resulting from the absence of a center of symmetry in the crystal structure, as this occurs in thin films, metallic compounds or insulators crystallizing in the B20 structure type (space group P213). In this topical field of research polarized neutrons provide unique insight on the structure and topology of the magnetic correlations, due to the specificities of the neutron spin. The presentation will focus on the case of a multiferroic insulator Cu2OSeO3 which orders at TC = 58 K into a chiral helical state with a period of ~ 650 Å along the (100) direction. Polarised neutron scattering and neutron spin echo spectroscopy were used to investigate the chiral properties and dynamics in Cu2OSeO3. We will discuss the chiral magnetic correlations and fluctuations in the very close vicinity of TC. And then focus on a systematic study of the scattering under a magnetic field, which leads to a complex temperature-field phase diagram with a well-defined skyrmion lattice phase. We will also report the dynamic phase transitions where the kyrmion lattice phases appear and then vanish spontaneously after switching off the magnetic field. The results will be discussed in the general context of chiral magnetism.

Th.J-P37 - Spin motive force driven by the skyrmion lattice in the presence of the Rashba spin-orbit interaction

J. Ohe [1], Y. Shimada [1]

1. Toho University, Japan

In a ferromagnetic metal, the dynamics of the non-uniform magnetic structure adds the spin Berry phase on the spin wave function. This geometrical phase induces the spin-dependent electromotive force that acts on the conduction electrons, called as a spin motive force. Recently, it has been pointed out theoretically that the dynamics of the skyrmion lattice induces the large spin motive force [1]. The measurable voltage is enhanced by the cascaded effect due to the phase-locked motion of skyrmions formed in a lattice structure. This non-uniform magnetic structure is realized in a chiral magnet in the presence of the Dzyaloshinskii-Moriya (DM) interaction. The DM interaction is originated from the spin-orbit interaction that may affect to the spin-motive force. In this report, we numerically investigate the spin motive force driven by the resonant motion of the skyrmion in the presence of the Rashba spin-orbit interaction. We consider the magnetic nanodisk where the boundary of the sample affects the resonant motion of the skyrmion motion. First, we show that the phase-locked motion of the skyrmion lattice is observed only in the lowest energy mode in an isolated nanodisk. We also show that the cascaded spin motive force is obtained in this lowest mode. Secondly, we show that the spin motive force is modulated by the by the Rashba spin-orbit interaction. The direction of the spin motive force is changed and the modulation of the spin motive force can be clarified by measuring the phase shift of the AC voltage. We also discuss the feedback effect that induced by the spin transfer torque due to the current by the spin motive force.

Research on MnAs films gave place to an intense activity in earlies 2000, due to its potential application in spintronic hybrid metal/semiconductor devices. Bulk MnAs presents a first-order magneto-structural transition that drives the system from a hexagonal ferromagnetic phase (a) to an orthorhombic paramagnetic phase (b). Instead, in MnAs thin films the a and b phases coexist in a wide temperature range below Tc (~283-313K). In the case of MnAs//GaAs(001), the a and b phases forms a characteristic stripes pattern alternating ferromagnetic ridges with non-magnetic grooves along the MnAs[0001] direction (c-axis). A large magneto-crystalline anisotropy ensures that all magnetic moments are aligned along the [1120] easy axis (a-axis).
X-ray photoemission electron microscopy (XPEEM) has been used for the direct imaging of magnetic domains of MnAs lithographed ribbons. We have investigated the dependence of the domain structures with films thickness and ribbons widths. The evolution of the magnetic domains structure and magnetic contrast with temperature has been studied in the ferromagnetic/paramagnetic phase coexistence temperature range. The temperature variation of the ferromagnetic signal close to the Curie temperature is strongly affected by the ribbons thickness. Results show that larger samples present domains patterns similar to films ones, composed of head-on domains separated by wedge boundaries. The magnetic domains shape and size are stable with respect to temperature. The magnetic domains of samples confined along the c-axis do not show significant change when their size is reduced. On the other hand, samples confined along the a-axis present a transition from head-on domains to regularly-stacked rectangular domains for the aspect ratio w/t~6.5. This behavior is ascribed to the balance between shape and magneto-crystalline anisotropies. The domain walls and size of the thinner samples are nearly independent of the ribbons width while notable but systematic changes were observed in the domains of the thicker samples.

TH.K-P02 - Ferromagnetism in Pd(100) ultrathin films enhanced by distortion

S. Sakuragi [1], H. Tajiri [2], T. Sato [1]

1. Department of Applied Physics and Physico-Informatics, Keio University, Japan
2. JASRI/SPring-8, Japan

We recently found the appearance of ferromagnetism in the ultrathin film of Pd(100) depending on the film thickness at a period which is consistent with the predictions based on d electron quantum-well (QW) state [1]. However, the spontaneous magnetization, which is comparable to that of nickel, is much higher than the value obtained from the calculation based on QW states. The magnetic enhancement of Pd(100) film is attributed to additional effects which were not assumed in the calculation. In this study, the in-situ rigorous structure analysis of ~ 16 mono layers Pd(100) ultrathin film deposited on SrTiO3 (STO) substrate was performed using SPring-8 beam line BL13XU in order to establish a more accurate picture of ferromagnetism in Pd(100) film. As a result, the in-plane and out-of-plane lattice in Pd showed the 0.2 and 2.3% expansions compared with the bulk value, respectively. The out-of-plane lattice expansion is unexpected because the lattice mismatch between Pd and STO is 0.4% which is consistent with the in-plane expansion. Previous theoretical calculations predicted that the bulk Pd should show ferromagnetism at the 4 - 6 % lattice expansion [2]. Thus, the out-of-plane lattice expansion in Pd(100) film is also favorable to stabilize the ferromagnetism. Based this, we propose a picture that the Pd(100) ultrathin film is spontaneously distorted to stabilize the QW state to express ferromagnetism. This explains the enhancement of spontaneous magnetization in Pd(100) ultrathin film compared with the calculation through the synergistic effect of distortion and QW states.

TH.K-P03 - MgO based tunnel junctions

L. Avilés Félix [1,2], J. González [1, 2], M. Sirena [1,2]

1. Consejo Nacional de Investigaciones Científicas y Técnicas, C1033AAJ Buenos Aires, Argentina
2. Centro Atómico Bariloche & Instituto Balseiro, Comisión Nacional de Energía Atómica-Universidad Nacional de Cuyo, San Carlos de Bariloche, Argentina

In the last years, MgO-based magnetic tunnel junctions (MTJ) with metallic electrodes (Fe, CoFe) have been widely studied due to their potential high TMR values (around 1000%). This is due to the coherent tunnelling of electrons in epitaxial MTJ.

In this work we will present the electrical and magnetic characterization of CoFe/MgO/CoFe patterned magnetic tunnel junctions grown on Si(100) and MgO(100) substrates. The obtained junctions are pillars with different areas (1600, 625, 100 and 25 μm^2) and fabricated by optical lithography. I(V) curves obtained by Conducting Atomic Force Microscopy of patterned MTJ were performed at room temperature in order to explore the reproducibility and homogeneity of their transport properties. The results show a more insulating behavior of the junctions grew on Si(100). The magnetic order of the structures was characterized by magnetization measurements so as their magnetic anisotropy and interlayer coupling. We also explored the influence of the substrate temperature during growth on the magnetic properties and the topographical features of the bottom electrode. An increase of the coercive field was achieved increasing the substrate temperature during the growth of the bottom electrode. These results are promising for the development of magnetic tunnel junctions.

TH.K-P04 - Submicrometric 2d Magnetic Domain Wall Ratchets

Magnetic domain walls (DWs) propagation is a relevant subject both in basic and applied science, such as the development of new technology based on DW memory or DW logic. It has already been demonstrated that a ratchet effect can be induced in the DW propagation by fabricating nanowires with asymmetric notches. The study was further extended to a 2D thin film by fabricating an array of holes with asymmetric shape and size in the tens-of-micrometers range [1]. Considering DWs as elastic lines with zero thickness, a phi-4 model [2] predicted the crossed-ratchet regime, in which a DW enters the array forward, and reversing the applied field causes it to propagate backward through kinks. In the present work, the study of DW propagation through 2D arrays of asymmetric holes has been extended to the limit of hole sizes of the order of the DW width, that is, about 500 nm. This closes the gap between previous studies in 1D nanowires and 2D arrays of holes in the tens-of-micrometers range.
The DW propagation through the entire array has been characterized by means of magneto-optical Kerr effect (MOKE) microscopy. On one hand, a clear ratchet effect has been observed in all the studied geometries. On the other hand, the small size of the holes hinders the kink nucleation, and thus no crossed-ratchet effect is observed. The DW morphology and local pinning at the holes have been investigated by means of X-Ray photoemission electron microscopy (XPEEM). This has provided a detailed picture of the pinning mechanism, which justifies the difficulty of nucleating a kink in the pinned DW.

In recent years, due to the technological importance in the realm of spintronic devices, there has been theoretical as well as experimental interest in the study of Fe films grown on metallic and on semiconducting substrates. Much effort has been devoted to the properties of nanometer thick Fe epilayers epitaxially grown on MnAs/GaAs(001)1.
This is motivated by the future potential applications of MnAs films as active magnetic templates controlling the magnetic properties of the overlayer through temperature tuning2. Within this context, the Fe monolayer (ML) coverage limit has not yet been approached.
In this presentation, we analyse the extreme case of a Fe monolayer deposited on MnAs using density functional theory.
It is found that a FeAs quasi 2D antiferromagnetic nanostructure emerges, which is magnetically almost decoupled from the substrate due to bridging effects of the arsenic atoms of the interface.
The magnetic interactions display an angular dependence characteristic of a superexchange-like behaviour, which are being modelled by a Heisenberg type Hamiltonian. The magnitude of the obtained interactions are similar to those appearing in Fe-based pnictides3. As a whole, the FeAs emerging nanostructure constitutes a 2D object which presents a nearly unsupported behaviour and that poses a challenge for heterostructure-based interface engineering.

TH.K-P08 – Resistance behavior in nanostructured $La_2/3Sr_1/3mno_3$ thin film

I. Arango [1], M. Gomez [2], A. Avila [3], P. Prieto [2,4]

1. School of Materials Engineering, Universidad del Valle, Cali, Colombia
2. Thin Film Group, Department of Physics, Universidad del Valle, Cali, Colombia
3. Department of Electrical and Electronic Engineering, Universidad de Los Andes, Bogotá, Colombia
4. Center of Excellence for Novel Materials - CENM, Universidad del Valle, Cali, Colombia

La2/3Sr1/3MnO3 (LSMO) is the most interesting compound of the manganite perovskite family due to its Curie temperature above room temperature that makes its remarkable physical properties desirable for practical applications as magnetic sensors. However, it is well known that the ferromagnetic properties of a material weaken in the presence of reduced dimensions. In this research, we have grown $La_2/3Sr_1/3MnO_3$ thin films by sputtering DC in pure oxygen atmosphere on $SrTiO_3$ (001) substrates at temperature of 830 ^oC. From x-ray diffraction (XRD) analysis, we found the Bragg peaks for LSMO thin films only (002) peaks are observed indicating a textured growth. We have characterized morphologically samples by scanning electron microscopy (SEM) and atomic force microscopy (AFM). LSMO thin film was patterned using standard UV photolithography and silver contacts bonded by copper wire were used to connect the pads to the sample holder. Dependence of resistivity with temperature shows a behavior typical of this ferromagnetic system with metal-insulator transition above 300 K. The electrical properties will be contrasted with thin film and bulk material. We carried out isothermal resistance and magnetization versus applied magnetic field loops to characterize the samples. We study the dependence of magnetic transport properties with film thickness (under 60 nm) and path size (under 1.5 micron) for potential applications like magnetic sensors.

TH.K-P09 - Domain Structure and magnetoresistance in Co_2MnGe zigzag structures

K. Gross [1], K. Westerholt [2], M. Gomez [3], H. Zabel [2]

1. CENM, Universidad del Valle, Cali, Colombia
2. Festkörperphysik, Ruhr Universität-Bochum, Bochum, Germany
3. Grupo de Peliculas Delgadas, Universidad del Valle, Cali, Colombia

We report a clear manifestation of the negative contribution to the magnetoresistance due to domain walls in Co_2MnGe-Heusler submicron zigzag wires in which the domain structure, domain size and domain wall density can be well controlled. The magnetic behaviour of these systems results from the interplay between the intrinsic magneto-crystalline (K4) anisotropy, tuneable growth induced uniaxial anisotropy (1.2x10^3 J/m^3 < KU < 6,1x10^3 J/m^3) and shape anisotropy (KS), as observed by magnetic-force microscopy (MFM) and longitudinal Kerr hysteresis loop measurements [1]. Magnetoresistance measurements were performed by the four-point method under a field applied in the plane of the wires and at different in-plane orientations at variable temperatures from 10 to 300 K. In these structures, DW-creation and annihilation occur in a coherent way. As a result, clear jumps of the resistance are detected during the transition from single-domain- to multi-domain states. At room temperature a value RDW = -1.1Ω was obtained; this result agrees in the order of magnitude with other experimental and theoretical findings [2,3]. The temperature dependent negative resistive contribution due to the domain wall is also discussed and compared with the existing theoretical models. Acknowledgements: This work has been partially supported by CENM-UNIVALLE and L'OREAL-UNESCO.

TH.K-P10 - Surface nanostructure and magnetism of ultrathin Pd(001) films on Au(001)

T. Kawagoe [1], N. Kutsuzawa [1], K. Kondoh[1]

1. Osaka Kyoiku University, Japan

Magnetism of Pd has been investigated for decades, e.g., ferromagnetism of ultrathin Pd films was theoretically predicted, although Pd was nonmagnetic in bulk. Increasing of a density of states (DOS) due to confinement effects is thought to be responsible for the origin of the ferromagnetism. Nevertheless, there is few direct experimental evidence of the origin of ferromagnetism. A simultaneous observation of between surface nanostructure and the spin-resolved DOS is essential for understanding the origin of the ferromagnetism of the Pd films. Here we report the surface structure and the result of differential conductivity (dI/dV) measurement of ultrathin Pd films. Experiments were performed in an UHV-MBE system equipped with an STM unit and an instrument for low-energy electron diffraction (LEED). After a cleanliness of a Au(001) reconstructed surface was confirmed by STM, Pd was then deposited on it at room temperature (RT). The LEED pattern of Pd(001) films shows a fourfold p(1ü~1) structure, verifying that the Pd layers grow epitaxially on the Au(001) surface with fcc structure. The observed STM images show that the RT growth of Pd layers was dominated by an island growth mode, whereas a surface morphology of Pd layers after post-annealing (PA) at 473 K consists of atomically flat terraces. It turns out from the observed lattice constants by the LEED patterns that the Pd(001) films show lattice expiations of 4.7% for 4ML, and 3% for 12ML. We also observed strain relief patterns on the surface, when the Pd layers exceed 12 ML. The dI/dV spectra of the RT growth of Pd films are featureless. The 4ML thick of Pd(001) films after PA, however, show a distinct peak at +250 mV, which may correspond to the spin-polarized surface states of Pd(001) surface. The details of experimental results are discussed together with ex-situ magneto-optical Kerr measurements at RT.

TH.K-P11 - Controlling the size and relaxation dynamics of superferromagnetic domains

S. Bedanta [1], N. Chowdhury [1], W. Kleemann [2]

1. National Institute of Science Education And Research, Bhubaneswar, India
2. Physics Department, Universität Duisburg-Essen, D-47057 Duisburg, Germany

Magnetic nanoparticles below a critical radius form a single domain in which all the atomic spins are oriented along one direction. The net magnetization of such single domain magnetic nanoparticles is called as a "superspin" or "macrospin". An ensemble of such single domain magnetic nanoparticles with dilute concentration and hence negligible inter-particle interactions will show single-particle behaviour. In this case the magnetization reversal can be explained in terms of coherent rotation of superspins as described by Stoner-Wohlfarth model. However in a dense ensemble of magnetic nanoparticles but still below physical percolation, sufficiently strong interactions can be experienced to form a "*superferromagnetic* (SFM)" state. [S. Bedanta et al., *Phys. Rev. Lett.* 98, 176601 (2007)].
Magnetization reversal processes using Magneto-optic Kerr microscopy in longitudinal configuration have been studied on a discontinuous metal-insulator multilayer sample $[Co_{80}Fe_{20}(1.3nm)/Al_2O_3(3nm)]_{10}$ showing superferromagnetic behavior. On applying the magnetic field at various angles to the in-plane easy axis we observe that both domain sizes and shapes can be changed. The reversal process by magnetizing along the easy axis (EA) is governed via domain wall motion followed by subsequent nucleation. However, as q is increased away from the easy axis, the ferromagnetic correlation strength decreases. It is found that the magnetization reversal occurs via domain wall motion and nucleation up to q = 60°, where q is the angle between the easy axis and external magnetic field. But near to the hard axis, magnetization reversal occurs via coherent rotation of superspins. Magnetization relaxation measurements were performed at various angles between the magnetic field and the easy axis. Also relaxation time increases at increasing ϑ.

Introduction

The recent surge in demand for miniaturization of power transformers and inductors requires core materials with low energy loss, high flux density, high permeability and high operating frequency. Recent developments in magnetic materials such as CoZrO granular films and CoNiFe alloy thin films, have been evaluated for integrated devices for high frequency applications. In this work, a commercial amorphous material (Metglas® 2605HB1M) with high flux density and low loss properties at lower frequencies is used for multilayered thin films with very promising properties at higher frequencies.

Sputtering procedure

Multilayered films were prepared using a magnetron sputtering system, with a base pressure of 4 x 10^{-7}Torr. A composite 2-inch target from amorphous ribbon $Fe_{85-95}Si_{1-10}B_{1-10}$ (commercially known as Metglas® 2605HB1M or HB1) was used. All the depositions were performed on SiO_2 substrates at 3mTorr Ar pressure.

Experimental analysis

The structural analysis was performed by X-ray diffraction using Cu-Kα radiation. In all cases, no peaks related to a crystalline phase were observed, verifying the amorphous nature of the sputtered samples.

AC hysteresis loops measurements were performed by a B-H Loop Tracer at 50Hz. It can be seen that the multilayers have the same saturation magnetization as the original material (1.62T). The coercivity varies between 80-500A/m, a very good result considering that the original material has 40A/m coercivity.

High-frequency complex permeability measurements up to 9 GHz were performed in a PMM-9G1 permeameter, The results show a constant μ' greater than 300 in all samples, with working frequency up to 900MHz, with relatively low initial μ''. The best sample has a constant μ', about 850.

Conclusions

The FeBSi/Al_2O_3 multilayer thin film properties in combination with their easy, fast and reproducible fabrication demonstrate that they may have applications in integrated inductive components used under high frequency in the megahertz range.

Th.K-P13 - Effect of planar magnetocrystaline anisotropy in vortex configuration of micro-scale disks

M. Martins [1], S. Parreiras [1, 2]

1. CDTN/CNEN, Belo Horizonte, Brazil
2. UFMG, Belo Horizonte, Brazil

Soft ferromagnetic dots with sub-micrometer size can exhibit in the ground state a curling spin configuration known as magnetic vortex. In the case of soft ferromagnetic materials in micron and submicron scales, small changes in shape, size and material's anisotropy can modify the energy equilibrium that defines the stable spin structure. In this work, we investigated the magnetic configuration of micron-sized $Co_{60}Fe_{40}$ and Permalloy disks by comparing the results of micromagnetic simulations and magnetic force microscopy (MFM) measurements. By comparing the results for $Co_{60}Fe_{40}$ and Permalloy it was possible to elucidate the effect of the planar magnetocrystaline anisotropy in the stability of the magnetic vortex configuration. The results for disks with diameters between 0.5 and 8 μm and nominal thickness of 20 nm showed that the anisotropy favors spins alignment and domains division, reducing vortex stability. Although the vortex is the lower energy state, the MFM results showed also different magnetic configurations. The proportion of disks in each configuration depends on the disk diameter. Additionally, a statistical analysis of the magnetic configuration distribution observed in MFM experiments was performed and compared with the simulation results.

2. CNRS and Universitė Pierre et Marie Curie, INSP, UMR7588, Paris, France

Tailoring of magnetic and structural properties of magnetic nanofilms by the slow highly charged ion irradiation is a work of interest for technological application [1]. To study the influence of such irradiation process on physical properties of zinc ferrite thin films a series of samples were fabricated in controlled condition at room temperature onto Si (111) substrates by pulsed laser deposition method (PLD) [2,3]. Structural and magnetic properties of these zinc ferrites thin films were under investigation before and after being irradiated by 90 keV neon beam. The crystallographic characterizations of the films were performed using X-ray diffraction (XRD). Information about films thicknesses were obtained with a scanning electron microscope (SEM), and profilometry measurements. The morphology of the thin films was characterized using an atomic force microscope (AFM). Vibrating sample and SQUID magnetometers where used to measure the magnetic properties of the laser ablated films. We have recorded the magnetization as a function of applied field at room temperatures (RT) and at lower temperatures (200K, 100K and 10 K) for the pristine and irradiated specimen in order to observe the change in the magnetic properties of the system under investigation. Further, thermal magnetic measurements in zero-field cooled (ZFC) and field cooled (FC) mode were carried out to understand the underlying physics responsible for the change in magnetic properties. It was observed that ion bombardment does not affect the chemical composition of the films, but changes significantly their magnetic properties. These modifications are related to local changes of the film structure during the irradiation and to the implantation of ions. More precisely, modifications of the film properties after irradiation, like coercivity, saturation magnetization, crystal lattice, etc., have been studied as a function of the ion species, the ion penetration depth and the irradiation fluence.

TH.K-P15 - Effect of lattice mismatch on the morphology and magnetic properties for $L1_0$-ordered FePt thin films

H. Iwama [1], M. Doi [2], T. Shima [3]

1. Tohoku Gakuin University, Japan

Recently, $L1_0$ FePt ordered alloy with high magnetocrystalline anisotropy (K_u=7.0×10^7 erg/cc) has attracted much attention, since they are believed to be good candidates for future magnetic devises such as next-generation ultrahigh-density magnetic storage media and biasing nanomagnets [1]. It is also thought to overcome the problem of thermal fluctuation in nano-meters scale. A lot of studies such as thin films and self-assembled nano particles have been investigated [2], [3]. However, magnetization process of FePt thin films has not been fully elucidated. In this study, in order to see the effect of lattice mismatch between FePt thin films and single crystal substrates on the magnetization process, FePt thin films have been fabricated on $MgAl_2O_4$ (MAO) and MgO single crystalline substrates and their structure, magnetic properties and magnetic domain structure have been investigated.
All the samples were prepared using an ultrahigh vacuum magnetron sputtering system. FePt films were prepared by co-sputtering Fe and Pt targets directly onto single crystalline MgO (100) or MAO (100) substrates. The substrates were heated to T_s = 700 ºC during deposition. The nominal thickness of FePt film (t_{FePt}) was varied in the range between 5 and 100 nm. The magnetic properties were measured by a superconducting quantum interference device (SQUID) magnetometer. The structure analysis was performed by X-ray diffraction (XRD) with Cu *K*α radiation. The magnetic domain structure was observed by a magnetic force microscope (MFM).
From XRD patterns, in addition to a fundamental (002) peak, (001) and (003) superlattice peaks from the $L1_0$-FePt phase have been clearly observed for all samples. Magnetization curves for the FePt films with MgO substrate. The maximum *Hc* of 54.3 kOe was observed for the film with t_{FePt} = 10 nm. From MFM images, the single-domain structure was observed at t_{FePt} = 10 nm.

TH.K-P16 - Confinement effects in lattices of nanoskyrmions

J. Hagemeister [1], A. Kubetzka [1], E. Vedmedenko [1], R. Wiesendanger [1]

1. University of Hamburg, Germany

In this Investigation ground states of two-dimensional nanoskyrmions lattices in structured magnetic elements of different shape are addressed. It is demonstrated by means of Monte-Carlo simulations that the nanoskyrmions couple to the edges of magnetic elements and demonstrate strong confinement effects. The measure of confinement is quantified and compared with experimental Spin-polirazed Scanning Tunneling Microscopy data on Fe/Ir(111).

TH.K-P17 - Splitting of spin-wave modes in periodically perturbed thin films: theory and experiment

R. A. Gallardo [1], A. Banholzer [2,3], K. Wagner [4], M. Körner [2,3] K. Lenz [2], M. Farle [4], J. Lindner [2], J. Fassbender [2,3], P. Landeros [1]

A joint theoretical-experimental study focusing on the description of the ferromagnetic resonance response of thin films in the presence of periodic perturbations introduced on the upper film surface is presented [1-2]. From the viewpoint of theory, these perturbations may exist in the form of any kind of one- or two-dimensional rectangular defect arrays patterned onto one surface of the magnetic film. Indeed, the defects may be pits or bumps, or ion-implanted regions with a lower saturation magnetization. The complete set of response functions, given by the components of the frequency and wave-vector dependent dynamic magnetic susceptibility tensor of the film exposed to microwave excitation, are provided and are used to explain the experimental data. This allows us to obtain the response of the system due to microwave absorption, from which the zero wave-vector spin-wave modes in the field-frequency spectra, including their intensity, are calculated. Explicit calculations for periodic defects featuring the shape of stripes, dots and rectangles are given in detail, as well as experimental results for stripe-like defects prepared either by topographical depressions or by ion implantation of thin magnetic films. The excellent agreement of the theoretical and experimental results manifests the validity of the presented model.

SrRuO3 have received intensive research interest because it is one of the very few ferromagnetic metallic 4d transition metal oxides, with a high Curie temperature of Tc=160 K, as well as unusual negative spin polarization and magnetoresistive properties. Ru^{4+} has S=1 spin state, however, very recently it has been suggested that a high spin state (S=2) of Ru^{4+} could be stabilized on compressively in-plane strained SrRuO3 films. We report a study of the local magnetism in thin films of $SrRuO_3$ grown on (111)- and (001)-oriented SrTiO3 substrates using x-ray magnetic circular dichroism spectroscopy (XMCD) at the Ru-L2,3 edges. The application of the sum rules to the XMCD data gives an almost quenched orbital moment and a spin moment close to the value expected for the low spin state S = 1. Analysis of the spectral lineshape using full-multiplet cluster calculations indicates that the low spin state is quite stable and suggest that the occurrence of a transition to the high spin state S = 2 in strained thin films of $SrRuO_3$ is unlikely as it would be too expensive in energy.

TH.K-P19 - Characterisation of polycrystalline heusler alloys

T. Huminiuc [1], J. Sinclair [1], H. Wu [1], G. Vallejo-Fernandez [1], A. Hirohata [1]

1. University of York, United Kingdom

Heusler alloys have significant potential for applications in spintronic devices because of their 100% spin polarisation at the Fermi level at room temperature. Some Heusler alloys exist in a ferromagnetic (F) state [1] and the others are predicted to be antiferromagnetic (AF) [2]. An antiferromagnetic Heusler alloy may be suitable to create a pinning layer via exchange bias for GMR and TMR devices. The standard alloy used for exchange bias is IrMn but Ir is a scarce element hence an alternative AF is required. Ni2MnAl and Fe2VAl are two Heusler alloys with potential to form an AF phase. The structural and magnetic properties of these alloys have been studied. Polycrystalline thin films of these materials were deposited using a HiTUS system. The thickness of the films was (100 - 2) nm. The samples were annealed in a vacuum furnace at a base pressure of 10-5mbar at temperatures in the range 250 to 700oC. Prior to annealing the samples exhibited a paramagnetic behaviour. It is predicted that the B2 phase of the Heusler alloys will develop an antiferromagnetic structure [3]. The degree of B2 ordering increases with both annealing time and temperature.
An increase in coercivity is observed when using Ni2MnAl as a pinning layer for the ferromagnetic Co2FeSi. Fe2.5V0.5Al is also predicted to have an antiferromagnetic phase [2]. Seed layers, heated substrate growth and doping have been investigated to promote crystallisation of the AF phase and an increase in the Neel temperature. Temperature dependent resistivity measurements are used to determine the Neel temperature of the AF Heusler alloy films.

Macroscopic system under the injection and dissipation of energy and particles can exhibit complex structures [1]. In the present work we study the pattern formation in one-dimensional na-nopillar in the presence of a spin-polarized current and an external magnetic field [2]. The com-bined effects of the spin-polarized current, spatial coupling, and dissipation allow for the existence of stable non-trivial uniform states as well as homogenous pattern states. These can be regular or chaotic. The temporal evolution is described by the Landau-Lifshitz-Gilbert-Sloczewski equation [3]. We numerically characterize the dynamical behavior of the system by monitoring the Lyapunov exponents and the magnetic energy.
We show that the system exhibits different types of spatiotemporal chaotic states [4] as a function of the current and intensity of the field. In addition, we find that the system presents local-ized chaotic patterns [5].

Current lithography techniques have allowed the fabrication of nanostructured magnetic materials in which size, shape and order have dramatic influence on their magnetic properties [1]. In this work we show that unusual hysteresis loops with negative remanence can be achieved by pattering ferromagnetic thin films. Trench-patterned Permalloy, NiFe (Py), films were fabricated by Laser Interference lithography (LIL) and magnetically characterized by vibrating sample magnetometry (VSM). Photoresist gratings obtained by LIL were used to deposit a Ti hard mask on a 100 nm thick Py layer. The Ti mask pattern was transferred onto the Py layer by Ar+ plasma etching. Four Py-trench depths (10, 15, 25 and 50 nm) with line periodicities of 0.4 and 1.9 microns were generated by varying etching times. VSM measurements revealed the existence of hysteresis loops with negative remanence at certain directions of the applied field with respect to the line axis. A theoretical approach based on the Stoner Wohlfarth model was carried out to simulate hysteresis loops at any orientation of the external field H. We obtained an excellent agreement between both theoretical and experimental results. Moreover, this model predicts the conditions that structural and magnetic parameters of ferromagnetic patterned films should satisfy to exhibit negative remanence. Although negative remanence was observed in continuous thin films of dissimilar materials or multilayer [2], it had not been achieved in artificially patterned structures of single ferromagnetic layers. Thus, this finding illustrates a method to control the magnetization reversal of thin films by a slight surface patterning.

Nanostructuring can strongly affect magnetic state through the shape anisotropy effect that can be used to control anisotropic magnetoresistance (AMR) effect. In this work we applied atomic force microscopy lithography to make nanostripe out of nickel film and investigated how nanostructuring affected AMR. The studied sample was in the form of 15 nm thick and 3 micron wide nickel microstripe with contact pads on the ends for AMR measurements. In the middle of the microstripe 60 nm wide bridge-nanostripe oriented perpendicular to the microstripe was formed by scratching nickel film using atomic force microscope probe. The structure was fabricated on silicon wafer with silicon dioxide buffer layer. Resistance was measured as a function of the bias magnetic field magnitude by four-probe method at different temperatures (from 10 to 300 K) for two tangential bias field orientations: along or perpendicular to the microstripe. Measurements performed before scratching showed positive and negative change in resistance at low field relatively to resistance at saturation field for perpendicular and parallel field orientation, respectively, indicating that at zero field average magnetization is oriented at some angle to the microstripe. Temperature affected only on magnitude of AMR but not on its sign. After scratching we observed change in AMR sign at room temperature indicating that resistance in this case is mostly due to the nanostripe where current is perpendicular to the current in the microstripe. In addition, for field applied along the microstripe we observed change in AMR sign as temperature decreased. This effect might be due to thermal deformation of the structure that causes additional anisotropy field through magnetostriction.

Ferrimagnetic cobalt ferrite gathers a number of characteristics that make it an extremely appealing material both from fundamental and applied standpoints. Among other applications, it is frequently used in hybrid systems to exploit interfacial effects, as for instance magnetoelectric-coupling to a ferro-/piezoelectric material or exchange-coupling to ferro and antiferromagnets.[1] However, in order to rigorously study these magnetic coupling effects, an accurate control of the quality of the surfaces/interfaces and the magnetic properties is mandatory.[3,4] In this work, we employ low-energy electron microscopy (LEEM) to monitor in-situ and tailor the epitaxial growth of high quality atomically flat iron-cobalt ferrite islands on a Ru(0001) substrate. The combined LEEM/XMCD-PEEM (x-ray magnetic circular dichroism-photoemission electron microscopy) capabilities of the CIRCE beamline at ALBA allow us to characterize the electronic and structural properties of the ferrite islands, as well as the magnetic domain structure. Cobalt ferrite grows in (111) orientation, and the composition corresponds to a cobalt-rich ferrite with a nominal Fe:Co ratio of 1:1. As expected, the comparison of the magnetic domain configuration at both the Fe and Co L-edges shows a perfect match. The magnetization remains mainly in the plane, and Bloch walls separate the domains. Surprisingly, the magnetic domains are also detected at the O K-edge. In addition, MFM experiments reveal an interesting spin reorientation as a function of thickness. Thinner islands show no out-of-plane contrast. As thickness increases above 40 nm, perpendicular magnetization starts to appear. We interpret this transition as a competition between shape and magnetocrystalline anisotropy.

Perovskite-type manganites, such as $La_{1-x}CaxMnO_3$ (LCMO), exhibit a variety of magneto-electronic properties depending on the concentration x. Substitution of (Ca2+) ion on the La site yields the formation of Mn4+ in addition to the original Mn3+ ions. Their ferromagnetic (FM) order is caused by double-exchange (DE) via (Mn3+)-(O2-)-(Mn4+), whereby interactions between localized spins are mediated by the hopping of itinerant electrons. In thin films, these interactions are sensitive to the preparation method and lattice mismatch, as a result competitions between orbital degrees of freedom, charge ordering and spin interaction. Doping the Mn site with Fe atoms decreases the DE and other mechanisms arise [Phys. Rev. B 77, 214430 (2008)]. In this work, the magnetic interaction between the Fe and Mn ions in La2/3Ca1/3Mn0.97Fe0.03O3 (LCMFO) thin films is probed by element-selective x-ray magnetic circular dichroism (XMCD). Samples have been grown by dc magnetron sputtering on SrTiO3-(100) and LaAlO3-(100) single-crystal substrates. XMCD measurements below the FM ordering temperature under an applied field of +/-1 T at the Mn and Fe L2,3 absorption edges, allow determination of the contributions and relative orientations of the Mn and Fe magnetic moments. A reduction in the Mn L2,3 XMCD signal in the LCMFO sample compared to the parent LCMO system reveals important modifications in the magneto-electronic properties with Fe doping. The Fe L2,3 x-ray absorption for the LCMFO is characteristic for Fe3+, and comparison with multiplet calculations [Coord. Chem. Rev. 277-278, 95-129 (2014)] suggests that the Fe dopants occupy octahedral sites in the crystal, which is consistent with Fe3+ substituting Mn3+ in LCMO. The magnetic moments of Mn and Fe are found to align antiferromagnetically, which suggests the presence of Mn-O-Fe superexchange coupling. This result is consistent with macroscopic magnetometry measurements on the LCMFO system, which show a decrease in saturation magnetization of LCMO with Fe doping.

Th.K-P25 - 360 degree magnetic domain wall injection via moving magnetic charge

J. Carter [1], D.M. Burn [1], W.R. Branford [1], L.F. Cohen [1]

1. Imperial College London

Domain walls (DWs) in magnetic nanostructures have long been a subject of much interest[1]. The majority of work so far has focused on 180 degree DWs. However, recently the field has seen promising developments in 360 degree DWs, stable topological defects consisting of two strongly-coupled 180 degree DWs of opposite chirality[2].
360 degree DWs have several unique properties. They are stationary under applied magnetic fields[3], interact interestingly with spin-waves[4] and have a small stray field, desirable for systems requiring high DW density[4].
Current methods for generating 360 degree DWs rely on fabricating injection structures and applying rotating fields[5] or current pulses[6]. These techniques are non-trivial in both device manufacture and field/current protocols.
We present a novel method for injecting 360 degree DWs into in-plane magnetised nanowires via the moving charge of an MFM tip.
Experimental evidence is presented from MFM images and supported by micromagnetic simulations. The method avoids fabricating injection structures and global field/current application. Additional benefits include localised injection via precise tip positioning and chirality selection of injected DWs.

Th.K-P26 - Crystallographical texture and coercivity in nanocrystalline thin films for magnetic recording

M. De Campos [1], J. de Castro [1], F. Sampaio da Silva [1]

1. Federal Fluminense University, Niteroi, Brazil

A very important application of magnetic materials is on the thin films for magnetic recording. Miniaturization requires phases with high crystalline anisotropy as PtFe, PtCo [1] or Nd2Fe14B [2]. Perpendicular magnetic recording (PMR) [3] with textured thin films are among the possibilities for improving the areal recording density [4,5]. Relationship between magnetic properties and nanostructures as those presented by Sun et al [4] or Zhang et al [5] can be studied with the Stoner-Wohlfarth model, which predicts that a sharp (00l) texture can result in improved squareness of the hysteresis loop. Texture effects in hard nanocrystalline materials or thin films can be evaluated with the Stoner-Wohlfarth (SW) model, since the particles are single domain size and non-interacting. The texture can be introduced in the SW hysteresis by means of an experimental distribution measured by X-Ray diffraction, or theoretically by using distribution functions as Gaussian, Cauchy or Pearson VII. Any symmetrical distribution function can be used for uniaxial texture description, since it represents well the experimental texture data.

Supermalloy thin films deposited by sputtering onto nanostructured non-magnetic metals were prepared following replica-antireplica process based on porous alumina membrane. Using a high deposition rate during deposition of the non-magnetic metal on the Al pattern, we have separated the two metallic surfaces and, thus, imprinted a pattern of nanohills on a non-magnetic metallic film (such as Au, Ag or Cu). The morphology of the nanostructured Supermalloy films on ordered metallic nanohills was determined by scanning electron microscopy. Thus, we have confirmed that the ordering degree of the Al template remained after the replication and coating processes. The room temperature magnetic behavior of these thin films is also studied. Interestingly, we have found that when the external magnetic field is applied perpendicular to the substrate, the coercivity increases linearly as we increase the radius of the nanohills. These soft magnetic films can open new opportunities for magnetic field sensor applications. We study magnetic properties of inverse opal-like structure (IOLS) based on Co. It was prepared by templating technique: the voids of face-centered-cubic (fcc) opal, which was constructed of 590 nm microspheres, were filled with Co by an electrochemical crystallization. Then, the microspheres were dissolved in toluene and free-standing ferromagnet net was obtained. The IOLS is built of unit elements, consisting of three parts: two quasitetrahedra and one quasicube with concave faces. These parts are connected by vertices along 111 directions of fcc structure. The IOLS are interesting as a 3D nanoscale analogue of spin-ice. In analogy to the "spin ice rule", the magnetic flux conservation law for the elements of the IOLS must be fulfilled. Previously, on this basis we have developed a model for the distribution of magnetization vectors along 111 axes within the IOLS. In this work we have performed neutron small angle diffraction experiment in attempt to verify the model. During the experiment external magnetic field was directed along [111], [100] and [121] axes. Magnetic scattering intensities as a function of the field for the Bragg peaks of 202-family have been obtained. A difference between the curves for these geometries can be explained, in terms of different scenarios of the interplay between of the "ice-rule" and the field. In the first one, the field competes to the "ice-rule", and the situation (3-in-1-out) arises, when the magnetic field breaks the ice-rule. In the second geometry the "ice-rule" and magnetic field interfere constructively, because the "ice-rule" is fulfilled, when all vectors have positive projections on the field direction, thus minimizing the Zeeman energy. In the third geometry, when one vertex is perpendicular to the field (i.e. does not depend on it), possible magnetic configurations in the IOLS are determined by the "ice-rule".

Th.K-P29 - Effect of disorder on the magnetic and electron-transport properties of a prospective spin gapless semiconductor CoFeCrAl

P. Kharel [1,2], W. Zhang [2,3], R. Skomski [2,3], S. Valloppilly [2], Y. Huh [1], R. Fulglsby [1], S. Gilbert [1], D.J. Sellmyer [2,3]

3. Department of Physics and Astronomy, University of Nebraska, Lincoln, United States

Spin gapless semiconductors (SGS) exhibit electronic band properties similar to those of half-metallic magnets and zero-gap semiconductors. This unique combination of electronic band structures leads to several remarkable properties such as high spin polarization (100%) of both the electrons and holes and voltage-tunable spin polarization [1]. However, these properties are hindered by structural disorder in these compounds. We have investigated experimentally and by model calculations the structural, electronic, and magnetic properties of CoFeCrAl alloy in a cubic Heusler structure to understand how the magnetic and electron-transport properties are affected by the structural disorder. Our rapidly-quenched samples are polycrystalline and show a weak B2–type structural disorder. These samples are ferrimagnetic at room temperature with a Curie temperature of about 456 K, which increases to 540 K after vacuum annealing at 600 ºC for 2 hours. The samples annealed at and above 650 ºC show a clear signature of two-sublattice ferromagnetism. The saturation magnetization of the as-quenched sample is 1.9 μ_B/f.u., which increases to 2.1 μ_B/f.u. after annealed at 600 ºC for 2 hours. The resistivity shows a nearly linear decrease with increasing temperature, from about 930 μΩcm at 5 K to about 820 μΩcm at 250 K, with $d\rho/dT$ of about -5×10^{-7} Ωcm/K. We explain this high resistivity and its temperature dependence as imperfect spin-gapless semiconducting behavior, with a negative band-gap parameter of 0.2 eV.

Th.K-P30 - Control of PEDOT orientation in conductive polymer PEDOT:PSS Film through the magnetic effects on oxygen and nitrogen gas

M.A. Guziak [1], K. Hashimoto [2], T. Nishizaki [3], Y. Honma [2], K. Watanabe [2], T. Sasaki [2]

2. Institute for Materials Research, Tohoku University, Sendai, Japan
3. Faculty of Engineering, Kyushu Sangyo University, Fukuoka, Japan

Poly(3,4-ethylenedioxythiophene):poly(4-styrenesulfonate) (PEDOT:PSS), due to high electrical conductivity, visible light transparency, low cost processing and flexibility is a potential candidate for indium tin oxide (ITO) replacement. Based on the recent structural model, existence of nano-crystalline PEDOT grown in highly conductive PEDOT:PSS film, and correlation between PEDOT nano-crystallization and electrical conductivity had been reported [1]. The focus of this research is the control of PEDOT:PSS structure by means of magnetic field utilization in the course of the PEDOT:PSS film fabrication.

The solid films of PEDOT:PSS were prepared from the PEDOT:PSS aqueous dispersion (Clevios PH1000, Heraeus). For the film fabrication, a superconducting magnet was used at the maximum homogeneous field H(0mm)=10T and the maximum magnetic force $|H\bullet(dH/dx)|$ H(90mm)=7.5T in air and under N_2 and O_2 gas flow (1000 ml/min). To evaluate orientation of the PEDOT nano-crystals, polarized optical reflectivity was measured at room temperature by using a FT-IR and NIR-UV-Visible spectrometers.

Polarized infrared reflectivity spectra show Drude response with the plasma edges at the frequencies ω_p with polarization direction E being parallel to the x ($E//x$, $//H$) and y ($E//y$, $\perp H$) directions. The plasma frequency of the films fabricated under 7.5T shifts to larger ω_p of 7900 (N_2) and 9000 cm^{-1} (O_2) for $E//x$ ($//H$), but remains unchanged ~7200 cm^{-1} for $E//y$ ($\perp H$). On the other hand, ω_p of the films fabricated in the air, shows somewhat reverse behavior, 7200 cm^{-1} for $E//x$ ($//H$) and 8400 cm^{-1} for $E//y$ ($\perp H$). The films fabricated under 10T, shows almost no w_p anisotropy. Independently on condition and direction, almost the same values of ω_p ~7800 cm^{-1} are observed for the films fabricated at 0T. We expect that the anisotropy of ω_p arises from orientation of the PEDOT nano-crystals in these films.

Th.K-P31 - Magnetic properties of Co/Pd multilayers deposited on alumina membranes.

J. Denardin [1], D. da Rosa [2], L. Dorneles [2], L. Schelp [2]

1. Universidad de Santiago, Santiago, Chile
2. Universidade Federal de Santa Maria, Santa María, Brazil

Magnetic films with perpendicular anisotropy (PA) are very important in the recording industry and as magnetic sensors. The research and potential applications of nano-patterned PA films is still more exciting, since the patterns can have length scales similar to the domain-wall widths and can be tailored to limit the domain-wall movements. Among the ways to produce nanostructured films, anodized alumina templates (AAO) have emerged as a low cost, simple and effective method for obtaining large areas of nano-patterns. Films deposited on top of AAO membranes with pores of different diameter and on the bottom of AAO membranes, forming bumps, shows different magnetic reversion mechanisms and can be interesting in basic and applied research in magnetism. In this work the magnetization reversal of Co/Pd multilayers deposited on different nanostructured substrates are investigated by magnetization curves, extraordinary Hall Effect and magnetic force microscopy (MFM) experiments. The magnetization curves of a Co/Pd film deposited on glass substrates shows a clear out of plane anisotropy, with Mr=Ms and a two-step magnetization reversal. In the Co/Pd multilayers deposited on top of AAO membrane the coercivity and remanence are large in both in plane and out-of-plane directions, indicating a completely different mechanism of magnetization reversion than in the continuous film. From the MFM images of the continuous film it is possible to observe large stripe magnetic domains, while the MFM images for the film deposited on top of AAO membrane shows magnetic domains that are smaller and clearly pinned by the nanoporous membrane.

Th.K-P32 - Micromagnetic investigation of planar hall effect sensors for magnetic nanobeads detection

I. Firastrau [1], E. Helerea [1], M. Avram [2], M. Volmer [1]

1. Transilvania University of Brasov, Department of Electrical Engineering and Applied Physics, Brasov, Romania
2. National Institute for Research and Development in Microtechnologies, Bucharest, Romania

Development of modern medicine led to exponential growth in demand of high sensibility magnetic field sensors, devoted to manipulation, detection and characterization of magnetic nanobeads (superparamagnetic nanoparticles) in a microfluidic system. In this context, Planar Hall Effect (PHE) sensors have gained much attention because of the high thermal stability, high field sensitivity, and low noise of the output signal. A superparamagnetic nanoparticle placed on the sensor surface generates a magnetic field that can modify the configuration of magnetic moments inside the ferromagnetic material of the sensitive layer of the sensor. In our study, the superparamagnetic nanoparticles were magnetised by an external magnetic field which can be (i) applied in the film plane or (ii) perpendicular to the film plane. Additionally, we have considered a biasing field, applied in the film plane, along the driving current, to have a better control of the linearity and sensitivity of the sensor. Using this setup, we performed full 3D micromagnetic simulations in order to investigate the magnetization dynamics of the PHE sensors in the presence of a magnetic nanoparticle. Three sensors geometries have been taken into account: cross-shaped, disk-shaped and ring-shaped structures. The sensitive layer made from Permalloy, 10-20 nm in thickness, has micrometric in-plane dimensions. The direction of the uniaxial magnetocristalline anisotropy is parallel to the polarizing field. For each type of structure we determined a biasing field for which the maximum detection sensitivity is achieved. The micromagnetic analysis reveals, also, that the setup with the applied field perpendicular to the film plane can assure the best detection sensitivity and linearity which is confirmed by our experiments.

Th.K-P34 - Alternating target laser ablation deposition of Cu doped cobalt ferrite thin films

G. Bulai [1], S. Gurlui [1], P. Rao [2], O. Florin Caltun [1]

1. Faculty of Physics, Alexandru Ioan Cuza University, Iasi, Romania
2. Andhra University, Department of Physics, Visakhapatnam, India

Cobalt ferrite thin films are used in magnetic data storage, sensors, actuators, wave guides applications due to their interesting magnetic properties (e. g.: moderate saturation magnetization, high coercive field, large magnetostrictive coefficient and high magneto-crystalline anisotropy generated by the strong L-S coupling of the predominantly B-sited coordinated Co2+ ions). Copper substitutions in various typed of ferrites was reported to enhance the magnetic properties, increase the cell parameter and decrease the Curie point. The aim of this study was to compare the structural and magnetic properties of the Cu doped cobalt ferrite films obtained by pulsed laser deposition (PLD) and by alternating target laser ablation deposition (ATLAD) using $CoFe_2O_4$/Cu targets. For the typical PLD deposition process, various target with chemical $Co_{1-x}CuxFe_2O_4$ (x=0-0.5, 0.1 step) were synthesized using standard powder ceramic technique. The Fe_2O_3, Co_3O_4, MnO_2 and Cu_2O_3 oxide powders were mixed in the targeted proportions, ball milled for 5 h and calcined in air at 950 oC for 5 h. The final sintering step was done at 1250 oC for 2 h. For ATLAD deposition we used a stoichiometric cobalt ferrite sample obtained in the same conditions as detailed above and a pure copper target. The concentration variation was achieved by modifying the number of laser pulse incidence upon each target. The other experimental parameters such as target-substrate distance (4 cm), deposition time (60 min), pressure (~10-5 Torr) and substrate temperature (400 oC) were mentained at the same values. The structural and chemical properties of the obtained films were studied by X-ray diffraction, scanning electron microscopy/energy dispersive X-Ray spectroscopy and Raman spectroscopy while the magnetic response was investigated using a vibrating sample magnetometer. The study revealed the influence of copper doping level on thin film properties and large differences in structural characteristics induced by PLD and ATLAD techniques.

Th.K-P35 - Tailoring magnetism, magnetoresistance and interactions of nanostructured ZnO-Co films

X. Li [1], Y. Gao [1], J. Li [1], J. Jia [1], Y. Li [1], G.A. Gehring [2], X. Xu [1]

2. Department of Physics and Astronomy, University of Sheffield, Sheffield, United Kingdom

Extensive studies of the magnetoresistance (MR) in heterogeneous structures including ferromagnetic metal/semiconductor have been performed with a view of potential spintronic applications[1-3]. Amorphous films of ZnO containing nanoparticles of cobalt metal deposited at room temperature (RT) have small nanoparticles giving a blocking temperature (Tb) at about 20K whereas the Tb is above RT for films deposited at 400 oC, which implies that the films contain large Co nanoparticles. We study structures that combine layers with large and small nanoparticles with a ZnO spacer layer in order to utilise the coupling between the magnetic ZnO-Co layers. The bottom ZnO-Co layers were firstly deposited by magnetron sputtering at substrate temperature (Ts) of 400 oC. And when the Ts was cooled down to RT, ZnO space layers and the top ZnO-Co layers were deposited by the same method. The results show that the resistance of the ZnO-Co/ZnO/ZnO-Co trilayer sample can be considered to be a result of a parallel combination of top, bottom ZnO-Co layers, and ZnO space layer. The top ZnO-Co layer can couple with the bottom one. And the strength of the interactions can be tuned by the thickness of the ZnO space layers. Accordingly, the MR and magnetic properties are dramatically changed. Moreover, the MR of the ZnAlO-Co/ZnO/ZnO-Co sample is much larger than that of the ZnO-Co/ZnO/ZnO-Co, which implies that doping Al in ZnO of top ZnO-Co layer can dramatically enhance MR of the sandwich samples. This study is helpful to make sense the MR and interactions thus making nanostructured ZnO-based films more suitable for applications in spintronics.

1. The Henryk Niewodniczanski Instytute of Nuclear Physics Polish Academy of Sciences, Krakow, Poland
2. Marian Smoluchowski Institute of Physics, Jagiellonian University, Krakow, Poland

The study concentrates on magnetic properties of L10 FePd alloy films deposited on U-shape nanopatterned substrates. The U-shape structures were formed with modified anodization process leading to the creation of nanopatterned aluminum foil with thin oxide layer on the top. Such substrates have U-shaped bowl-like structure with protruding elements at cavity edges. They show long range spatial order and have diameters varying between 60 nm and 400 nm. The L10 FePd alloys were prepared by sequential deposition of Fe and Pd multilayered system with appropriate stoichiometry and the total thickness equal to 1/8 of the U-shape diameter. The as deposited multilayers were transformed to L10 phase by annealing in vacuum at elevated temperatures (500-600 C). The magnetic characterization of obtained samples, studied with SQUID magnetometer, was supplemented with SEM and AFM/MFM measurements. The easy axis of magnetic anisotropy in all studied cases was in plane of the sample. The change of U-shape diameter from 400 nm to 60 nm resulted in the decrease of coercive field. However, the saturation field for out-of-plane geometry was smaller than for continuous films on flat substrates, indicating the role of complicated morphology of patterned samples observed in microscopy images.

Th.K-P37 - Hard/soft bilayer thin films and antidots

4. Instituto de Microelectrónica de Madrid (CNM-CSIC), Madrid, Spain

Exchange coupled hard/soft bilayer thin films can be used as model systems to study the properties of exchange-spring magnets. Moreover, the inclusion of artificial defects such as nanoholes (also called antidots) helps to engineer their magnetic properties. As a result, the magnetic anisotropy, the coercivity and the remanence can be tailored by modifying the antidot diameter, the separation among them and the film thickness. In this work, bilayers of 20 nm-thick Co with 10 to 30 nm-thick Permalloy (Py) thin films and protected with 5 nm-thick Pt were fabricated by DC sputtering in a UHV system with rotating substrate to avoid any preferential direction. For comparison, the magnetic systems were prepared both in thin films and in antidots morphologies, using thermally oxidized silicon and nanoporous alumina templates as substrates, respectively. For the antidots, small (35 nm diameter, 105 nm interpore distance) and large (175 nm diameter, 275 nm interpore distance) pores geometries were compared.
In-plane magnetostatic characterization obtained by means of VSM and NanoMOKE showed that the bilayers were coupled for the Py thickness range investigated. However, careful analysis done via first-order reversal curve (FORC) technique evidenced that the coupling is worsening as the Py thickness increases, with the apparition of an additional irreversible distribution. Both local and global coercivities decrease with Py thickness, with the values for the antidots always being larger than those of the continuous films.

Th.K-P38 - Synthesis and characterization of PLD CoFe thin films as a function of composition and deposition conditions

Nowadays, the emerging technologies based on spintronics devices, driven by the increasing demand for miniaturization, require a strict monitoring of the physical properties of the materials used in the spin-valve structures, which play a key role in the functioning of the GMR-TMR [1]. Among the magnetic materials used as electrodes in the spin-valve structures, the magnetically soft CoFe-based alloy, characterized by high saturation magnetization and high Curie temperature, showed the best magnetoresistive response in TMR systems with in-plane anisotropy [1]. However, the magnetic behaviour results to be strictly dependent on both composition and microstructural features of the alloy. In this work, we present a study of thin films of CoFe with 50:50 and 75:25 compositions deposited on MgO substrate by Pulsed Laser Deposition.
The effect of the deposition temperature on the crystallographic orientation is determined by means of XRD and HRTEM analysis and correlated with the anisotropic properties measured by angle dependent hysteresis loops. All the films showed a granular structure with a high degree of crystallographic order even at the lowest deposition temperature. The cubic symmetry is reflected in the angular dependence of remanent magnetization, showing a four-fold character, whose in-plane distribution is consistent with the different crystallographic orientation of the films.

The inverse spinel system $CoFe_2O_4$ can be considered as a paradigmatic material for the study of magnetic transition metal oxides. The more recent advent of self-assembled perovskite-spinel structures has now opened new possibilities for the engineering of previously inaccessible functionalities, among others by making use of the ferromagnet-antiferromagnet interface coupling of nano-objects with an enhanced surface-to-volume ratio such as the above $CoFe_2O_4$ nano-pillars. The well-known "classical" core-shell particle systems may serve as another example for these interface-driven magnetic materials. We have investigated two different nanostructured transition metal oxide sytems: (i) $CoFe_2O_4$ nano-pillars in $BiFeO_3$ and (ii) Co/CoO-MgO core/shell nanoparticles in MgO using soft x-ray magnetic circular dichroism (XMCD), SQUID magnetometry, and transport measurements. Single-crystalline $CoFe_2O_4$ has also been investigated as a bulk reference material. The results from the XMCD data indicate the importance of microscopic mechanisms such as local distortions (e.g., of CoO_6 octahedra in $CoFe_2O_4$ nano-pillars) as well as magnetic interactions across the ferr(i/o)magnetic/antiferromagnetic interfaces (based on the uncompensated spin model) for the bulk magnetic properties.

Th.K-P43 - Lattice effects on the magnetic and magnetoresistance properties of nanometer-Thick $La_{0.9}Ba_{0.1}MnO_3$ (LBMO) Films and LBMO/$BaTiO_3$/ LBMO Heterostructures

S. Pegah Mirzadeh Vaghefi [1], M. Georg Willinger [2], A.A. Cardoso dos Santos Lourenço [1], V. Brás de Sequeira Amaral [1]

1. Department of Physics & CICECO, University of Aveiro, Aveiro, Portugal
2. Fritz Haber Institute, the Max Planck Society, Department of Inorganic Chemistry, Berlin, Germany

We have fabricated $La_{0.9}Ba_{0.1}MnO_3$ (LBMO) thin-films and LBMO/$BaTiO_3$/LBMO (LBMBT) heterostructures, using UHV RF magnetron sputtering technique, on oriented single crystalline (100) silicon and (0001) Al_2O_3 substrates. A number of complementary methods, such as X-ray diffraction, cross section transmission electron microscopy, Piezoresponse force microscopy, magnetoresistivity and SQUID magnetometry were used to characterize local and in-depth structure features, also their physical properties.
TEM studies shows the stressed layer of LBMO on different substrates, including the $BaTiO_3$ thin-film in heterostructures. The different growth condition in depositions created polycrystalline structure of the films. The thicknesses of the films on Al_2O_3, Si are 70 and 145 nm and for heterostructures are 40/30/40 nm. The mismatch between substrate and film is 0.82% for Si and 13.58% for Al2O3 substrate. The magnetic transition temperature (Tc) of the LBMO film on the Si and Al2O3 substrates are found to be 197K and 210K, respectively, slightly higher than the bulk form, 185K. The Tc of the heterostructure on silicon substrate, measured in SQUID, shows resemblance with the single layer LBMO, at 200K, while the magnetoresistance measurements shows a surprising change in transition temperature, at 250K. Local electric poling of the heterostructures was done by PFM, along with local piezoelectric hysteresis measurements to modify the nearby ferroelectric areas via the mechanical stress and field effects. Using different voltages, ranging +/-10 V to +/-30 V, one can detect electric field-induced deformation at a nanoscale and confirm the ferroelectric state of the BTO layer.
It is important to note the strain related behavior of the grown film with the substrates and the ferroelectric BaTiO3 thin-layer, between two LBMO layers. This strain is found to influence the magnetic properties and magnetoresistive behavior of the grown film and heterostructures.
This work was developed within the project CICECO-Aveiro Institute of Materials (Ref. FCT UID/CTM/50011/2013).

Th.K-P44 - Thermal dependencies of the magnetic symmetries of low dimensionality systems, studied with novel variable temperature/full angular range vectorial MOKE technique

J.L.F. Cuñado [1,2], J. Pedrosa [2], F. Ajejas [1], A. Bollero [2], P. Perna [2], F.J. Terán [2], R. Miranda [1,2], J. Camarero [1,2]

1. Departamento de Física de la Materia Condensada and Instituto Nicolás Cabrera, Madrid, Spain
2. Instituto Madrileño de Estudios Avanzados IMDEA nanociencia, Madrid, Spain

Magneto-optical Kerr effect (MOKE) magnetometry is one of the most widely used techniques for the characterization of magnetic nanostructures. MOKE presents high sensitivity (down to nanometer thickness), vanishing substrate effects (limited penetration depth), immunity to external fields (photon-in/photon-out approach), and relatively simple experimental implementation. We present a new versatile full angular resolved / broad temperature range / vectorial MOKE instrument, capable of probing qualitatively and quantitatively the temperature and angular dependencies of magnetization vector during the reversal processes. Quantitative studies are only possible if the apparatus can work without the need to make any manual intervention on it. The setup combines a cryostat with a vectorial v-MOKE bench. Its optical access to a motorized rotatable sample holder with azimuthal correction allows for measuring at different temperatures from 4 K up to 500 K and in the whole angular range without neither changing magnet orientation nor opening the cryostat. The measuring process is fully controlled by software. Measurements performed in a model system with competing collinear biaxial and uniaxial contributions are presented to illustrate the set-up capabilities. The temperature dependence of the effective magnetic anisotropy as well as its influence on relevant magnetic parameters are shown. The set-up provides direct views on magnetization reversal processes and magnetic transitions, unravelling magnetic symmetry effects of magnetic nanostructures.

Th.K-P46 - Sub-50 nm magnetic tunnel junctions fabrication by reactive ion etch on 150 mm wafers

A. Moskaltsova [1,2], S. Knudde [1,2], A.V. Silva [1,2], D.C. Leitao [1,2], P.P. Freitas [1,3], S. Cardoso [1,2]

1. Instituto deEngenharia deSistemas E Computadores-Microsistemas E Nanotecnologias, Lisbon, Portugal

3. INL - International Iberian Laboratory, Av. Mestre Jose Veiga, Braga, Portugal

Today, magnetic tunnel junctions (MTJs) with tunnel magnetoresistance higher than 150% are widely used as MRAM elements and sensing devices [1]. However, efforts have been done towards reducing dimensions of the critical features towards 30nm, integrated on larger area wafers. Here we focus on MTJs nanometric pillars fabrication using Reactive Ion Etch (RIE) [2-3]. Besides material selectivity, it has shown improved wafer uniformity, being a relatively fast process, with oxide etch rates ~1nm/s. MTJs circular nanopillars were defined using electron beam lithography (EBL) and ion milling etching, with sizes from 100nm to 30nm. A thick (50 nm) metal cap layer was used to avoid damaging the free layer. A 300 nm SiO2 layer insulated the top and bottom electrodes. With such a thick oxide becomes challenging to establish a robust electrical contact to the nanopillar. Access to nanopillars was performed by RIE with CF4 and controlled by atomic force microscopy. Surface scans show difference in oxide thicknesses with an etch rate of ~0.5nm/s inside $2\mu m^2$ To further extend the RIE based nanofabrication process for large area wafers, micrometric test pillars were firstly fabricated in 150 mm substrates with the following MTJ stack Si/SiO_2/Ru 40/MnIr 18/CoFe 3/ Ru 0.84/CoFe 3/Al 9+20s oxidation/CoFe 3/Ru 40 (nm). Test structures were devised and included in order to monitor RIE end point (e.g. micrometric pillars array) and map uniformity of the several steps during microfabrication over large area wafer. Transfer curves yielding 80% of working devices, square response (3.5 mT switching field) and expected resistance values (300 O) for RA product of $2k\Omega\mu m^2$.

Th.K-P47 - Enhancement of order degree and perpendicular magnetic anisotropy of L10 ordered Fe(Pt,Pd) alloy film by introducing a thin MgO cap layer

Y. Noguchi [1], M. Ohtake [1], M. Futamoto [1], F. Kirino [2], N. Inaba [3]

1. Chuo University, Japan
2. Tokyo University of the Arts, Taito, Japan
3. Yamagata University, Yamagata, Japan

FePt ordered alloy with L10 structure shows Ku greater than 10^7 erg/cm^3 and the films have been investigated for HDD media and MRAM device applications. When an L10 film is formed on a (001)-oriented underlayer or substrate, the film may involve (100) crystal with the c-axis lying in the film plane in addition to (001) crystal with the c-axis perpendicular to the substrate surface. In the last Intermag conference, we reported a possibility in controlling the c-axis of FePt crystal perpendicular to the substrate surface by employing a thin MgO cap layer. In order to control the magnetic properties, replacement of Pt site in FePt structure seems useful. In the present study, 10-nm-thick Fe50(PtxPd1-x)50 (at.%, x=0-1) films with and without 2-nm-thick MgO cap layers are prepared on MgO(001) substrates by using a two-step method consisting of deposition at 200 ºC followed by annealing at 600 ºC. The structural and magnetic properties are investigated by RHEED, XRD, and VSM. For the investigated compositions, L10 ordered single-crystal films with the c-axis perpendicular are obtained for the samples with MgO cap layers, while crystals with the c-axis lying in-plane are included for the samples without cap layers. The values of order degree, S, estimated for the films of x=0, 0.25, 0.5, 0.75, 1 with and without cap layers are (0.7, 0.6), (0.7, 0.5), (0.6, 0.4), (0.7, 0.4), and (0.8, 0.6), respectively. The data show that the films with cap layers show higher order degrees and that S value becomes minimum around the $Fe_{50}Pt_{25}Pd_{25}$ composition. The films with cap layers show very small in-plane coercivities less than 0.8 kOe, whereas those without cap layers show coercivities around 1 kOe. An employment of MgO cap layer is effective in controlling the c-axis perpendicular, achieving higher order degree, and thus enhancing the perpendicular magnetic anisotropy.

Th.K-P48 - Magnetisation reversal in Co nanoparticle arrays on corrugated MnF2(110) surface

S. Gastev [1], B. Krichevtsov [1], D. Baranov [1], V. Fedorov [1], S. Suturin [1], N. Sokolov [1], J.L.F. Cuñado [2,3], A. Bollero [2], J. Camarero [2,3]

3. Dpto.Física Materia Condensada & Ins. Nicolás Cabrera, UAM, Madrid, Spain

Identifying the mechanism of magnetization reversal is the main objective of the study the properties of magnetic materials. The use of magneto-optical Kerr effect (MOKE) to accomplish this task proved to be extremely effective. In this work we applied the longitudinal Kerr effect for different orientation of in-plane magnetic field and Kerr microscopy for study of magnetization switching in Co(X nm)/ MnF_2 / CaF_2 / Si (001) epitaxial structures with X from 2 to 7 nm. Co layer represents an ensemble of nanoparticles grown on corrugated surface of MnF_2 / CaF_2 / Si (001) substrate. The magnetization vector (M) in these structures is oriented in-plane. The easy axis of magnetization (EA) is along of corrugations, i.e. [1-10] crystal direction of Si(001). Magnetic field dependencies of longitudinal Kerr effect for S-polarization of incident light (λ = 633 or 405 nm) were measured for two orientations of magnetic field: along and perpendicular to the light incidence plane. This makes it possible to carry out a vectorial analysis, i.e. get information about both the magnitude and orientation of magnetization vector during the magnetization reversal. In all structures the decrease of magnetic field from saturation to zero value is followed by rotation of magnetization M from the direction of magnetic field H to direction of EA. Then the magnetization changes its sign that is followed by appearance of zero value of $|M|$. Such behavior of magnetization evidences the magnetization reversal due to domain wall (DW) movement, that is confirmed by observation of domains by Kerr microscopy for structures with X>3 nm. In structures with X = 2 and 3 nm the domains have been not observed but the disappearance of $|M|$ indicates the DW movement also in this case. Further increase in magnetic field results in rotation of magnetization to direction of EA.

Th.K-P49 - Morphology and magnetic properties of exchange biased natively oxidized py antidot arrays fabricated on anodized porous silicon

A. Maximenko [1,3], C. Cirillo [2], A. Zarzycki [1], M. Marszalek [1], J. Fedotova [3], S. Prischepa [4]

3. Research Institute for Nuclear Problems of Belarusian State University, Minsk, Belarus
4. Belarusian State University of Informatics and Radioelectronics, Minsk, Belarus

Magnetic structures with well-defined nonmagnetic porous defects acting as pinning sites for magnetic domain walls and with exchange biased interface of ferromagnetic (FM) and antiferromagnetic (AF) layers possess larger coercivity (Hc) and exchange bias fields (HEB) in comparison to the continuous and free FM structures. This makes them attractive materials for magnetic memory devices and magnetic sensors. For the first time antidot arrays (AA) consisting of FM/AF bilayers with exchange bias (EB) were fabricated on templates of anodized porous silicon (PS) and their morphology, structure and magnetic properties with respect to different pinning mechanisms are reported. Antidot diameters (da) and distances between them were varied by changing PS anodization regimes. FM/AF bilayers contain permalloy and capping native thermal oxide layer constituting the superposition of NiO, FeO, Fe_2O_3 originating from natural oxidation of Py surface. To determine the influence of FM/AF interface and antidot morphology on magnetic properties of the system, oxidized and non-oxidized samples were also prepared on flat Si substrate. XRR of flat oxidized samples proved formation of 1.5 nm oxide layer made of Ni and Fe oxides. The exchange bias effect was observed only at 3 K and HEB increased from -30 Oe for AA with da=15 nm to -90 Oe for AA with da=30 nm. The HC values of AA with da=30 nm was much larger as compared to flat samples and non-oxidized AA. This indicates that two pinning mechanisms are present in this system, one related to the interface of bilayers and the second one is associated with the substrate antidot morphology. The latter is present in the broad temperature range, whereas the other exists only at 3 K confirming that the main pinning effect is governed with the antidots.

Th.K-P55 - Selective suppression of domain wall in artificial spin ice network lattice

S. Goolaup [1], C. Sekhar Murapaka [1], W. Siang Lew [1]

1. Nanyang Technological University, Singapur

Observation of magnetic monopoles and other interesting thermodynamic properties has motivated recent research interest in artificial spin ice network structures. Controlling the domain wall (DW) trajectory in magnetic network structures is crucial for the study of fundamental properties like observation of magnetic monopoles at room temperature in artificial spin ice lattice. The creation and absorption of DWs at the vertex of a network structure governs the net magnetic charge and give to rise to the formation of artificial magnetic monopole. The DW trajectory in the network structure has been shown to be dependent on the DW chirality. In this work, we show that the DW trajectory can be remotely controlled or completely suppressed by introducing an elliptical nanodot near the bifurcation in the branch of a network structure. When the DW is driven through the structure, it is observed that the magnetostatic coupling between the DW and nanodot pins the DW at the bifurcation. The magnetostatic coupling arises due to the interaction between the DW stray field and edge stray field form the nanodot. With the increase in the magnetic field, the DW annihilates at the bifurcation to generate a magnetic monopole. The annihilation of the DW and the generation of the magnetic monopole follow the conservation of topological charges in the branch network structure. By varying the distance between the bifurcation and the nanodot, different magnetization reversal processes of network structures have been observed. By selectively introducing nanodots in the array of network structures, different Dirac string configurations (i.e. arm chair and staircase) can be readily realized.

Th.L-P01 - Magnetic properties of FePt-Fe nano-composites with core/ shell structure

R. Kurosu [1], H. Iwama [1], M. Doi [1,2], T. Shima [1,2], A. Kato [3,4], N. Sakuma [3,4], H. Kishimoto [3,4], K. Washio [3,4], M. Yano [3,4]

3. Toyota Motor Corp., Aichi, Japan
4. Higashi Fuji Branch, MagHEM, Aichi, Japan

The demand of renewable and sustainable energy drives us to develop high efficient electromagnetic conversion system. In particular, the development of high performance motors consisting of rare-earth permanent magnets are strongly needed to fulfill the automotive applications such as hybrid vehicles (HVs), plug-in hybrid vehicles (PHVs) and electric vehicles (EVs). However, due to an environmental and geometrical issues, the reduction of indispensable elements from the Nd-Fe-B sintered magnets and consequently, high performance new permanent magnets are required. In this work, in order to confirm the effect of nano-composite structure and to find the optimum configuration, ring-shaped (shell-type structure) samples embedded with another magnetic materials have been investigated. L10 ordered FePt phase and bcc-Fe phase are selected as “hard” and “soft” magnetic phase, respectively. The samples were prepared by using an ultra-high vacuum magnetron sputtering system. A Fe seed layer of 1 nm and epitaxial Au buffer layer of 40 nm were grown on a MgO (100) single crystal substrate at room temperature (R.T.). The FePt layer with the thickness of 10 nm was deposited at a substrate temperature (Ts) of 225 ˚C. Then, the sample was annealed at Ta = 475 ˚C for 1 hour. The ring-shaped FePt arrays with 2.0 mm in outer diameter were microfabricated by using an electron beam lithography followed by an Ar ion milling. Then, soft magnetic Fe was deposited and embedded into the FePt rings (shells). It is confirmed that well-defined shape of the FePt rings embedded with Fe core have been successfully prepared by a multiple microfabrication process. It was confirmed that Hc of the composite sample was improved from 4. 5 kOe to 8.43 kOe after post-annealing at 500 ºC for 1 hour.

Th.L-P02 - Nickel nanorod/gelatin hydrogels - tracking the genesis of a hybrid material

A. Tschöpe [1], C. Schopphoven [1], K. Birster [1], R. Birringer [1]

1. Saarland University, Saarbrücken, Germany

Magnetic hybrid materials composed of ferro- or superparamagnetic particles dispersed in a soft-elastic matrix feature large changes in shape and/or elastic properties by remote magnetic stimulation. Their response depends on the applied field (homogeneous, inhomogeneous), the magnetic properties (ferro-/superparamagnetic) and spatial arrangement (textured, homogeneous) of the nanoparticles and essentially on the magneto-mechanical coupling between the particles and the non-magnetic matrix. The latter aspect is closely related to the chemical and mechanical interaction between the inorganic inclusion and the polymeric network.

The objective of the present study was to investigate the evolution of the magneto-mechanical coupling between ferromagnetic nickel nanorods and gelatin hydrogels in the course of physical or chemical gelation. For this purpose, we prepared nickel nanorods with diameters of 20 nm and average length in the range of 200-1000 nm by the AAO-template method. The nanorods were released from the template and dispersed in gelatin solutions in the semi-dilute range. We took advantage of the uniaxial ferromagnetic single domain state and the optical anisotropy of the nanorods by using them as probe particles for microrheometric characterization of their local hydrodynamic properties. Magneto-optical measurements in static and dynamic fields revealed strong chemical interaction in terms of gelatin adsorption in the sol state as well as progressive trapping of the nanorods in the polymer network during gelation.

Th.L-P03 - Domain wall pinning driven by nanoscale phase coexistence in Ni/V_2O_3 bilayers

3. Helmholtz-Zentrum Berlin für Materialien und Energie, Berlin, Germany

Nanoscale manipulation of thin film magnetic properties can be achieved through proximity effects in bilayer or multilayer structures. For example, the proximity of a ferromagnetic (FM) film with a vanadium oxide results in a reversible modification of the magnetic properties due to the magnetoelastic anisotropy contribution caused by the interfacial stress [1]. Recently, large changes in coercivity and noticeable modifications of the magnetization in Ni/V_2O_3 bilayers across the structural phase transition (SPT) of V2O3 have been reported [1,2].
In this work, we combine photoemission electron microscopy (PEEM) with X-ray magnetic circular dichroism (XMCD) to map the temperature-driven variation of the FM domain structure of Ni (10 nm-thick) across the SPT of V_2O_3 (100 nm-thick) deposited onto a r-plane sapphire substrate. Upon crossing the SPT, the initial FM saturated state splits into a pattern of small domains with opposite orientation. The fraction of such inverted domains monotonically grows across the SPT with the predominance of one of the coexisting structural phases. The domain nucleation sites are randomly distributed across the sample for several image series, indicating that the domains are not pinned by structural defects. The analysis of the domain nucleation and growth across the SPT indicates a distribution of local transition temperatures across the sample. Furthermore, we study the lateral correlation length of the inverted domains using a radial distribution function analysis from the images.

Th.L-P04 - Magnetic and microstructural investigation of $Fe_{79.7-x}TixB_{20}Nb_{0.3}$ glassy alloys for hyperthermia application

N. Lupu [1], L.C. Whitmore [1], G. Ababei [1], M. Grigoras [1], H. Chiriac [1]

1. National Institute of Research and Development for Technical Physics, Iasi, Romania

Nowadays, the use of self-regulating magnetic hyperthermia for curing cancer appears to be an extremely viable alternative. Now Fe oxides nanoparticles with superparamagnetic behavior (SPIONs) are extensively used in clinical tests involving magnetic hyperthermia. As an alternative to SPIONs, we have developed a new type of ferromagnetic material, with the nominal composition $Fe_{79.7-x}TixNb_{0.3}B_{20}$ (x = 12¸20 at.%) and Curie temperature in the 0-700C range depending on the Ti content, more suitable for self-regulating magnetic hyperthermia. The saturation magnetization decreases slowly by increasing the amount of Ti (from 0.7 T for 12 at.%Ti to 0.25 T for 18 at.% Ti) and the material behaves as a weak ferromagnet for 20 at.% Ti. The larger the Ti content, the more reduced the Curie temperature is. To explain this specific magnetic, especially the low TC, we investigated the microstructure using transmission electron microscopy (TEM) and energy dispersive X-ray spectroscopy (EDX). The 12 at.% Ti melt-spun ribbon is found to be amorphous, with no sign of nanocrystalline formation. EDX mapping within the amorphous matrix, shows that Fe and Ti are separated out into Fe-rich cells and Ti-rich cell-boundaries. B is also found to form a cellular distribution, but not directly related to either Fe or Ti. This phenomenon appears in electron diffraction as two overlapping sets of amorphous rings, indicating a different mean particle spacing in the two different regions. From x = 16 at.%, all compositions contain nanocrystals embedded within the amorphous matrix. Using EDX mapping, the nanocrystals are shown to be Ti-rich; and using electron diffraction and JEMS simulation, the nanocrystalline rings are shown to correspond to titanium diboride (TiB2). High resolution TEM investigation, in conjunction with Crystal Maker simulation software, supports this. The size of the crystals and their phase fraction are found to increase with Ti concentration.

This work was financially supported by the CNDI-UEFISCDI Grant #148/2012 (HYPERTHERMIA). L. Whitmore acknowledges the financial support of the European Commission (FP7-REGPOT-2012-2013-1, Grant Agreement no. 316194, NANOSENS).

Th.L-P05 - Magnetic and structural characterization of hybrid CFO-YBCO nanocomposites prepared by chemical solution deposition

E. Bartolomé [1], P. Cayado [2], S. Ricart [2], E. Solano [3], M. Coll [2], J. Ros [4], B. Mundet [2], J. Gázquez [2], A. Medelin [5], G. van Tedeloo [5]

5. EMAT, University of Antwerp, Antwerp, Belgium
6. ALBA Synchrotron Light Source, Barcelona, Spain

High Tc superconductor-ferromagnetic heterostructures constitute an appealing playground to study the interplay between flux vortices and magnetic moments. We have prepared hybrid YBCO nanocomposite epitaxial thin films on LAO substrates via a Chemical Solution Deposition technique, by introducing ex situ grown cobalt ferrite ($CoFe_2O_4$) nanoparticles (NPs) into the YBCO precursor solution. A one-pot, microwave radiation assisted route had to be developed to synthesize spherical, monodispersed NPs of size 5 nm that could be dispersed in the polar alcoholic solvent used for YBCO growth. The structural characterization of the nanocomposite, performed by HAADF STEM and EDS, shows that after the YBCO growth process, the NPs dissolve and the matrix contains intergrowths of a new $YBaCuFeO_5$/$YBaFe_2O_5$ phase. SQUID measurements carried out above Tc show that embedded NPs present a magnetization cycle, though the saturation value is much smaller than for synthesized CFO NPs. Besides, the critical current density Jc and Tc of the nanocomposite are decreased with respect to standard YBCO thin films due to Fe diffusion. Element-selective X-ray Absorption Spectroscopy (XAS) and X-ray magnetic dicroism (XMCD) measurements were performed at BOREAS beamline in ALBA synchrotron to gain insight into the structure and magnetic behavior of the hybrid nanocomposite. XAS&XMCD(H) measurements at the L2,3 edge of Fe and Cu were performed on a 16% CFO-YBCO nanocomposite at temperatures below (1.6 K) and above (60K) Tc, at fields up to 6 T. Results at the Fe-edge evidence the spinel is not present in the matrix, but a mixture of Fe3+/Fe2+ remains yielding a paramagnetic cycle. The XMCD(H) at the Cu-edge deploys also paramagnetic behavior, with the magnetic moments of Cu and Fe pointing in the same direction, the Cu saturation moment being an order of magnitude smaller than in YBCO standard thin films.

Th.L-P06 - Magnetotransport properties of $SrTiO_{3-\delta}$ thin films grown by Molecular Beam Epitaxy on p-Si(001) substrates

N. Theodoropoulou [1], R. Cottier, D. Currie, B. Koehne, P. Jalili

1. Texas State University

$SrTiO_3$ (STO) films were grown on p-Si (001) and STO (001) bulk substrates using molecular beam epitaxy (MBE). Oxygen vacancies were introduced by controlling the Oxygen pressure during growth resulting in $SrTiO_{3-\delta}$ with $\delta \sim 0.02\%$ for the lowest $P(O_2)$. The single-phase STO/Si films were of high crystalline quality as verified by x-ray diffraction, transmission electron microscopy, and atomically flat. Transport measurements were performed on the STO/Si structures in a Van der Pauw configuration. The $P(O_2)$ during growth determines the conduction behavior which changes from strongly localized transport that fits a Variable Range Hopping (VRH) model (low $P(O_2)$-high disorder) to thermally activated transport (high $P(O_2)$-low disorder). The resistivity of the strongly disordered STO/Si films decreased from $1x10^{-2}$ Ohm cm to $3x10^{-2}$ Ohm cm as the film thickness increased (3nm-60nm) for all temperatures (T). The perpendicular magnetoresistance (MR) is positive at 300K and at T=3-20K becomes negative for low magnetic fields (H). The MR behavior combined with the Hall effect data indicates the presence of localized electrons that delocalize with H and T. To identify the origin of the resistivity thickness dependence and MR behavior, we consider different competing effects on the STO/Si heterostructure such as 1.7% compressive strain induced by lattice mismatch to Si, defects due to oxygen vacancies, the bulk STO antiferrodistortive phase transition at 105K, and structural dislocations.

Th.M-P01 - Magnetic and magnetotransport study of the crossover from antidot to dot arrays

C. Castán-Guerrero [1,2], J. Herrero-Albillos [1,3], J. Bartolomé [1,2], F. Bartolomé [1,2], P. Strichovanec [1], J. Sesé [4,2], L.M. García [1,2]

1. ICMA (Universidad de Zaragoza - CSIC), Zaragoza, Spain
2. Dpto. de Física de la Materia Condensada (Universidad de Zaragoza), Zaragoza, Spain
3. Centro Universitario de la Defensa, Zaragoza, Spain
4. INA-LMA (Universidad de Zaragoza), Zaragoza, Spain

The control of magnetic properties of thin films can be achieved through the patterning of nanostructures, such as dot arrays or their negative pattern, antidot arrays. The magnetic crossover from antidot to dot regime (i.e. in series of arrays with fixed antidot diameter, *d*, varying the array period, p, from an array of well separated antidots when $p >> d$ to an array of dots formed by the intersecting antidots when $p < d$) has been studied by means of MOKE magnetometry and XPEEM images of the magnetic domain structure [1]. The study revealed for the first time an intermediate regime with a dual nature, morphologically consisting on an antidot array which behaves magnetically as an array of isolated dots.
In the present study, a new series of arrays have been fabricated and characterized by magnetoresistance (MR) and MOKE magnetometry. The antidots were fabricated by means of a gallium focused ion beam, causing some damage in the edges of the antidot. This results in a broadening of the effective antidot diameter calculated from MOKE and MR measurements, d_{eff} and d^{*}_{eff} respectively. The morphological diameter of the holes, *d*, is fixed in all the fabricated arrays, and $d^{*}_{\mathrm{eff}} < d_{\mathrm{eff}} < d$. The array period p has been varied from array to array, from $p >> d_{\mathrm{eff}}$, belonging to the antidot regime, to $d^{*}_{\mathrm{eff}} < p < d_{\mathrm{eff}}$, which is in the magnetic dot regime, although the magnetic islands are still connected by conductive channels. Therefore, this work not only proves that the intermediate regime can be measured by MR, but opens the door to the fabrication of magnetic dot arrays which are measurable by magnetotransport techniques.

Th.M-P02 - The effects of interlayer coupling on the static and dynamic behavior of $Ni_{80}Fe_{20}$/Ru/$Ni_{80}Fe_{20}$ Nanostripes

P. Lupo [1], Z. Haghshenasfard [2], L. Xiong [1], X. Ming Liu [1], M. Cottam [2], A. Adeyeye [1]

1. Information Storage Materials Laboratory, Department of Electrical and Computer Engineering, National University of Singapore, Singapore
2. Department of Physics and Astronomy, University of Western Ontario, London, Canada

Artificial ferromagnetic nanostripe arrays have been the focus of much attention recently because of fundamental research into magnonic crystals and for their wide range of potential applications as microwave resonators, filters, non-volatile memory and spin-wave (SW) logic devices. We have studied the static and dynamic properties of systems of two $Ni_{80}Fe_{20}$ nanostripes, separated by a thin spacer stripe of Ru, using a vibrating sample magnetometer and ferromagnetic resonance (FMR) spectroscopy respectively. By varying the Ru layer thickness (in a range from 0 to about 1.6 nm) we effectively control the Ruderman-Kittel-Kasuya-Yosida (RKKY) interlayer exchange interaction, and in some cases, a biquadratic interlayer exchange. Together with the effects of varying the width of the nanostripes over the range from 90 nm to 300 nm, which changes the shape anisotropy of the samples, we can realize an overall antiferromagnetic, spin-flop, or ferromagnetic ordering of the $Ni_{80}Fe_{20}$ stripes depending on the external magnetic field applied along the length of the stripes. The switchings between states of different magnetic order are accompanied by distinctive features observed in the FMR spectra of the lowest quantized spin-wave branches. The results obtained are contrasted with those found recently for $Ni_{80}Fe_{20}$/Ru/$Ni_{80}Fe_{20}$ complete films [1], where there is no in-plane shape anisotropy as in the stripes. The detailed theoretical analysis of the static and dynamic behavior, which is carried out using a combination of a phenomenological magnetization-vector model, a micromagnetic simulation package, and microscopic dipole-exchange theory, provides broad confirmation of the experimental data.

Th.M-P03 - Monte Carlo simulation of magnetic properties in Bit Patterned Media

O.D. Arbeláez Echeverri [1], E. Restrepo Parra [1], J.D. Agudelo Giraldo [1,2]

1. PCM Computational Applications, Universidad Nacional de Colombia, Manizales, Caldas, Colombia
2. Escuela de Materiales, Facultad de Minas, Universidad Nacional de Colombia, Medellín, Colombia

A two dimensional geometric model of Bit Patterned Media is proposed, the model is based on the crystal structure of the materials commonly used to produce the nano islands in bit patterned materials and the possible defects that may arise from the interaction between the nano islands and the matrix material. The magnetic properties of the material are then computed using the Monte Carlo method. The Hamiltonian takes into account both the spatial and topological disorder of the sample as well as the high perpendicular anisotropy that is pursued when building bit patterned media. The main finding of the research was the double phase transition in the Magnetization observed when computing curves of Magnetization vs. Temperature, further simulations were performed in order to stablish the relation of the this effect with the interaction between the nano islands and the interstitial material.

Th.M-P04 - Spin-wave modes and magnetization reversal in ferromagnetic nanostructures subjected to asymmetric magnetostatic interactions

Understanding and control of the magnetization behavior in magnetic nanostructures remains a key issue in fundamental physics and for various technological applications. In this framework, the desired single-domain and Ising-like behavior is commonly achieved by exploiting the shape anisotropy in elongated nanostructures. However, the energy landscape determined by the geometry and material properties comprises various stable and metastable states, which cannot be explored under the sole action of a uniform externally applied magnetic field. We have experimentally observed that Permalloy nanobars (720 nm x 170 nm x 25 nm) arranged in a chiral square unit can form a stable vortex state of predefined chirality during system remagnetization, even if only the single-domain state is achievable in the isolated nanostructure. Measurement of 2nd order Diffracted MOKE hysteresis loops and inspection of MFM images of frozen remanent states in the chiral unit reveal the presence of a critical angle in the applied field direction, which separates the single-domain magnetization reversal path from the magnetic vortex state reversal path [1]. This mechanism has been studied by micromagnetic simulations [2] and the Dynamic Matrix Method [3] in order to trace the origin of the difference in the reversal paths in the dynamic evolution of the magnetization [4]. The symmetry breaking induced by the inhomogeneous and asymmetric interaction in the chiral unit leads to the formation of new localized dynamic end-modes: the nucleation of the vortex state is connected to the softening of the lowest frequency localized end-mode occurring at certain angles of the applied field, while a partial softening of this mode gives rise to the conventional single-domain magnetization reversal path. Our results demonstrate that localized magnetic field sources can be used to actively induce the reversal paths of nanomagnets beyond what is achievable via lateral confinement and anisotropy engineering alone.

We have fabricated arrays of elliptical ferromagnetic nanoislands, made of Permalloy, with different dimensions (smallest nanomagnets 500x120x25nm3) and aspect ratios (length/width) of 4, 5.7, and 8. They are arranged in chiral square and rectangular units formed by four nanomagnets, so that the stray fields created by each pair of parallel nanomagnets interact asymmetrically on the nanomagnets perpendicular to them. Under the action of a uniform magnetic field the only possible magnetic configuration that is induced in the nanomagnets is a single-domain state, i.e. the nanomagnets have an Ising-like bistable behavior of the magnetization. Micromagentic simulations indicate that a vortex state, if induced, would be stable although energetically highly unfavoured with respect to the single-domain state. Here we demonstrate that indeed, under the action of asymmetric fields, it is possible to nucleate magnetic vortex states that are stable at remanence. We demonstrate experimentally [1] the existence of these vortex states by analyzing the magnetization reversal process by means of standard and diffracted MOKE magnetometry [2], and Magnetic Force Microscopy. Our micromagnetic simulations, performed using OOMMF [3], replicate the obtained experimental results.

Th.M-P06 - Quantized energy states in spin ice due to magnetic coupling

C. Sheng Soh [1], I. Purnama [1], S. Krishnia [1], W. Siang Lew [1], R. Maddu [1]

1. School of Physical and Mathematical Sciences, Nanyang Technological University, Singapur

Spin ice structures have been used to investigate the possibility of creating magnetic monopoles when they are geometrically aligned to a vertex collectively[1]. Here, we show that the total energy of such system is quantized into several energy levels due to the coupling between the islands[2]. The energy levels are shown to be stable over a range of temperature, and it is possible to change the temperature range significantly by adjusting the strength of the coupling between the islands.

In this work, an octagonal square design with 50nm/100nm separation between the islands as shown by Figure 1(a) is being investigated. The energy values for the 8 possible magnetic configurations are calculated and shown in Figure 1(b). By running simulations on his tessellation, the density of low/medium/high energy vertices at its relaxed state is recorded and plotted against temperature (T) from 1K to 250K. The system was first randomized. Then a random island is selected to be flipped. If the energy in the vertex after flip becomes lower, the flip is accepted with a probability (P) of 1, else P is calculated using $P = e^{\frac{-\Delta E}{kT}}$. It is repeated until the system has reached equilibrium as shown in Figure 2.

The simulation results show that there is quantization in the distribution of vertices. In our design, the discrete energy levels are not observed at higher temperatures (i.e. >250K) due to minute change; however, the quantization can be observed at T<250 K. Moreover, the robustness of the quantization is shown to increase significantly as separation distance is reduced; the temperature range for the vertices fixed in the ME level is extended to ~190 K as the separation distance is reduced to 50nm. Thus, our design can potentially be used as a framework to investigate the quantization phenomenon of frustrated magnetic system at elevated temperature.

Th.M-P07 - Spin wave bound modes in a circular array of magnetic inclusions embedded into a ferromagnetic matrix

S. Nikitov [1,2], Y. Barabanenkov [1], S. Osokin [1,2], Dmitry Kalyabin [1,2]

We have developed a theory which is capable to calculate scattering of magnetostatic spin waves propagating in a ferromagnetic film with finite array of cylindrical inclusions. We have restricted our analysis by considering magnetic inclusions having different value of magnetization in comparison with a material of the film and considering a case of a magnetic structure being saturated in a magnetic field perpendicular to the film surface.
The main result obtained in our paper is that due to spin wave multiple scattering by an ensemble of finite number of inclusions in circular array bound wave modes are excited along the path connecting inclusions. The physical origin of the bound modes propagating along circular array of inclusions is in variation of a phase a scattered magnetic potential related to a spin wave. Thus, these bound spin wave modes appear as a wave of a phase due to scattering. Scattered field spatial-phase modulation is related to spin wave reciprocity breaking due to asymmetric magnetic susceptibility tensor. Further, this fact leads to that the plane spin wave scattering by a single inclusion transforms the magnetic field potential in a form of helix lines. Such scattering can also be visible for a greater number of inclusions depending on the product of the wave number of the spin wave on distant between two nearest inclusions in circular array (collective wave parameter). If the collective wave parameter is not grater than π the helix lines appear in a scattered field. If it is grater than π the scattering spin wave potential is distributed by Bragg interference. In the case the plane wave is scattered by four inclusions specific radial nodal lines appear in a scattered field.

We analyzed with MFM and MOKE finite squared (rectangular) arrays of circular (elliptical) magnetic dots and performed simulations with MuMax, a GPU-based software [1]. We showed as for limited size of the periodic arrays the transition of the magnetization during the reversal starts at the edges and corners of the array and propagates inside the pattern, so that in a restricted field range the magnetization results to be not uniformly distributed. While the shape of the dots (circular, elliptical, etc.) introduces a Configurational Anisotropy [2], we find that the finite array dimensions introduce an additional Global Configurational Anisotropy (GCA) [3]. Both effects originate at the demagnetizing interactions playing at different space scales: the dot and total array space scale, respectively. Simulations of dot arrays are often restricted to one dot assuming isolated non-interacting magnetization processes. Periodic boundary conditions are sometimes used to incorporate interdot interactions, still limiting computations to a restricted number of dots and assuming infinite lattice periodicity. Then, configurational anisotropy is accounted for, but GCA is not. We show that mutual dot interactions together with finite array dimensions have a non-negligible impact on the magnetization reversal of a dot array. We numerically and experimentally study the hysteresis properties of Permalloy (Py) arrays of 16x16 circular and elliptical dots, with thickness ranging between 10 and 25 nm and lateral size between 300 and 500 nm. In magneto-optical Kerr effect (MOKE) measurements, in-field magnetic force microscope (MFM) measurements and simulations, we find that GCA steers the magnetization reversal of the array: the dots run through different magnetization states depending on the dot location and collective magnetization processes occur, leading to transition avalanches and formation of magnetization chains. These findings are important in the development of applications that rely on a robust control of dot magnetization states in dot arrays.

Th.M-P10 - Magnetic properties of FeCoCu/Cu multilayer nanowire arrays

E.M. Palmero [1], C. Bran [1], C. Magen [2], R.P. del Real [1], F. Beron [3], M. Vazquez [1]

FeCo alloy nanowires have been proposed as an alternative novel family of permanent magnets with high saturation magnetization and coercivity [1]. The addition of non-magnetic materials has been proved to tailor the magnetic properties of the nanowires [2]. Series of ordered [FeCoCu(y)/Cu(x)]10 multilayer nanowire arrays, with various Cu and FeCoCu layers thicknesses and constant diameter of 35nm, were fabricated by electrodeposition from a single electrolytic bath into self-assembled pores of anodic alumina membranes, in order to study the influence of magnetic and non-magnetic layer thickness on their magnetic properties. Transmission Electron Microscopy analysis confirm the segregation of layered structures, with well-defined Cu layers (fcc cubic structure) separating FeCoCu alloy layers (bcc cubic structure). Magnetic measurements indicate an overall magnetization easy axis parallel to the nanowires in all the samples. For constant FeCoCu thickness, the coercivity, remanence and susceptibility increase with Cu layer thickness, while for the series with constant Cu layer thickness, a significant decrease of susceptibility with FeCoCu thickness was observed. Complementary Henkel curves study indicates that the net inter/intra nanowires magnetostatic interactions always contribute to demagnetization of nanowires. The results show a decrease in the effective magnetostatic interactions for multilayer nanowires with thicker Cu and thinner FeCoCu layers arising from stray fields at the surface of intra-wire and adjacent inter-wires magnetic layers. FORC method was use to quantify the effect of the inter/intra nanowire magnetostatic interactions on the coercivity and interaction field distributions. For the samples with thinner FeCoCu and thicker Cu layers, sharper peak along the interaction field axis is observed, suggesting that the increase of the non-magnetic to magnetic layer thickness ratio promote the reduction in the magnetostatic interactions.

Th.M-P11 - Collective magnetic properties in nanoparticle assemblies highlighted by shape anisotropy and interparticle distances

B. Pichon [1], D. Toulemon [1], M. Pauly [1], S. Fleutot [1], S. Bégin-Colin [1]

1. Institut de Physique et Chimie des Matériaux de Strasbourg, Strasbourg, Switzerland

Owing to their unique properties depending on their environment, nanoparticles are of particular interest with regard to develop the next generation of magnetic devices. Magnetic nanoparticles are featured by a single magnetic domain, and can be assimilated to elemental nanomagnets which interact together through dipolar interactions. Therefore their magnetic properties can be strongly modulated as function of the structure of their assemblies, which interparticule distances and dimensionality of the assembly are the most significant parameters to play with. Here, we report on the modulation of the collective properties of iron oxide magnetic nanoparticles assembled in films as function of the dimensionally of the assembly and of the interparticule distance by using the Langmuir-Blodgett technique [1,2] and substrate functionality by self-assembled monolayers (SAMs) of organic molecules.[3,4,5] Decreasing the dimensionality from multilayers (3D) to monolayer (2D) and finally to chains (1D) demonstrated the enhancement of the dipolar interactions thanks to shape anisotropy which forces the preferential alignment of magnetic moments in the directions of the assembly. Dipolar interactions being long range interactions, they have been also studied as function of inter particle distances.

Th.M-P12 - Challenges to realising topological control of domain wall transit in artificial spin ice

W. Branford [1], S. Walton [1], K. Zeissler [1], D. Burn [1], M. Chadha [1], L. Cohen [1]

1. Imperial College London, London, United Kingdom

I will discuss arrays of single domain nanomagnets with frustrated interactions, known as Artificial Spin Ice. The structures studied electrically continuous permalloy honeycombs. [1-2] Here I report direct magnetic imaging studies of magnetic charge flow in artificial spin ice. [3-5]. The magnetic charge is carried by either transverse or vortex domain walls (depending on bar dimension) and the chirality of the domain wall is found to control the direction of propagation. Recently it has been shown that in isolated Y-shaped junctions that support vortex domain walls, selectivity can be robustly determined by chirality (or topology), indicating that vortex wall chirality is robust in the Walker breakdown process.[6,7] Here I will show that in Y-shaped junctions, magnetic switching in the important topologically protected regime exists only for a narrow window of field and bar geometry, which is challenging to access in field-driven Artificial Spin Ice. This work has implications for the wider field of magnetic charge manipulation for high density memory storage.

Th.M-P13 - Dipolar interactions in finite arrays of elliptical Fe(001) particles

M. Hanson [1], T. Antosiewicz [1,2]

1. Chalmers University of Technology, Göteborg, Sweden
2. Centre of New Technologies, University of Warsaw, Warsaw, Poland

Arrays of ferromagnetic nano-sized particles are of great interest for applications. To obtain any desired functional static and dynamic magnetic properties, the individual particles as well as their interactions, determined by the design of the arrays, must be controlled. We made an extensive study of Fe ellipses prepared with their axes along the easy magnetization directions in epitaxial Fe(001) films. Here we present results from calculations of interactions in different array configurations of ellipses with axes 50 nm x 150 nm and thickness 10 nm. We show that this system is in a range where no collective effects are observed and the interactions can be tuned to either promote or delay the magnetization reversal in the individual particles.
The interaction field at different positions in a saturated array was calculated with high spatial resolution by summing the dipolar interactions from all ellipses divided into tiny cubes with 2 nm sides. As an example, for a rectangular lattice with lattice constants twice the corresponding axis of the ellipses the main component of the interaction field lies along the long axes of the ellipses and at the onset of switching it reinforces an external switching field. For a square array with 3 by 7 seven ellipses the strength is about $B_y = 11$ mT at the center. B_y decreases with the array size; being about 10 mT for 21 by 61 ellipses. The strongest interactions are felt by the ellipses at the top edge of the array; about14 mT for the 21 by 61 array. B_y approaches 9.3 mT in the limit of large arrays.
Quasi-static micromagnetic simulations were applied to follow the array of ellipses during stepwise demagnetization. The ellipses were seen to switch individually in a range of fields, starting earlier than for corresponding single-particle switching.

Th.M-P14 - Magnetic interactions in *3d* metal chains on $Cu_2X/Cu(001)$ (X = N, O): comparison with corresponding unsupported chains

M.C. Urdaniz [1], M.A. Barral [1,2], A.M. Llois [1,2], A. Saúl [3,4,5]

1. Departamento de Física, Comisión Nacional de Energía Atómica, San Martín, Buenos Aires, Argentina

4. Department of Civil and Environmental Engineering, Massachusetts Institute of Technology, Cambridge, United States
5. MultiScale Material Science for Energy and Environment, Cambridge, United States

In this work we present a systematic study of the magnetic interactions within *3d* transition metal chains adsorbed on Cu_2N and Cu_2O monolayers grown on Cu(001). We are interested in the particular geometric adsorption configuration which gives rise, after relaxation, to the development of diatomic TM-X (X = N, O) chains. Using Density Functional Theory we calculate the energy difference between the ferromagnetic and antiferromagnetic intrachain configurations for Ti, V, Cr, Mn, Fe, and Co. Both substrates give rise, with minor differences, to the same magnetic trends, the only chains which result being ferromagnetic after adsorption are Cr ones.
By performing similar calculations in unsupported chains and introducing a Tight-Binding model Hamiltonian based on physically reasonable assumptions we have been able to reproduce the magnetic trends obtained from the DFT calculations.

Th.M-P15 - Controlling magnetization reversal in planar nanostructures with wire-ring morphology

R. Corona [1], A. Aranda [1], J.L. Palma [1,2], C. López [1,2], J. Escrig [1,2]

1. Departamento deFísica, Universidad deSantiago de Chile, Santiago, Chile
2. Center for the Development of Nanoscience and Nanotechnology, CEDENNA, Santiago, Chile

Magnetization reversal in planar nanowires has been controlled using structures with a larger area pad connected to a nanowire or by means of patterned variations in the planar nanowire such as notches. In this work, we have introduced a magnetic nanostructure defined as a planar nanostructure with wire-ring morphology. In particular, we have performed micromagnetic simulations to investigate how the magnetic properties (coercivity and remanence) change as a function of the geometric parameters of the nanostructure. Additionally, we observe that when the ring is very thin, the system reverses its magnetization by nucleation and propagation of domain walls along the nanowire. Conversely, when the ring has very thick walls, or directly turns into a solid cylinder, the system nucleates a vortex in the ring/cylinder, and then propagates the domain walls toward the nanowire sections. This reversal process is characterized by a step or plateau in the hysteresis curve, that is, a region in which differential magnetic susceptibility presents a local mínimum or, ideally, vanishes. Finally, this nanostructure can be used in many potential applications related to the control of domain walls in planar nanowires.

Th.M-P16 - Magnetostatic interactions between wire-tube nanostructures

D. Salazar-Aravena [1], J.L. Palma [1,2], J. Escrig [1,2]

1. Departamento de Física, Universidad de Santiago de Chile, Santiago, Chile
2. Center for the Development of Nanoscience and Nanotechnology, CEDENNA, Santiago, Chile

We have investigated the magnetostatic interactions between wire-tube nanostructures. We have obtained that decreasing the distance between the nanostructures, decrease the coercivity of the array. Besides, when the external magnetic field is applied along the axis of the nanostructures, the two Barkhausen jumps observed for an isolated wire-tube nanostructure give rise to several minor jumps for a weakly interacting array, that eventually become a single jump for the most interacting case. Additionally, the angle at which maximum coercivity is obtained varies as a function of the center-to-center distance between the nanostructures, while that remanences obtained for arrays with different distances between the nanostructures coincide. In this way, magnetostatic interactions between wire-tube nanostructures is an interesting topic of research in connection with potential applications where it is usually desirable to avoid such interactions or at least control them. We thank K. R. Pirota and R. López-Ruiz for useful discussions. The authors acknowledge financial support from the Fondecyt Grants 3130393 and 1150952, and the Financiamiento Basal para Centros Científicos y Tecnológicos de Excelencia, under project FB0807. CONICYT Ph.D. Program Fellowships is also acknowledged.

Th.M-P17 - Spectroscopic and spatially resolved magneto-optical characterizations of 1D magnetic gratings

V. Kletecka [1], L. Beran [1], R. Antos [1], M. Veis [1]

1. Charles University, Prague, Czech Republic

Magneto-optical (MO) methods are often used as high sensitive non-destructive techniques to probe physical properties of various magnetic materials down to the nanometer scale. Spatially resolved MO experiments are suited for visualization of magnetic domains larger than 0.15 um. Samples have to be reasonably smooth, however there are many advantages such as non-destructiveness, high time resolution or easy manipulation with samples, which enables great way to analyze wide variety of nanostructured magnetic materials. In combination with spectroscopic ellipsometry (SE) as a complementary tool MO spectroscopy can provide important information about the geometrical and material properties. MO spectroscopic scatterometry combines theoretical and experimental investigation of MO spectral response of patterned periodic magnetic nanostructures.

Here we report on analyzing two types of one-dimensional gratings formed by magnetic materials, permalloy ($Ni_{81}Fe_{19}$) and nickel by specially designed MO microscopy and MO scatterometry. Periodic lamellar grooves were etched by electron-beam lithography and ion milling on a 32-nm-thick permalloy layer deposited on an Si substrate. Periodic Ni wires were fabricated by the lift-off procedure on Si substrate with a 500-nm-thick SiO_2 overlayer. For the theoretical calculations fast Fourier factorization rules with complex polarization bases were employed. Spatially resolved MO experiments provided the information about the amplitude of MO Kerr effect across the sample and allowed to estimate the thickness of magnetic material in lines and grooves separately. This demonstrated the ability our specially designed MO microscope. The half-micrometer SiO_2 layer caused significant interference in scatterometric experiments, which enabled sensitive monitoring of both the thickness and the material properties. The Ni was found partially oxidized with homogenous concentration of NiO in depth. The concentration of NiO within the Ni layer was determined equal to 52 %. The material constants of the system of Ni+NiO was modeled by the effective-medium approximation.

Th.M-P18 - Thermal ordering and correlations in an artificial two-dimensional Ising system

U. Arnalds [1], J. Chico [2], H. Stopfel [2], V. Kapaklis [2], O. Bõrenbold [2], M. Verschuuren [3], U. Wolff [4], V. Neu [4], A. Bergman [2], B. Hjörvarsson [2]

2. Department of Physics and Astronomy, Uppsala University, Uppsala, Sweden
3. Philips Research Laboratories, Eindhoven, The Netherlands
4. IFW Dresden, Institute of Metallic Materials, Dresden, Germany

The ability to create artificial analogues of model spin systems using lithographic techniques allows interactions and symmetries to be directly tuned through the array geometry [1]. Using magnetic microscopy tools the local ordering of individual artificial spins in relation to their neighbors can be determined and thereby the microstate of the system [2]. Here, we present a direct experimental investigation of the thermal ordering in an artificial analogue of an asymmetric two dimensional Ising system. The system is composed of a rectangular array of magnetostatically interacting elongated amorphous CoFeZr thin film islands. Below a critical thickness of the magnetic material, during the fabrication of the array, the islands are thermally fluctuating and thus the system is able to explore its phase space. Above the critical thickness the islands freeze-in resulting in an arrested state for the array corresponding to a low energy state at the fabrication temperature. Imaging the array by magnetic force microscopy the magnetization direction of individual islands can be resolved and thereby the state of an extended area of the array, composed ~10.000 islands, determined. Analyzing the pairwise correlations and ordering in the array and comparing our results to Monte-Carlo simulations we establish the array to represent a genuine artificial two-dimensional Ising system which can be analyzed in the context of nearest neighbor interactions.

Th.M-P20 - Highly anisotropic dynamical magnetic properties of needle-shaped arrays of iron oxide nanocubes

E. Wetterskog [1], R. Stjernberg Bejhed [1], P. Svedlindh [1]

1. Solid state physics, Deparment of Engineering Sciences, Uppsala University, Uppsala, Sweden

In this work we have investigated the AC-magnetic properties of needle-shaped arrays composed of monodisperse iron oxide nanocubes with average edge lengths of 9.6 and 12.6 nm. The particles are synthesized by a thermal decomposition method and assembled on a solid surface in a lateral magnetic field by an evaporative approach. This generates a hierarchical structure of needle-shaped particle arrays (d~10 Ám) with very long aspect ratios. The temperature dependence of the AC-susceptibility was measured both parallel and transverse to the long axes of the needle shaped arrays. The results were compared with measurements on non-interacting particles in dilute dispersions. In the needle-shaped arrays there is a significant anisotropy of the magnetic susceptibility. This effect is strongly particle size dependent and clearly differing from the behavior of the non-interacting systems meaning that the properties of the needle-shaped arrays are collective in origin. A number of other effects will also be discussed such as differing energy barrier distributions of the arrays and the dispersions, and the very large changes in magnetic susceptibility by the application of bias fields. Our results show in a dramatic fashion that collective shape and demagnetization effects can be significant and strongly influence the magnetization dynamics of nanoparticle arrays.

Th.M-P21 - Magnetostatic coupling in arrays of FeCo monolayer and bilayer long aspect ratio nanoribbons

M. Abuín [1], M.A. García [2], M. Maicas [3], L. Pérez [1], A. Mascaraque [1]

1. Universidad Complutense de Madrid, Madrid, Spain
2. Consejo Superior de Investigaciones Científicas, Madrid, Spain
3. Universidad Politécnica de Madrid, Madrid, Spain

Magnetic nanostructures are of great interest for the ever increasing requirements in information storage in the development of Magnetic Random Access Memories, spintronic devices, nanomagnetic logic or magnetic sensor technologies. Scientific knowledge of the magnetization behavior for the reproducible control of magnetic states is essential in these areas. This behavior depends mainly on the shape and geometry of the nanostructures as well as their relative location. Micromagnetic simulations can be used for the study of magnetization processes in large arrays of magnetic nanoelements by using Periodic Boundary Conditions (PBCs) under the assumption that all the nanostructures behave the same way. Although PBC are not absolutely convergent in 3-D they can be successfully used in large 2-D arrays.

In this work we report on the magnetostatic coupling between magnetic nanostructures in 2-D arrays of mono and bi-layer (two magnetic layers with a non-magnetic spacer) FeCo nanoribbons with dimensions 1000x100x20 (mono-layers) and 1000x100x20-10-20 (bi-layers magnetic-non magnetic-magnetic). The magnetostatic coupling between ribbons is studied as a function of the ribbon thicknesses, spacing in the array as well as other parameters. This analysis is carried out by means of micromagnetic simulations with PBCs using the LLGMicromagnetics simulator. Results are compared with magnetic measurements on FeCo arrays fabricated with sputtering and e-beam lithography. These magnetic measurements have been carried out using Diffracted Magneto-Optical Kerr Effect (D-MOKE). Results show the coupling between adjacent ribbons and how this coupling depends mainly on ribbon thicknesses and spacing. This coupling decreases rapidly when the spacing becomes larger than ribbon thickness. The zero remanent magnetization state is not found after saturation in balanced magnetic bilayers. These results agree well with magnetic measurements obtained by D-MOKE.

Th.M-P22 - Template morphology dependent control of magnetic interactions between magnetic nanostructures

K. Rumpf [1], P. Granitzer [1], P. Poelt [2], H. Michor [3]

1. Karl-Franzens-University Graz, Institute of Physics, Graz, Austria
2. University of technology Graz, Institute for Electron Microscopy, Graz, Austria
3. Vienna University of Technology, Institute of Solid State Physics, Vienna, Austria

This presentation discusses the fabrication of self-organized three-dimensional arrays of magnetic nanostructures with controllable magnetic properties. The magnetic structures are deposited electrochemically within a porous silicon matrix. Since the magnetic characteristics of the nanocomposite depend not only on the size, shape and mutual arrangement within the pores but also on the template morphology, the structure of the porous silicon has been modified and a correlation between these parameters has been figured out. The porous silicon templates offer a self-organized pore-arrangement with a dendritic pore-growth which cannot be suppressed completely in the investigated mesoporous regime. These porous silicon templates have been filled with diverse ferromagnetic metals and alloys by electrodeposition and the deposition process has been elucidated with respect to the roughness of the pore-walls and the resulting deposited nanostructures (wires, particles). The texture of the pore-surface plays a crucial role concerning magnetic coupling between adjacent pores. Furthermore the kind of metal is of importance, whereat for each metal the deposition parameters have to be adjusted individually. The nucleation of the metal deposition starts at surface asperities and the growth of the nanostructures can be influenced by using pulsed electrodeposition and also by the electrolyte. A study of the metal deposition dependent on the morphology and the resulting adjustability of the magnetic properties of the 3-dimensional nanostructure array will be presented.

Th.N-P01 - Superparamagnetic gold nanotriangles by microwave polyol synthesis

S. Yu [1], A. Laromaine [1] N, A. Roig [1]

1. Institut de Ciència de Materials de Barcelona (ICMAB-CSIC), Campus de la UAB, Bellaterra, Spain

The combination of magnetic and optical properties in a nanomaterial offers enormous potential in bio-sensing, imaging and therapeutical applications. However, uncomplicated approaches to synthesize hybrid magneto-plasmonic nanoparticles with anisotropic plasmonic shapes avoiding cytotoxic reactants remain a huge challenge. Microwave heating is an attractive non-conventional energy source for chemical synthesis due to the high acceleration and yield of the performed chemical reactions. In comparison to conventional heating methods, microwave radiation avoids production of temperature gradients decreasing occurrences of asynchronic nucleation and heterogeneous nanocrystal growth. In addition, microwaves heats polar substances rapidly and intensely promoting selectively heat at desired sites. Thus, based on heating selectivity and the increase of the molecular motion, complex nanostructured materials can be fabricated. We will report on a facile, fast and bio-friendly microwave-assisted polyol route to synthesize gold nanotriangles decorated with a monolayer of iron oxide nanoparticles (Figure 1). The overall synthesis time is less than one hour. The obtained hybrid nanoparticles are readily dispersable in water, superparamagnetic at room temperature and display local surface plasmon resonance in the near infrared region. This is interesting since particles absorbing at the near-infrared region were reported to produce heat more efficiently compared to spherical gold nanoparticles absorbing in the UV-Vis. The effect of the reaction conditions and the magnetic and plasmonic properties of the nanoconstructs will be presented.

Th.N-P02 - Optimization of MTJ nano-contact on pn-GaAs photodetector for a high-speed non-volatile optical memory

V. Zayets [1], H. Saito [2], K. Ando [3], S. Yuasa [4]

1. Spintronics Research Center, AIST, Ibaraki, Japan

The high-speed non-volatile optical memory has been proposed [1], which utilizes a high-speed spin injection of a spin-polarized photo current from a semiconductor-made pn-junction into a metal nanomagnet.
For the successful operation of the memory it is essential to inject photo-excited electrons form the semiconductor detector into the nanomagnet within a time interval shorter than the spin life time in the semiconductor. The spin life time in GaAs is short and it does not exceed 100 picoseconds at room temperature. In the case when the injection time is longer than the spin life time, the spin information is lost inside the semiconductor before it is injected into the nanomagnet. The injection time significantly depends on the nanocontact resistance. The lowest contact resistance is important to shorten the photocurrent injection time from the pn-photdetector to the nanomagnet.
The photocurrent was excited by 170-fs 10-pJ optical pulses at wavelength of 860 nm. The area of the MTJ nanocotact was 0.01 μm^2. The tunnel magneto resistance was 100%. The injection time was measured to be 3 ns, 350 ps and 75 ps for the MTJ nanocontacts with the contact resistance of 7000, 250 and 30 Ohm μm^2, respectively. An injection time shorter than the spin life time in GaAs was achieved. The dependence of the tunnel magneto-resistance on the light intensity was observed.

Th.N-P03 - Experimental demonstration of long-distance propagation of a surface plasmon on the surface of a ferromagnetic metal

V. Zayets [1], H. Saito [2], K. Ando [3], S. Yuasa [4]

1. Spintronics Research Center, AIST, Ibaraki, Japan

At present, there is a significant commercial demand for an optical isolator, which can be integrated into the Photonic Integrated Circuits (PIC). An optical isolator, which utilizes unique non-reciprocal properties of surface plasmons, can be a good candidate as the integrated optical isolator [1], because of its small dimensions and its technological compatibility with the fabrication technology of the PIC. The main obstacle for a practical realization of the plasmonic isolator is the substantial propagation loss of the surface plasmons in structures containing a ferromagnetic metal [2]. Because of the high loss, a thick buffer layer of a noble metal is required between a ferromagnetic metal and a dielectric in order to observe a long-distance propagation of surface plasmons [3]. The reduction of the propagation loss of a surface plasmon is the key to make the plasmonic isolator competitive with other designs of the integrated isolator. It was demonstrated experimentally that by utilizing an optimized double-dielectric plasmonic waveguide it is possible to reduce significantly the optical loss in a plasmonic waveguide. For a $Fe/SiO_2/AlGaAs$ double-dielectric plasmonic waveguide the low propagation loss of 0.03 dB/um was obtained. As far as we know at present it is the lowest propagation loss demonstrated for a plasmon propagating at the surface of a ferromagnetic metal. For a $Co/Ti_2O_3/SiO_2$ double-dielectric plasmonic waveguide integrated with a Si nanowire waveguide on a Si substrate the optical loss of 0.7 dB/um was demonstrated.

Th.N-P04 - Using antiferromagnets as a route to tunable negative refraction

R. Macedo [1], R. Stamps [1], T. Dumelow [2]

1. SUPA, School of Physics and Astronomy, University of Glasgow, Glasgow, United Kingdom
2. Departamento de Física, Universidade do Estado do Rio Grande do Norte, Costa e Silva, Mossoró RN - Brazil

The phenomenon of negative refraction of a beam of electromagnetic radiation occurs when, on passing from one medium to another, the incident and refracted beams are situated at the same side of the surface normal. Here, we consider all angle negative refraction in uniaxial antiferromagnets. This phenomenon is possible when two of the principal components of the permeability tensor have opposing signs, which occurs around the magnetic resonance frequencies (typically in the terahertz range). In the absence of a magnetic field (B_0 = 0), the tensor component along the uniaxis is unity at all frequencies, with poles in the perpendicular components at the magnon resonance frequency (8.94 cm^{-1} in the case of MnF_2) [1]. If the uniaxis lies along the crystal surface, in the plane of incidence, the angle of refraction becomes negative immediately above this frequency. When an external magnetic field B_0 is applied perpendicular to the plane of incidence, the magnetic spins will be canted toward this field. The main effect of this is to shift the magnetic resonance frequency to higher frequencies so that, at a given frequency, the angle of refraction will change. We therefore show that antiferromagnets such as MnF_2 open the possibility of negative refraction being tuned with an external magnetic field, and also show that this can occur to such an extent that the sign of the refraction can be inverted.

Th.N-P05 - Plasmonic hollow cylindrical nanostructures fabricated by nanoimprint lithography and non-directional metallization

A. Conde-Rubio [1], M. Kovylina [1,2], N. Alayo [3], X. Borrisé [3], F. Pérez-Murano [3], G.D. Hibbard [2], A. Labarta [1], X. Batlle [1] N

1. Dept. Física Fonamental, Universitat de Barcelona and Institut de Nanociencia i Nanotecnologia, Barcelona, Spain
2. Dept. Materials Science and Engineering, University of Toronto, Toronto, Canada
3. Instituto de Microelectrónica de Barcelona (IMB-CNM, CSIC) UAB, Barcelona, Spain

A high-throughput, low cost process for the fabrication of hollow cylindrical nanoparticles with a precise control of their geometry and variable composition has been developed. The process is based on combining concepts from stencil and nanoimprint lithography (NIL), together with the use of non-directional metallization, allowing an accurate positioning of nanostructures in large arrays. The process starts by imprinting a trilayer structure consisting on a bottom layer of polymethyl methacrylate (PMMA) 950k MW, an intermediate thin layer of SiO2 and a top layer of PMMA 75k MW, which are deposited on a substrate. Then, the top layer is patterned by NIL using Si dotted stamps. A dry reactive ion etching process is carried out to transfer the pattern to the bottom PMMA layer obtaining an optimal undercut for the final lift-off process. Metal deposition is performed by sputtering.
The unique properties of Au such as its chemical stability, biocompatibility and easy functionalization as well as its surface plasmon resonance which entails effects such as absorption and scattering enhancement or concentration of the electromagnetic field, make it the perfect candidate for applications in areas such as photovoltaics, sensing, and medicine. Optical absorption experiments and finite difference time domain simulations of Au hollow cylindrical nanostructures with a diameter and a height of about 400 nm and a wall and base thickness of about 30 nm demonstrate a great enhancement of the electromagnetic field, which is promising for fabricating functional devices based on surface Raman enhanced spectroscopy. This fabrication procedure also allows an easy combination of different materials making it possible to obtain multifunctional nanoparticles which could have interest for magnetoplasmonics.

This work was supported by Spanish MINECO (MAT2012-33037), Catalan DURSI (2014SGR220, 2014SGR1025), and European Union FEDER funds (Una manera de hacer Europa). A. Conde-Rubio acknowledges Spanish MINECO for a Ph.D. contract (BES-2013-065377).

Th.N-P06 - Enhancement of transverse magneto-optical intensity effect in active magneto-plasmonic structures

O. Borovkova [1], N. Khokhlov [1,2], A. Kalish [1,2], V. Belotelov [1,2], P. Vetoshko [1]

2. Lomonosov Moscow State University, Faculty of Physics, Moscow, Russia

Magneto-optical (MO) effects find their applications in modern data storage devices. Previously, it was shown that such effects can be significantly enhanced by the excitation of surface plasmon-polaritons (SPPs). SPPs propagating along the interface of ferromagnetic dielectric film and the nanoscaled grating of noble metal increase the MO effect in both reflected and transmitted light.
However, SPPs dissipate their energy through the interaction with metal that limits their propagation length. Moreover, the ferromagnetic material containing iron ions contributes additional losses. Thus, the problem of loss compensation and amplification of SPPs is crucial for the enhancement of the MO effect.
In our work we consider a ferromagnetic film of BiIG garnet doped by Cr ions or ions of rear-earth elements (Tb, Eu, Tm, Yb, and Nd) as a resonant amplifying medium. We address a magneto-plasmonic crystal of 1D gold grating deposited on the doped iron garnet grown on top of the non-magnetic gadolinium gallium garnet substrate. Due to the optical pump at certain frequencies of visible and IR-range dopant ions in ferromagnetic film are excited and their further emission increases the intensity and propagation length of the SPP wave. We are focused on the intensity MO effects like transverse magneto-optical Kerr effect (TMOKE) when the magnetization vector is perpendicular to the light incidence plane. We analyse the amplification of transmittance and TMOKE effect for various levels of optical gain, metal film width, and type of dopants. It is shown that by the employment of amplifying ferromagnetic film the intensity of the transmitted light can be increased by 50%. At the same time, the intensity of the TMOKE effect also increases by 50%.

1D magneto-photonic crystals (1D-MPCs) based on Bi-substituted yttrium-iron-garnet (Bi: YIG) films are very fruitful for applications in magneto-optical (MO) devices. The temperature could be one of the additional parameter allowing one to control the MO properties of 1D-MPCs, especially in the case when MO layers have a composition with a magnetic compensation temperature Tcomp. The purpose of this research is the further study [1] of the low-temperature behavior of the optical and MO properties of single (Bi, Gd, Al)-substituted YIG films (M) prepared by reactive ion beam sputtering on GGG substrates and microcavity 1D-MPCs GGG/(TiO2/SiO2)4/M/(SiO2/TiO2)4 on their base. Three types of microcavity 1D-MPCs with MO films of different compositions, types of magnetic anisotropy and Tcomp (including composition $Bi_{2.8}Y_{0.2}Fe_5O_{12}$ without Tcomp) as a cavity layers were prepared and investigated.
It was found that the garnet films completely determine the MO properties of 1D-MPCs. The sign inversions of Faraday rotation angle ΘF in the films and in MPCs are observed at the same Tcomp and is associated with compensation of Fe- and Gd-sub-lattice magnetic moments.
In the films and in 1D-MPCs the temperature hysteresis in the ΘF(T) dependence was observed around Tcomp. Temperature hysteresis phenomena is caused by first-order phase transitions “collinear phase – non-collinear phase – collinear phase” and is due to the need of additional energy for the nucleation of a new magnetic phase. The observed slope of the ΘF(T) dependence may be cause by possible inhomogeneous distribution of garnet-constituting elements along film thickness, mechanical stresses and structural inhomogeneities of the films.

The basic problem in creation of one-dimensional magnetophotonic crystals (1D-MPCs) for various electronic and optical applications is the increasing of magneto-optical quality factor and finding the optimum ratio of the rotation angle of polarization plane and intensity of the light propagating through the crystal. The solution of this problem is complicated by the peculiarities of the synthesis of iron-garnet films with high Bi content (more than 1 at. / f. u.). At the first in [1] the double layer Bi-substituted iron garnet (Bi: IG) films composed of buffer layer with low Bi content and main layer with high one is proposed for synthesis of 1D-MPCs on non-garnet non-magnetic layers. As was shown the use of such films in microcavity-type structures is most effective. The aim of this research is to determine the optimal configurations and detail the magneto-optical properties of this type of structures.
Some series of microcavity 1D-MPCs of general formula (TiO2/SiO2)m/M1/M2/(SiO2/TiO2)m with different repetition number of Bragg oxide mirrors m and double layered magneto-active defects M1/M2 of different compositions and thickness on the substrates of fused quartz were fabricated and investigated. Before fabrication, to determine the optimal parameters of layers the simulation of magneto-optical spectra of microcavity 1D-MPCs in transmission and reflection was performed. The obtained values of rotation angle of polarization plane of synthesized microcavity-type 1D-MPCs exceed the known experimental results by 2-3 times. The maximal values of Faraday and Kerr rotation angles are mines 20.6 deg (-66 deg/μm) and 8.9 deg at 655 nm.

The authors thank the Russian Science Foundation for support (grant # 14-32-00010).

Th.N-P09 - Magnetic behavior of SiO_2 opals with embedded Fe nanoparticles

C.E. Ávila Crisóstomo [1], E. Sánchez Mora [1], V. Cerdán Ramírez [1], F. Pérez Rodríguez [1]

1. Instituto de Física, Benemérita Universidad Autónoma de Puebla, Heroica Puebla de Zaragoza, Mexico

Using the Stöber method, silica spheres were obtained and arranged in an fcc lattice. Fe has been introduced into void spaces of the artificial opals by means of the reduction of $FeSO_4$ with NaBH4. Magnetization curves of artificial opals with Fe nanoparticles were measured by using the vibrating sample magnetometry (VSM) technique. In the measurements, the applied magnetic field was oriented along the [111] direction of the artificial crystals. In order to interpret the hysteresis cycles of magnetization, the homogenization theory developed in the work [1] has been applied. Such a theory provides explicit formulas for all the components of the permittivity and permeability tensors for a magnetodielectric photonic crystal in terms of the parameters of the inclusions and the host material in the quasistatic limit. On the basis of this homogenization theory, we have elaborated a computing program to calculate the effective permittivity and permeability of the SiO_2 opals with Fe nanoinclusions of different shape. Using the effective permeability, depending on the applied magnetic field, curves of magnetization vs magnetic field are straightforwardly calculated. The theory reproduces the general features of measured magnetization curves. In particular, the strong dependence of hysteresis loops on the Fe filling fraction, which was experimentally observed, is numerically confirmed by using an appropriate magnetic-field dependent permeability for Fe nanoparticles.

The presence of surface plasmons in magnetic nano-structures can strongly influence the magneto-optical properties of magnetic films and multilayers [1-3]. In spite of the numerous studies on the plasmonic behaviour of magneto-plasmonic lattices and the enhanced magneto-optic signal, the physical understanding of coupling between plasmonic and magneto-optic properties is not clarified yet. Here we further elucidate the mechanisms of coupling between surface plasmons and magneto-optic properties for the case of Ni and Co antidot patterns. The antidot pattern has an hexagonal form with hole sizes ranging from 220-280 nm. With photo-emission electron microscopy (PEEM) images we show how light of different energies and polarization states is localized on the patterned magnetic surface. By using p- and s- polarized light we reveal that light takes different forms on the surfaces: either is concentrated in bright spots that are arranged in an hexagonal lattice (use of p-light) or it forms continuous lines perpendicular to incident polarization of light (s-light). These effects are only present when the energy of the incident light is close to where excitations of surface plasmons polaritons are expected. The localization of light at the plasmonic resonances leads to a significant enhancement of the polar magneto-optic response of the patterned magnetic material. Furthermore, the type of light localization on the surface defines the size of the enhancement of the polar magneto-optic Kerr effect.

Th.N-P11 - Optical, magneto-optical and structural properties of Mn(2)Rh(1-x)Co(x)Sn Heusler compounds

J. Hamrle [1], K. Postava [1], J. Pistora [1], R. Silber [1], J. Enders [2], P. Cejpek [2], J. Macek [2], M. Veis [2], V. Hol² [2], O. Meshcheriakova [3]

1. VSB - Technical University of Ostrava, Ostrava, Czech Republic
2. MFF, Charles University in Prague, Prague, Czech Republic
3. Max-Planck-Institut für Chemische Physik fester Stoffe, Dresden, Germany

We studied structural, optical and magneto-optical and structural properties of bulk Mn(2)Rh(1-x)Co(x)Sn Heusler compound, where Co concentration x ranges from 0 to 0.7 [1,2]. The structural properties was studied by XRD and EDAX. XRD shows that those polycrystalline samples have cubic (for x=0.7) and tetragonal (for x<0.7) lattice (space groups F-43m and I-4m2, respectively); element site occupation is within 10% of fully ordered compounds. EDAX data shows constituent element concentrations agree with the nominal ones within 5%. The optical properties was studied by ellipsometry and reflectometry. The determined permittivity reveals small optical absorption of samples in UV spectral range for all the compounds. Furthermore, at photon energy about 4.5 eV the photon absorption of Mn(2)Rh(0.7)Co(0.3)Sn compound nearly vanishes, an unusual feature for metallic systems. Furthermore, this material also provides vanishing reflectivity for s-polarized light at this photon energy range, suggesting a plasmonic behaviour of Mn(2)Rh(0.7)Co(0.3)Sn compound in this UV region. Financial support from GACR 13-30397S and EU project IT4Innovations is acknowledged.

4. Moscow Institute of Physics and Technology, Dolgoprudny, Russia

The work is devoted to the investigation of the surface plasmon polaritons (SPPs) in the metal – dielectric heterostructures containing magnetoelectric materials, chromium (III) oxide (Cr2O3) namely. An important feature of Cr_2O_3 is that its magnetoelectric response can be switched between axion-like and toroidal types via external magnetic field applied parallel to the crystal axis causing so-called spin-flop effect.
We analyze and classify the impact of the magnetoelectric effect on the properties of SPPs in various configurations of $Cr_2O_{3\text{-metal}}$ heterostructure.
The axion-like effect causes slight rotation of the polarization ellipse of the SPP wave around the axis corresponding to the SPP propagation direction.
The impact of the toroidal effect on the SPP significantly depends on the orientation of the toroidal moment vector τ. We address three basic configurations:
1. The longitudinal configuration: τ is directed along the SPP propagation direction. The SPP propagation constant acquires non-reciprocal addition different for the SPPs propagating along τ and opposite to τ. Although the SPP polarization remains pure TM, the relations between the electromagnetic field components are slightly modified in a non-reciprocal way.
2. The transversal configuration: τ lies in the interface plane and is perpendicular to the SPP propagation direction. The plane of the SPP polarization ellipse is rotated around the axis normal to the interface.
3. The polar configuration: τ is perpendicular to the interface plane. The localization constant for the dielectric acquires small imaginary term associated with the toroidal moment and causing a slight energy leaking.
Therefore Cr_2O_3 can be considered as a unique object on which one can trace the similarities and difference between the axion-like and toroidal effects. Such magnetoelectric plasmonic heterostructure also might act as an optical tool for control of the SPP dynamics via external electric and magnetic fields.

The work is supported by RFBR (grants No.13-02-01122, 14-29-08216)

We report a broadband proton NMR study of the spin dynamics of coated maghemite and gold-maghemite hybrid nanostructures with two different geometries, namely dimers and core-shells. All the samples have a superparamagnetic behavior, displaying a blocking temperature (T = 80 K for maghemite, T = 105 K for dimer, T = 150 K for core-shell), and the magnetization reversal time follows the Vogel-Fulcher law. We can explain this behaviour by taking into account three different contributions to the spectral spin density, each one following the Bloemberger-Purcell-Pound (BPP) equation and characterized by a specific correlation time. Indeed, we hypothesize that: the peak at high temperatures is associated with the re-orientational motion of CH3 and CH2 groups of the organic coating; the peak observed at intermediate temperatures is related to the superparamagnetic blocking temperature TB, i.e. to the Néel reversal of the magnetization; finally, the low temperature peak, whilst of still unclear origin, could be related to the surface spins dynamics of the magnetic core. The 1/T1 data for T > 100 K were successfully fitted with a BPP based heuristic model. The estimated correlation times for rotation and superparamagnetic reorientation are in good agreement with leterature values for methyl group rotations and ac susceptibility data, respectively.

The controlled and reversible modification of the optical response of plasmonic systems, -active plasmonics- is a highly prized goal in today's research in materials science and nano-optics, due to an attractive potential for high-tech applications, from ultrasensitive refractometric sensing, to switchable plasmonic optical circuits. Magnetoplasmonics is the branch of active plasmonics that uses a magnetic field to influence surface plasmon resonance. [1] Currently, great efforts are being devoted to fully understanding the nature and effect of such interaction, with the ultimate goal of increasing its magnitude through rational design. While the magneto-optical activity of magnetic materials is a well known property, recently also important magneto-optical activity was observed in non-magnetic plasmonic materials - such as gold or silver [2,3] - in correspondence with the plasmonic resonance. In this study, using a combined approach with the aid of magnetometry and x-ray spectroscopy in addition to magneto-optics, we investigated several routes to design magnetic-plasmonic hybrid nanoparticles containing gold and iron oxides with different geometries, exhibiting different levels of conjugation, thus a variable extent of interaction of the magnetic and plasmonic functions. [4] We found that the chemical composition of the magnetic part critically affects the synergy of the two moieties; this finding paves the way to a largely rational design of material candidates for magnetoplasmonics.

Magneto-plasmonic (MPs) is a novel concept of nanostructured materials composed by components that exhibit plasmonic and magnetic activity. However the combination of the two properties in a single nanosystems is not easy. Most of MPs are nano-heterostuctures composed by ensembles noble metals and magnetic metals and oxide moieties in different morphologies like core@shell, onion-like nanoparticles, heterodimers, etc... [1-4] . Both type of properties are preserved due to the different electronic and chemical nature of the two moities, being considered MPs nanostructures a classical example of multifunctional nanomaterials. Moreover new properties have been discovered, in particular, the enhancement of the magneto-optical response in correspondence of the plasmon excitation and the modification of the plasmon dynamics and of the magnetic properties. The chemical and physical mechanisms that will produce the such correlations are under study.
In this work we present a detailed study of the magnetic, structural and chemical properties of colloidal Au@iron oxide nano-heterostructures having both a range of core@shell morphologies, and dumbbell-like heterodimers with different dimensions. Our investigation was carried out by combining several nanostructural studies like TEM characterizations, XANES spectroscopies, Pair Distribution Function and powder X-Ray Diffractions with optical, magneto-optical and SQUID magnetometry for investigating structural, nanostructural, chemical, optical and magnetic properties. MPs nanostructures exhibit novel optical, magnetic and plasmonic features different than those of the bare nanosystems. We will show that most properties can be related to chemical and structural changes related to the synthesis process and the morphology. This work has been financed by the EC through FP7-214107-2 NANOMAGMA, and by Fondazione Cariplo through Project No. 2010-0612

Th.N-P16 - Novel type of highly sensitive alternating magnetic field detector based on the magnetoplasmonic crystal

V. Belyaev [1], A. Grunin [2], A. Fedyanin [2], V. Rodionova [1]

1. Immanuel Kant Baltic Federal University, Kaliningrad, Russia
2. Lomonosov Moscow State University, Moscow, Russia

Continuous improvements in nanofabrication and nanocharacterization capabilities have changed predictions about the role of the metals in the development of the new optical devices and in particular of the Surface plasmon resonance (SPR) sensors. One way of increasing of the sensitivity of the SPR sensors is using of the magneto-optical (MO) effects. Using of the magnetoplasmonic crystals (MPlC) - subwavelength periodical structures made of noble and ferromagnetic metals allows one to modify MO properties by excitation of the surface plasmons at resonant conditions. Optical response of the MPlCs strongly depends on the magnetization and consequently on the magnitude of the external magnetic field. This fact allows one to design and fabricate magnetic field detectors based on this effect. MPlCs were fabricated by ion beam sputtering of the noble (gold or silver) and ferromagnetic (iron or nickel) metals on the substrates with different spatial profiles. After the fabrication, atomic force microscopy images of the surface were obtained in order to determine parameters of the spatial profile. Magnetic properties were measured by VSM at room temperature. MO properties were measured by a homemade setup consisting of a halogen lamp with a monochromator as the light source, Glan-Taylor prism as the polarizer and a photomultiplier tube with a lock-in amplifier as the detector. Investigation of the magnetic properties showed a non-linear dependence of the coercive force (16 - 300 Oe) and saturation magnetization (16 - 1300 Oe) on thickness and material of the ferromagnetic layer. Changing the magnetic properties it is possible to control the sensitivity and working range of the magnetic field detector based on MPlC. Dependences of MO response showed that signal-to-noise ratio is more than 200 and sensitivity is about 10^-6 Oe. Summarizing, in this work a new type of the magnetic field detector and a way to control its parameters are represented.

Th.O-P02 - Temperature dependent magnetostrains in Mn and Ga-doped Fe-Pd ferromagnetic shape memory ribbons

M. Sofronie [1], F. Tolea [1], A. Crisan [1], M. Enculescu [1], M. Valeanu [1]

1. National Institute of Materials Physics, Magurele, Romania

Ferromagnetic shape memory alloys (FSMA) have attained strong interest over the last years because of the large strains which can be obtained by the application of an external magnetic field. Fe-based FSMA are more suitable for applications, mainly due to their enhanced ductility than the well-known Ni_2MnGa alloy. The shape memory effect in disordered Fe-Pd (30 at.% Pd) is associated with an f.c.c - f.c.t. thermoelastic martensitic transformation (MT). By further cooling, an irreversible transformation occurs from f.c.t. to b.c.t. structure. The addition of a third alloying element may promote the stabilization of the fct martensite and the melt - spinning technique removes the precipitation of b.c.t. irreversible phase in Fe-Pd (30 at.% Pd) binary system. Prepared as ribbons by rapid quenched technique, these alloys are suitable for sensors designs.

The magnetic field-induced strains (MFIS) are the result of the preferential nucleation of martensitic variants with the easy magnetization direction parallel to the applied magnetic field during cooling across MT. So, high magnetocrystalline anisotropy of the martensite phase as well as large mobility of the twin boundary is required. The magnetic field assisted linear thermal expansion (LTE) measurement is an appropriate method to evaluate the influence of atomic ordering (induced by thermal treatments) on the magnetoelastic properties of highly textured ribbons.

Here we report the changes of the magnetostriction and MFIS of as prepared and thermal treated ribbons as effect of Mn and Ga substitution in $Fe_{70-y}Pd_{30}Xy$ (X= Mn, Ga and y= 0,1,3) alloys. Results have shown a degradation of the MT characteristics and of the magnetoelastic properties for the Ga substituted alloys. In contrast, Mn substitution enhanced not only the MT temperature and the transformation enthalpy, but MFIS on the thermal treated ribbons with 3% Mn (~120x10-6) is twice that obtained on the parent alloy.

Th.O-P03 - Liquid pressure wireless stress sensor based on magnetostrictive microwires for applications in cardiovascular localized diagnostic

P. Marin [1], A. Hernando [1], A.M. Aragón [1], M. Hernando-Rydings [2]

1. Instituto deMagnetismo Aplicado, Las Rozas, Spain
2. Hospital de Basurto, Vizcaya, Spain

In this paper, we report a method to measure changes in a fluid pressure flowing through a flexible pipeline by means of a ring of magnetic microwire concentric to the pipeline. The detection is based on the modulated scattering of electromagnetic waves by the magnetoelastic ring. The modulation is driven by applying a bias magnetic field that tunes the magnetic permeability of the ferromagnetic microwire. The magnetostrictive character of the microwire allows pressure detection by means of magnetic permeability changes. The experimental work developed has, also, allowed the fluid pressure detection in a hydraulic circuit connected to a ventricular assist systems where a fluid with a viscosity close to blood flows.

Th.O-P05 - Electrical control of magnetostatic and magnetoelastic waves in ferrite-piezoelectric structure

Y. Khivintsev [1,2], Y. Filimonov [1,2], S. Vysotsky [1,2]

1. SB Kotel'nikov IRE RAS, Saratov, Russia
2. Saratov State University, Saratov, Russia

Possibilities to tune wave properties through the electrical control are subject of the great interest for microwave signal processing. In this work we experimentally studied effect of electrically tuned mechanical stress on properties of the magnetostatic waves (MSW) and magnetoelastic waves (MEW) in contact structure based on yttrium iron garnet (YIG) film epitaxially grown on gadolinium gallium garnet (GGG) substrate and piezoelectric actuator. The YIG/GGG sample was placed on two separate alumina plates with microstrip antennas for MSW excitation and detection. The actuator was placed on the YIG/GGG structure in the middle and fixed mechanically using a support from above so that under voltage the actuator presses on the YIG/GGG structure and slightly bends it. External magnetic field was applied along the antennas corresponding to magnetostatic surface wave (MSSW) propagation. Scattering parameters were measured as a function of the frequency for various bias magnetic fields and voltages applied to the actuator using a vector network analyzer. At zero voltage the MSSW transmission band contained the equidistant narrow absorption peaks corresponding to the resonant interaction of the MSSW with the elastic waveguide modes of the YIG/GGG structure resulting in MEW formation. Applying voltage we observed the shift of the MSSW transmission band to higher frequencies. For the maximum voltage of 140 V extending the actuator length by 5 micron the shift was ~50 MHz. This shift can be attributed to appearance of the additional magnetic field of ~10 Oe due to the stress and magnetostriction. Also, we found effect of the voltage on the magnitude of the magnetoelastic absorption peaks that might be related with the change in distribution of the elastic oscillations across the YIG film thickness under the stress.

Th.O-P06 - Preparation and characterization of porous magnetoelastic composites for magnetic field controlled flow applications

M. Krautz [1], D. Werner [1], M. Schrödner [2], J. Popp [2], A. Waske [1], J. Eckert [1]

1. Leibniz Institute for Solid State and Materials Research, Dresden, Germany
2. Thuringian Institute of Textile and Plastics Research e.V., Rudolstadt, Germany

Magnetoelastic composites (MEC) based on elastic polymer matrix and a magnetic filler material, have drawn attention in various research fields, such as sensor technology, damping mechanics or biomedicine. This material class is highly responsive to an externally applied magnetic field triggering the change of intrinsic and extrinsic properties, e. g. size and shape, permeability, magnetization or mechanical behavior [1]. In our study, commercially available thermoplastics with different mechanical properties are extruded together with spherical Carbonyl-Fe particles (CIP-SQ, BASF Co.)[2]. These strands can be subsequently bundled, in order to achieve an arrangement with continuous channels for perfusion by a liquid or gaseous medium. By the application of an external magnetic field, the dipole-dipole interactions between the Fe - particles form chains, consequently the MEC strand is deformed[3,4]. In a bundle each deformed strand would lead to a change of the channel's width and therefore a change of the hydraulic pressure. In this presentation we focus on the magnetic properties of single strands as function of the polymer matrix material and the magnetic particle content. Magnetic measurements reveal that the magnetic hysteresis is crucially affected by the Young's modulus of the polymer matrix. This can be attributed to the increased particle movement in matrices with low Young's modulus. On the other hand, hysteresis is reduced with increasing filler fraction, since the modulus increases with larger particle content. This study links the evolution of the magnetization behavior as function of filler fraction and initial mechanical properties determined by the polymer matrix.

Th.O-P07 - Oscillation of standing spin wave in nanostructured ring resonator with spin transfer torque

B. Peng [1], X. Ya [2], K. imamura [3], T. Tanaka [4], K. Matsuyama [5]

1. ISEE Kyushu University Japan, Nishi, Japan

The collective magnetic excitation of spin wave (SW) is recently attracting renewed research interests from dispersive nonlinear physics and practical applications to wave-based logic or signal processing devices. Active ring resonators, made of the SW guide and an external feedback loop, have offered a stage for exploring various nonlinear SW dynamics. We report on numerical analysis on oscillation of standing spin wave (SSW) excited in a nanostructured active ring resonator, consists of a ferromagnetic nanowire (20x20 nm2 cross section, 80 nm length) with perpendicular anisotropy. The following material parameter set are assumed in the simulation, Ms = 680 emu/cc, perpendicular anisotropy field Hk = 5.0 kOe, damping constant a = 0.01. The SSW was excited with an alternative spin transfer torque assuming a spin polarized current vertically applied through a part of the wire. The magnetization direction of the overlaid fixed layer, spin polarized current source, was assumed to be in-plane, at which the most efficient SSW excitation was observed in preliminary simulations. The wave vector of the SSW is along the nanowire length. A positive feedback with proportional-integral-derivative (PID) gain control was adopted in the active ring. Stable excitation of the 1st order standing spin wave has been demonstrated with micromagnetic simulations. The stationary SSW with a pre-determined set variable of precession amplitude was attained within less than 5 ns by optimizing the PID parameters. The obtained fosc value of 7.95 GHz practically agrees with the theoretical prediction from dispersion relation of the magneto static forward volume wave. The fosc can be tuned with the value of the perpendicular anisotropy and also with the structural parameter such as the wire length.

Th.O-P08 - Enhancement of the magnetic field sensor sensitivity through tailoring of the magnetic disk profile

P. Vetoshko [1,4], M. Kozhaev [1,3], N. Gusev [1,3], A. Zvezdin [1,3], I. Syvorotka [5], I. Syvorotka [5], V. Belotelov [1,2]

A special place among the tools for registration of the magnetic fields is taken by magneto-modulation sensors (MMS), which are based on magnetically ordered materials. The MMS provide high energy of interaction with the measured field and the potentially high sensitivity, also they are cheap and practically feasible, and do not require cryogenic temperatures. Here we investigate MMS with a magnetic disk of epitaxial rear earth iron garnet (111) with easy plane magnetic anisotropy. Magnetization saturated (single-domain) state of the magnetic disk of the sensor is a necessary condition for achieving high sensitivity. In order to minimize noise from the electromagnetic system of the MMS, the magnetic disk must have sufficiently large magnetic susceptibility, i.e. its saturating field has to be small. At a given ratio of thickness to diameter of the sample, a magnetic disk of an oblate ellipsoid shape has the lowest saturation field. However, its practical implementation is a very complex technological problem. In this work we overcome this problem by approximation of the semi-elliptic profile of the magnetic disk by a multi-step profile fabricated by photolithography. Both theoretical and experimental studies of the capability of the multi-step profile approximation for the magnetic disk core of the MMS are conducted. Our study shows that the four-step approximation of the semi-elliptic profile of the magnetic disk significantly reduces the saturation magnetic field and, consequently, reduces the noise level of the corresponding MMS down to 10^(-9) Oe/Hz^(1/2). Further increase in the number of the approximation steps should further reduce the noise level and increase the MMS sensitivity by an order of magnitude that makes the MMS comparable to SQUID magnetometers. Main advantages of the MMS are room temperature operation and much lower cost. This work was supported by the Russian Science Foundation: grant No. 14-32-00010.

Th.O-P09 - Magnetic properties and domain structure in stress-annealed METGLAS 2714AZ

P. Sarkar [1], K. Zaveta [2], K. Jurek [2], J. Vcelak [1], P. Ripka [1],

1. University Centre for Energy Efficient Buildings, Technical University In Prague, Czech Republic
2. Institute of Physics, AS CR, v. v. i., Prague, Czech Republic

The domain structure of as-cast and stress-annealed 2.5mm wide Metglas 2714AZ was studied by means of type II magnetic contrast in SEM. The material was stress-annealed without magnetic field to obtain magnetic properties suitable for low-noise fluxgate sensor core. Various types of domain structures were observed on the shiny surface of ribbons with variations of annealing temperature (350°C and 390°C), stress (50-200 MPa) and time (5-30 minutes). The observed domain structures were compared with the processes of magnetization. During the annealing well above the Curie temperature of 250°C and below the crystallization temperature of 558°C we observed a change of the magnetic easy axis from the original longitudinal to the required transverse one, but for short annealing times the process was more complicated. The observed stripe structure with magnetization in the domain essentially transverse to ribbon direction and parallel to the easy direction leads to the demanded shape of the magnetization curve with low coercivity and remanence and linear between the saturation states. For annealing above TC the effect of ribbon cooling on the ribbon properties is decisive and we found distinct differences for annealing and cooling in the static regime or when the ribbon was moved continuously through the furnace. The latter procedure gave apparently the best properties for the intended use in fluxgate sensors. This work was supported in part by the European Union OP RDI Project under Grant CZ.1.05/2.1.00/03.0091 - University Centre for Energy Efficient Buildings and in part by the European Social Fund within the framework of realizing the project “Support of inter-sectoral mobility and quality enhancement of research teams at Czech Technical University in Prague” under Grant CZ.1.07/2.3.00/30.0034.

Th.O-P10 - GMI sensor for component integrity evaluation

P. Sarkar [1], R.K. Roy [2], A.K. Panda [2], A. Mitra [2], J. Vcelak [1], P. Ripka [1]

1. University Centre for Energy Efficient Buildings, Technical University, Prague, Czech Republic
2. CSIR-National Metallurgical Laboratory, Jamshedpur, India

A giant magneto-impedance (GMI) based magnetic sensing device has been developed using (Co50Fe50)74Si8B14Cr4 microwire as the magnetic sensing core having great potential to monitor the microstructural changes that takes place in steel during in-service operation. In the present work experiment has been carried out with various test samples simulated at the laboratory condition. Experiments were conducted involving 9Cr-1Mo sample subject to various heat-treated conditions to generate various microstructure. A correlation between the GMI sensing voltages for different tempered 9Cr-1Mo steels and the corresponding hardness was found which demonstrates the usefulness of the developed sensor to monitor tempering condition of the steel. Experiment was extended for the plastically deformed 18-8 Cr-Ni (304SS) where stress induced martensite is formed. In this case GMI sensing voltage increased with percentage of deformation in steel. The formation of magnetic phase, martensite, during deformation of non-magnetic 304SS is the cause of such changes. The work was also been extended for detection of defective weld joints in 304SS oil refinery pipes collected from the petrochemical industry. The sensing device has also been used to evaluate the compressive residual behaviour in pure iron and pressure vessel steel. A field study was conducted where the developed GMI sensor was taken to the refinery unit of a petrochemical industry to find the feasibility of using the sensor for evaluation of carburization in steel which is the main cause of failure of the structure.

Th.O-P11 - Composite FexOy/TiO2 powders - microstructure and magnetic properties

O. Zivotsky [1], J. Seidlerova [2], I. Safarik [3], J. Lunacek [1], M. Safarikova [3], K. Mamulova Kutlakova [2]

1. Institute of Physics, VSB-Technical University of Ostrava, Ostrava, Czech Republic
2. Nanotechnology Centre, VSB-Technical University of Ostrava, Ostrava, Czech Republic
3. Institute of Nanobiology and Structural Biology of GCRC, Academy of Sciences of the Czech Republic, Prague, Czech Republic

Titanium dioxide (occurring in three modifications: anatase, brookite and rutile), especially the anatase can be used in various technology applications such as photovoltaic solar cells, sensors and photocatalytic processes. Particles of titanium are suitable and effective an adsorbent for removal of toxic ions from aqueous solutions due to their high stability, low cost and safety toward both humans and the environment. To improve the separation of solid sorbents from liquids the composite adsorbent/magnetic particles were prepared by precipitation iron hydroxides from water solution of $FeSO_{4.7}H_2O$. The prepared suspension of iron hydroxides suspension was treated standard kitchen microwave oven (700 W, 2450 MHz) for 10 min at the maximum power. The formed magnetically responsive composite with iron oxide content was captured using an appropriate magnetic separator or NdFeB magnet. Then the magnetic TiO2 formed was washed with water and air dried at cca 333 K.
Magnetic properties of powders were analysed by vibrating sample magnetometer (VSM) Microsense EV9. Parameters obtained from the hysteresis loop (coercive field - 1.11 kA/m, saturation magnetization - 3.38 Am2kg-1) are supplemented by the thermomagnetic curve, when sample is heated up to 950 K (Curie temperature cca 878 K) and cooled back to room temperature. Dominance of negative (dipolar) magnetic interactions between particles was detected from the Henkel plot. In such a case they are produced by the magnetic moment of each particle and depend on the number of Fe atoms inside the particle. Interactions increase to their maxima at 12.72 kA/m and subsequently fall down to zero at higher fields. Marked increase of coercive field (approximately 10 times) followed by the shift of interactions maxima towards higher fields is observed after the temperature treatment (heating and cooling back to room temperature).

Th.O-P13 - Improved Microtransformer design utilizing Fe-Co magnetic core

D. Dinulovic [1], M. Haug [1], A. Gerfer [1], M. Kaiser [2], M. Wurz [2], L. Rissing [2]

1. Wurth Elektronik EiSos, Niedernhall, Germany
2. IMPT, Leibnitz Universitõt Hannover, Hannover, Germany

INTRODUCTION: This paper presents the design, fabrication, and characterization of on Silicon integrated micro-transformers for high frequency power applications.
Increasing trend in electronics for higher power density and mobility causes the miniaturization of power supply and therefore the miniaturization of passive components like inductors or transformers. A permanent increase of a switching frequency of an electronic power circuit sets new requirements for inductive components regarding to size and inductance and current capability. Inductors and transformers should provide smaller inductivity and smaller size. Decreasing of inductivity causes a decreasing of the inductor size and of the inductor profile height, therefore in thin-film fabricated micro microinductors and microtransformers are ideal components for fulfill this issue.
DESIGN: First fabricated microtransformer device is presented before [1]. This is a new improved design regarding to improve of a current capability and of an efficiency. The microtransformer consists of a closed CoFe magnetic core and four coils. Two coils are on the primary and two coils are on the secondary transformer side. The design was simulated using Finite Element Method (FEM). The software tool Ansys Maxwell« was applied.
The microtransformer device is fabricated using thin-film technology. As a magnetic material for the transformer core, Co-Fe alloy is chosen based on excellent magnetic properties. Co-Fe magnetic core has been deposited by Co-Fe electroplating. Coils are fabricated using Cu electroplating. Coils and magnetic core are embedded in polyimide.
The microtransformer has an inductivity of 60 nH, resistance of 300 mOhm and can be appled for current up to 1.5 A.

Th.O-P14 - Anomalous thermal expansion in (Pr,Ca)MnO_3 due to orbital ordering

J. Tikkanen [1], H. Huhtinen [1], P. Paturi [1],

1. Wihuri Physical Laboratory, Department of Physics and Astronomy, University of Turku, Finland

The perovskite manganite family Pr(1-x)Ca(x)MnO(3) (PCMO) shows a multitude of functional properties that can be accessed by tuning the molar ratio between Pr and Ca. Species near the "half-doped" composition, Pr(0.5)Ca(0.5)MnO(3), exhibit an insulating antiferromagnetic ground state with pronounced charge and orbital ordering (CO and OO). The disruption of this state, using electromagnetic fields or mechanical stress, leads to most of the functionality of PCMO by revealing a charge-disordered, ferromagnetic metallic state.
Practical devices using PCMO will most likely employ epitaxial films of the material. The characterization of the physical properties of such films is, however, complicated by the fact that thermal expansion cannot be isolated from lattice stress due to the epitaxiality condition. To resolve the problem, we have used x-ray diffraction to measure the temperature dependence of the lattice constants of polycrystalline bulk PCMO at the Ca concentrations x=0.4 and 0.5, where CO and OO are known to be present, and also at x=0.1, where regular thermal expansion is expected. The data were obtained at temperatures from 83 K to 403 K. SQUID magnetometry was employed within the same temperature range to identify the onset of OO (or the lack thereof, for x=0.1) around 250 K.
Each of the OO species produced a distinctive structural anomaly around the onset temperature of OO, signaled by a region of negative temperature expansion just above the transition temperature. During the anomalies, unit cell volume excesses of order 0.1 % were estimated in x=0.4 and 0.5, whereas none was found in x=0.1. The magnitude of the anomalies was comparable to an expected regular thermal expansion across a temperature change of ca. 150 K. The results bear direct consequences for designing thin film devices that operate in the mentioned temperature region, since the OO anomaly will effectively modify the film-substrate lattice mismatch.

Th.O-P17 - Electromagnetic properties of Fe granular composite materials

T. Kasagi [1], T. Tsutaoka [2], S. Yamamoto [3], K. Hatakeyama [3]

1. National Institute of Technology, Tokuyama College, Yamaguchi, Japan
2. Graduate School of Education, Hiroshima University, Hiroshima-shi, Japan
3. Graduate School of Engineering, University of Hyogo, Hyogo, Japan

Ferromagnetic metal granular composites (FMGC) with particle content below the electrical percolation threshold show a relatively high magnetic permeability in the GHz range. The FMGC can have the negative permeability spectra which are caused by the magnetic resonance of the ferromagnetic composite structure. This negative permeability spectrum is affected by the shape anisotropy of embedded particles [1]. The electrical conductivity of the composite structure also depends on the particle shape; the flaky particle composite shows the larger conductivity and the lower percolation threshold than the spherical particle one. Furthermore, the FMGC such as the $Fe_{50}Co_{50}$ flaky particle composite indicates the negative permittivity spectrum in the metallic state above the percolation threshold by the low frequency plasmonic oscillation. Hence, the high frequency permeability and permittivity spectra of FMGC can be controlled by the shape and content of dispersed particle.
In this work, the electromagnetic properties of Fe granular composite materials have been studied in the microwave frequency range. The micrometer-sized Fe spherical particles, which were heat-treated in air to suppress the eddy current effect, were used. Composite materials were prepared by mixing Fe particles with Polyphenylene sulfide resin. SEM observations revealed that both the coagulated and the isolated Fe particles were dispersed in the binder matrix. It was revealed that the low-frequency permeability of Fe composites was larger than that of the Co and $Fe_{50}Co_{50}$ granular composites at the same particle content. However, the Fe composites don't show the negative permeability spectrum in the microwave range. On the other hand, the Drude type negative permittivity spectrum was obtained in the metallic state at 68 vol.% particle content. This can be attributed to the low frequency plasmonic oscillation of electrons in the percolated Fe cluster chain in the Fe composite.

2. Optospintronics Department, National Institute for Optoelectronics INOE 2000, Bucharest-Magurele, Romania
3. Laser Department, National Institute for Laser, Plasma and Radiation Physics, Bucharest-Magurele, Romania

Optical glasses with high magneto-optical effects are known to be useful for optical isolators and switches. According to the Faraday effect, a rotation of the polarization vector is observed for a light passing through specific transparent materials, if a magnetic field is applied along the wave-vector. The rotation is proportional to the passing length (l), the intensity of the magnetic field (B) and the intrinsic electric properties of the material as taken into account by the so-called Verdet constant (V). The Verdet constant itself depends on the electronic structure of the glass atoms and is it implicitly related to its magnetic properties through possible doping ions.
The effect of low-level doping with different elements (La, Y, Dy, Tb, Pb, Bi) of a new aluminophosphate glass (Li_2O-BaO-Al_2O_3-La_2O_3-P_2O_5) is investigated in this work, in relation to magnetic properties and specific Faraday rotations. The wavelength dependence of the Verdet constant, measured on the entire visible spectrum, was analyzed by taking into account both Westenberger's dispersion model for the diamagnetic contribution and VanVleck-Hebb theory for the paramagnetic contribution, according to the relation: $V=V_{dia}(\lambda) + V_{para}(\lambda, T)$. It was observed that the Faraday rotation is not changed as effect of doping with La or Y but it is slightly increasing for Pb and Bi doping ions (with rare-earths producing its sigh change). Responsible for the Faraday rotation in Dy and Tb containing glasses was find to be the effective electric dipole transition $4f^n \rightarrow 4f^{n-1}5d^1$ corresponding to λ_n=171 nm for Dy^{3+} and λ_n=216 nm for Tb^{3+} whereas for the diamagnetic matrix, the resonance wavelength is 110 nm. The proportionality between the magnetic susceptibility and the paramagnetic Verdet constant is good for low level of rare-earth doping. A Verdet constant of 0.036 min/(cm Oe) corresponds to the glass doped with 1.2×10^{21} Tb at./cm^3 and with the room temperature susceptibility of 2.18 10^{-5} emu/g Oe.

Th.O-P20 - Magnetic properties of the reactive sorbents based on the CeO_2/Fe_2O_3 composite powders

J. Lunacek [1], O. Zivotsky [1], P. Janos [2], J. Henych [2,3], V. Stengl [2,3]

1. VSB - Technical University of Ostrava, Department of Physics, Ostrava, Czech Republic
2. University of Jan Evangelista Purkyne, Faculty of the Environment, Ústí nad Labem, Czech Republic
3. AS CR v.v.i., Institute of Inorganic Chemistry, Prague, Czech Republic

Recently, new magnetically separable reactive sorbent based on gama-Fe_2O_3 (maghemite) grains and active CeO_2 surface layer which successfully decompose certain dangerous organophosphate compounds (parathion methyl, chemical warfare agents soman and VX), were discovered. The CeO_2/ alfa-, gama-Fe_2O_3 composite materials exhibit the different magnetic properties caused by various calcination temperature in the interval from 300 to 900°C. Vibrating sample magnetometer (VSM) EV9 was used for analysis of the powders. Magnetic properties were studied through the hysteresis loops, Henkel plots, and the switching field distribution function (SFD). All samples show the negative Henkel plots implying dominance of the dipolar interactions, according to the position of Henkel minima they can be divided into two groups. The first group consists of the powders annealed at the temperature below 600°C. Observed negative interactions start practically at zero magnetic field and reach their maxima in weak fields about 2.4 - 3.2 kA/m. Magnetic properties of the samples in the second group reflect the increasing calcination temperature from 700°C to 900°C. The nucleation magnetic fields linearly increase from 40 kA/m to 49.52 kA/m, and the minima of the Henkel plots move from 108.8 kA/m over 252.88 kA/m to 265.68 kA/m. Changes in the magnetic behavior, when the calcination temperature exceeds 600°C, are related apparently to the phase transition of the maghemite to the alfa-Fe_2O_3 (hematite). Rapid increase of coercive field corresponds with the growth of the crystallite sizes of the weakly ferromagnetic hematite and cerium oxide.

Th.O-P21 - Crystal structure and magnetic properties of the new R_3Pd_5 compounds (R = rare earth)

A. Provino [1], S.K. Dhar [2], N.S. Sangeetha [2], P. Manfrinetti [1], L. Petit [3], K.A. Gschneidner Jr [4]

1. Department of Chemistry, University of Genova, Genova, Italy

4. Ames Laboratory, & Department of Materials Science and Engineering, Iowa State University, Ames, United States

We report the synthesis, crystal structure and magnetic properties of the new series of compounds R3Pd5 (R = rare earth). The R_3Pd_5 compounds form by a peritectic reaction and adopt the orthorhombic $Pu_3Pd_{5\text{-type}}$ structure (oS32-Cmcm); the unit cell presents two inequivalent crystallographic sites occupied by R atoms. The R_3Pd_5 compounds have been found to form for R = Sc, Y, and the heavy rare earths (Tb to Lu, including Yb).
Magnetic properties of R3Pd5 (R = Tb, Dy, Ho, Er, Tm and Y) have been studied by using the techniques of magnetization, heat capacity and electrical resistivity. Y_3Pd_5 is a Pauli paramagnet with a low Sommerfeld coefficient of 4.8 mJ/mol K2. The other compounds are antiferromagnets, each showing two antiferromagnetic transitions, most likely associated with the separate magnetic ordering of the two distinct rare-earth sublattices. The highest Néel temperature, TN1, of 13.5 K is observed in Tb_3Pd_5. The bulk nature of the magnetic transitions is confirmed by heat capacity which shows two peaks at temperatures corresponding closely to the peak temperatures in the magnetic susceptibility. Metamagnetic like transitions at relatively low fields are observed in Tb_3Pd_5 and Dy_3Pd_5. Their hysteretic behavior indicates first order nature of the field induced transitions. The electrical resistivity of these compounds shows normal metallic behavior. Theoretical calculations have been performed in order to explain the antiferromagnetic behavior of these compounds.

Th.O-P22 - Controlling of demagnetizing field distribution on thin-film magnetoimpedance element for miniaturization and improvement of sensitivity

H. Kikuchi [1], S. Oe [1], H. Uetake [2], S. Yabukami [2], T. Nakai [3], S. Hashi [4], K. Ishiyama [4]

4. Tohoku University, Miyagi, Japan

Magnetoimpedance (MI) element is utilized for magnetic sensor applications in various industrial fields such as biomedical field and nondestructive testing because of its higher sensitivity. Demands for a miniaturization of MI elements increase on the miniaturization of electronic devices and on the detection with high spatial resolution. MI element fabricated using a thin-film gives a solution for the demands because the configuration is compatible with integrated electronic devices. On the contrary, when a thin-film MI sensor is miniaturized, decrease in the sensitivity due to a demagnetizing field is unavoidable. To overcome the disadvantage, we controlled the distribution of demagnetizing field in the elements and evaluated the impedance characteristics of the elements. We prepared MI elements in which the sensor shapes have a typical rectangular and a quasi-ellipsoidal shape for avoiding the demagnetizing field distribution. The impedance was measured by a network analyzer and a wafer probe with an applied DC field to the elements. Impedance for both elements increase with increasing applied field and have a peak during 8 - 10 Oe, this field strength corresponds with the anisotropy field of the film. The maximum slope of the impedance (dZ/dH) for the quasi-ellipsoidal shape is larger than that for rectangular shape. On the rectangular element, the demagnetizing field near the edge increases rapidly compared with the central parts, and the change ratio of the demagnetizing field, is maxima at the end of the element, decreases toward central part and becomes constant. This distribution modifies rapid impedance changes, consequently the sensitivity is reduced. For quasi-ellipsoidal shape element, the demagnetizing field is uniform, which is attributed to keeping higher sensitivity. The evidence of the results was confirmed by the domain observations with a Kerr - effect microscope. Our results indicate a potential of a miniaturized MI element with higher sensitivity.

Th.O-P23 - Optimizing the sensing performance of fluxgate magnetometer using amorphous metallic wire cores

U. Topal [1], C. Birlikseven [1], H. Sözeri [1], H. Can [1], S. Tanrýseven [1], P. Svec Jr. [2], P. Svec Sr. [2], J. Bydzovsky [3]

3. Institute of Electrical Engineering, Slovak University of Technology in Bratislava, Bratislava, Slovak Republic

In this work we present the experimental results on parallel type fluxgate magnetometer using amorphous wire cores having a diameter of 100 micrometer. Single wire with 1 cm length was put into a hollow cylindrical ceramic rod having almost same inner diameter with that of the wire and outer diameter of just 1 mm. In order to find the best core properties the wires were annealed under argon atmosphere at different temperatures and magnetic field. The driver coil and the pick up coils were wrapped over these ceramic rods. The optimal driving frequency was determined depending on the magnitude of 2f signal with a frequency span between 0-50 kHz at constant amplitude of ac field and constant applied DC field. After determining the optimal frequency, which is around 23-24 kHz and not reported before, the same experiment was repeated for finding optimal amplitude of ac field. Then, the sensitivity measurements and noise analysis were carried out using these optimal parameters for the driving signal. In this way we could achieve to sense DC fields as low as 1 nT (even less) with noise level of as small as several decades of /√Hz at 1 Hz. Besides, the V_{2f} vs H_{DC} graphs have shown perfect linearity up to 0.6 Oe with fitting parameters of 99.996. Such linearity has not been seen in such a large dynamical range till now. We also recognized that there is no hysteresis on V2f-HDC graphs even after applying fields as high as 10 Oe.

Th.O-P24 - Microwave detectors based on giant and tunneling magnetoresistive devices

W. Skowroñski [1], S. Ziêtek [1], P. Ogrodnik [1,2], J. Wrona [1,3], P. Wiśniowski [1], A. Żywczak [4], M. Frankowski [1], J. Chęciński [1], J. Barnaś [5], T. Stobiecki [1]

5. Faculty of Physics, Adam Mickiewicz University, Poznan, Poland

Ferromagnetic thin films can emit or absorb electromagnetic signals in a microwave frequency range due to spin waves excitations. By means of spin torque diode effect [1] absorption of the signal at the frequency determined by the ferromagnetic resonance can produce a DC voltage that is used in radio frequency (RF) detectors [2].
In this work we present experimental and theoretical investigations of two types of detectors based on giant magnetoresistance (GMR) and tunneling magnetoresistance (TMR) elements. The GMR stripe with multilayer structure: buffer/ PtMn(16)/ CoFe(2)/ Ru(0.85)/ CoFe(2.1)/ Cu(t)/ CoFe(1)/ NiFe(5)/ cap (thickness in nm) stripe produces a DC signal when supplied by an RF current due to the Oersted field, that drives the magnetic free layer (CoFe/NiFe) into precession via the Oersted field[3]. We will show that the detection can be realized also at the frequencies below the resonance, i.e., in a much broader range. The sensitivity dependence on the Cu spacer thickness $1.9 < t < 2.3$ nm , which influences the interlayer exchange coupling will be also discussed. The GMR stripe with the dimensions of 2.5×70µm2 and the GMR ration of 7.4% reached the sensitivity 0.54 V/W.
On the contrary, in the TMR nanopillar device with CoFeB(2.3)/MgO(2)/CoFeB(1.6) trilayer the free layer oscillations are caused by the spin transfer torque effect. Because of greater MR ratio of up to 100 %, higher sensitivity above 10 V/W is measured. In addition, the application of the bias voltage on the top of RF signal enables us to tune the resonance frequency up to 100 MHz/V thanks to the voltage controlled magnetic anisotropy effect. Thus, we can change the peak-detection from 1.4 up to 1.6 GHz [4].Experimental results were confirmed by the micromagnetic simulations

3. Natl. Autonomous Univ. Mexico, Ciudad de Mexico, Mexico

Future communication systems demand higher bandwidths and higher operating frequencies. Satellite-supported communication currently uses frequency bands up to 40 GHz. For this technology, microwave ferrites for applications in the K-band and capable of being integrated into LTCC multilayer components are required. Scandium-doped hexagonal M-type Ba-ferrites of the stoichiometric composition $BaSc_xFe_{12-x}O_{19}$ or iron-deficient $BaSc_xFe_{12-z-x}O_{19}$ exhibit significant potential for microwave applications such as isolators and circulators and are well suited for the required frequency range.
Sc-doped Ba ferrites with $0 \leq x \leq 2$ were prepared by the mixed oxide route. After calcination (1300 °C) as well as after sintering (1370 °C) single-phase ferrites were obtained. The sintering behavior of the ferrites was modified by the addition of BBSZ glass sintering additive and sufficient densification at 900 °C was obtained. The influence of BBSZ content and sintering temperature on microstructure formation and magnetic properties was studied. Static magnetic measurements show that both, the saturation magnetization and coercive force decrease with increasing concentration of scandium. The ferromagnetic resonance frequency of the ferrites as determined by reflectance measurements in U- and K-band (30-60 GHz) waveguide decreases with Sc content. The resonance studies in the X-band complete the investigations of the HF behavior of the ferrites. Ferrite multilayers were prepared by tape casting and stacking were co-fired at 900°C. The magnetic properties of multilayers are compared to those of sintered compacts. First results on integration of ferrite multilayer structures into LTCC multilayer architectures are reported.

Th.O-P27 - Effect of planar microantenna geometry on microwave properties of integral YIG-antenna structures

Integral structures based on yttrium iron garnet (YIG) films and micro-sized planar microwave antennas (MAs) are promising candidates for operation of short wavelength spin waves (SWs) and miniaturisation of magnonic devices. Here, we report on the effect of the antenna geometry upon microwave properties of such YIG-MA structures. We have fabricated and tested structures with three different types of MAs. The MAs had form of either three coplanar stripes of the same width (type 1), or two coplanar stripes of the same width (type 2), or a tandem of one narrow and one wide coplanar stripes (type 3).
The structures were fabricated using a combination of photo or electron beam lithographies and magnetron sputtering followed by lift-off. The microwave characteristics of the structures were acquired using a vector network analyser along with a microwave probe station for bias magnetic field applied along the SW propagation direction.
The MAs of types 1 and 2 were found to have similar insertion loss and positions of the SW propagation bands corresponding to the different spatial harmonics of the MA structures. The MAs of type 3 were found to yield a more efficient excitation of SW within a broader frequency band. The direct electromagnetic cross-talk was minimal for type 1 MAs and maximal for type 3 MAs. The measurements of type 1 MAs with different stripe widths demonstrated a possibility to broaden the SWs excitation bands by decreasing the stripe width.
However, this was accompanied by a significant decrease in the SW excitation efficiency. In structures with type 3 MAs with 0.5 and 1 micrometre wide stripes, the excitation and propagation of sub-micrometre wavelength SWs and their resonant interaction with surface acoustic waves were observed.

Th.O-P28 - Towards integrated magnetoresistance sensors for electrical read-out in perpendicular nanomagnetic logic systems

I. Eichwald [1], S. Breitkreutz-v. Gamm [1], G. Ziemys [1], M. Becherer [1], D. Schmitt-Landsiedel [1],

1. Technische Universitõt München, Munich, Germany

Perpendicular Nanomagnetic Logic (pNML) is an emerging technology providing a unique way to combine logic and memory functions [1]. Elementary computing operations are performed, exploiting purely magnetic field-interaction between nanoscale, non-volatile magnets, arranged in two- or even three-dimensions [2, 3]. Directed signal flow is achieved by one-side-irradiation of the magnets with a focused ion beam. This process sensitizes a magnet to the stray field of its nearest neighbors [4, 5]. pNML devices are low-power, radiation-hard, and can be integrated with CMOS circuits, extending their functionality.
For integration in CMOS, the magnetic signal must be translated into an electrical one. Commonly, sensors exploiting magneto-resistive effects, like GMR or MTJ are applied. Hereby, electrical resistivity changes are detected depending on the alignment of the free layer magnet (FM) to the pinned layer magnet (PM).
The challenging part for such a sensor type for pNML is, that FM must be sensitized to the stray field of its previous neighbor magnet, which performs logic operation. At the same time, the sensor reading out the magnetic information must be integrated, without interrupting the signal flow through the FM of the magneto-logic circuit. This requires a special sensor structure.
Therefore, a special two-step-patterning process is applied. FM is fabricated as a wire. The anterior half lies free and can be side-irradiated to get sensitized for the signal flow of the logic circuit. The posterior half of FM is covered by the spacer- and pinned layer, containing the sensor stack.
MOKE-measurements of the sensor confirm the sensitivity of FM in the predefined irradiated spot and the unimpeded signal flow. Resistivity changes in the sensor stack are clearly detected and show values in the 20mΩ range. These experiments prove correct functionality of the integrated sensor. However, further research will be done to further enhance resistivity change.

Th.O-P29 - Optimum laser exposure for setting exchange bias in spin valve sensors

M. Almeida [1], O. Ueberschõr [1], M. Müller [2], R. Ecke [1], H. Exner [2], S. Schulz [1],

1. Fraunhofer ENAS, Chemnitz, Germany
2. Hochschule Mittweida, Laserinstitut, Mittweida, Germany

The specific local alignment of the magnetization of a reference layer in spin valves has a rapidly growing significance in the implementation of monolithically integrated sensor devices. The spatial sensitivity of such sensors is defined by the exchange bias effect arising at the interface between the “pinned” ferromagnetic and the adjacent antiferromagnetic layer. The locally (re-)setting of the orientation of the exchange bias direction can be achieved through local annealing by means of a focused laser beam and subsequent cooling in the presence of a magnetic field. Particularly in the case of bottom-pinned spin valves, the parameters of such a laser exposure will also have a significant effect on the magnetic properties of the free layer, which ultimately defines the sensing characteristics. In order to analyse this effect, bottom-pinned IrMn / CoFe / Cu / NiFe-CoFe spin valves (given film order as from substrate to top) are patterned into a meander shape and further annealed using a focused pulsed laser beam. Different processing peak intensities are tested. The analysis of the electric and magnetic transport properties after this exposure shows how strongly the resistance is affected for higher intensities, as well as the effect of the laser peak intensity on the magnetic coupling between the ferromagnetic electrodes. Furthermore, this results in a decrease of the GMR. These changes are discussed as a result of the structural modifications induced by the laser exposure on the spin valve nanolayers.

Th.O-P30 - Phase stability and magnetic properties of $D0_{22\text{-type}}$ $Mn_3Ga_xGe_{1-x}$

H. Okada [1], T. Sasaki [1], R. Umetsu [2]

1. Tohoku Gakuin University, Miyagi, Japan
2. Tohoku University, Miyagi, Japan

Ferrimagnetic Mn_3Ga and Mn_3Ge with a tetragonal $D0_{22}$ structure have been expected to be candidates for spintronics materials. The compounds exhibit high uniaxial magnetic anisotropy in spite of 3*d* transition metal compounds, and show high Curie temperature and low magnetization. These magnetic properties are considered to be attributed to the $D0_{22}$ structure. It has been known that the single phase of the $D0_{22}$ structure is obtained in off-stoichiometric composition. In the case of Mn-Ga alloy, the $D0_{22}$ phase exists in the Ga-rich $Mn_{75-x}Ga_{25+x}$ composition. On the other hand, the Mn-rich $Mn_{75+x}Ge_{25-x}$ composition is required for obtaining the $D0_{22}$ single phase. In this study, we have investigated the phase stability and the magnetic properties of $D0_{22}$-type $Mn_3Ga_xGe_{1-x}$ without the deficient and excess Mn.
Polycrystalline samples were prepared by arc-melting method. The ingots were annealed at 1073 K for a week, and then heated at 673 K for two weeks. The phase identification and characterization of the samples were performed by powder x-ray diffraction experiment. The phase stability was observed by differential scanning calorimetric measurement. The magnetization measurements were carried out using vibrating sample magnetometer.
The prepared samples of $Mn_3Ga_xGe_{1-x}$ (x = 0.3 - 0.7) were confirmed to be single phase of the $D0_{22}$ structure by powder x-ray diffraction experiment at room temperature. A phase transition temperature from the ferrimagnetic $D0_{22}$ phase to the paramagnetic $D0_{19}$ phase monotonically decreases with increasing Ga content. The magnetization of the $D0_{22}$ phase vanishes at the transition temperature. The disappearance of the magnetization accompanied by the phase transition of the $D0_{22}$ phase indicates that the Curie temperature of the $D0_{22}$ phase is higher than the phase transition temperature. It is thought that the phase stability of the $D0_{22}$ phase is corresponding to the decrease of the valence electron caused by the Ga substitution.

Th.O-P31 - Excitation of a uniform rotational magnetization mode in easy-plane iron-garnet films for flux-gate sensors

P.M. Vetoshko [1], D.V. Dodonov [1, 2], M.A. Kozhaev [1,3], I.I Syvorotka [4], I.M. Syvorotka [4], A.K. Zvezdin [1,2,3], V.I. Belotelov [1,5],

4. Department of Crystal Physics and Technology, Scientific Research Company "Carat", Lviv, Ukraine
5. Lomonosov Moscow State University, Moscow, Russia

Nowadays, iron-garnet film are of prime interest for spintronics and sensorics. In particular, ultra-sensitive flux-gate magnetometers based on the rear-earth iron-garnets were proposed and fabricated recently [1]. For getting large values of the sensitivity it must have easy-plane anisotropy and be kept in a monodomain state. For that reason, investigation of the uniform rotational magnetization mode is of importance. In this work we fabricated magnetic films suitable for the flux-gate magnetometers and investigated their magnetic properties. In the technological part of the work we fabricated 4 types of the iron-garnet samples with different degree of Fe3+ substitution by Sc3+ ions. We found experimentally a nonlinear character of the anisotropy field Hc dependence on the degree of Fe3+ substitution in octahedral positions. In parallel to the technological aspects, we studied theoretically magnetization dynamics in the magnetic films for the flux-gate magnetometers. A non-linear equation for the in-plane magnetization dynamics in easy-plane iron-garnets films was obtained. Conditions of the excitation of the uniform magnetization rotation in (111) plane at a constant angular speed are determined. In particular, it is found that two types of the uniform rotational modes exist. One of them is excited by a magnetic field rotating in plane. On the contrary, the second rotational mode can be excited by a rapidly varying component of the magnetic field orthogonal to the magnetic film. Using orthogonal component of the excitation magnetic field implies parametric interrelation among all three components of the magnetization. It can be used for novel types of parametric amplifiers and sensors.

Th.O-P32 - Magnetoimpedance and field sensitivity in arrangement of CoFeSiB amorphous microwires

J.M. Gomez Cruz [1], H. Montiel Sánchez [1], G. Alvarez Lucio [2],

1. Centro de Ciencias Aplicadas y Desarrollo Tecnológico, Universidad Nacional Autónoma de México, Delegación Coyoacán, México
2. Escuela Superior de Física y Matemáticas IPN, San Pedro Zacatenco, México D.F., México

The arrangement of amorphous wires is a new method, cheap and fast in magnetoimpedance (MI) sensor applications. For these reasons, we purpose a simple design of sensor with the arrangement of two parallel CoFeSiB amorphous wires. MI and the field sensitivity in the arrangement of CoFeSiB amorphous wires were investigated at frequencies from 1 MHz to 70 MHz. Experimental results indicate that MI in CoFeSiB amorphous wires can be significantly improved. The MI maximum response occurs at frequencies between 7 MHz and 25 MHz, at higher frequencies the MI response decrease. Field sensitivity of 3.5%/Oe is obtained at 16 MHz. Sine wave colpitts oscillator at 16 MHz was designed, later this signal is pre-amplified in order to increase the current that flows throw the sensing element. For the acquisition phase, we used a Freescale Microcontroller (MC9S08MM128) whose work is to attune the signal with its ADC module and subsequently, the data is sent to the PC for processing.

Th.O-P33 - Paramagnetic anisotropy of amorphous silica measured by ESR and by field-induced rotational oscillation in microgravity

C. Uyeda [1], M. Yokoi [1], K. Hisayoshi [1]

1. Osaka University, Osaka, Japan

Anisotropy of paramagnetic magnetization at the level of 10^-7 emu/g was detected at the surface of an amorphous silica block by measuring its depth profile with spatial resolution of 50 microns [1]. The anisotropy was obtained in a synthetic block as well as in various natural samples. The magnetic unstable-axis (uni- axial) was normal to surface plane for the measured samples. Fe concentration of the samples were about 1 mol %. In the experiments, a quadrangular prism separated from the sample block (long axis was normal to surface) was cut into square plates with a length of 1.0 mmü~1.0 mmü~0.05 mm. Field-induced rotational oscillation of each plates with respect to applied field (B = 0.6T) were measured one by one in microgravity area, and its anisotropy was obtained from period of oscillation [2]. ESR measurements were performed on the same sample plates, and the anisotropy of crystal field deriving from isolated Fe ions were consistent with those obtained by the microgravity experiments [1]. The cause of anisotropy is investigated by changing the chemical composition, Fe concentration or cooling velocity of the synthesized samples. Assuming that an amorphous silica generally possesses the observed anisotropy, an amorphous particle will possess anisotropy that is uniquely determined by its 3-dimensional shape. In the case of a rod-shaped grain, a stable axis for the rod itself will be directed along the long axis of rod, since total anisotropy of particle is an integration of the uni-axial unstable anisotropy that is assigned to the local surfaces of rod [1]. Amorphous materials are believed to be isotropic at present, and application of magnetic alignment has not been considered as yet for amorphous particles.

Th.O-P34 - Identification of weak magnetic & ferro/ferri-magnetic particles included in grain ensemble using magnetic volume force

C. Uyeda [1], K. Hisayoshi [1], K. Kuwada [1], R. Ynagihara [1],

1. Graduate School of Science, Osaka University, Osaka, Japan

Field-gradient force has been conventionally used to extract and identify of ferro (ferri)-magnetic materials because the forces that operated on the spontaneous magnetizations of these materials considerably exceeded gravity and various frictions in terrestrial condition. Solid materials are often formed as ensemble of grains composed of different materials, and it is generally desirable to extract and identify the material of individual particles of such ensemble before investigating the sample with refined devices. Such method has been well established in analyzing heterogeneous organic solutions by introducing the technique of chromatography; such procedure has not been established as yet for mixtures of heterogeneous solid grains. A principle based on magnetic volume force was previously proposed to identify various diamagnetic grains in a simple manner; here an ensemble of heterogeneous grains is released at a point located in an area of monotone decreasing field [1][2]. The material of the translating grain was identified by comparing the value of susceptibility, obtained from terminal grain velocity in the area of B~0, with a list of compile published values. Here we extend this method on paramagnetic oxide particles with different iron concentrations. Microgravity was generated by a compact drop shaft system; duration of microgravity time was about 0.6 second. The apparatus was set inside a box which had a size of 30 x 30 x 20 cm. The compact setup was realized by introducing a magnetic-circuit that was composed of l NdFeB magnets in generating the required field distribution. By proceeding the present study, the identification becomes possible for almost all the magnetic categories of solid materials.

Th.O-P35 - Fast and deterministic generation of single DW in in-plane ferromagnetic nanowire using local oersted field

C. Guite [1], K. Inn Seng [1], C. Murapaka [1], R. Maddu [1], G. Sarjoosing [1], W. Siang Lew [1]

1. Nanyang Technological University, Singapore

Domain walls (DWs) in magnetic nanowire have been recognised to have potentials to be used in ultra-high density storage, non-volatile logic devices and sensors. For technological applications, the creation of DW on the nanosecond timescale and perfect control of its dynamics is critical. The existing method for creating DW in the nanosecond regime using localized Oersted field always nucleates two DWs; a head-to-head (HH) and a tail-to-tail (TT) DWs. Due to the intrinsic characteristics of these DWs, they either annihilate or form a coupled DW. This results in the stochastic behaviour of DW generation in in-plane ferromagnetic nanowires. It has been previously reported that the minimum separation of two DWs for stable existence is approximately 2.5 Ám. To have a reliable DW generation, an external magnetic field or long electric current pulses were used. In this work we have proposed and experimentally verified a technique for deterministic single DW generation. We exploit the stray field that emanates from the edge of the ferromagnetic nanowire conduit to overcome the mutual interaction between the DWs. Our experimental results showed that deterministic generation of DW was achieved at 10 ns pulse duration with a current density of ~1.1x1012 Am-2 in the given device. Our simulation results showed that the injection stripe line can be placed as far as 500 nm from the edge of the nanowire, depending on the shape of the nanowire edge. Therefore in this work we show that it is possible to deterministically generate DW in in-plane ferromagnetic nanowires using localized Oersted field.

Th.O-P36 - Temperature robustness of a fluxgate current sensor with electroplated Fe-Ni-Co cores

Y. Watanabe [1,2], M. Otsubo [2], T. Yanai [2], M. Nakano [2], H. Fukunaga [2]

1. Mitsubishi Electric Corp. , Amagasaki, Japan
2. Nagasaki Univ. , Nagasaki, Japan

Recently, a fluxgate high-precision current sensor available for a wide temperature environment is strongly desired in the industrial market. Although the commercial sensors using Co-based amorphous or Fe-Ni-based alloys have high sensitivity, it is generally known that the sensitivity fluctuates more than 10 % as the temperature changes. We, therefore, focused on Fe-Ni-Co alloys which have higher Curie temperatures than those of Fe-Ni and Co-based amorphous alloys. In order to compare the temperature variation of the sensitivity, we fabricated two current sensors comprising each Fe-Ni and Fe-Ni-Co ring core, respectively.

An $Fe_{21}Ni_{79}$ or an $Fe_{15}Ni_{46}Co_{39}$ film with the thickness of approximately 20 micrometers was plated on the Cu ring (I.D.=36.7 mm, O.D.=44.1 mm). The turn number of excitation coil and detection coil were 100 and 300 turns, respectively. Each sensor was excited at 1 kHz by a triangular-wave current with the maximum value range from 220 to 430 mA. The temperature and dc current varied from -10 to +125 degrees and from -3 to +3 A, respectively. Moreover, a FFT signal processing was carried out for output of detection coil.

An optimization on the excitation current enabled us to obtain almost the same sensitivity of two sensors operated at 25 degrees, and the result is considered to indicate the excellent soft magnetic properties of not only the Fe-Ni ring core but also the Fe-Ni-Co ring one. Furthermore, we confirmed that the sensitivity fluctuation due to the varying temperature of the Fe-Ni-Co core was smaller than that for Fe-Ni one under the same conditions of the excitation current. The Fe-Ni-Co electroplated core, therefore, is one of effective material for a fluxgate current sensor because of the excellent temperature characteristics and equivalent sensor sensitivity in the case of using the Fe-Ni core.

Th.O-P37 - Influence of the non-magnetic material on the magnetization dynamics and spin pumping in NiFe and CoFeB multilayer systems

A. Ruiz Calaforra [1], T. Braecher [1], V. Lauer [1], P. Pirro [1], B. Heinz [1], M. Geilen [1], A.V. Chumak [1], A. Conca [1], B. Leven [1], B. Hillebrands [1]

1. TU Kaiserslautern, FB Physik and Landesforschungszentrum OPTIMAS, Kaiserslautern, Germany

The inverse spin Hall effect (ISHE) has received increased interest as a new means of spin current detection. In this context, the non-magnetic (NM) material Pt has been identified as a promising material due to its large observed spin Hall angle. However, an unexpectedly large damping enhancement was observed in the ferromagnetic (FM) layer in FM/Pt bilayers. It was demonstrated that the introduction of a Cu spacer can reduce this damping enhancement. Still, the role of the spacer material on the spin current injection from the FM into the NM, as well as on the magnetization dynamics in the FM is not yet completely resolved, which calls for a more detailed study.

Here, we analyzed the influence of selected NM materials on the magnetization dynamics in the technologically relevant FM materials $Ni_{81}Fe_{19}$ and $Co_{40}Fe_{40}B_{20}$ in FM/NM/Pt and FM/Pt layer systems. By means of ferromagnetic resonance spectroscopy, we reveal that the NM materials Al and Cr have no large influence on the magnetization dynamics in an adjacent $Ni_{81}Fe_{19}$ layer. In contrast, an adjacent Ru, Pt as well as MgO layer increase the effective damping α_{eff} and lower the effective magnetization M_{eff}. This highlights that even in the absence of spin pumping, other interface effects affect the dynamics in the $Ni_{81}Fe_{19}$. In contrast, in the case of $Co_{40}Fe_{40}B_{20}$ only Pt has a notable influence on the dynamics in the $Co_{40}Fe_{40}B_{20}$ layer.

By additional measurements of the rectified DC voltage in ferromagnetic resonance in ISHE measurement, where the symmetry ratio V_s/V_a of the voltage is compared. These measurements reveal that strong spin rectification effects always leads to an output voltage. Moreover, an adjacent Pt layer in all cases results in a change of the symmetry, indicating the presence of a spin current pumped into the Pt and a consequent ISHE.

Th.O-P38 - Optimal design for performance improvement of permanent magnet assisted synchronous reluctance motor by enhancing saliency ratio

S. Seo [1], S. Jung [1]

1. SungKyunKwan University, Seoul, South Korea

Recently, Interior Permanent Magnet Synchronous Motor(IPMSM) type motors are widely used by the high output density and efficiency. But rising cost of rare earth magnets requires substitution of IPMSM. One of the alternatives is Synchronous Reluctance Motor which has simple structure and cost-efficient. But it has low efficiency because of not using permanent magnet. Otherwise, PMa-SynRM inserts ferrite magnets into flux barriers of SynRMs to add up alignment torque. PMa-SynRM has great advantage in cost reduction compared to IPMSM by using ferrite magnets which is much cheaper than neodium magnets. PMa-SynRM uses reluctance torque mainly and uses alignment torque adjunctively. In this paper, we increase saliency ratio to improve torque performance by various types of flux barrier and magnet. Analysis model is PMa-SynRM of internal rotational type and has 4 pole, 42 slots and rotor 5 layers. To analyze this model, we use common analyzing tool JMag to conduct 2 Dimensional Finite Element Method(2D FEM). Fractional slot distributed winding is employed because of lower cogging torque due to removal of periodicity through slots and poles. To enhance saliency ratio, we consider various shapes of flux barriers including rotating angle and magnets. Forms of flux barrier has circular barrier, sharp barrier. In the case of the magnets, design variables are thickness, length of magnet and whether it divided or not. This paper conducted 2D FEM about various models to enhance saliency ratio. In the case of flux barrier, sharp barrier type of edge of magnet and lower angle type between main and side barriers shows better performance. In the case of magnets, undivided and thick type shows better performances. Take into account overall variables, we can verify the effects on saliency ratio caused by flux barrier and magnets. When designing form of rotor for PMa-SynRM we can choose appropriate type.

Th.O-P39 - A Study on 3D design and characteristic of outer-rotor type brush-less dc motor considering upper end cover of housing

M. Seo [1], T. Lee [1], Y. Kim [2], S. Jung [1]

1. Sungkyunkwan University, Seoul, South Korean
2. Chosun University, Gwangju, South Korea

In this study, we have dealt with a design characteristic of outer rotor type Brush-less DC (BLDC) motor applied for Engine Cooling Fan (ECF) based on a non-linear 3D Finite Element Method (FEM). The BLDC motor is used in various fields by virtue of its higher efficiency and lower cost compared with general DC motor. The driving motor for ECF is usually designed as outer rotor type since it has a decided advantage on rotation under constant speed with high inertia characteristic. The carbon steel is employed as material of a housing part and it allows the housing part roles as a rotor. When design a motor with the structure mentioned above, it is required as a requisite to consider 3D effect by implementing a non-linear FEM due to an upper end cover of housing part, which is perpendicular to the axis of rotation. We have analyzed identical models under three different conditions. One is 2D analysis model. Another is 3D analysis model without considering the upper end cover of housing. The other is 3D analysis one considering whole parts. The analysis has been performed through both a magnetic equivalent circuit method and a non-linear FEM. Finally, the results have been compared with back electro-motive force value of actual motor model. As a result, the upper end cover of housing functions as an additional flux path and the operating point on B-H curve of rotor material is shifted to non-saturation region relatively. Accordingly, magnetic flux linkage can be increased and motor size can be decreased under same input condition to satisfy ECF specification such as torque. We suggest not only analysis result but also design strategy considering both 2D and 3D FEM in this study.

Th.O-P40 - Spin lifetime in nano-particles

J. Rousseau [1,2], R. Morel [1,2], A. Brenac [1,2], I. Berbezier [3], L. Favre [3], L. Vila [1,2], C. Beigné [1,2], A. Marty [1,2], L. Notin [1,2]

2. Univ. Grenoble Alpes, Grenoble, France
3. IM2NP, CNRS, AMU, Marseille, France

A long spin lifetime is one of the more important parameter to create high efficiency spintronic devices. This key parameter control the time during which a given spin-mediated information can be stored or manipulated.
It has been shown that, in nano-particles, the spin lifetime is strongly enhanced compare to bulk material. In very small clusters (less than 1 nm), the underlying physic is well understood and theoretical models give good agreement with experiment [1]. Longer spin lifetime has also been observed in larger cluster, even in size range where theoretical models would predict bulk value [2].
The spin lifetime in nano-clusters can be assessed by studying magneto-transport properties in the Coulomb blockade regime [3]. To do so requires to connect a unique nano-particle with two magnetics electrodes, via tunnel junctions. Such a device work as a spin-dependent single electron transistor (SD-SET). We have develop a versatile method for the fabrication of SD-SET by e-beam lithography and double angle shadow-edge evaporation technique [4]. A nano-gap is formed between the two deposited electrodes where the nano-particle is, with an underlying gate electrode. This simple and versatile device offers the possibility to study magneto-transport properties in a wide range of nano-particles. In this talk, we will present our results on germanium and cobalt clusters, and we will show how our results can be explained in regards of numerical calculations of the device.

6. Institute for Physics of Microstructures RAS, N.Novgorod, Russia

The operation concept of surface plasmon resonance (SPR)-sensors is based on the excitation of the surface waves under resonant conditions that experience significant variations upon the small changes of the surrounding medium.
We propose a novel type of the SPR-biosensor that is based on the combination of the plasmonic metal-dielectric structure with a magneto-optical material and photonic crystal. The several-orders of magnitude improvement of the SPR-sensor sensitivity is achieved due to the measurement of magnetooptical spectra of the transversal magneto-optical Kerr effect (that are sharper than reflection spectra) as well as the use of specially designed 1D photonic crystals as a support for ultralong-range propagating plasmons that significantly increases the quality factor of the optical resonances.
In this work, two novel types of magnetophotonic plasmonic sensor heterostructures were designed and fabricated, with the magnetic response of the first being provided by a dielectric layer (bismuth-substituted iron garnet) and the second by containing magnetic metal (cobalt). Although the structure with a magnetic metal has higher losses that decrease quality factor of the considered system its advantages are the ease of the fabrication and the low value of the saturation magnetic field. We performed experiments demonstrating the sensing process by both detecting the shift of the magneto-optical resonance position as well as its absolute value variation for the fixed wavelength and angle. The several orders of magnitude improvement of the sensitivity is caused by a very sharp magneto-optical resonance of a width of about 0.1 degrees and magnitude up to 15%. The fabricated spectral sensor sensitivity is 2300 nm/RIU (45 deg/RIU) while the magneto-optical response to the refractive index change is 10%/RIU. Estimations show that such configuration might raise the threshold sensitivity up to 10^-8 RIU and significantly shorten the measurement time.

The work is supported by Russian Science Foundation (grant No.14-32-00010).

Th.O-P42 - Transfer torque characteristic analysis of dual-stage magnetic gear with rare-earth magnets and non rare-earth magnets

C. Kim [1], M. Kim [1], S. Jung [2], Y. Kim [1]

1. Department of Electrical Engineering, Chosun University, Gwangju, Republic of Korea
2. School of Information and Communication Engineering, Sungkyunkwan University, Suwon, Republic of Korea

The magnetic gear that solves the physical contact problem of the mechanical gear has advantage of no mechanical friction loss, very little noise and vibration, and no need for lubricant. Due to this unique non-contact characteristic, the magnetic gear which is capable of non-contact torque transmission has replaced mechanical gear. However, the magnetic gear with a high gear ratio is disadvantageous to implement the exact gear ratio because the number of rotor poles increases. Therefore, dual-stage type magnetic gear was proposed in order to distributes the gear ratio by using two magnetic gears as to the mechanical gear is used the multi-stage in order to implement the high gear ratio. The dual-stage type magnetic gear composed of first magnetic gear for low torque, high speed and second magnetic gear for high torque, low speed. The power is input to the inner rotor of first magnetic gear when operating as a reducer. The outer rotor of first magnetic gear and inner rotor of second magnetic gear are connected in order to transmit power. As a result, the power is output through the outer rotor of second magnetic gear. However, dual-stage magnetic gear has reverse process when operating as an accelerator. The dual-stage type magnetic gear can improve the power density and efficiency compared to the conventional magnetic gear. Also, the dual-stage type magnetic gear can be designed differently permanent magnet type because the use of the two magnetic gear. Therefore, in this paper, permanent magnet material of second magnetic gear was not changed and only permanent magnet material of first magnetic gear was changed to bonded NdFeB magnet or ferrite magnet from sintered NdFeB magnet. Transfer torque and magnetic field analysis method for dual-stage magnetic gear was used numerical analysis with coupled finite element method and boundary element method.

Th.O-P43 - Design of interior permanent magnet synchronous motor for minimizing axial force by adapting novel skew method

G. Park [1], B. Son [1], Y. Kim [2], S. Jung [1]

1. School of Electronic and Electrical Engineering, Sungkyunkwan University, Seoul, South Korea
2. Department of Electrical Engineering, Chosun Universtiy, Gwangju, Republic of Korea

Interior Permanent Magnet Synchronous Motor is applied to various fields, since it has superior power density and efficiency by utilizing reluctance torque owing to its saliency as well as alignment torque. However saliency also causes relatively higher torque ripple than the other type of motor.
One of the methods to compensate this problem is skewing. Skewing is the method of canceling the ripple of torque by skewing either rotor or stator. Skewing can reduce torque ripple and cogging torque dramatically, however it produces the unexpected axial force at the same time. This axial force can give continuous mechanical load to the part connected to the motor, and also has effect on generate noise and vibration. In this paper, V-shape skewing method is applied for designing IPMSM to reduce the axial force preventing side effect of skew, which is generation of noise, vibration and mechanical load.
Owing to the development of stacking technology, skew is applied to stator considering magnetization. It also maximizes the effect of skew with continuous configuration, unlike step-skew generally applied in rotor skewing method.
Non-skewed model, conventional-skewed model and proposed V-shape skewed model are comparatively analyzed to identify the effect of skew to axial force, and 3D numerical analysis based on Finite Element Method is conducted to consider the force in axial direction. Axial Force is calculated on both end of the rotor since most of the axial force appears at the ends. Axial force is produced due to the orientation of current flow and nonlinear magnetic flux saturation. It produces different magnitudes of axial force at each ends of the motor which resulted as the residual axial force. Proposed V-shape skewed motor also produces constant axial force, however, upper and lower parts produce axial forces in opposite direction to make net force zero.

Th.O-P44 - High sensitivity disk shaped planar Hall effect sensor for capture and detection of superparamagnetic nanoparticles

M. Volmer [1], M. Avram [2], A. Avram [2], I. Firastrau [1]

1. Transilvania University of Brasov, Brasov, Romania
2. National Institute for Research and Development in Microtechnologies, Bucharest, Romania

The aim of this study is to develop high sensitivity and low cost Permalloy based planar Hall effect (PHE) sensors which can to be used for various applications and, in particular, for Lab on a Chip (LOC) platforms. Using typical photolithographic technique, disk-shaped structures made from Permalloy, 1 mm diameter and 20 nm thick, were deposited on to oxidized Si substrate. No anisotropy axis has been defined. Four PHE sensors are patterned and interconnected on a chip. To control the sensor sensitivity and linearity, a biasing field has been applied along the driving current. By this, different magnetization states in the sensor layer can be generated. The strong magnetostatic interaction between the magnetic nanoparticles and the sensor magnetic layer is responsible for the actuation, capturing and sensing of magnetic particles. These aspects are explained by means of micromagnetic simulations. From aqueous solution containing maghemite nanoparticles, 10 nm mean diameter, functionalized with PEG 6000, were placed droplets with volumes between 0.2 to 1 Ál over the sensor surface. Special field configuration has been used to capture the nanoparticles on the sensor surface. In addition to biasing field, a magnetic field, used to magnetize the nanoparticles, was applied perpendicular to the sensor surface in order to avoid the saturation of the PHE signal. We used different techniques to sweep the fields and the results show that high detection sensitivity, of the order of 0.1 emu/V, can be obtained for different magnetization states in the sensing layer. We observed large signal variations of the sensor output when the magnetic layer is polarized closed to the coercive state.
The authors are grateful for the financial support from the project PN2 CELLIMUNOCHIP No. 2/2012 in the frame of the National Partnership program.

Th.O-P45 - Investigation of the variation in magnetic nature of Ba - Fe magnetoplumbite with Li - Ti substitution

R.R. Deshmukh [1], P. Bhatia [2], R. Srinivasan [3]

1. Institute of Chemical Technology, Prague, Czech Republic
2. Guru Nanak College of Arts , Science and Commerce, Maharashtra, India
3. University of Mumbai, Department of Physics, Mumbai, India

Pure barium ferrite and its substituted variants are synthesized;
$BaFe_{12}O_{19}$ - HXF $Ba_{0.95}Li_{2.85}Fe_{8.55}Ti_{1.9}O_{19}$- HXF1.
$Ba_{1.688}Li_{0.422}Fe_{8.018}Ti_{2.532}O_{19}$- HXF2.
$Ba_{1.266}Li_{0.844}Fe_{7.596}Ti_{2.954}O_{19}$- HXF3.
$Ba_{1.688}Li_{0.844}Fe_{6.752}Ti_{3.376}O_{19}$- HXF4.
$Ba_{0.95}Li_{3.8}Fe_{5.7}Ti_{3.8}O_{19}$- HXF5.
X-Ray diffraction studies indicate the single phase formation of hexagonal magnetoplumbic type with space group P63/mmc . The 'a' and 'c'values determined for HXF agree very well with those reported . The SEM images of the pellet surfaces show dense grain structure. An elongation of grains is also observed in substituted samples as titaniumcontent rises. Grain size is observed to increase considerably by substitution with Li and Ti. Magnetic properties of hexaferrite are investigated. Room temperature magnetic hysteresis loops are reported. MR / Ms reduces as substitution increases with respect to pure HXF. The Hc is seen to depend on the Ti plus Li content. The normalized susceptibility vs. temperature curves are drawn. Susceptibility curve corresponding to pure HXF drops a little near room temperature, rises slowly to peak at the curie temperature Tc = 713K which agrees well with the reported value. The curves corresponding to substituted hexaferrites are most peculiar. They could be interpreted as two curie temperatures . With increase in Ti substitution, the separation between the two Tcs tends to increase. The curie temperatures are observed to be higher in HXF1, HXF 3 and HXF 5 and lower in HXF2, HXF 4. The lowered Tc values demonstrate that some inter- sublattice exchange interactions are strongly diminished. The substitution of Fe^{3+} ions with Ti^{4+} ions in the hexaferrite reduces its intrinsically high universal magnetic anisotropy and enhances faraday rotation in order to make it suitable for perpendicular magnetic recording.

Th.O-P46 - Multicore off-diagonal magnetoimpedance sensors utilising amorphous wires

N. Yudanov [1], A. Rudyonok [1], L. Panina [1,2], A. Morchenko [1], A. Zhukov [3]

1. National University of Science and Technology (MISIS), Moscow, Russia
2. Institute for Design Problems in Microelectronics RAS, Moscow, Russia
3. Dept. Material Physics, Chemistry Faculty, University of San Sebastián, San Sebastian, Spain

Magnetoimpedance (MI) sensors are attractive for realising a localised detection of weak magnetic fields owing to micro-size and high sensitivity of the MI elements. In the case of Co-rich amorphous wires of diameter 10-30 microns used as MI elements, the relative change in impedance at MHz frequencies can be over 100%/Oe. MI sensors in off-diagonal configuration [1-2] when the signal is taken from the coil mounted on the wire have a number of advantages including linearity, enhanced output voltage, and resonance detection circuitry. Utilising a pulse-driven MI and a detection coil of 600 turns the resolution of about few pT/Hz0.5 was achieved. However, a many-turn detection coil may be a problem considering the complexity of sensor construction, sensor-head size, and increased electronic noise. In this work, the off-diagonal impedance of a number of Co-rich glass-coated amorphous wires placed in the same coil is investigated. The wires are connected in parallel and excited by harmonic or pulsed current. The best sensitivity of about 300mV/Oe is obtained for two wires excited by a sinusoidal current and realising the resonance conditions for the detection circuit, which has only 40 turns. The full scale and linearity range are also increased more than twice in comparison with those when only one wire is used. The response drops if the distance between the wires is increased which is due to a strong effect of the magnetostatic interaction between the wires. We conclude that off-diagonal MI sensors with multiple wires can provide higher transfer function per one turn and could be advantageous for localised field detection.

Th.O-P47 - Magnetization and magnetic losses of powders from metallized particles at microwaves

A. Anzulevich [1], L. Butko [1], V. Buchelnikov [1], I. Bychkov [1], D. Kalganov [1]

1. Chelyabinsk State University, Chelyabinsk Oblast, Russia

Powders from metallized dielectric particles have such advantages as instant microwave heating, low heat capacity of the particles and controlling the heating temperature within a narrow range. Owing to all these advantages powders from dielectric particles covered by metallic layer can be used in various fields of science and technology. For example, they would be useful as fillers in the thermal catalyst reactors in the oil refining industry or as a transfer and active agent at treatment of cancer or localized bacterial diseases.
In this work, we modeled dielectric spherical particles covered by metallic shell. To study the mechanisms of instant microwave heating of powders consisting of metallized particles, we obtained dependencies of real and imaginary parts of the effective permittivity and permeability of these powders on frequency of the incident electromagnetic wave, radius and permittivity of the particle, thickness and conductivity of the metallic shell. We used finite element method for calculation of the electromagnetic fields in the investigated model and combination of impedance lows for perfect electric conductor and perfect magnetic conductor to calculate effective electrodynamics parameters. According to obtained real part of the dynamic effective permeability the powder from such kind of particles exhibits diamagnetic properties. The imaginary part of the effective permeability is large enough compared with imaginary part of the effective permittivity and reaches its maximum values at the thickness of the metallic layer less than the skin depth. Moreover, in this case powder can be heated twice effectively than the powder consisting of entirely conductive metallic particles.

Th.O-P48 - Magnetic micro-mechanical systems for magnetic field mapping by optical effect

G. Ortiz [1,2,3], M. Morcrette [1,2,3], T. Dietsch [1,2,3], P. Sabon [1,2,3], I. Joumard [1,2,3], H. Joisten [1,2,4], B. Dieny [1,2,3]

1. Univ Grenoble Alpes, INAC-SPINTEC, Grenoble, France
2. CEA, INAC-SPINTEC, Grenoble, France
3. CNRS, SPINTEC, Grenoble, France
4. CEA, LETI, MINATEC Campus, Grenoble, France

In many areas, magnetic sensors play a very important role. Different types of sensors exist: those based on Hall effect, the magnetoresistive ones (GMR, TMR) , those based on magneto-optical effects (Kerr, Faraday), etc. Optical magnetic sensors are often used to perform imaging or magnetic field mapping. A first known method to visualize magnetic fields of materials is based on magneto optical Kerr or Faraday effects. Another method for obtaining information on the intensity and direction of magnetic fields by optical visualization uses ferrofluidic materials. In this work, we propose a novel method for optical visualization of the magnetic field based on the use of magnetic flexible cantilevers. The basic idea is to create a dense assembly of cantilevers, at the micro- or nanoscale, which deform under the effect of an external magnetic disturbance. Under local magnetic perturbation, the cantilevers bend and consequently, alter the reflectivity of the system producing an image of the magnetic field to which the system is subjected. The fabricated cantilevers have micron-size dimensions and covers an area of about 1 cm * 2 cm. A magnet of 1 cm^2 was placed under the silicon substrate, which is perfectly opaque. Surprisingly, a magnet image appears as in transparency through the substrate due to the deflection of the cantilever caused by the magnetic field radiated by the magnet. The cantilevers were obtained by clean-room microfabrication techniques. They are made of magnetic NiFe (~ 100 nm thick) to make them deformable under the effect of a magnetic field. To allow mechanical bending, one end of the cantilevers is freed from the substrate while the other is kept attached to it. A correlation between the reflectivity modification of the surface wearing the cantilevers, and the applied magnetic field is under evaluation.

Th.O-P49 - Spin polarized transport in graphene spin valves with amorphous carbon interfacial layers

J.F. Sierra [1], B. Raes [1], I. Neumann [1], M.V. Costache [1], S.O. Valenzuela [1]

1. Institut Catala deNanociencia I Nanotecnologia (ICN2), Barcelona, Spain

We demonstrate a large enhancement of the spin accumulation in monolayer graphene following electron-beam induced deposition of an amorphous carbon layer at the ferromagnet-graphene interface. The enhancement is 10^4-fold when graphene is deposited onto poly(methyl metacrylate) (PMMA) and exposed with sufficient electron-beam dose to cross-link the PMMA, and 10^3-fold when graphene is deposited directly onto SiO_2 and exposed with identical dose. We attribute the difference to a more efficient carbon deposition in the former case due to an increase in the presence of compounds containing carbon, which are released by the PMMA. The amorphous carbon interface can sustain very large current densities without degrading, which leads to very large spin accumulations exceeding 20 meV at room temperature. Furthermore, Hanle measurements in large monolayer graphene flakes (20-40 µm long) deposited on SiO_2 show long spin diffusion lengths (7 µm), which corresponds to spin life times of 1.5 ns.
Surprisingly, the results are comparable to the spin life times measured in graphene on hexagonal boron nitride substrates.

Th.O-P50 - Local magnetic resonance spectroscopy with spin electronics based magnetic sensors

P.A. Guitard [1], R. Ayde [1], E. Paul [1], G. Jasmin-Lebras [1], M. Pannetier-Lecoeur [1], C. Fermon [1]

1. Service de Physique de l'Etat Condensé, CEA Saclay, UMR CNRS 3680, Gif sur Yvette, France

Nuclear Magnetic Resonance Spectroscopy (NMRS) is a widely known technique for chemical and biological molecule analysis. However due to the weakness of the NMR signals, it is very difficult to work on volumes lower than a mm3. That limitation has led to the development of miniaturized sensors such as microcoils, NV centers and atomic magnetometers.
We will present our approach based on the use of Giant Magneto-Resistive sensors (GMR) as wide band magnetic sensors to detect locally the NMR signal. GMR sensors and an NMR setup have been specifically designed to have a detectivity in the range of 20pT/sqrt(Hz) and able to work with an external magnetic field up to 1 Tesla.
We will present results of NMR spectroscopy of model liquids like Ethanol on a volume of the order of 20x20x20 μm^3 with two different configurations: a first one where local NMR spectroscopy can be performed in a large volume and a second one, where the liquid of interest in constrained in a small microchannel.

Th.O-P51 - Grain orientation and magnetostrictive properties of Tb-Dy-Fe alloys

X. Mu [1], C. Wang [1], X. Gao [1]

1. State Key Laboratory for Advanced Metals and Materials, University of Science &Technology, Beijing, China

The microstructure and crystal orientation of $Tb_{0.3}Dy_{0.7}$ (Fe, M) $_{1.95}$ alloys, prepared by super high temperature directional solidification device, has been studied by XRD and electronic backscatter diffraction (EBSD) technique to find out the relationship between grain orientation and magnetostrictive properties. The results of XRD indicate that the directionally solidified alloys with different parameters (including velocity V and temperature gradient G of solid-liquid interface) have <110> crystal orientation towards sample axis. Based on the XRD data, we calculate the magnetostriction coefficients, and the calculate values disagree with the measured ones without prestress. According to EBSD maps, it is found that samples with <110> preferential orientation actually have many other grain orientations, such as <113> and <111>. Meanwhile, the highly magnetostrictive samples have more volume fraction of <110> and <111> grain orientations which orientation has larger magnetostriction than <113>. Due to the limitation of XRD in volume texture characterization, the calculated result achieved from XRD is inaccurate.

Th.O-P52 - Ultra-high frequency tunability in low-current and low-field spin torque oscillators based on perpendicular magnetic tunnel junctions

T. Le [1], A. Eklund [2], S. Chung [1,3], H. Mazraati [1], A. Nguyen [1,4], M. Yamanouchi [5,6], E. Enobio [6], S. Ikeda [5,6], H. Ohno [5,6], J. Akerman [1,3]

6. Center for Spintronics Integrated Systems, Tohoku University, Miyagi, Japan

All-perpendicular magnetic tunnel junctions (p-MTJs) based on CoFeB/MgO structure offer the advantages of high thermal stability, low switching current density and strong adaptability to current semiconductor technology [1] in the fabrication for spin-transfer-torque (STT) memory [2,3], Here we present a detailed study of the STT driven microwave generated signals in CoFeB/MgO/CoFeB p-MTJ nano-pillars subject to an in-plane (IP) oriented magnetic field, Owing to the different perpendicular magnetic anisotropy strengths of the two CoFeB layers, their magnetizations are tilted differently away from their equilibrium in IP fields, leading to a misalignment of their magnetizations, and consequently to substantial microwave generation. Fig. 1 show the field-dependent frequency of the STT-induced generated signal. At low fields, the frequency primarily red-shifts with field towards a minimum point, before turning to blue-shift. Clear red-shift behavior of frequency with current is also observed at low fields. The low-field red-shift dependence of frequency on the bias current implies that oscillation originates from large-angle precession around perpendicular easy axis and the precession angle increases with current, consistent with the strengthening of microwave power density with current at field <3.5 kOe (Fig. 2). In contrast, both the blue-shift behavior of frequency and weakening of microwave power at higher fields suggest a change to small-angle in-plane precession. The different behaviors are correlated to the field-dependent cosine-manner of device resistance in Fig.1-inset (a), interpreted as the misalignment between the CoFeB layer magnetizations. A broad maximum of resistance corresponds to maximum misalignment and approximately coincides with the maximum generated power. In conclusion, the microwave signals of p-MTJ nano-pillars are observed at low biases with fundamental frequencies from 5 to 10 GHz, and show ultra-high current tunability of 4.4 GHz/mA (Fig. 1-inset (b)).

5. Department of Physics, University of Mumbai, Kalina, India

The magnetostrictive properties of Boron substituted polycrystalline samples of SmFe2 and (Tb,Dy) Fe_2 alloys (TerFeNOL-D) for Boron substitution less than 4 at% were studied. These binary and pseudo-binary Laves phase intermetallic compounds are known to show large magnetostriction.

The ingots of the polycrystalline alloys, obtained by induction melting the constituents, were cut in slices of about 4mm x 6mm x 1mm. The magnetostrictive measurements in microstrain using the half-bridge method were done with a standard resistive strain gauge of about 3mm x 5mm in magnetic field upto 1 Tesla generated by an electromagnet.

For the $(Dy_{.27}\ Tb_{.73})Fe_2Bx$ alloys, the parent compound (x=0) shows saturation in microstrain at fields between 0.6-0.7 Tesla, reaching a value of 1400 micron, that agrees with the earlier reported value for polycrystalline Terfenol-D alloys. The addition of Boron did not produce significant change in the structure as observed from X-ray diffraction as well as the room temperature magnetization. However, the values of microstrain decreases with increasing B concentration and the strain does not saturate up to the highest achievable field of 1.2 T.

In case of the SmFe2B alloys, the maximum magnetostriction of about 860 microstrain was noted for the parent compound and it does not show saturation upto the highest available field of 1.2T. This value of magnetostriction goes on decreasing with addition of B up to 3 at%. An earlier study on the Boron substituted $SmFe_2$ alloys showed the suppression of spin reorientation observed from ac susceptibility measurements in the parent compound at a temperature of 190K. The substitution of Boron produces a reduction in the magnetostriction of these compounds without causing significant change in the structure and magnetization.

Th.O-P54 - AlOx and MgAlOx barrier based magnetic tunnel junction sensing devices for industrial application

S. Knudde [1,2], J. Valadeiro [1], A. Moskaltsova [1,2], A.V. Silva [1,2], D.C. Leitao [1,2], S. Cardoso [1,2]

1. Inesc-Mn, Lisbon, Portugal
2. Instituto Superior Tecnico, Lisbon, Portugal

In the last decade, magnetic tunnel junctions (MTJs) research has been focused on MgO due to high tunnel magnetoresistance (TMR), ranging 200% in sensors. Still, when compared to Al_2O_3 junctions (with 50% TMR), MgO technology is expensive, while noise levels [1] place Al_2O_3 junctions as a competitive alternative for sensing devices. Another material of interest is MgAlOx: epitaxial spinel crystal MgAlOx barriers seem to provide the better of two world by both their signal and noise [2]. We explore these barriers using ion beam deposition, targeting large area and large scale production.
AlOx and MgAlOx-based MTJs were deposited from metallic targets. Deposited stacks have the structure of Glass/Ru 400A/IrMn 180A/CoFe 22A/Ru 8.5A/CoFeB 30A/Barrier/CoFeB 30A/Ru 150A. The barriers consisted of Al layers (7A,9A,11A,13A,15A) or Mg/Al multilayers (total thickness 8A to 16A), where 0.5 to 2A-thick individual layers are used to promote layer intermixing. Both were oxidized through an Ar/O remote plasma [3]. For the Mg/Al barriers, the effect of Mg seed layers to promoting the crystallinity was investigated. The MTJ stacks were microfabricated from 4 to 676um^2 and aspect ratio's from 1 to 20. Linearization was achieved by shape anisotropy or external biasing. Samples were annealed at 250^{o}C for 30minutes. Statistical data from 5000 devices was analysed and AlOx MTJs showed TMR up to 35% with 20s oxidation. Lower times of oxidation (5s,10s) resulted in TMR of 20% down to 9% for thicker barriers due to under-oxidation with RxA from 150 to 4500 Ohm.um^2, consistent with previously reported values. Noise levels down to 90pV/sqrt(Hz)) were measured. MgAlOx barriers showed TMR of 20%, indicating an amorphous Al_2O_3-like behaviour. A second annealing of 2hours at 330^{o}C was performed as in MgO for crystalization, TMR decreased, indicating the onset for a diffusion mechanism.

Th.O-P55 - Effect of the molybdenum content on magnetic characteristics of amorphous magnetic glass coated temperature sensing microwires in biomedical applications

R. Hudak [1], R. Varga [2], I. Polacek [1], P. Klein [2], R.P. del Real [3], M. Vazquez [3]

1. Department of Biomedical Engineering and Measurement, Faculty of Mechanical Engineering, Technical University of Kosice, Kosice, Slovakia
2. Department of Condensed Matters Physics, Institute of Physics, Faculty of Science, P. J. Safarik University, Kosice, Slovakia
3. The Instituto de Ciencia de Materiales de Madrid, institute of the Consejo Superior de Investigaciones Cientificas, Madrid, Spain

Validation of post-implantation processes on a tissue-implant interface requires to control several biomechanic processes including temperature changes caused by inflammation or friction, in order to prevent possible negative effects. Regarding to this, the adhesion of a amorphous magnetic glass-coated microwires (AMGCM) to surface structures of a implant can be used, to enable the wireless measurement of local human body temperature. The dimensions of the microwires (20 mm X 50 µm) simultaneously do not affect the structure, construction and biocompatibility of an implant, at significant level.
The temperature sensor suitable for such biomedical applications needs to have the sensitivity in the range of 35 - 45 °C, the Curie temperature (TC) about 300 °C and in order to achieve proper sensitivity, it is necessary to produce microwires with TC about 50°C.
To allow the amorphous magnetic glass-coated microwires measure the temperature, different contents of molybdenum were added into the metal core composition. Samples with composition of a metal core $Fe_{72}Mo_9B_{18}Cu_1$, $Fe_{71}Mo_{10}B_{18}Cu_1$, $Fe_{70}Mo_{11}B_{18}Cu_1$ were produced in order to decrease TC. During the production, samples with higher amount of molybdenum tend to crystallize, which was also confirmed by hysteresis loops measurement. $Fe_{72}Mo_9B_{18}Cu_1$ and $Fe_{71}Mo_{10}B_{18}Cu_1$ microwires remained amorphous while $Fe_{70}Mo_{11}B_{18}Cu_1$ microwire crystallized.
According to saturation magnetization measurement, the amorphous microwires in the maximum temperature of 146.85 °C, did not reach the Curie temperature.
Addition of the molybdenum exhibits possibility to decrease Curie temperature but its high melting point also increases the melting point of the master alloy, what may obstruct the production of the microwires and preservation of a nominal composition of a metal core, regarding to relatively low melting point of a Pyrex. With respect to the results achieved, the actual composition of amorphous magnetic glass-coated microwires will be the object of a further study.

Th.O-P56 - Study on the DC linear stepper motor to industrial applications

N.F. Baggio Filho [1], R. Belusso [1], F. Hoefling Santos [1], T. Francisca Baggio [2]

1. Federal Institute of Rio Grande do Sul, Rio grande do Sul, Brazil
2. Federal University of Rio Grande do Sul, Rio grande do Sul, Brazil

Actually, many industrial processes require a precise linear motion. Usually, this movement is achieved with the use of rotary motors combined with electrical control systems and mechanical systems such as gears, pulleys and bearings. Other types of devices are based on linear motors, where the linear motion is obtained directly. The Linear Stepper Motor (MLP), proposed by this work, is an excellent solution for industrial applications that require precise positioning and high speed. This study presents an MLP formed by a linear structure and static ferromagnetic material, and a mover structure in which three coils are mounted. Mechanical suspension systems allow a linear movement between static and mover parts, maintaining a constant air gap. The operating principle is based on the tendency of alignment of magnetic flux through the path of least reluctance. The force proportional to the intensity of the electric current and the speed proportional to the frequency of the excitation coils. The study of this device is still based on the use of a numerical and experimental analysis to verify the relationship among electric current applied and planar force developed. In addition, the magnetic field in the air gap region is also monitored.

Th.O-P57 - The development of the physical foundations of the actuator based on the magnetically bi-phase partially covered microwire

K. Chichay [1], I. Machay [1], I. Iglesias [1], J. Jimenez [2], M. Vazquez [2], N. Perov [1,3], V. Rodionova [1]

3. Faculty of physics, Lomonosov Moscow State University, Moscow, Russia

There are many devices for the manipulation of the nano- and micro- objects and all of them have some disadvantages needed to overcome. In this work we propose the physical foundations of the manipulator based on the magnetically bi-phase partially covered microwires. They consist of a ferromagnetic core - amorphous glass-coated microwires, and a polycrystalline ferromagnetic shell partially covering the core along its axis.
Within our activities, we investigated the bending properties of the partially covered microwire. The bend of the partially covered microwire in the magnetic field directed parallel to the microwires axis occurs because of different signs of the magnetostriction of the core and the shell materials. So, we used following materials for preparation of the core (by Taylor-Ulitovsky technique) and of the shell (by electrodeposition and by magnetron sputtering): Fe-based(positive magnetostriction)/FeCo-based(negative magnetostriction) and FeNi(positive magnetostriction)/Co(negative magnetostriction), respectively.
Main objectives of our investigations were development of the method of the bending control of the partially covered microwires in the magnetic field, estimation of the bending value for different combinations of materials and sizes of the core and the shell and demonstration of the possibility to create a novel type of actuator.
Our measurements and theoretical estimations demonstrated that the actuators have rather good working characteristics: it is able of working at large distances - up to hundreds microns and exert strong forces to move the objects - up to tens of pN. These advantages allow to work with quite large objects. Also we demonstrated that it can have two operating regimes: control of the objects by the magnetic field or by the mechanical forces. Moreover this actuator is able to work with nontransparent objects. and the last advantage: the prototype will have a low fabrication cost and will be compact.

Th.P-P01 - The role of the coating on the degradation and hematotoxicity of magnetic nanoparticles evaluated in a rat model

L. Gutiérrez [1], A. Ruiz [1,2], P.R. Caceres [3], D. Santos [3], S.B. Chaves [3], M.L. Fascineli [3], M. García [3], R.B. Azevedo [3], M. Puerto Morales [1]

3. Universidad de Brasilia, Brasilia, Brasil

In the last decade there has been a spectacular development of iron oxide magnetic nanoparticles (MNPs) for biomedical applications and the evaluation of their potential risk on human health has become a priority objective in nanomedicine. Our main aim in this work was to evaluate the effect of two coatings (DMSA and PEG) on two important parameters related to the risks associated to the particles: the hematotoxicity of the particles and the degradation process in different tissues. For this purpose, in vivo experiments were performed by administration of a single dose of particles to a rat model and analysis of blood and organs at different times during 30 days after administration. The hematotoxicity tests showed that, at this low dose, the particles do not affect erythropoiesis or increase the number of immature erythrocytes in the bone marrow. Interestingly, DMSA coated nanoparticles showed a significant effect on the leukocytes counts 24 h after injection that was not observed if the particles were coated with PEG. The transformations of the particles in tissues were followed by AC magnetic susceptibility measurements. Due to their iron-containing core, MNPs accumulated mainly in spleen, liver and lungs tissues, where they were quickly metabolized by the animals. In particular, the DMSA coated particles were not longer observed in the tissues 24 h after their administration. Consequently, an increased amount of ferritin, the iron storage protein, was found in liver tissues in comparison with the control ones, suggesting a rapid metabolization of maghemite into ferritin iron. The PEG coating slowed the degradation process, and particles coated with this compound were still detectable in several organs 24 h after their administration.
Knowledge on the toxicity, biodistribution, and degradation processes of these materials is fundamental for their safety evaluation before their use in biomedical applications.

Th.P-P02 - Field and frequency dependence of the SAR/ILP value in magnetic hyperthermia using magnetic multi- and single core particles

P. Southern [1], L. Bogart [1], Q. Pankhurst [1], F. Ahrentorp [2], A. Sarwe [2], J. Blomgren [2], C. Jonasson [2], F. Westphal [3], C. Grüttner [3], R. Costo [4]

Magnetic hyperthermia is a promising novel method in cancer therapy where an AC magnetic field induces local heating in magnetic particles. Whilst both multi-core and single core particles are used in magnetic hyperthermia applications, the heating properties and efficiency of each system are quite different. Multi-core particles comprise several single-domain nanocrystals geometrically positioned in different types of configurations, while a single-core particle only contains an individual nanocrystal. For multi-core particles, the size distribution and configuration of the nanocrystals inside the particle, together with the overall particle size distribution, gives rise to different magnetic relaxation characteristics (Brownian or Néel relaxation, or a combination of both). The value of the specific absorption rate (SAR) and/or the intrinsic loss parameter (ILP) in the particle systems depends on the applied field amplitude (H0), excitation frequency (f) and, in some instances, the viscosity of the medium. The relationship between SAR/ILP and H0 and f depends on the properties of the particle system as well as magnetic interactions between the nanocrystals in the multi-core particles. In this work we study the SAR/ILP values of several iron oxide multi-core and single core particles with a range of particle and nanocrystal sizes. SAR/ILP values are determined from temperature vs. time curves at different H0 and f and are correlated with magnetic losses determined from AC susceptometry and dynamic Monte-Carlo simulations. Typical values of the SAR value of the studied particle systems are in the range of 43 W/g (corresponding to an ILP value of 1.0 nHm2kg-1) at a field amplitude of 6.6 kA/m and excitation frequency 989 kHz. One of the goals is to map the relationship between SAR/ILP, dynamic magnetic loss (from AC susceptometry), and nanocrystal/particle sizes determined from TEM images, that could potentially be used to determine an optimum hyperthermia frequency for a specific nanoparticle system.

Mechanical disruption is an emerging form of cancer therapy where magnetic particles injected into a tumour cause physical damage to cells under an applied magnetic field. We show, both theoretically and experimentally, how magnetic particles can be optimized for this application by consideration of the symmetry and strength of their magnetic anisotropy. The torque on the magnetization of the particle from an applied magnetic field is transferred to a mechanical torque through the magnetic anisotropy. A particle with an easy axis and hard plane under a specified applied rotating magnetic field is shown to provide the maximum possible torque on the particle, independent of the relative orientation of the particle and field. Previous experiments have used easy plane, for example, magnetic vortex, particles where the existence of the easy plane allows the magnetization change without exerting a torque on the particle, reducing its effectiveness. We demonstrate this finding experimentally using an in vitro test of both easy axis and Permalloy vortex particles. The easy axis particles are made from CoFeB/Pt layers coupled by RKKY interactions through Ru spacers. The CoFeB/Pt provides perpendicular anisotropy with an easy axis and large anisotropy. The RKKY coupling leads to an antiferromagnetic ground state which prevents agglomeration. The 2 micron diameter particles are incubated with the human-derived glioma brain tumour cell line U87 for 24 hours before being subjected to a 1 T rotating field. We find that for vortex particles 12 ± 2 % of the particles are destroyed after one minute of applied field whilst for the easy axis particles 62 ± 3 % are killed. This work demonstrates how mechanical disruption of cells can be optimized by consideration of the symmetry of the particles used and provides a path for increased effectiveness of this prospective cancer therapy.

Th.P-P04 - Encapsulation of VEGF165 in magnetic PLGA nanocapsules for potential local delivery and bioactivity into human brain endothelial cells

The administration of pro-angiogenic proteins is an attractive therapeutic strategy to enhance angiogenesis after an ischemic event [1,2]. Nevertheless a labile structure and short circulation time in vivo are the main obstacles that reduce protein bioactivity and dose at the target site. Biodegradable magnetic nanomaterials, intravenously administrated and accumulated at the diseased zone under an external magnetic field, may circumvent these limitations.
We report on the synthesis of poly(D,L-lactic-co-glycolic acid) (PLGA) nanocapsules (diameter less than 200 nm) loaded with the vascular endothelial growth factor-165 (VEGF165) confined into the inner core and superparamagnetic iron oxide nanoparticles (SPIONs) embedded in the polymeric shell. The system showed high encapsulation efficiencies and sustained protein release over 14 days. In vitro studies confirmed protein bioactivity after encapsulation. Moreover, through MRI measurements we demonstrated excellent T2 contrast image properties. We therefore suggest the nanoconstruct as new targeted protein delivery carrier useful in pro-angiogenic treatments, especially after an ischemic event [3].

Barcoded microcarriers can be found in bioassay, point-of-care diagnostic and combinatorial chemistry applications. Encoding can be achieved using various approaches, including fluorescence, shape and magnetic based techniques [1]. Previous designs for magnetic bit encoded microcarriers [2,3] were severely limited in reliability and barcodes could only consist of up to 3-5 bits [4].
Here we present a new composite element (CE) bit design [5] that overcomes these limitations. We discuss the intricacies which govern the magnetic behaviour of the CE bit design and demonstrate how highly reliable barcodes with up to 14 bits (16,384 codes) can be fabricated. We demonstrate a multi-bit in-plane encoding and detection process, and discuss how CEs make magnetically encoded microcarriers relevant for microfluidic bioassays and modern combinatorial chemistry applications.
Furthermore, we present a new variant of the CE barcode designed to produce strong out-of-plane flux patterns, proving additional benefits to detection resolution and bit packing density. We analyse out-of-plane domains using MFM measurements and illustrate the multi-bit encoding process using MOKE imaging techniques. This talk aims to convey the significant benefits that magnetic encoding of microcarriers provides over other barcoding techniques.

Th.P-P06 - Dynamically varying magnetic microstructures as NMR tranducers of physiological conditions.

G. Zabow [1,2], S. Dodd [2], A. Koretsky [2]

1. National Institute of Standards and Technology (NIST), Boulder, United States
2. National Institutes of Health (NIH), Maryland, United States

Magnetic micro- and nanoparticles find use across many biomedical fields ranging from imaging, therapy and drug delivery, to cell separation, magnetotransfection, and even magnetic control of cell signaling pathways.
As varied as these applications are, common to all is the use of relatively simple, chemically synthesized magnetic particles.
But what additional applications might be enabled through the use of precision, microfabricated magnetic particles and / or complexes that benefit from the improved geometrical control common to top-down, lithographically defined structures?
One recent example are new multispectral magnetic resonance imaging (MRI) contrast agents that add not just contrast, but “color”, to MRI through specifically shaped magnetic microparticles with magnetic field profiles that impart unique, distinguishable NMR frequency shifts to the surrounding water[1].
Here we take this work a step further. Since different particle shapes yield different field profiles and associated NMR frequency shifts, a dynamically morphing magnetic microstructure can impart novel, geometrically dependent, dynamically varying NMR frequency shifts.
If the magnetic microstructure is designed to change shape in response to some local physiological or environmental condition, then the resulting change is microstructure field profile can transduce changes in local conditions into quantitative NMR frequency shifts in the surrounding water.
Stimuli-responsive shape-changing magnetic microparticles/structures therefore enable a new class of radio-frequency addressable sensors that can be small (and thus relatively non-invasive), that require neither electrical contact nor optical access, and that can be probed with regular NMR equipment.
In this presentation we will focus on the magnetics behind these new tranducers, demonstrate, as a first example, the ability of such new shape-changing magnetic microstructures to measure local pH levels, and consider their potential for sensing other variables.

Magnetic hyperthermia relies on killing cancer cells by heating biocompatible magnetic nanoparticles under alternating magnetic fields and is envisaged as one of the most promising bids of nanotechnology in cancer therapy. The role of magnetic interactions in nanoparticle systems is still regarded as a complex issue and is not fully understood, particularly in an ever-changing physical and dynamic environment such as that presented during magnetic hyperthermia. Studies of magnetic interactions rely heavily on theoretical models [1,2] and their impact on the heating performance can still not be described with ease by a single measureable characteristic.
We present an experimental study on the occurrence of interparticle interactions in a selected set of commercial and non-commercial [3] samples consisting of single-core and multi-core iron oxide nanoparticles based on the analysis of Henkel plots. The nature and intensity of the interactions are discussed are derived from DeltaM plots and the mean interaction field values estimated for each system. The role played by the core-to-aggregate ratio and the number of constituting cores on the interactions and the effect of the latter on the heating capabilities of the nanoparticles is also discussed. As a rule of thumb, samples with less intense dipole interactions between constituent nanoparticles (intra-aggregate) show better heating capabilities.

Th.P-P08 - Synergy on magneto-plasmonic nanoprobes: Combined magneto-photonic hyperthermia

J.G. Ovejero [1], E. Mazario [2], U. Silva [3], A. Hernando [1], P. Herrasti [2], P. Crespo [1]

3. Department of Physics of Materials, Universidad Autonoma de Madrid, Cantoblanco, Madrid, Spain

The properties of nanoparticles for biomedical applications have been largely improved in the last years [1]. Further development can be achieved by the combination of different functionalities in a single nanoprobe [2]. One very interesting approach to the multifunctionalization is the creation of hybrid nanoparticles by the conjugation of individual nanoparticles. Magneto-plasmonic hybrid nanostructure is a perfect example of a synergetic system which allows the creation of dual methods of imaging, therapy and sensing [3]. The present work studies the conjugation of silica coated nanorods (Au/SiO NR) with magnetic nanoparticles (MNP) based on different types of ferrites and their potential as dual probes for combined hyperthermia.
Both Au/SiO NR and MNP have been individually synthesized to improve their features independently. Afterwards, each part has been complementarily functionalized. On one side, APES was attached to Au/SiO NR surface to reduce their citotoxicity and introduce reactive amine groups. While on the other side, MNP were functionalized with citric and folic acid to create carboxylic groups that allowed the nanoparticle conjugation. Electrostatic and covalent bindings have been compared as mechanism of conjugation. The later has used the EDC/NHS protocol to bond amine and carboxylic groups [4].
Au/SiO NR and MNP has been tested as efficient nanoheaters and currently magneto-photonic hyperthermia system is been used to evaluate heating power of magneto-plasmonic hybrid nanoparticles. The device developed for this purpose is able to apply high frequency AC magnetic fields and infrared radiation in a small volume at the same time. The heat dissipated by the nanoparticles is registered with an infrared camera. Dual hyperthermia presents interesting advantages against the currently used methods.

Magnetic nanoparticles (MNP) can generate heat once exposed to an alternating magnetic field which has been employed in magnetic hyperthermia. MNP are rutinely tested in water based suspentions to determine the specific absoption rates (SAR). However, cell microenvironment can greatly influence the relaxation mechanism of MNP which in turn can decrease the SAR. The aim of this study is to determine the effect of cell microenvironment on magnetic response of MNP. The in situ magnetic response of anionic iron oxide nanoparticles, from water-based suspensions to cell culture media, following their cellular internalization was investigated, using a novel application of AC susceptometry. The results obtained demonstrate that cellular internalisation can disable Brownian relaxation, which has significant implications for designing suitable nanoparticles for intracellular hyperthermia applications. Further, the stability of anionic iron oxide nanoparticles in various biologically relevant solutions was also investigated. The MNP stability was tested in phosphate buffered saline (PBS) with and without foetal bovine serum (FBS) and in different dilutions of PBS to determine the effect of ionic strength, but also the protein coating from FBS, in cell culture media with and without FBS. The aim is to determine the optimal conditions with a view to minimise the clustering of MNP. We observed that the stability of MNP is micro-environment dependant and that the protein corona developed significantly incerases the stability of MNP. Our results also provide evidence that the stability of MNP influences the sedimentation of nanoparticles, which in turn significantly affects cell uptake. AC susceptometry was used to monitor and quantify the uptake of MNP in live cells - a novel non-invasive method that has a potential for monitoring the uptake of MNP in vivo.

Th.P-P10 - NMR as evaluation strategy for cellular uptake of nanoparticles

T. Orlando [1], A. Paolini [2], F. Pineider [3], E. Clementi [2], F. Pasi [2], Y. Guari [4], J. Larionova [4], L. Sacchi [2], R. Nano [2], M. Corti [1]

5. Department of Physics, Università degli Studi di Milano, Milan, Italy

Magnetic nanoparticles of novel synthesis can both improve the efficiency of already existing and widely used clinical techniques, like Magnetic Resonance Imaging or Magnetic Hyperthermia, and work as single multifunctional agents for theranostic purposes. However, despite the engineering background in this field is very advanced, there remain some fundamental problems involving the interaction mechanisms between nanostructures and cells. We studied the cellular uptake of rhamnose-coated magnetic nanoparticles (MNPs) in human tumor (glioblastoma) cells using a new experimental method based on 1H Nuclear Magnetic Resonance relaxation.
After the incubation of the cells with different concentrations of MNPs, transverse nuclear magnetization relaxation process was investigated for each in vitro sample. In particular, 1H-NMR is able to distinguish between the fast relaxing signal (T2,FAST) coming from intracellular protons and the slow relaxing signal (T2,SLOW) from extracellular protons. Given that the T2 value is inversely proportional to the magnetic particle concentration, T2,FAST and T2,SLOW are indirect measurements of the amount of MNPs in the intracellular and in the extracellular environment, respectively. The relaxation data as a function of the MNPs concentration were fitted with a logistic curve and the uptake law for our MNPs was extracted. Furthermore, the weight of each component gives a quantitative estimation of the amount of protons in each biological environment (i.e., intra- and extracellular), allowing to follow the cellular swelling, that is directly connected to the cellular stress due to the injection of an exogenous agent in the biological system. The proposed experimental protocol, which was successfully tested also with gold nanoparticles and antitumor drug on two different cell lines, provides a new way to investigate in a quantitative way the general problem of cellular uptake for a variety of biocompatible nanostructures and drugs.

Th.P-P11 - On the double role of the magnetic anisotropy for magnetic-fluid hyperthermia

D. Serantes [1], K. Simeonidis [3], M. Marciello [1], M. Angelakeris [4], O. Chubykalo-Fesenko [1], M. del Puerto Morales [1]

Achieving a large and well controlled heating performance according to the properties of the biological tissue are crucial milestones in the magnetic-fluid hyperthermia roadmap. Aiming to shed some light in this significant issue, here we report the double role played by the magnetic anisotropy of ellipsoidal magnetite nanoparticles to control both aspects. On the one hand, the increased effective anisotropy of the elongated particles mimics the multiplicative heating performance of chain formation in cell-like biology conditions [1], with the additional benefit of being more robust vs. thermal and/or mechanical forces. On the other hand, with the characteristics of the applied magnetic field it is possible to induce a preferential orientation of the easy magnetization axes of the particles that allows for more a better field-controlled heat release. The particles have average dimensions 250 nm/50 nm long/short axes, i.e. are comparable to the nanoparticle chains for which enhanced performance was observed [1] and, noteworthy, experiments in HeLa cells show no toxicity thus supporting their adequacy for biological use. The combined theoretical work using micromagnetic simulations explains that the unexpected frequency-dependence measured experimentally is due to a non-coherent reversal mechanism. Remarkably, from the comparison between angular-dependent experiments measured after the AC field treatment and simulations it is concluded that the induced preferential orientation of the ellipsoids point perpendicular to the AC field direction. Our results therefore demonstrate that even if Brownian rotation may be negligible regarding heat dissipation [2], it may be crucial in determining the heat dissipated by Néel reversal mechanism.

Th.P-P12 - Synthesis and characterization of magnetic nanogranular Fe_3O_4/biomimetic hydroxyapatite for potential applications in nanomedicine

L. Del Bianco [1], I. Giorgio Lesci [2], G. Fracasso [2], G. Barucca [3], F. Spizzo [4], R. Scotti [5], L. Ciocca [5]

5. Dipartimento di Scienze Biomediche e Neuromotorie, Università di Bologna, Bologna, Italy

A major concern about the biomedical application of magnetic nanoparticles is their biocompatibility. A possible solution is coating them with hydroxyapatite (HA) [Ca5(PO4)3OH], which is the inorganic component of biological hard tissues, e.g. bone and teeth. This approach appears especially appealing for uses in the field of bone tissue engineering.
We have synthetized a novel nanogranular system, consisting of magnetite nanoparticles embedded in biomimetic carbonate HA, through an original two-step method: i) magnetite nanoparticles are prepared by refluxing an aqueous solution of Fe(SO4) and Fe2(SO4)3 in an excess of Tetrabutilammonium hydroxide acting as surfactant; ii) the nanoparticles are coated with a Ca(OH)2 layer, to induce the growth of HA directly on their surface, by reaction of Ca(OH)2 with HPO42-.
Two samples have been collected with magnetite content ~ 0.8 wt. % and ~ 4 wt.%. The magnetite nanoparticles and the nanogranular material have been investigated by X-ray Diffraction, Fourier Transform Infrared Spectroscopy and Transmission Electron Microscopy. These analyses have provided structural information on the as-prepared nanoparticles (mean size ~ 6 nm) and revealed the presence of surface hydroxyl groups, which promote the growth of the HA phase featuring a nanocrystalline lamellar structure. Hysteresis loops (temperature range 5-300 K), thermal and time dependence of the magnetization under different magnetic fields and field dependence of the remanence have been measured by SQUID magnetometer. Both the as-prepared and the HA-coated magnetite nanoparticles are superparamagnetic at T=300 K. However, the magnetization relaxation process is affected by dipolar magnetic interactions of comparable strength in the three samples, also inducing the onset of a collective frozen magnetic regime below T~20 K. The results indicate that the magnetite nanoparticles form agglomerates in the as-prepared state, which are not substantially altered by the HA growth, coherently with the creation of electrostatic hydrogen bonds among the surface hydroxyl groups.

Th.P-P13 - Dynamics of $CoFe_2O_4$ single-core nanoparticles in viscoelastic media

The dynamics of magnetic nanoparticles in time-varying magnetic fields in both the suspended and immobilized state have been extensively studied. In the latter case, the dynamics is determined by the Néel mechanism whereas in the former case Brownian and Néel relaxation can take place. In a Newtonian fluid and provided that the magnetic moments are magnetically blocked, the dynamics can be described by the well-known Brownian time constant with a purely real viscosity. Here we focus on the dynamics of magnetically blocked single-core nanoparticles in a viscoelastic matrix. $CoFe_2O_4$ nanoparticles with a mean core diameter of 15 nm, as determined from TEM and magnetization measurements, and a hydrate shell were dispersed in DI water-gelatin suspensions with gelatin contents between 2.5 and 10 wt%. After equilibrating the sample at 40°C for 60 min - thus being in the sol state - , it was rapidly cooled to 23°C and periodic measurements of the ac susceptibility and magnetorelaxation signal were performed. With increasing gelation time, a systematic shift of the maximum of the imaginary part of the ac susceptibility and a pronounced broadening were observed. In magnetorelaxometry, the characteristic time constant clearly increased. The detailed behavior depends on the given gelatin content and thus the stiffness of the gel matrix. The experimental data are analyzed applying the theoretical model by Raikher et al. [1], providing the temporal evolution of viscosity and shear module during the gelation process. Financial support by the Deutsche Forschungsgemeinschaft, DFG Priority Program 1681 is acknowledged.

4. Institute for Cell Engineering and Regenerative Medicine (ICERM), University of Florida - Florida, United States

Nanomagnetic transfection is a method for delivering genes into a cell using an external magnetic force to increase the interaction between cells and magnetic nanoparticle-DNA complexes. We are developing various functionalized magnetic nanoparticles as carriers for gene delivery. Thermal decomposition, co-precipitation and flame spay methods were used to synthesise the nanoparticles allowing us to obtain different chemical compositions (magnetite, maghemite, metallic iron, and metallic cobalt), various core sizes and magnetic behaviour (magnetically blocked and superparamagnetic). MNPs used for nanomagnetic gene transfection generally consist of iron oxide cores, which respond to external magnetic fields, with cationic polyethylenimine (PEI) polyplexes for DNA adsorption. The particles were functionalized with oleic acid-PEI and citric acid-PEI to obtain different binding efficiencies. The binding and release efficiency of DNA to PEI-MNP was investigated at different pH to mimic conditions in the cell using AC susceptometry. Two oscillating dynamic magnetic systems (magnefect-nano and MICA) that enhances particle/DNA uptake through promotion of endocytosis are being used to investigate the transfection efficiency on different cell types. Future work involves a better understanding of the trafficking of the magnetic nanoparticle-DNA complex in cells when exposed to an oscillating magnetic system.

Th.P-P16 - Synthesis and characterization of surfactant coated superamagnetic iron oxide nanoparticles for various biomedical applications

R. Srinivasan [1], N. Momin [1], A. Deshmukh [2]

1. Department of Physics, University of Mumbai, Mumbai, India
2. Department of Biotechnology, Thakur College, Mumbai, India

We report synthesis of superparamagnetic iron oxide nanoparticles (SPIONs) by simple chemical co-precipitation method followed by coating with surfactant (Polyethylene glycol-6000 and sodium oleate) for future biomedical applications. The synthesized particles are characterized using X-ray diffraction (XRD), Fourier transform infrared spectroscopy (FTIR), Raman, UV-visible, Dynamic light spectroscopy (DLS) and Brunauer-Emmett-Teller (BET) technique for crystal structure, average size, functional group, phase, energy band gap, hydrodynamic size and surface area determination. The surface morphology was studied by Scanning electron microscope (SEM). Magnetic properties of the synthesized particles, viz field and temperature dependent magnetization in zero field cooled and field cooled conditions between 5K-300K and up to fields of 3 Tesla have been investigated by Quantum Design physical property measurement system (QD-PPMS). Analysis of cytotoxicity of the nanoparticles was carried out by examining their effect on cell viability of human peripheral blood lymphocytes so as to assess biocompatibility for various biomedical applications. Sodium oleate coated SPIONs shows better biocompatibility as compared to the uncoated and PEG-6000 coated ones.

Th.P-P17 - Magnetic nanowires and hyperthermia: the influence of geometry and material on heat production efficiency

M.F. Contreras Gerenas [1], A. Zaher [2], J.E. Perez [1], A. Alfahdel [1], L.A.S. de Oliveira [3], K.R. Pirota [4], T. Ravasi [1], J. Kosel [1]

3. Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil
4. Univerdad Estadual de Campinas, Campinas, Brazil

Magnetic hyperthermia, which refers to the production of heat by magnetic nanostructures under an alternating magnetic field (AMF), is very promising using magnetic nanowires (NWs), as they have been shown to have a larger magnetic moment per unit of volume compared to nanobeads. Moreover, Fe nanowires (NWs) proved to have a higher heating efficiency compared to Fe nanobeads, when exposed to an AMF at the same concentration1.
In this work we investigate the dependence of heating power of NWs with of different materials (Fe, Ni, and Co) and diameters (thin, 35 nm and thick, 180-300 nm). NWs with lengths of tens of microns and two different diameters were prepared using a two-step aluminum anodization process followed by electrodeposition2,3. The morphology and composition of the wires are investigated using scanning and transmission electron microscopy. The magnetic properties of the NWs are studied using a vibrating sample magnetometer. After fabrication, NWs are released from the substrate and rinsed with ethanol several times.
The specific absorption rate (SAR) is commonly used to quantify the magnetic heating efficiency. SAR measurements were performed over 30 minutes for different NW concentrations using an inductive heater system that provided a field of 600 Oe at a frequency of 425 kHz. The NWs were suspended in ethanol inside of a thermally isolated tube. The ethanol's temperature was monitored with an optical temperature probe.
The results showed a strong dependence of the heating power on the magnetic properties of the NWs. The NWs with the highest SAR are those with a coercive field equal or lower to the value of the AMF applied. This effect is strongly accentuated in case of Fe and Ni, due to the magnetic single domain behavior4, leading to no hysteresis losses for fields less than the coercive field. Since, the coercive field is strongly controlled by the geometry5, the temperature increase (ΔT) of thin NWs was always lower (< 10°C for Fe) than the one of thick NWs (~40°C, for Fe).

2. Baltic Federal University, Kaliningrad, Russia

Nowadays many industrial and medical technologies use magnetic fields with large magnetic inductions (1-5 T). However the risks arising from human exposure to these fields have not been fully determined and the possible mechanisms of the influence of relatively weak and strong dc and ac magnetic fields on human being are not understood. So it is important to get information on the magnetic field effect on the different human cells. We present our preliminary results on the vital activity of the human mononuclear cells in dc magnetic field with different strength. In the experiments there were used the mononuclear cells of healthy donors. Some experiments in the same conditions were made. The average results for all experiments were analyzed. By flow cytometry method there were evaluated the viability and total number of cells in the samples. The content of pro - and anti-inflammatory cytokines in supernatant cell cultures for all experiments was investigated with enzyme-linked immunosorbent assay. It was found the non-monotonic change of vital activity of investigated cells with magnetic field increase: till magnetic field 2000 Oe it was larger than for control series and for upper field it was less. The content of pro - and anti-inflammatory cytokines in supernatant non-monotonically depended on magnetic field strength. The maximum change with magnetic field for some parameters exceeded 50% of control value. The possible mechanism of these effects is discussed.

Th.P-P19 - A Monte Carlo study of the Susceptibility losses in heating of magnetic core/shell nanoparticles for hyperthermia

M. Vasilakaki [1], K. Trohidou [1], C. Binns [2]

1. Institute of Nanoscience and Nanotechnology, NCSR "Demokritos", Aghia Paraskevi, Attiki, Greece
2. Department of Physics and Astronomy, University of Leicester, United Kingdom

Optimizing the heating properties of magnetic nanoparticles is of great importance for hyperthermia applications[1].
Recent experimental results [2] show that core/shell nanoparticles could give an increased SAR compared to the magnetic oxide nanoparticles currently used.
We have developed a modified phenomenological model based on the linear Néel-Brown relaxation model to calculate the SAR due to susceptibility losses in complex nanoparticles with ferromagnetic(FM) core/ ferrimagnetic(FiM) shell [1]. We use the Monte Carlo simulations technique with the implementation of the Metropolis algorithm to study the effect of the size and shape on the magnetization behaviour of FM/FiM nanoparticles covered by a surfactant layer [3]. The simulations results for spherical, cubic, octahedral and truncated cuboctahedral nanoparticles are used as an input in our modified model for the calculation of the SAR. We find that for all the sizes and shapes the complex FM/FiM nanoparticles give higher SAR values than the pure FiM nanoparticles. For all sizes the nanoparticles with the truncated cuboctahedral shape give the highest SAR values and the cubic the lowest ones. The decrease in the surfactant thickness results in an increase of the SAR values. Our results are in good agreement with experimental findings for Fe/Fe_3O_4 nanoparticles.

Cancer cure schemes are based on accurate diagnosis and treatment protocols that could have minimal side-effects for a patient. For this purpose the scientific community seeks cost-efficient advanced materials that serve the combined role of diagnosis and therapy. However, it is imperative that a so-called theranostic material is characterised in depth for its physical, chemical and biocompatibility properties.
In order to address this challenge, we have developed size-controlled (50-100 nm), water-dispersible clusters of maghemite nanoparticles (NPs), named Colloidal Nanoclusters (CNCs). Characterization techniques (including, HRTEM, X-ray scattering, Mössbauer spectroscopy, SQUID magnetometry), combined with theoretical Monte Carlo simulations have probed the microscopic mechanisms that govern the growth and magnetic behaviour of these CNCs. We have found that such controlled nanoparticle assemblies, display collective magnetic behaviour as an outcome of the intra-cluster dipolar interactions and the intra-particle exchange interactions. Our capability to engineer these interactions has a direct impact on the transverse ^{1}H-NMR Relaxivity (r_2), as well as on the Specific Loss Power for MRI and Hyperthermia applications, respectively. The CNCs show 4-5 times enhanced r_2 (400-500 mM^{-1} s^{-1}) with respect to superparamagnetic contrast agents like the commercial product Endorem (100 mM^{-1} s^{-1}). In addition, the CNCs' ferrimagnetic nature and the corresponding intra-cluster interactions provide the mechanisms for size-dependent, efficient heating response (180-420 W/g). Further on, preliminary incubation experiments of the CNCs with mice spleen cells support the low-cytotoxicity and biocompatibility of these nanosystems. We argue that all the above-mentioned characteristics pave the way for an advantageous multifunctional theranostic agent in biomedicine.

Th.P-P21 - Effect of pulsed magnetic field stimulation on circulatory diagnosis of acupuncture meridian system

H. Sook Lee [1], Y. Shin [1], D. Guwn Hwang [1]

1. Dept. of Oriental Biomedical Engineering, Sangji University, Wonju-si, South Korea

Objectives: Although many previous studies related to acupuncture and magnetic field have been done, much remains unclear [1]. This study was undertaken to examine the effect of pulsed magnetic field stimulus (PMFS) on the circulatory of the acupuncture meridian system (AMS). With recent increasing attention on PMFS as non-invasive medical treatment, diverse studies are being conducted to elucidate its effects on human physiology [2]. According to traditional Chinese medicine (TCM), pericardium meridian (PC) among the twelve AMS is known as 'protector of heart' meridian and its primary function is to control the balance of heart and blood functions. In order to measure quantitatively the change of meridian circulation after PMFS, PC meridian is used due to its efficacy on diseases of the circulatory and nervous system.
Methods: After PMFS on the left side of palm, Galvanic skin response was used to measure MAX/ID score at five acupoints-PC4, PC6, PC7, PC8 and PC9 in PC meridian of the subject's right arm. Ten subjects in their 20s were participated. MAX score means initial reaction for maximum compensation of electrons in the tissue and ID means cell defense capability for maintaining the current state of the cell.
Results and Conclusions: While MAX score was out of normal range of 45-58 before PMFS, it converged to normal range after PMFS. ID score also dropped to zero after PMFS, so it tells smooth blood circulation. Our results showed that more exposure of PMFS provided MAX/ID score to be stable. For application to the circulatory diagnosis of AMS, additional experiments need with optimum conditions of exposure time and intensity of PMF as well as the subjects with heart and blood stagnation disease.

Th.P-P22 - Influence of magnetic nanoparticle surface modification on circulation time

V. Zavisova [1], M. Koneracka [1], M. Muckova [2], N. Tomasovicova [1], J. Kovac [1], M. Kubovcikova [1], I. Antal [1], P. Kopcansky [1]

1. Institute of Experimental Physics, Slovak Academy of Sciences, Kosice, Slovakia
2. Hameln, rds a.s., Modra, Slovakia

Superparamagnetic nanoparticles have great utilization potential in drug delivery, diagnostic biosensors and as contrast agent for magnetic resonance imaging (MRI) as well. Threshold parameter for these applications is their short circulation time in bloodstream, as they are relatively quickly cleared by the reticuloendothelial system (RES). One of the ways to decrease RES clearance and prolong the circulation time is surface modification of magnetic nanoparticles.
Magnetic particles (Fe_3O_4) prepared by chemical coprecipitation method were modified by different biocompatible substances such as poly(ethylene glycol), dextran, and polyvinylpyrrolidone. Prepared samples were characterized by transmission electron microscopy (TEM), dynamic light scattering (DLS) and SQUID magnetometry. Spherical shape of magnetic core with the mean diameter of 10 nm observed by TEM was in agreement with the magnetic core diameter obtained by fitting magnetization measurements by the Langevin function. Further on, our results demonstrate that prepared samples have the hydrodynamic diameter measured by DLS ranging from 53 to 69 nm.
To evaluate the kinetics of magnetic particle uptake by RES, magnetic particles which remained in the bloodstream were detected after blood collection at preselected intervals by measuring their magnetic moment by SQUID magnetometer.
Magnetic moment of the magnetic particles in blood decreased exponentially, magnetic particles were gradually cleared by the RES. The obtained results showed that unmodified magnetic nanoparticles were trapped by RES within 1 hour. On the other hand, the magnetic nanoparticles modified by poly(ethylene glycol), dextran, and polyvinylpyrrolidone circulated in bloodstream up to 3 hours. Prolongation of the magnetic particles blood circulation time achieved by their surface modification has potential in future in vivo applications.

Th.P-P23 - Resonance absorption of microwaves by tissue with ferromagnetic particles

D. Kalganov [1], L. Butko [1], A. Anzulevich [1], D. Pavlov [1]

1. Chelyabinsk State University, Chelyabinsk, Russia

The wide clinical application of remote local microwave hyperthermia for treatment of superficially located malignant tumors allowed to enhance results of the treatment and, at the same time, showed limitations of this method [1]. They include: impossibility of uniform heating of tumors with sizes more than 5 cm, insufficient depth of the heating, skin burns. So, only 50% of cancer tumors of the mammary gland are managed to heat till temperature 42°C. Thus, till half part of the tumors remains insufficiently heated, which reduces effectiveness of the thermoradiotherapy of the cancer.

In order to overcome disadvantages of the local hyperthermia, it is proposed to administer into the tumors ferromagnetic microparticles. Most of these studies are still at an early stage owing to complexity of the calculation of absorption of microwave electromagnetic radiation in tissues with large values of the permittivity and containing of ferromagnetic particles. Investigation of the technical aspect allows to develop a clinically effective system of Microwave hyperthermia[2].

In this work absorption of electromagnetic radiation of range 10MHz-4GHz in system from dielectric matrix (ε = 80) and embedded ferromagnetic particles (carbonyl iron, r = 5μm) are investigated. Dependencies of the absorption factor on the volume fraction of ferromagnetic particles in the range 0-50% are experimentally and theoretically investigated. Dependency of the absorption factor on the size of ferromagnetic particles is theoretically calculated.

The obtained dependencies indicate the presence the wide absorption maximum in the range of electromagnetic radiation 1-2,5GHz. The highest absorption is obtained for composited with 30% volume fraction of ferromagnetic particles. With decreasing particle sizes, broadening of the absorption maximum and shift it into the high frequencies are appeared.

Th.P-P24 - Simulation of magnetocapacitance effect in magnetic elastomers

D. Isaev [1], A. Semisalova [1], E. Kramarenko [1], Nikolai Perov [1], A. Granovsky [1]

1. Lomonosov MSU, Faculty of Physics, Moscow, Russia

In this work we present the results of numerical simulation of magnetocapacitance effect in magnetorheological elastomers - the change of capacity of plane capacitor filled with magnetic elastomer and placed under the external magnetic field. The computer model of effect is based on the assumption about the displacement of magnetic particles inside the elastic matrix under the external magnetic field and the formation of chain-like structures. Such displacement of metallic particles between the planes of capacitor leads to the change of capacity, which can be considered as a change of effective dielectric permittivity of elastomer caused by magnetic field (magnetodielectric effect). In this work we simulated such effect for series of samples varying with concentration of magnetic filler, size and space distribution of particles, elastic properties of matrix. We have found the value of capacity can change up to 4%, the effect tends to saturation and has hysteretic feature due to the elastic response of matrix. The influence of orientation of magnetic field and capacitor plane was studied as well, the change of sign of the effect for parallel and perpendicular orientation was observed which is in perfect agreement with physical model we used as a base. The quantitative discrepancy between simulation and recent experiments results should be noted - the experimental value of effect was found to be up to 80%. Such big difference with simulation can be related to the simplicity of used computer model - we took into account only dipole-dipole interaction between the particles. Nevertheless, the developed model resulted in perfect qualitative agreement with all experimental data obtained earlier for Fe-based elastomers. So, the proposed model is useful to study these novel functional materials, analyze the features of magnetodielectric effect and predict the optimal composition of magnetorheological elastomers for further profound experimental study. Supported by RFBR (15-08-99554, 13-03-00914, 13-02-12443).

Th.P-P25 - Magnetic nanoparticle cryogels as hyperthermia cancer therapeutics

R. Jackson [1], P. Southern [1], J. Sullivan [1], Q. Pankhurst [1]

1. UCL Healthcare Biomagnetics Laboratory, London, United Kingdom

Magnetic hyperthermia is widely thought as a promising cancer therapy in which magnetic nanoparticles are activated by an externally applied alternating magnetic field, releasing therapeutic levels of heat within cancerous tumours. The majority of magnetic nanoparticles are delivered into the body in aqueous form and rely upon the "absorbent" properties of tissue to retain the nanoparticles at the injection site, however cancerous tumours can often be highly vascular and nanoparticle retention cannot be guaranteed.
We present here a method of preparing a magnetic hyperthermia agent in the form of a flexible, facile gel system. These cryogels are biodegradable, non-toxic, gelate physically rather than chemically and can be tuned to degrade back to liquid form at a range of therapeutically useful temperatures. Further simple processes can generate a range of micron sized gel particles which can be composited with other nanoparticle systems, namely magnetic nanoparticles. The combination of these two disparate methods can generate an effective cancer therapeutic that increases adhesion to leaky vascular systems, limits unwanted diffusion to healthy tissue as well as providing a thermally self-limiting system to avoid overheating in the case of particle bioaccumulation.

Th.P-P26 - Preparation and in vitro experiments of carboxymethyl chitosan-coated Fe-Ti-Nb-B micro/nanoparticles for self-controlled magnetic hyperthermia

C. Danceanu [1,2], D.D. Herea [1], K. Palanisamy [1], E. Radu [1], N. Lupu [1], H. Chiriac [1]

2. Department of Physics, "Alexandru Ioan Cuza" University, Iasi, Romania

In this study, Fe-Ti-Nb-B magnetic nanoparticles with low Curie temperature, were embedded in chitosan matrix and used as micro-scaffolds for growing osteosarcoma cells and magnetic hyperthermia tests. The viability of the cells bound to chitosan surface was investigated against control cells before and after treatments in alternating magnetic fields (AMF). The cell viability, measured after incubation with chitosan-coated particles, in AFM-free conditions and against control cells, followed a linear increase from 220 % after 4 hours of incubation to about 450 % after 24 hours of incubation. The coated-magnetic nanoparticles are embedded into the membrane of the osteosarcoma cells, as shown by the investigation performed using an optical inverted microscope. The cells detached from the growth support in the presence of the AMF. This increase of the viability (the chitosan-coated particles offer a good support for the cells growth) is inappropriate for the cellular viability assays with high concentration of coated nanoparticles (10 mg/ml). For this reason and since the solubility of chitosan is low, the magnetic nanoparticles were coated with a chitosan derivate, caboxymethyl chitosan (CMC) and the cells were incubated with nanoparticles for 48 h, using a maximum concentration of 2 mg/ml. CMC is known to have better solubility in water, low toxicity, antimicrobial properties and apoptosis inhibitory ability. The incubation of the cells in the presence of Fe-Ti-Nb-B nanoparticles (40-200 nm in diameter) leads to a viability decrease of 5-10 % for both CMC-coated and uncoated particles. The presence of AMF leads to a temperature increase up to 46°C and a decrease of the cell viability down to 40% was observed. Thus, the chitosan-coated magnetic nanoparticles (especially carboximetil chitosan) could be used as thermo-seeds to kill cancerous cells through self-controlled magnetic hyperthermia and as microscaffolds to mimic a tumor environment, taking also advantage from the magnetic properties of the Fe-Ti-Nb-B particles that allows magnetic manipulation and separation.

Th.P-P27 - Study of the optimal thermal dose in the magnetic hyperthermia with low Curie temperature particles

I. Astefanoaei [1], I. Dumitru [1], H. Chiriac [2], A. Stancu [1]

1. Alexandru Ioan Cuza University, Iasi, Romania
2. Institute of Research & Development for Technical Physics, Iasi, Romania

Magnetic hyperthermia with low Curie temperature particles is a very promising approach in the therapy of cancer. This novel healing method offered to the scientific community convincing reasons for experimental and theoretical studies [1, 2]. The Fe-Cr-Nb-B magnetic particles (MPs) with low Curie temperature (Tc) in range of 42-44 oC have special magnetic and thermal properties for their use in magnetic hyperthermia [3, 4]. This paper analyzes the temperature field induced by the heating of the magnetic particles with low Tc in an ac magnetic field. The particles have a spatial distribution after their injection within the tumor as a result of diffusion and convection. Their spatial distribution near the injection sites (IS) was computed as a solution of the general convection-diffusion equation in a porous tissue. The ferrofluid flow within the tissue was modeled using the continuity and Darcy`s equations. The ferrofluid injection rate during the injection process influences significantly the spatial distribution of the particles and temperature field within tumor. Higher values of the ferrofluid flow rate determine a strong convection of the particles to the tumor center. The FeCrNbB system determines an automatic control of tumor heating. The temperature field increases from 37oC to the Curie temperature of the particles which becomes the maximum temperature within tumor (Fig.1). The heating of tumor can be managed by controlling the Curie temperature of the MPs. Small quantities of ferrofluid 0.1 - 0.3 cm3 and implicitly a small dosage of Fe-Cr-Nb-B particles per unit gram of tumor determine a temperature rise in the therapeutic temperature range in a tumor. The ferrofluid injection rate influences significantly the spatial distribution of the particles within tumor. The FeCrNbB systems open new borders in the application of the magnetic hyperthermia with low Curie particles in the cancer therapy.

Th.P-P28 - Bendable probes integrating ultrasensitive magnetoresistive sensors for local field detection in neurosciences

J. Valadeiro [1], J. Amaral [1], J. Gaspar [2], R. Ferreira [2], S. Cardoso [1,3], P. Freitas [1,2]

1. INESC - Microsistemas E Nanotecnologias, Lisbon, Portugal
2. International Iberian Nanotechnology Laboratory, Braga, Portugal
3. Instituto Superior Tecnico, Universidade de Lisboa, Lisbon, Portugal

Recently a wide range of customized spintronic devices has been developed for biomedical applications [1]. In particular, the detection of neuronal activity has been pointed as a key application where the use of magnetoresistive sensors can offer unmatched advantages for local field detection [2], combined with small footprint, portability and room temperature operation [3]. The probe's design can be adapted to match the requirements of a neurological experiment, where the substrate flexibility allows a more adaptable tool able to reach further within the signal sources and thus provide in-situ detection of ultra-small local magnetic fields (pTesla range).
Giant magnetoresistive (GMR) sensors based on $Ni_{80}Fe_{20}$ 3.5/$Co_{80}Fe_{20}$ 2.3/Cu 2.3/$Co_{80}Fe_{20}$ 2.3/$Mn_{76}Ir_{24}$ 8.0 stacks and tunneling magnetoresistive (TMR) sensors $Ir_{20}Mn_{80}$ 7.5/$Co_{70}Fe_{30}$ 2/Ru 0.85/$Co_{40}Fe_{40}B_{20}$ 2.6/MgO>1/$Co_{40}Fe_{40}B_{20}$ 3/Ta 0.21/$Ni_{80}Fe_{20}$ 16 (thickness in nm; alloy compositions in %) were used. These structures were incorporated in micromachined Si probes with different thicknesses (700um to 50um), allowing tunable flexibility. Si-probes were designed with two different tip configurations: (i) sharp tip (18‖) for in-vivo experiments, to penetrate the brain and place the sensors near field sources; (ii) flat tip (104‖) for in-vitro measurements, to place sensors on top of a brain slice without damage. The Si-probes showed a maximum bending induced stress of 300MPa, and a single TMR element with integrated flux guides (Co93Zr3Nb4) displayed TMR=179% and sensitivity of 264%/mT. Also, a detection level of 30pT/sqrt(Hz) at 1kHz was demonstrated in partially bendable Si-probes competing with rigid technologies. The bending impact on sensor performance was evaluated, under controlled bending tests and also upon penetration into tissues/viscous media. The sensor characteristics (sensitivity, noise levels) was correlated with the Si-probe mechanical robustness. The results can provide guiding lines while selecting the optimum probe thickness for in-vivo/in-vitro experiments.

Th.P-P29 - Magnetic properties and microstructures of polymer functionalized Fe_3O_4 nanoparticles-enhanced surface plasmon resonance (SPR) biosensor

E. Suharyadi [1], S. Nuzully [1], T. Kato [2], S. Iwata [2], K. Abraha [1]

1. Department of Physics, Gadjah Mada University, Yogyakarta, Indonesia
2. EcoTopia Science Institute, Nagoya University, Nagoya, Japan

Surface plasmon resonance (SPR)-based biosensor is known to be a sensitive, simple and label free optical method for detecting biomaterials that is able to do quantitative detection. For some application, biomolecules-coated magnetic nanoparticles (MNPs) are used to enhance the signal of SPR spectroscopy. Here, we report the magnetic properties of magnetite (Fe_3O_4) MNPs functionalized by polyethylene glycol (PEG-4000) polymer as SPR enhancing agents. Fe_3O_4 MNPs with various particles size of 11-20 nm have been chemically synthesized by co-precipitation method using $FeSO_{4.7}H_2O$ and $FeCl_{3.6}H_2O$ with ratio 1:2. The results of X-ray diffraction (XRD) and transmission electron microscopy (TEM) confirmed that Fe_3O_4 MNPs have cubic inverse spinel structure with homogeneously spherical shape. Fe_3O_4 MNPs with smaller grain size has higher response to external magnetic field and low coercivity (Hc). The saturation magnetization (Ms) Fe_3O_4 with particle size of 14 nm is 70 emu/g and then decreased by the increase of PEG-4000 concentration. Ms of PEG-coated Fe_3O_4 with 20% and 50% PEG is 60 emu/g and 37 emu/g, respectively. However, the coercivity is almost constant of about 60 Oe. The bonding analysis by Fourier transform infrared spectroscopy (FTIR) shows that surface of Fe_3O_4 MNPs can be modified with PEG-4000. The covalent bond Fe-O has been created by Fe atoms of Fe_3O_4 and O atoms of PEG-4000. It is well known that the magnetic properties of Fe_3O_4 MNPs are dependent on the particle size, morphology, crystal structure, and concentration of coating agents (PEG-4000). In addition, SPR signal has been investigated in Fe_3O_4 MNPs coated by PEG-4000 and alpha-amylase. FTIR analysis also shows that Fe_3O_4 functionalized by PEG-4000 layer can bind alpha-amylase effectively. Fe_3O_4 MNPs with smallest grain size and highest Ms have great potency to improve the performance of SPR-based biosensor.

Th.P-P30 - Protein influence on MRI contrast properties of magnetite nanoparticles

O. Strbak [1], D. Gogola [1], L. Baciak [2], A. Krafcik [1], M. Masarova [1], I. Antal [3], M. Kubovcikova [3], M. Koneracka [3], V. Zavisova [3], P. Kopcansky [3]

3. Institute of Experimental Physics SAS, Kosice, Slovakia

Proteins are biomarkers of many serious diseases (e.g. inflammation, cancer), and their changes in concentration levels are associated with various pathological processes. Our aim is to find out whether the presence of proteins could have an influence on the contrast properties of MRI contrast agents, affecting such desired contrast information. Secondly, it is to find the possibility for specific protein imaging in combination with contrast imaging of tissue, providing such simultaneous information about the presence of biomarker and tissue pathology, without additional invasive diagnostics.
Our model system consists of BSA as a specific protein, and magnetite nanoparticles stabilized with PEG as a carrier. MRI measurements were performed on 4.7 T (VARIAN) and 0.2 T (ESAOTE) systems. Images were acquired with standard T2 weighted protocols, and relative contrast, T2 relaxation time, and relaxivity r2 were evaluated and compared.
The best interval for contrast imaging of our model system is in range of 4-60 μg/ml. Relative contrast of nanoparticles with and without BSA shows difference up to 20 %, affecting such signal in rate visible also to the naked eye. Differences in T2 are as follows (magnetite concentration [μg/ml] - relative T2 [%]): 0.5-19; 1-36; 2-7; 4-0.6; 7-10; 15-5; 30-1.5; 60-3; 120-2. The relaxivity values of nanoparticles are 358.73 ± 1.4 mM-1s-1 without BSA, and 375.16 ± 3.2 mM-1s-1 with BSA.
We showed that BSA protein influence the MRI contrast properties of magnetite nanoparticles in significant way without special optimization procedures (in the best imaging interval in rate up to 20 % for relative contrast, and up to 10 % for relative T2). On the one side, it can affect the desired contrast information from contrast agents, but on the other side, it have potential to provide the information about the presence of biomarker together with tissue pathology, without additional stressful diagnostics.

Th.P-P31 - Magneto-plasmonic nanoparticles as theranostic platforms for magnetic resonance imaging, drug delivery and NIR hyperthermia applications

I. Urriés [1,2], C. Muñoz [1,2], L. Gómez [1,2], C. Marquina [3,4], V. Sebastián [1,2,4], M. Arruebo [1,2,5], J. Santamaría [1,2,5]

PEGylated magneto-plasmonic nanoparticles consisting in a continuous but porous Au nano-shell with a hollow or semi-hollow silica interior containing magnetic cores have been successfully synthesized. Their physico-chemical characteristics have been exhaustively investigated, by means advanced electron microscopy techniques as TEM and STEM imaging, and EDS-HAADF analysis, and by UV-VIS-NIR spectroscopy, among others. The magnetic characterization has been performed by magnetization and relaxivity measurements.
The hollow interior space can be used to store drugs or other molecules of interest, whereas their magnetic characterization shows their potential as contrast agents in magnetic resonance imaging (MRI) applications. In addition, their plasmonic characteristics in the near infrared (NIR) region make them efficient in photothermal applications producing high temperature gradients after short irradiation times.
We have seen that by controlling the etching conditions the inner silica shell can be selectively dissolved to achieve a hollow or semi-hollow interior without compromising the magnetic or plasmonic characteristics of the resulting nanoparticles. Magnetic measurements (in particular relaxivity measurements) and transmission electron microscopy observations have been used to demonstrate the precise control during the etching process. At this respect, the use of these techniques has been crucial to select the optimal concentration of the etching reagent and contact time to preserve the inner superparamagnetic iron oxide nanoparticles and the plasmonic properties of the constructs.
Drug loading capabilities have been also evaluated for both semi-hollow and as-synthesized nanoparticles using Rhodamine B isothiocyanate as a model compound. The results have shown that our nanoparticles could be potentially used as “theranostic” nanoparticles, with both imaging capabilities and a dual therapeutic function (drug delivery and hyperthermia).

Ferrofluids based on Zn-Mn ferrite nanoparticles constitute promising nanomaterials for heat-exchange applications such as in liquid cooling system by mean thermomagnetic effect and also as heat sources in magnetic fluid hyperthermia. Aqueous ferrofluids based on $Zn_xMn_{(1-x)}Fe_2O_4$@γ-Fe_2O_3 nanoparticles were synthesized by a well proven chemical route [1] (coprecipitation followed by a surface treatment). The produced nanomaterials were characterized by chemical analysis, TEM and X-ray powder diffractogram. Magnetization measurements were performed in a VSM magnetometer for diluted fluid samples (Φ <1%). The magneto-induced birefringence was also measured as a function of the external field. In both cases, the Langevin´s formalism is applied and allows the determination of size distribution characteristics, particles magnetization and birefringence. Through DC magnetization measurements performed under ZFC procedure we obtained the temperature dependence of the magnetization in a small applied field. The curves, typical of superparamagnetic behavior, present a maximum at a temperature related to the blocking temperature. The extracted values of the anisotropy constant are approximately two orders of magnitude larger than bulk values, probably due to a surface contribution to the magnetic anisotropy. Finally, we investigated SLP in hyperthermia measurements and the pyromagnetic coefficient of nanoparticles by measuring the thermal dependence of the magnetization above 300K. Both values show that our samples are suitable for heat exchange applications. In particular the SLP values could be increased by using the exchange coupling between a hard ferrite core and a soft ferrite shell or vice versa [2].

Th.P-P33 - Biodegradation of PolyChlorinated Biphenyls (PCB118) by SPION coated microbial cells of Pseudomonas mendocina

Radha S. [1], A. Kothare [2], A. Surti [2]

1. Department of Physics, University of Mumbai, Mumbai, India
2. Department of Microbiology, Sophia College, Mumbai, India

Polychlorinated biphenyls (PCBs) are mixtures of chlorinated hydrocarbons that have been used extensively in various industries as dielectrics, as heat exchange fluids, as paint additives and in plastics. The toxicology of PCBs is affected by the number and position of the chlorine atoms. Some of the established remedial technologies for their removal from the environment like incineration, solvent extraction, thermal desorption etc are not cost effective; hence the industries generating PCB containing wastes are tempted to discard these residues without treatment into soil or water. Bioremediation using microorganisms (free or immobilized) can be used as a biofriendly method for removal of PCBs from the environment. A novel bacterial strain degrading PCB 118 was isolated from soil identified as Pseudomonas mendocina strain CL-10.4. by 16S rRNA sequence analysis. PCB degrading activity was checked by GC-MS analysis and Enoic acids, Acetophenones, Acetic acids were degradation products. Pseudomonas mendocina cells were coated with magnetic Fe_3O_4 nanoparticles or SPIONs (Superparamagnetic Iron Oxide Nanoparticles), immobilized by external application of magnetic field. The ferrite nanoparticles synthesized by chemical co-precipitation were monodispersed in aqueous solution with an average size of 9.56 nm, magnetization of about 15emu/g and near zero coercivity indicating that the Fe_3O_4 nanoparticles had superparamagnetic properties. Degradation of PCB 118 by free and coated cells of this bacterium was studied. The rate of degradation of PCB118 coated cells was at par to the free cells with advantage of magnetic separation and possible reuse for second batch of PCB degradation.

Th.P-P34 - Interaction of superparamagnetic nanoparticles and quantum dots with pathogenic fungi: internalization and toxicity profile

For several years now, nanoscaled materials have been implemented in biotechnological applications related to animal (in particular human) cells and related pathologies. However, the use of nanomaterials in plant biology is far less widespread, although their application in this field could lead to the future development of plant biotechnology applications. For any practical use, it is crucial to elucidate the relationship between the nanomaterials and the target cells. In this work we have evaluated the behavior of two types of nanomaterials, superparamagnetic nanoparticles and quantum dots, on Fusarium oxysporum, a fungal species that infects an enormous range of crops causing important economic losses and is also an opportunistic human pathogen [1].
Our results indicated that both nanomaterials rapidly interacted with the fungal hypha labeling the presence of the pathogenic fungus, although they showed differential behavior with respect to internalization. Thus, whereas magnetic nanoparticles appeared to be on the cell surface, quantum dots were significantly taken up by the fungal hyphae showing their potential for the development of novel control approaches of F. oxysporum and related pathogenic fungi following appropriate functionalization.
In addition, the fungal germination and growth, accumulation of ROS, indicative of cell stress, and fungal viability have been evaluated at different nanomaterial concentrations showing the low toxicity of both types of nanomaterials to the fungus. This work represents the first study on the behavior of quantum dots and superparamagnetic particles on fungal cells, and constitutes the first and essential step to address the feasibility of new nanotechnology-based systems for early detection and eventual control of pathogenic fungi.

Th.P-P35 - Resonance frequency of alternating magnetic field stimulus on proliferation suppression of rat basophilic leukemia cancer cells

H. Park [1], J.Y. Lee [1], S. Kim [1], E. Cheong [2], H.S. Lee [1], D.G. Hwang [1]

1. Department of Oriental Biomedical Engineering, Sangji University, Wonju, South Korea
2. Department of Biotechnology, Yonsei University, Seoul, South Korea

Frequency dependence of alternative magnetic field stimulus on proliferation of rat basophilic leukemia (RBL-2H3) cancer cells was investigated in the intermediate frequency of 500 Hz to 2 kHz. To keep constant field intensity of 5 mT as the frequency increases, we developed the switched-mode power supply with insulated gate bipolar transistor and a digitally controlled circuit which modulates a duty ratio. The alternative pulse magnetic field has a sawtooth waveform with time duration of 100 μsec. The coil temperature of our designed stimulus system have been maintained at 37℃ in incubator using a cooling system as the frequency increased. The 6-well culture plate was placed on the coil, and the cell temperature during the stimulus did not exceed 37±1.0 ℃. The RBL-2H3 cells were cultured under applied magnetic field during 24 hour, and its cell morphologies and proliferation rates were analyzed. For reliability of this study, we tried to repeat the experiments 4 - 6 times during 6 months. After the cells were stimulated at 500 Hz and 2 kHz, the proliferation rates of stimulated cells were almost same as that of control cells. However, the proliferation rates in the range of 1 kHz - 1.4 kHz were suppressed up to 78 - 74% compared with control cells. And proliferation suppression of the cancer cell was found at a special frequency of 1 kHz. Further studies need to clarify physiological mechanism at this frequency. To investigate the biological change in protein after magnetic stimulus, we measured Western Blot analysis at this frequency, and found the level of ERK1/2, which is related to growth regulated protein, was much reduced than that of control cells.

Th.P-P37 - MRI tracking of the magnetite nanoparticles encapsulation in PLA spheres

M. Koneracka [1], I. Antal [1], M. Kubovcikova [1], V. Zavisova [1], O. Strbak [2], D. Gogola [2], L. Baciak [3], A. Krafcik [2], M. Masarova [2], P. Kopcansky [2]

1. Institute of Experimental Physics, Slovak Academy of Sciences, Kosice, Slovakia
2. Institute of Measurement Science, Slovak Academy of Sciences, Bratislava, Slovakia
3. Faculty of Chemical and Food Technology, Slovak Technical University, Bratislava, Slovakia

Poly (D, L-lactide) (PLA) based polymers are currently widely used in biomedical applications, mainly because of their excellent biocompatible, and biodegradable properties. Although the general properties of PLA-based magnetic carriers are quite well described, there is lack of information about contrast properties of such carriers in MRI applications. We studied the relative contrast, transverse relaxation time (T2), and transverse relaxivity (r2) changes induced by different magnetite nanoparticles loading into PLA nanospheres. PLA-magnetite carriers were prepared by a modified nanoprecipitation method. Prepared PLA samples were divided into three groups: (i) PLA without magnetite nanoparticles, (ii) PLA with non-encapsulated magnetite nanoparticles (exterior particles), and (iii) PLA with encapsulated magnetic nanoparticles (interior particles). The last group of PLA samples was prepared with different magnetic nanoparticle input concentration (2, 5, 7, 17, 30 mg/ml), resulting in diverse loading factor of magnetic nanoparticles into PLA. MRI measurements were performed on 4.7 T system. Images were acquired with T2-weighted Multi Echo Multi Slice (MEMS) sequence. Transverse relaxation time T2 was obtained spectroscopically. Relative contrast (RC= [I - I0]/I0), relaxation time T2, and relaxivity r2 (R2 = r2C + R20) values were evaluated and compared. We found that PLA itself has negligible influence on relaxation properties of medium, as well as on contrast properties of magnetic nanoparticles. The studied MRI parameters (relative contrast, T2, r2) of the magnetic nanoparticles encapsulated in PLA showed that we are able to distinguish between loaded and non-loaded nanoparticles, as well as to determine the rate of encapsulation.

Th.P-P39 - Magnetrodes: Exploring the neuromagnetic field at the cellular level

L. Caruso [1], V. Trauchessec [1], J. Tréjo Rosillo [1], E. Paul [1], C. Fermon [1], G. Ouanounou [2], A. Mikroulis [2], F. Barbieri [2], T. Bal [2], A. Destexhe [2]

1. SPEC - CEA Saclay, Gif-sur-Yvette, France
2. UNIC-CNRS Gif-sur-Yvette, France

We have developed a new generation of neuroscience tools able to detect the electromagnetic signature of neurons at local scale under stimulation. We use Giant Magneto-Resistive sensors (GMR) based on spin electronics, which offer the possibility to be miniaturized and sensitive enough to probe very small magnetic fields like those emitted by the ionic currents flowing within neurons at cellular scale (in the picotesla to nanotesla range).
The probes developed called 'magnetrodes', as magnetic counterpart of elctrophysiological electrodes, are composed of two GMR sensors with an electrode allowing recording both magnetic and electric components at local scale. Some probes are planar, for recordings at mesoscale, and other probes with a needle shape are dedicated to microscopic scale. In this second type of probes, the sensors are located on a sharp tip allowing penetrating easily in brain's tissues.
These magnetrodes reach sensitivity ranging from 3 to 12%/mT with a field level detectivity of between 50pT to 1nT/sqrt(Hz) at 100Hz, depending on the probes type. We have tested the probes in-vitro and we present the first magnetic recordings obtained.
We have also investigated the response of a neuronal array in a hippocampus slice to a magnetic stimulation and recorded responses by means of electrical recordings in the extracellular medium. Here, we will describe the first probes that have been fabricated for the in-vitro and in-vivo experiments, show results of the first magnetic recordings and responses to magnetic excitation in small assemblies of neurons.

FR.A-P01 - Topological insulators in random magnetic fields

H. Fehske [1], A. Pieper [1], I. Orue [2]

1. Intitute of Physics, University Greifswald, Greifswald, Germany
2. University of The Basque Country, Leioa, Spain

We study the effect of random magnetic fields on the two-dimensional surface state of three-dimensional topological insulators. To this end we investigate a minimal four band model (describing weak, and strong topological insulators, as well as conventional band insulators), which is completed by terms that allow for the breaking of inversion symmetry by magnetic fields and the Zeeman effect [1]. Calculating the local density of states, the single-particle spectral function, and the conductance for a (contacted) slab geometry by exact numerical techniques based on the kernel polynomial method, we analyse how field-randomness affects the ground-state, spectral and transport properties of the resulting insulating massive Dirac fermion state. We establish a relationship to experimental angle-resolved photoemission results for magnetically doped topological insulators [2]. The effects of (nonmagnetic) surface disorder will be discussed too [3].

4. Department of Physics and Astronomy, Seoul National University, Seoul, South Korea

We have demonstrated that the evolution of the two-dimensional electron gas (2DEG) system at an interface of metal and the model topological insulator (TI) Bi_2Se_3 can be controlled by choosing an appropriate kind of metal elements and by applying a low temperature evaporation procedure. In particular, we have found that only topological surface states (TSSs) can exist at a Mn/Bi_2Se_3 interface, which would be useful for implementing an electric contact with surface current channels only. Based on the ARPES and core-level x-ray photoemission spectroscopy measurements, we propose a cation intercalation model to explain our findings.

FR.A-P03 - Topological surface states in $SrIrO_3$ based interfaces

W. Fan [1], Y. Sun [2], S. Yunoki [1,3,4]

1. Computational Condensed Matter Physics, RIKEN, Wako, Saitama, Japan

Recently, perovskite oxide SrIrO3 has been proposed to be a topological semimetal hosting a Dirac point in its bulk band structure protected by crystal symmetry [1][2]. The surface states, depending on different directions, shows either a flat band ([110] surfaces) or Dirac cone ([001] surfaces) protected by either mirror symmetry or time reversal symmetry.
However, due to the metallic nature of bulk, there are mixed density of states of bulk states and topological edge states in all the Fermi surfaces. This severely impeded the observation of edge states for this material.
We propose several $SrIrO_3$ based interfaces by using DFT calculations together with constructing minimum Hamiltonian models. The topological surface states are explored by building slabs along different crystal directions based on maximally localized Wannier orbitals. We choose several heterostructures based on different surfaces of $SrIrO_3$ and show the Dirac cone edge mode can be differentiated out from bulk states. By this means, it will be much easier to discern by experimental tools such as STM or ARPES. Finally, we would like to comment on possible ways to realize other topological phases inherent in this 5d transition metal oxide.

FR.A-P04 - Metal-insulator transition in $NdNiO_3$ by hydrogen doping

C. Oh [1], S.Y. Heo [1], H.M. Jang [1], J. Son [1]

1. Postech, Gyeongsangbuk-do, South Korea

The rare-earth nickelate is perovskite oxide which is sensitive to the orbital occupancy of electrons. The corner sharing NiO_6 octahedra experience charge disproportionation in order to stabilize the $t_{2g}^6e_g^1$ electrons leading Ni^{4+} $t_{2g}^6eg^0$ and Ni2+ $t_{2g}^6e_g^2$ configuration. Recently, hydrogen is reversibly intercalated in $SmNiO_3$ leading band gap modulation and giant resistance switching. The electron configuration of hydrogen doped $SmNiO_3$ is modified from Ni^{3+} t_{2g}^6 e_g^1 to Ni^{2+} $t_{2g}^6e_g^2$ and it suppresses charge disproportionation of NiO_6 octahedra. It opens up new directions to explore emerging electronic devices with nickelate systems. Here we report a giant resistance change in $NdNiO_3$ epitaxial thin films by hydrogen doping. We prepared 25 nm-thick $NdNiO_3$ thin film by pulsed laser deposition (PLD). Pt top electrode is utilized as hydrogen dissociating catalyst. Clear metal-to-insulator transition was observed by color change in hydrogen-treated $NdNiO_3$ thin films. Electrical characteristic shows the giant change of resistance. X-ray diffraction (XRD) and atomic force microscopy (AFM) datum indicate that the perovskite structure is maintained during hydrogenation accompanying unit cell expansion. We demonstrated the resistance change is related to doping concentration of hydrogen and lattice strain.

FR.A-P05 - Majorana fermions in the superconducting island

R. Akzyanov [1,2,3], A. Rakhmanov [1,2,3], A. Rozhkov [2,3]

1. All-Russian Research Institute of Automatics, Moscow, Russia
2. Moscow Institute of Physics and Technology, Moscow, Russia
3. Institute for Theoretical and Applied Electrodynamics, Moscow, Russia

We investigate the properties of the edge states in the cylindrical superconducting island placed on the surface of the topological insulator in the magnetic field. We found that the Majorana fermions arise in such a system if the number of the flux quanta (vorticity) in the island is odd. The Majorana states are localized near the center of the vortex core and near the island edge. If the vorticity is even or there is no vortex in the island the Majorana states in the system are absent. We study the case of the single vortex in the island in details. We found that splitting between edge and vortex Majorana fermions is exponentially smal regard to the radius of the island. We analyze the robustness of the Majorana fermion at the edge of the island. The stability of the states versus gate voltage should be performed to distinguish the edge Majorana fermion from conventual Dirac fermions. We found that the energy gap between edge Majorana fermion and the first excited state is of the order of superconducting gap induced at the surface of the topological insulator for the typical parameters value.

FR.A-P06 - Local magnetoresistance at an interface between a ferromagnetic metal and a three dimensional topological insulator due to the spin-momentum locking

Y. Ando [1], T. Hamasaki [1], F. Yang [2], M. Novak [2], S. Sasaki [2], K. Segawa [2], Y. Ando [2], M. Shiraishi [1]

1. Kyoto University, Kyoto, Japan
2. Osaka University, Osaka, Japan

Surface state of the three-dimensional (3D) topological insulators (TIs) has been expected to represent the spin-momentum locking, i.e., spin quantization axis of the conduction electron in the TI surface state is perpendicularly locked to the carrier momentum.[1,2] Due to the spin-momentum locking, it is expected that charge current naturally induces spin polarization, whose axis and the sign can be controlled by the direction of the charge flow. Therefore, magnetoresistance at an interface between ferromagnetic metal and TI, caused by a spin polarized current in TI surface state has been expected.[3] In this presentation, we report successful detection of the local magnetoresistance at a ferromagnetic $Ni_{80}Fe_{20}$(Py) film / a bulk-insulating TI, $Bi_{1.5}Sb_{0.5}Te_{1.7}Se_{1.3}$ (BSTS) interface. BSTS have been used to demonstrate the surface-dominated transport in this compound,[4] and the ARPES study has confirmed its Fermi level to be located in a bulk band gap,[5] realizing the intrinsic insulating state. In the magnetoresistance measurement, we observed a rectangular hysteresis behavior which is governed by the resistance at the interface between BSTS and the Py electrode. The interface resistance changed both with the magnetization direction of the Py electrode and with the current direction. This magnetoresistance disappeared when the BSTS device was heated to 300 K. Spin polarization of injected (extracted) spin current into (from) TI was estimated to be 0.05~0.5 %.

FR.A-P07 - Structure and induced stress of Fe on Bi_2Se_3(0001)

K. Novakoski Fischer [1], S. Ouazi [1], A. Cavallin [1], V. Sevriuk [1], D. Sander [1], J. Kirschner [1]

1. Max Planck Institute of Microctructure Physics, Halle, Germany

The topological insulator Bi_2Se_3 has attracted an intense research activity since its discovery 5 years ago [1]. This is also due to the novel physics arising when doping Bi_2Se_3 with ferromagnetic impurities [1-3]. A detailed description of the stress change of Bi_2Se_3 upon Fe deposition may help to settle the debate about the distribution of magnetic atoms within the host material [4], and ultimately lead to an improved understanding of phenomena such as the topological magnetoelectric effect or the half-quantum Hall effect which are relevant to the design of new spintronic devices [2]. Here we present the first experimental study of the stress change induced by deposition of Fe on Bi_2Se_3(0001). Deposition of 0.2 ML Fe at 300 K induces a compressive stress change of -2.3 N/m. Deposition of Fe at 150 K leads to a much smaller stress change of the order of -0.1 N/m, whereas deposition at 473 K induces a stress change of -3.4 N/m. Low energy electron diffraction (LEED) reveals that the hexagonal diffraction pattern of the substrate gets blurred for Fe deposition at 150 K, whereas deposition at higher temperature of 473 K induces faint diffraction spots indicative of the formation of orthorhombic FeSe. Post-deposition annealing of films deposited at 300 K, at 600 K for 30 min triggers the formation of FeSe, as confirmed by our LEED and STM measurements. We discuss the stress results in view of a previous STM study on sub-monolayer deposition of Fe [3] and in view of epitaxial misfit between orthorhombic FeSe and hexagonal Bi_2Se_3.

4. Radboud University, Nijmegen, The Netherlands

The materials with strong electron correlations are important because of the fundamental properties, and the technological applications. Recently, Sm and Pu hexaborides were proposed as 3D topological insulators. The electronic structure calculations are performed combining the LDA with an exact diagonalization of the Anderson impurity model for [Sm,Pu]B6. For the Sm atom in Sm hexaboride, intermediate valence ground state (GS) is found with the f-shell occupation of 5.6. The GS is a singlet, and the first excited triplet state 3 meV higher in the energy. The f-orbital density of states is in agreement with experimental PE spectra. It is a narrow band insulator already in LDA, with the direct band gap of 10 meV. The electron correlations increase the band gap which now becomes indirect.
For the Pu atom in Pu hexaboride, we also find intermediate valence singlet GS.
The LDA yields indirect band insulator with the band gap of 60$meV, which becomes direct when the electron correlations are included. The calculations illustrate that
many-body effects are relevant to form the indirect band gap, and support the idea of "topological Kondo insulator" in SmB_6.

FR.A-P09 - Low-energy muSR study on the tetradymite topological insulator $Bi_{1.5}Sb_{0.5}TeSe_2$

K. Matsui [1], T. Goto [1], T. Adachi [1], T. Ohtsuki [1], H. Tu [2], Y. Tanabe [2], I. Watanabe [3], Z. Salman [4], A. Suter [4], T. Prokscha [4]

The surface state of three dimensional topological insulators is characterized by a Dirac-cone dispersion which has been claimed to have a helical spin texture, where the spin vector points parallel to the surface and perpendicular to the momentum ("spin-locking"). However, the Kramers-degeneracy prevents it to be detected by magnetic resonance techniques, because of the cancellation of hyperfine field within the surface. We have addressed this problem by applying a weak field B_par parallel to the sample surface, which is expected to break the time-reversal symmetry and hence induce a spin cant, which must cause a finite local field perpendicular to the surface. The necessary field strength of B_par is roughly estimated to be 40 Oe from the criterion that the magnetic flux lines penetrate each coherent wave packet of conduction electrons, a typical size of which is determined by the inelastic scattering length to be 1 micron at 2 K.
We have applied this method on the quaternary tetradymite topological insulator $Bi_{1.5}Sb_{0.5}TeSe_2$, and investigated the effect of B_par by utilizing the low-energy muon spin relaxation (LE-μSR) at PSI. The sample was 60 nm-thick film on a mica plate. The incident muon energy was set 1 keV, at which approximately 50 percent of muons stop within the surface layer of 10 nm. Under the B_par of 100 Oe, the muon spin relaxation at 5 K was revealed to contain the two components, the TF-oscillating part and the anomalously-fast relaxing part with tau \simeq 0.028 \mu sec. The fraction of the latter showed significant dependence on the incident muon spin direction and took maximum of 50 percent when the muon spins were set perpendicular to both B_par and the muon momentum. This fast relaxation may be caused by a large hyperfine coupling due to the Fermi-contact interaction, and possibly reflects to the anomalous surface spin state in the topological insulator.

FR.A-P11 - Rotation effect of RuO_6 octahedron at the Sr_2RuO_4 surface on thermal transport properties

Y. Imai [1], K. Wakabayashi [2], M. Sigrist [3]

1. Saitama University, Saitama, Japan
2. National Institute for Materials Science, Ibaraki, Japan
3. ETH Zurich, Zurich, Switzerland

Motivated by superconductivity in Sr_2RuO_4 we investigate the thermal transport properties for a chiral p-wave superconductivity. It is well known that the low-energy properties of bulk Sr_2RuO_4 include three bands, the alpha, beta and gamma bands. The bulk Fermi level of the gamma band is close to a Lifshitz transition. The surface reconstruction doubling the unit cell occurs due to the RuO6 octahedron rotation at c-axis oriented surfaces of Sr_2RuO_4. Since the rotation effect gives rise to the change of the Fermi surface topology, the topological property characterized by the so-called Chern number depends on the Fermi surface structure of the gamma band. While the Chern number switches at the Lifshitz transition, the chiral edge current resulting from time-reversal symmetry violation in the chiral p-wave phase is essentially unaffected around Lifshitz transition [1]. To observe the topological property directly, we consider the thermal transport property by means of the tight-binding model with electron-like Fermi surfaces corresponding to the gamma bands of Sr_2RuO_4 within a self-consistent Bogoliubov-de Gennes approach. We focus on the interplay between the topological aspect and the lattice distortion effect, and demonstrate that the thermal conductivity consists of the temperature-linear term and exponential term and thermal conductivity is directly associated with the Chern number and the gap function.

FR.A-P13 - Topological phase transitions in extended Hubbard-type models at half filling

S. Ejima [1], F. Lange [1], H. Fehske [1]

1. Institute of Physics, University Greifswald, Greifswald, Germany

At present symmetry-protected topological (SPT) phases attract a major attention in the physics of low dimensional systems. An example is the odd Haldane (OH) phase in the spin-1 XXZ chain [1]. Interestingly all the spin-1/2 ladder system, the extended Bose-Hubbard model with longer-range interactions at density ρ=1 [2], and the (Peierls-)Hubbard model with additional spin interaction at half filling [3] can be mapped onto an effective spin-1 chain system. In this work we consider extended Hubbard-type models with spin J-term at half filling. Employing the infinite density matrix renormalization group technique the degeneracy of entanglement spectra can be taken as hallmark of the formation of a SPT phase in this model. Thereby the boundary between trivial-nontrivial Haldane phases belongs to the Ising universality class with central charge c=1/2, similar to the OH-antiferromagnetic phase boundary in the spin-1 chain system. Likewise the neutral gap, Δ-n=E1(0)-E0(0), closes at the transition point (here, E0(M) and E1(M) denote the ground-state energy and first excited energy within the M=Σj Sjz subspace, respectively). Decreasing the strength of the spin interaction J, the trivial-nontrivial phase boundary approaches those of the extended Hubbard-type model without spin term. This provides one means of determining the phase boundaries in the extended Hubbard model even in the weak- and intermediate-coupling regime.

FR.A-P14 - Tunable two-dimensional Dirac fermion gases at the surface of topological insulators

H. Aramberri [1], J.I. Cerdá [1], C. Muñoz [1]

1. Instituto de Ciencia de Materiales de Madrid (ICMM) Consejo Superior de Investigaciones Científicas (CSIC), Madrid, Spain

Bi-chalcogenides, Bi_2X_3 (X=Se, Te), Topological Insulators (TIs) represent a new quantum phase defined by a bulk insulator with Z2-invariant topology and metallic Dirac states at the surface. They exhibit a layered structure along the (0001) direction with quintuple layers (QLs) coupled through Van der Waals forces, therefore they frequently present extended structural planar defects. Via density functional theory calculations we demonstrate that in Bi_2X_3 TIs, self-doping of topological surface states can be tuned by controlling the sequence of stacking defects (SDs) inside the crystal. In particular, twin boundaries -reversal of the stacking sequence between QLs- drive large surface dopings, which achieve values of 10^12-10^13 e/cm2 and can be adjusted by the SD distribution. Remarkably, depending on the chirality of the twin, either n- or p-type self-doping can be optionally tuned. Its origin relies on the spontaneous polarization generated by the dipole moments created at the lattice defects. Our results provide a simple explanation for the local charging of the Dirac states recently reported in epitaxial (0001) Bi_2Se_3 films [1]. This mechanism allows, by controlling the SD sequence, to fine-tune the Fermi level to the electron or hole conductive regimes and hence, to generate a preselected two-dimensional massless Dirac fermion gas with a well defined spin-helicity. Therefore, our findings open the route to the fabrication of Bi_2X_3 surfaces and nanostructures with tailored surface charge and spin densities in the absence of dopants or external electric fields. Furthermore, because of the large Rashba splitting, highly-efficient spin manipulation might be realized. In addition, in a thin film geometry two-dimensional electron and hole Dirac gases with reversed spin-helicity coexist at opposite surfaces. Consequently, thin films of Bi-chalcogenides TIs with SDs provide a playground for exotic excitations such as topological exciton condensates.

FR.A-P15 - Electrical conductivity and weak ferromagnetism at the magnetic domain walls of the all-in/all-out order in $Cd_2Os_2O_7$

T. Hirose [1], J. Yamaura [2], Z. Hiroi [1]

1. ISSP, The University of Tokyo, Tokyo, Japan
2. MCES, Tokyo Institute of Technology, Tokyo, Japan

The pyrochlore oxide $Cd_2Os_2O_7$ show a metal-to-insulator transition at T_{MI} = 227 K. Below the T_{MI}, the Os^{5+} ($5d^3$) spins undergo an all-in/all-out (AIAO) magnetic order accompanied by a weak-ferromagnetism. Moreover, an unusual temperature dependence in resistivity is observed in the "insulating" state, which is strongly sample dependent [1]. Similar features have been observed in a series of Ir pyrochlore oxides $R_2Ir_2O_7$ (R: rare earth elements) and intensively discussed in terms of the Weyl semimetal [2]. In both systems, the finite electrical conductivity has been attributed to magnetic domain walls (MDWs) in the AIAO order, though there is no direct evidence for this [3, 4]. Besides, the origin of the weak ferromagnetism remains controversial. In this study, we focus on the electrical and magnetic properties of the MDWs in $Cd_2Os_2O_7$. We have observed a marked difference in the temperature dependence of resistivity below TMI between field-cooling and zero-field cooling measurements on several crystals. In addition, it is found that a robust, tiny remanent magnetization emerges when a crystal is cooled in 7 T field below T_{MI}, which cannot be reversed by sweeping field between ± 7 T. These findings evidence that both the finite electrical conductivity and ferromagnetic moments are induced at MDWs, which may give a reasonable explanation to the mysteries previously observed in $Cd_2Os_2O_7$.

FR.A-P16 - The changes in surface states of La, Ce, Eu doped SmB_6

B. Kang [1], C.H. Min [2], M. Song [1], B. Cho [1]

1. School of Materials Science and Engineering, Gwangju Institute of Science and Technology (GIST), Gwangju, Japan
2. Universitat Wurzburg, Experimentelle Physik VII & Center for Complex Material Systems RCCM, Würzburg, Germany

Recently, samarium hexaboride (SmB6) has received intensive attention because its metallic surface state was found to give rise to constant resistivity at T < 5 K. This temperature-independent resistance has been considered a signature of topologically protected surface states. In this study, the differences of the electrical transport properties of high-quality single crystals of $Sm_{1-x}RxB_6$ (R = La, Ce, Eu) that were synthesized using high-temperature Al solution growth methods were investigated. When either non-magnetic La or Eu ions were lightly doped in SmB6, the surface states were maintained. This was confirmed from the observation of the failure of Ohmí»s law. When the thickness of a single crystal is reduced, resistance should be inversely proportional to thickness in a normal metal. However, the resistance of non-magnetic ion doped SmB6 was the same, due to the existence of metallic surface states. On the other hand, when magnetic Ce ion 3 % was used as the dopant, the change of resistance followed Ohm's law. As a result, the surface states were found to vanish. The metallic surface states are sensitive to magnetic ions, which break the time reversal symmetry. SmB6 exhibits contrasting behavior depending on the presence of magnetic or non-magnetic dopants. This result indicates that SmB_6 has the required property of topological surface state protected by time reversal symmetry.

FR.A-P21 - Electronic structure and phonon modes of SmB_6

F. Kuroda [1], T. Shishido [1], T. Oguchi [2]

1. ADSM. Hiroshima University, Hiroshima-Shi, Japan
2. ISIR, Osaka University, Osaka, Japan

Being predicted as a Z2 topological Kondo insulator, SmB6 has been drawing revised attentions. Density-functional theory and related calculations show that the d-f hybridization leads to the parity-switching band inversion at X, making this material being topologically nontrivial.
Extensive efforts have been paid to observe the topologically-protected metallic surface states. Although Dirac-cone like dispersion is not seen, several experiments indicate the existence of metallic (001) surface states, which form Fermi surface around X in the surface Brillouin zone and show temperature-dependent evolution being connected with the onset of d-f hybridization in bulk.
It seems that the long-standing issue of the exotic temperature dependence of SmB_6 conductivity can be resolved by admitting the temperature evolution of surface states.
A decade ago, Ogita et al. have measured Raman scattering spectra for the RB6 series (R= rare earth element) and found an anomaly in the T2g mode of SmB_6 and divalent systems, whose origin has not been discussed well. In this talk, in order to resolve this issue and discuss its possible connection with the nontrivial electronic structure of SmB_6, we carry out first-principles calculations based on the all-electron FLAPW method with a relativistic LDA+U approximation.
The zone-center phonon modes of SmB6, LaB6 (trivalent representative), and CaB6 (divalent representative) are obtained by the frozen phonon approach. The calculated frequencies of Raman-active A1g and Eg modes show universal lattice-constant dependence while the T2g frequency has apparent valency dependence, accounting for Ogitaüfs experiment.
We analyze the conduction states in detail. They consist of not only the Sm d states but also B 2p pi states, whose lobe extends along the B atomic displacement of T2g mode, being able to screen the T2g mode.

FR.A-P22 - DFT+DMFT study of composition and temperature dependent electronic structure of $NiS_{2-x}Se_x$

C.Y. Moon [1], J.H. Shim

1. Korea Research Institute of Standards and Science
2. Department of Chemistry, Pohang University of Science and Technology

The electronic correlation is known to play important roles in condensed matter systems and results in rich structures in the phase diagram of materials, often dramatically changing materials property by small adjustment of external parameters. Nickel chalcogenide alloy $NiS_{2-x}Se_x$ is a good example to exhibit such complex phase diagram where metal-insulator transition (MIT) as well as magnetic phase transition occurs by varying Se composition x, temperature, and also pressure. Although the phenomenological phase diagram itself was well established earlier, detailed nature of the each phase and the transition among them have been controversial. Here we investigate the evolution of the electronic structure of nickel chalcogenide alloy $NiS_{2-x}Se_x$ with varying composition x and temperature using the combined theoretical method of density-functional theory and dynamical mean-field theory. Using real alloy structures containing both S and Se species in the cell, we map electronic correlation strength of the alloy on the phase diagram, and observe the metal-insulator transition along both the composition and temperature axes, consistent with the experimentally established phase diagram of this alloy system. The temperature dependence of the local magnetic susceptibility is obtained and shows an evolution from typical Curie-Weiss-like behavior for insulating phases to the constant behavior for metallic phases with increasing x. Comparison of electronic structures among NiS_2 and $NiSe_2$ in different lattice structures suggests that the composition-driven metal-insulator transition in the alloy results from the change of the hybridization strength between Ni *d* and chalcogen *p* orbitals.

FR.A-P23 - Elastic softening in the tetrahedrite $Cu_{12}Sb_4S_{13}$

T. Suzuki [1,2,3], H. Goto [1], Y. Noguchi [1], S. Kamikawa [1], K. Suekuni [1], H. Tanaka [1], T. Takabatake [1,2], I. Ishii [1]

1. Department of Quantum Matter, AdSM, Hiroshima University, Hiroshima-shi, Japan
2. Institute for Advanced Materials Research, Hiroshima University, Hiroshima-shi, Japan
3. Cryogenics and Instrumental Analysis Division, Hiroshima-shi, Japan

The tetrahedrite $Cu_{12}Sb_4S_{13}$ has a cubic structure (space group I-43m) and is expected to be a thermoelectric material. At 85 K, a metal-semiconductor phase transition accompanied by a structural change is reported by the electrical resistivity and magnetic susceptibility measurements. The origin of the phase transition has not been determined yet. To investigate the phase transition at 85 K, we measured the elastic modulus using an ultrasonic technique on polycrystalline samples. The longitudinal modulus shows elastic softening from above 300 K, suggesting that there is an instability of the structure or the electronic state, such as a band structure. The softening continues down to 85 K, and it turns into increase below 85 K accompanied by hysteresis. The phase transition is of first-order. The elastic hardening indicates disappearance of the instability by the phase transition.

FR.A-P24 - Phase diagram of graphite in the ultra-quantum limit

F. Arnold [1,3], A. Isidori [1], E. Kampert [2], B. Yager [1], M. Eschrig [1], J. Saunders [1]

1. Royal Holloway, University of London, London, United Kingdom
2. Dresden High Magnetic Field Laboratory, Dresden, Germany
3. Max Planck Institute for Chemical Physics of Solids, Dresden, Germany

Semimetals like graphite are subject of renewed attention due to the unique possibility to drive these systems into their magnetic quantum limit by applying large magnetic fields. Thus graphite is an ideal model system for the study of magnetic field driven phenomena, such as charge density waves and new topological phases.
Using state of the art pulsed magnetic fields up to 60 T, we brought a single crystal of natural Tanzanian graphite in the magnetic ultra-quantum limit. By measuring its electrical transport properties, we observed a new sub-phase and phase transitions within the known resistance anomaly below 54 T. Supported by new calculations of the renormalized Landau level structure, we identified the observed phase as collinear charge-density waves in the (0,up) and (-1,down) Landau levels, where the charge-density wave associated with the (0,up) Landau level undergoes a lock-in transition at 47 T and becomes commensurate with the crystal structure. Both charge-density waves are destroyed in a first order phase transition when their respective Landau levels cross the Fermi energy at 52.3 and 54.2 T.
Extending our model to higher magnetic fields, we are able to explain the resistance anomaly above 55 T by charge-density waves in the (0,down) and (-1,up) Landau levels. In this magnetic field region graphite enters a topological state, where the bulk is isolating and the surface is characterized by chiral edge states supporting both charge and spin currents.

FR.A-P25 - Mirror-symmetric magneto optical kerr rotation of [(GeTe)2(Sb2Te3)1]n Superlattices

Since the invention of interfacial phase change memory (iPCM), which has recently been newly named topological switching random access memory, TRAM or TSRAM, the switching energy in phase change memory (PCM) has greatly been suppressed less than 1/20. On the other hand, iPCM has recently been studied as a topological insulator (TI). Since in TI both time-reversal symmetry and spatial inversion symmetry are preserved, TI is usually non-magnetic. However, breaking the symmetries may emerge spin-related properties. Therefore, it is very interesting to confirm if iPCM changes the Kerr-rotation by the breaking of the time reversal symmetry and spatial inversion symmetry.
Superlattice structures used in the experiment were designed based on ab-initio computer simulations, and [(GeTe)2(Sb_2Te_3)1]n (n = 1-20) superlattices were fabricated by r.f. magnetron sputtering using two-inch composite targets: GeTe and Sb_2Te_3.
In this study, the actual experimental results at room temperature and high temperature beyond the phase transition from RESET to SET were in good agreement with our prediction. At room temperature, the Kerr signal of the superlattice film was within noise. However, when the temperature was increased to larger than a threshold (~380 K), the Kerr signal showed several peaks at certain magnetic fields which correspond to resonant conditions induced a giant Kerr rotation. This observed Kerr signal of the SET phase is attributed to the breaking of time reversal symmetry by application of an external magnetic field as well as the degenerated electronic bands due to the replacement of a Ge atomic layer along the c-axis at high temperature. On the other hand, the threshold temperature for observing Kerr resonant peaks is in good agreement with the SET and RESET phase transition temperature observed in the electrical resistance measurements.

FR.A-P27 - Classification of symmetry protected topological phases by the Chern-Simons approach

T. Yoshida [1]

1. RIKEN, Saitama, Japan

In these years, it became clear that spatial symmetries can protect topological structures; a topological crystalline insulator has been reported for SnTe [1,2]. Furthermore, nontrivial phases in correlated systems are realized not only in fermionic systems but also in bosonic and spin systems. These are referred to as symmetry protected topological (SPT) phases. Applying classification scheme based on the Chern-Simons theory [3,4], we have classified SPT phases protected by a reflection symmetry. Besides we have proposed a spin model which shows nontrivial phase protected by the reflection symmetry. This phase can be regarded as bosonic extension of topological crystalline insulator [5]. In study of femionic systems, we have pointed out that correlation effects can reduce topological classification; topological classes in free fermion systems are reduced into those of ZN in the presence of local discrete symmetry. Here, N denotes order of the local symmetry [5].

FR.A-P28 - Shubnikov-de Haas oscillations in the antiferromagnetic superconductor HoPdBi

O. Pavlosiuk [1], D. Kaczorowski [1], P. Wisniewski [1]

1. Institute of Low Temperature and Structure Research Polish Academy of Sciences,Warsaw, Poland

The compound HoPdBi, crystallizing with a cubic MgAgAs-type structure, belongs to the family of half-Heusler phases, intensively studied owing to their possible nontrivial topological properties [1]. For some materials, topologically-nontrivial state has been theoretically predicted to arise due to a specific antiferromagnetic structure [2]. HoPdBi was previously studied on polycrystalline samples only, and found to order antiferromagnetically at TN = 2 K [3]. Here, we report on the physical behavior in flux-grown single crystals of HoPdBi. The magnetic susceptibility, specific heat and electrical resistivity data confirmed the antiferromagnetic ordering setting in below 2 K. Additionally, the temperature dependencies of the AC magnetic susceptibility and the electrical resistivity indicated the onset of superconductivity at Tc = 0.7 K. However, no clear evidence of superconducting state was revealed from the heat capacity data, alike reported for a few related non-magnetic superconductors, e.g. LuPdBi, YPtBi and LuPtBi [4-8]. Remarkably, below 50 K, the transverse magnetoresistance of HoPdBi was found to be governed by weak antilocalization effect in small magnetic fields, with phase coherence length of about 300 nm - similar as in the above mentioned non-magnetic compounds, while below 7K Shubnikov–de Haas oscillations were detected in high magnetic fields, revealing cyclotron mass of 0.3me and Berry phase close to 1/2.

FR.A-P29 - Orbital polarization, spin-spin correlations and metal-insulator transitions in the $Ca_{2-x}SrxRuO_4$ system

Y. Utsumi [1], D. Kasinathan [1], S. Agrestini [1], Z. Hu [1], K.T. Ko [1], M. Haverkort [1], K.D. Tsuei [2], Y.H. Wu [2], Y.F. Liao [2], A.C. Komarek [1]

1. Max Planck Institute for Chemical Physics of Solids, Dresden, Germany
2. National Synchrotron Radiation Research Center, Hsinchu, Taiwan

The single layered perovskite system $Ca_{2-x}Sr_xRuO_4$ has been attracting a great attention because of its rich properties depending on the Ca/Sr concentration. The end material Sr2RuO4 is isostructural to the high- TC cuprate and is known as an unconventional spin-triplet p-wave superconductor (TC= 1.5 K) [1]. With the increase in Ca substitution for Sr, the system changes from a paramagnetic metal (2.0>x>0.5) to a magnetic metal (0.5>x>0.2) accompanied by a crystal structural distortion [2]. In the Ca rich phase (0.2>x>0), the system becomes a Mott insulator. The end material Ca_2RuO_4 is an antiferromagnetic insulator below TN~110 K and a paramagnetic insulator between 110 and 350 K. Furthermore, Ca_2RuO_4 shows a first-order metal-insulator transition (MIT) at 350 K and becomes paramagnetic metal above 350 K accompanied by a crystal structural distortion [3]. We performed hard x-ray photoemission on $Ca_{2-x}Sr_xRuO_4$ (x= 0, 0.09, 0.2, 2.0) at the BL12XU beamline of SPring-8 with hν~6.5 keV. High-quality single crystals of $Ca_{2-x}Sr_xRuO_4$ were cleaved insitu under the base pressure of 3×10-10 mbar. The valence band spectrum of Ca_2RuO_4 shows dramatic changes across the MIT. The valence band spectrum of $Ca_{1.91}Sr_{0.09}RuO_4$ displays similar temperature evolution across the MIT. Details of the changes in the spectrum as a function of temperature and composition will be critically compared to recent predictions from LDA+DMFT calculations [4].

In 5d transition metal oxides (5d TMOs), the combination of strong spin-orbit coupling, electronic correlation and frustration produces unusual ground states. Orthorhombic calcium osmate ($Ca_2Os_2O_7$) is a ''half frustrated'' bad metal with an unusual phase transition at 327 K, where its resistivity increases by an order of magnitude coincident with magnetic ordering. We have investigated the magnetic ordering process by neutron powder diffraction and single crystal resonant x-ray diffraction. Our results reveal a complex reordering process, likely induced by magnetic frustration. A similar coupling of magnetic order and electronic transport characteristics has been in observed in other families of 5d TMOs. Given the itinerant character of these materials, one cannot explain such behaviour in a Mott-Hubbard scenario. We hope that the interpretation of the magnetic ordering process in $Ca_2Os_2O_7$ will aid the understanding of this peculiar interplay of spin-orbit coupling, correlation and frustration.

FR.A-P31 - Doping-induced single-particle states due to magnetic excitation of a Mott insulator

M. Kohno [1]

1. National Institute for Materials Science, Ibaraki, Japan

In the Mott transition, single-particle states generally emerge in the Mott gap following the doping. These states are called doping-induced states and are observed in materials such as cuprate superconductors and in various theoretical calculations. To clarify the nature of the doping-induced states, relationships with the magnetically excited states of the Mott insulator are investigated. In t-J models, using the commutator between the Hamiltonian and an electron creation operator, a weighted sum rule for the overlap between the doping-induced states in the small-doping limit and the single-spin excited states of the Mott insulator is derived. In addition, it is shown in t-J models that the spectral weight of spin-1 states for each magnetization is equal to that of spin-0 states. These results imply that in general, the magnetically excited states of the Mott insulator significantly contribute to the doping-induced states in the small-doping limit.

FR.A-P32 - Magnon waveguides from topological magnon insulators

A. Mook [1], J. Henk [2], I. Mertig [1,2]

1. Max Planck Institute for Microstructure Physics, Halle, Germany
2. Institute of Physics, Martin Luther University Halle-Wittenberg, Halle, Germany

Topological magnon insulators exhibit a nontrivial topology due to the Dzyaloshinskii-Moriya interaction, which opens up band gaps in the magnon dispersion relation causing nonzero Berry curvature and nonzero Chern numbers. Obeying the bulk-boundary correspondence, topological magnon insulators host topologically nontrivial edge magnons and, consequently, energy as well as spin currents along their edges [1,2].
Bringing two topological magnon insulators into contact results in topologically protected unidirectional interface magnons. As these interface modes decay toward both bulk regions, their currents are confined to a few nanometer wide strip around the interface, which is considered a waveguide for magnons. Owing to the topological nature of the edge states, the edge currents follow any geometry.
We study theoretically interfaces of semi-infinite kagome ferromagnets in various topological phases, with a focus on the formation and the confinement of nontrivial interface magnons [3]. We analyze generic magnon dispersions with respect to the number of band gaps and the respective winding numbers. An investigation of the heat current profiles about the interface is followed by a proposal of two recipes of composing magnon waveguides with nano-scale confinement, one from topologically different phases, another from identical phases. On top of this, we identify material classes to construct these magnon waveguides.

FR.A-P33 - Magnon hall effect of topological magnon insulators

A. Mook [1], J. Henk [2], I. Mertig [1,2]

1. Max Planck Institute for Microstructure Physics, Halle, Germany
2. Institute of Physics, Martin Luther University Halle-Wittenberg, Halle, Germany

The family of Hall effects has recently been extended by the magnon Hall effect (MHE). For the insulating ferromagnet $Lu_2V_2O_7$ with pyrochlore lattice Onose et al found a transverse heat current upon application of a longitudinal temperature gradient [1]. The MHE is owing to uncompensated magnon edge currents [2] that originate from the non-trivial topology of the magnon band structure of topological magnon insulators [3]. The Dzyaloshinskii-Moriya interaction opens up band gaps in the magnon dispersion relation causing nonzero Chern numbers. The transverse thermal conductivity is consequently expressed as an integral over the Berry curvature.
In our theoretical investigation [4] we deduce the rich topological phase diagram of the ferromagnetic kagome system. The bulk-boundary correspondence---the connection of the Chern numbers with the number and propagation direction of the nontrivial edge modes---holds for the topological magnon insulator. It turns out that for specific systems the transverse thermal conductivity changes sign in dependence on temperature.
Studying semi-infinite kagome systems, we explain the link between a topological phase, identified by its Chern numbers, and the flow direction of the magnon Hall heat current. Furthermore, we derive a figure of merit for the strength of the magnon Hall effect.

FR.A-P34 - Absence of magnetic fluctuation in the topological Kondo insulator SmB6 revealed by polarized low energy muons

P. Kumar Biswas [1], Z. Salman [1], G. Balakrishnan [2], M. Ciomaga Hatnean [2], M.R. Lees [2], D. McK. Paul [2], E. Morenzoni [1], A. Amato [1]

1. Paul Scherrer Institut, Villigen, Switzerland
2. University of Warwick, Coventry, United Kingdom

We present the magnetic behavior of the 3D Kondo topological insulator SmB6 at different depth and its detailed temperature dependence using low-energy muon spin relaxation/rotation (LE-muSR) measurements. Magnetic field fluctuations which are present in the bulk of SmB6 found to decrease rapidly with decreasing depths and probably disappear completely at the surface of SmB6. This could be either due to faster fluctuation of the magnetic moments or more probably the suppression of the magnitude of the magnetic moments towards the surface. We propose that the topologically protected surface states modify the spectrum/size of magnetic field fluctuations at the surface of SmB6.

FR.A-P35 - Preparation and characterization of the topologically non-trivial half Heusler compound YPtBi

A. Kronenberg [1], H.J. Elmers [1], G. Schönhense [1], M. Jourdan [1]

1. University of Mainz, Mainz, Germany

Three dimensional topological insulators present electronic surface states, which allow dissipation less spin transport. These edge channels are topologically protected by time reversal symmetry (TRS) and can therefore only be perturbed by TRS breaking i.e. magnetic impurities.
Half-Heusler materials of the family LaPtBi are predicted to show 3D-topological order [1] i.e. present topologically protected electronic surface states. Additionally, according to band structure calculations, a bulk band gap can be opened around the Fermi level by lateral strain [2]. The planned in situ spin-resolved ARUPS directly after deposition is the ideal tool to investigate the electronic structure including surface states of thin films of this material class as recently shown for highly spin polarised ferromagnetic Heusler compounds [3]. We present results on the preparation and characterization of thin films of the YPtBi compound, fabricated by magnetron sputtering from three separate elementary sputtering sources. The crystal phase forms at elevated substrate temperatures under excessive Bi flux. Investigations by x-ray diffraction reveal a preferred growth direction along the [111] or [100] axes of the crystal with in plane order depending on the choice of substrate and buffer layer. Scanning electron microscopy shows a clustered growth of the material and the formation of segregations on the film's surface, which are identified to be Bi-rich as probed by EDX.

FR.A-P37 - Nd-ion substitution effect on f-electron multipole order of $PrRu_4P_{12}$

K. Iwasa [1], A. Yonemoto [1], S. Takagi [1], S. Itoh [2], T. Yokoo [2], S. Ibuka [2], C. Sekine [3], H. Sugawara [4]

1. Department of Physics, Tohoku University, Miyagi, Japan
2. Institute of Materials Structure Science, High Energy Accelerator Research Organization, Ibaraki, Japan
3. Graduate School of Engineering, Muroran Institute of Technology, Hokkaido, Japan
4. Department of Physics, Kobe University, Kobe, Japan

We studied an effect of magnetic Nd-ion substitution to the metal-nonmetal transition at T_{MI} = 63 K of $PrRu_4P_{12}$, which is accompanied by antiferro-type electric multipole ordering of Pr-ion 4f electrons in the nonmetallic phase below T_{MI} of $PrRu_4P_{12}$ [1]. The transition temperatures of $Pr_{1-x}Nd_xRu_4P_{12}$ are determined from evolution of x-ray superstructure reflection, which is caused by transformation from the simple-cubic structure above T_{MI} to the body-centered-cubic (bcc) structure below T_{MI}. The ordered multipole, characterized by the staggered alignment of inequivalent crystal-field-splitting schemes of Pr $4f^2$ electrons in the bcc structure [2], is investigated by inelastic neutron scattering performed at the neutron spectrometer HRC installed at BL12 of MLF, J-PARC. Based on these experimental results, the ordered state in the Nd-substituted material is rather robust against the substitution concentration, x, than the La- and Ce-substituted materials [3]. We observed also low-temperature enhancement in magnetic susceptibility of $Pr_{1-x}Nd_xRu_4P_{12}$, which is very similar to the ferromagnetic ordering in $NdRu_4P_{12}$. The ferromagnetic interaction between the Pr ions and the incorporated Nd ions in $Pr_{1-x}Nd_xRu_4P_{12}$ assists stability of the magnetic triplet ground state of the Pr ions that appears in the antiferro-type multipole ordered phase, and reduces the site-dilution effect. Therefore, the nonmagnetic multipole ordered phase of $PrRu_4P_{12}$ is compatible with the magnetic perturbation.

FR.A-P40 - Magnetic properties of gadolinium substituted Bi_2Te_3 single crystals

S.W. Kim [1], K. Lee [1], M.H. Jung [1]

1. Sogang University, Seoul, South Korea

Topological insulators have attracted a lot of interest in condensed matter physics because of the gapless surface state inside the bulk gap. Various quantum phenomena arising from the topological surface states could be useful for low-power electronics and error-tolerant quantum computing. Long-range magnetic ordering is a key to achieve such quantum phenomena, and it can be attained simply by magnetic impurity doping. As for a relevant system, Gd doped Bi_2Te_3 has been proposed because gadolinium is isovalently substituted for Bi and exhibits the largest magnetic moment [1]. However, no ferromagnetic order has been observed so far, and a wide variety of Gd solubility limits have been reported [2-4]. Here, we prepared single crystals of $GdxBi_{2-x}Te_3$ with various x (= 0.04, 0.06, 0.08, 0.12, 0.15, 0.20). All the experiments were carried out for the single crystals with shiny surface in the center part of the ingot. Although the amount of Gd substitution increased, the transport and magnetic properties did not show any big differences. For all the samples, the magnetic susceptibility data were well fitted by the Curie-Weiss law, from which the actual composition of Gd substitution was estimated in the vicinity of x' = 0.08. Then, a question can arise; where the excess or deficient Gd atoms are. In experimental, crumbly parts on the upper part of ingot were clearly visible. X-ray diffraction data revealed that the crumbly parts are Gd-rich or Gd-lack phases such as GdTe or BiTe for $x > 0.08$ and $x < 0.08$, respectively. These observations suggest that the most stable phase of gadolinium substituted Bi_2Te_3 is $Gd_{0.08}Bi_{1.92}Te_3$.

FR.A-P41 - Antiferromagnetic order competing with topological state in $Ce_xBi_{2-x}Te_3$

H.S. Lee [1], K. Lee [1], S.W. Kim [1], J. Kim [1], M.H. Jung [1], A. Jelen [2], S. Vrtnik [2], Z. Jaglicic [2], J. Dolinsek [2]

1. Department of physics, Sogang University, Seoul, South Korea
2. J. Stefan Institute and University of Ljubljana, Ljubljana, Slovenia

Topological insulator (TI) is a new material platform with time-reversal symmetry and non-trivial topology. Previous theoretical works reported that antiferromagnetic order can coexist with the topological state, even though the magnetic order breaks the time-reversal symmetry [1-3]. A candidate for antiferromagnetic topological insulator (AFTI) has been proposed to be GdBiPt [1], but only magnetic structure has been reported to be type-II antiferromagnetic [4]. The specific magnetic structure, that the magnetic moments are aligned ferromagnetically in layers which are stacked antiferromagnetically, is required for AFTI. Here, we prepared single crystals of $Ce_xBi_{2-x}Te_3$ with various x (= 0.04, 0.06, 0.08, 0.10, and 0.12). The obtained crystals were characterized by X-ray diffraction and scanning electron microscopy. The magnetic susceptibility data revealed that the Ce atoms are well substituted for Bi into Bi_2Te_3. From the Curie-Weiss fits, we obtained that the effective magnetic moments μ_{eff} are close to 2.54 μ_B for free Ce ion and the paramagnetic Curie temperatures θ_p are negatively increased from -3.04 to -59.28 K with increasing x. The magnetization data clearly showed antiferromagnetic orders around TN = 4 K for $x \geq 0.08$, where θ_p suddenly increases. Only for x = 0.06, exotic physical properties arising from topological states were observed such as non-metallic behavior in the electrical resistivity and linear dependence of the magnetoresistance. Otherwise, for $x \geq 0.08$ the electrical resistivity is simply metallic and the magnetoresistance is parabolic. Especially, it is noteworthy that the carrier density is in an order of 10^{19} cm^{-3} for $x \geq 0.08$, while it is ~1017 cm^{-3} for x = 0.06. These observations propose that the antiferromagnetic order is strongly competing with the topological state in $Ce_xBi_{2-x}Te_3$. This result seems to be contradictory to the previous works, but be reasonable by assuming type-I antiferromagnetic order.

4. Clarendon Laboratory, Department of Physics, University of Oxford, Oxfprd, United Kingdom

The pyrochlore $Ln_2Ir_2O_7$ (Ln=rare earth) has become a hotspot of condensed matter physics due to their tunalbe metal-insulator behaviour and the insight of physics. For this system, the Ln=Eu, Sm, Nd materials are of particular interests because of their setting on the proximity of Metal Insulation Transition (MIT). Previous studies have reported that the MIT can be suppressed by physical pressure [1,2]. The insight of this change is still not clear. Therefore, we carried out our investigations on the crystal structure of $Ln_2Ir_2O_7$ as a function of pressure. High pressure x-ray diffraction (XRD) was performed on Ln=Eu and Nd single crystals up to 40GPa at Diamond Light Source, United Kingdom. The pressure range is enough to suppress MIT and new long-range ordering is believed to occur at high pressure[2]. Our results reveal that there is no obvious first-order structural transition induced by the pressure, implying that lowering the cubic symmetry does not change in the electronic state and magnetic orderings of these compounds. Therefore, the magnetic order of Ir moments are likely to play a major role for the MIT.

FR.A-P43 - Pressure-induced semimetal-to-semiconductor transition in bismuth

P. Brown [1], K. Semeniuk [1], A. Vasiljkovic [1], F. Malte Grosche [1]

1. Cavendish Laboratory, Cambridge, United Kingdom

The semimetal bismuth stands out among the elements for its extremely low carrier concentration. This arises from small electron and hole Fermi surface pockets, which result in only around one mobile electron per 100,000 atoms. Situated very close to the transition to a semiconductor, the electronic structure can be tuned further by doping with antimony or by applied hydrostatic pressure.
We investigate the electrical resistivity, Hall effect and Shubnikov de Haas oscillations of single crystal bismuth under hydrostatic pressure of up to 25 kbar in a piston cylinder pressure cell. A novel field modulation technique enables us to observe quantum oscillations down to fields below 0.2 T and temperatures above 20 K. While the temperature dependence of the resistivity is metallic at ambient pressure, it develops a pronounced kink and subsequently a maximum near 40 K with increasing pressure. The maximum shifts towards lower temperature with further increasing pressure until, above about 20 kbar, the resistivity of bismuth resembles that of a narrow-gap semiconductor.
These results suggest that the Lifshitz transition from semimetal to semiconductor can indeed be studied in bismuth at pressures less than 25 kbar; above this pressure a structural transition into a fully metallic state takes place. This makes it possible to access ultra-low carrier density states at intermediate pressures, in which the quantum limit can be reached at very low applied fields.

FR.A-P44 - Topological phases of periodically-driven system on a hexagonal lattice

M. Maksymenko [1], I. Cosma Fulga [1]

1. Department of Condensed Matter Physics, Weizmann Institute of Science, , Rehovot, Israel

Characterization of topological phases in periodically driven systems can require immensely new set of topological invariants, which are defined over the full driving period. We investigate in details the phase diagram of the periodically driven two-dimensional system of fermions on the hexagonal lattice. Here the hopping integrals along the three distinct bonds are switched on and off sequentially in a stroboscopic manner implying effective chirality of the fermion hoping along the hexagon.
We find that the system exhibits a new set of topological phases for which a standard band Chern numbers fail to identify whether the phase is topologically non-trivial. Such phases can be characterized by a set of new strong and weak invariants defined over the period of time. The conductance of the finite system with different types of edges provides a clear evidence for the presence or absence of the edge-states contribution. We investigate the role of disorder as well as the possibility of breaking of rotational/translational symmetries and time periodicity.

FR.A-P46 - Weak antilocalization and magnetic field driven metal insulator transition in $Bi_2Te_{2.1}Se_{0.9}$ single crystals

B. Irfan [1], R. Chatterjee [1]

1. Indian Institute of Technology Delhi (IITD), New Delhi, India

Topological insulators (TIs) are a new phase of matter with bulk insulating and conducting surface states. In three dimensional topological insulators such as Bi_2Se_3, large numbers of selenium vacancies push the Fermi level inside the conduction band; due to which the charge transport is generally dominated by the bulk current in this crystal and the as grown crystals of Bi_2Te_3 are p-type because of Te-Bi exchange defects. Bi_2Te_2Se is the hybrid material in which the selenium ion occupies the innermost layer in each quintuplet. This will suppress both vacancy formation and Te-Bi exchange defects. Thus, among the known topological insulators, Bi_2Te_2Se with basic quintuple layer as Te-Bi-Se-Bi-Te, emerged as a promising material for studying the topological insulating properties.
In this work we present our results on $Bi_2Te_{2.1}Se_{0.9}$ single crystals grown using modified Bridgeman technique. The R-T behavior of $Bi_2Te_{2.1}Se_{0.9}$ single crystals shows a magnetic field driven metal insulator transition. The results reveal a conventional temperature dependence metallic behavior at high temperature (i.e. above 250 K) under applied magnetic field and insulating behavior at low temperatures. A sharp drop in resistance is observed in $Bi_2Te_{2.1}Se_{0.9}$ single crystals at zero magnetic field due to weak antilocalization (WAL) effect, which arises from quantum interfering nature of topological insulators. The devices were fabricated (using mechanical exfoliation technique) to investigate the effect of WAL arising from topological surface states. The WAL coefficient of conductance can be tuned by gate voltage and separated in to coherently independent channels, which in topological in topological insulators include both the bulk conduction and topological surface conduction. We also report the experimental evidence of universal conductance fluctuation (UCF) in bulk insulating $Bi_2Te_{2.1}Se_{0.9}$ micro flakes.

FR.A-P47 - Laser-induced phase transitions of topological Kondo insulators

K. Takasan [1], M. Nakagawa [1], N. Kawakami [1]

1. Department of Physics and Astronomy, Faculty of Science, Kyoto University, Kyoto, Japan

Controlling the nature of matter by laser light is an important topic in strongly correlated electron systems. We theoretically investigated how high-frequency laser field changes the nature of topological Kondo insulators. The topological Kondo insulator is a strongly correlated insulator that has a surface state protected by time-reversal symmetry (TRS) [1]. Recent theoretical and experimental studies suggest that SmB6 is a strong candidate for the topological Kondo insulator.
By employing a prototypical model of the topological Kondo insulator [2], we treated the effect of the laser field with the effective Floquet Hamiltonian, which gives the information of the system in the high-frequency limit. It enables us to map the time-periodic systems to static systems. We treated electron correlation effects by the slave-boson method, which allows us to calculate the renormalization effect self-consistently and thus determine the Kondo temperature.
From the topological point of view, we showed how the laser light changes the topological phases of this system. We calculated the topological number at the mean field level and found how topological phase transitions occur according to laser intensity. Especially when the light is circularly polarized, we showed that the system is driven to a quantum Hall phase and a Weyl semi-metallic phase.
In terms of the heavy fermion physics, we calculated the Kondo temperature as a function of laser light intensity and discussed the intensity-temperature phase diagram. Our calculation elucidated that there are the photo-induced hopping and the photo-induced hybridization under the laser irradiation, and that these photo-induced effects change the nature of the heavy electrons in the system quantitatively.

(Hg,Cd)Te quantum wells exhibit a topological phase transition as a function of the well width [1]. For widths larger than the critical width, the quantum-well has an inverted band gap and becomes a two-dimensional topological insulator. In the topological phase, the system supports an odd number of chiral edge states, which give rise to the quantum spin Hall effect. The low-energy physics of these systems is well described by the 4x4 Bernevig-Hughes-Zhang model [2].
Here we calculate the static spin susceptibility of the 2D quantum-well states using a k-dot-p expansion starting from the 6x6 Kane Hamiltonian. Due to the coupling between the light-hole and conduction bands, the spin susceptibility is not proportional to the charge response function given in Ref [3]. We study the dependence of the spin-susceptibility tensor on doping both in the trivial and topological phase. We obtain analytical results in the limit of vanishing wave vector (q=0), while the full wave-vector dependence of the spin susceptibility is computed numerically. Interestingly, for zero doping we find a q=0 intrinsic contribution to the spin susceptibility that in the topological phase does not depend on the Dirac mass parameter. We discuss the physical ramifications of this unusual result, including its implications for the RKKY interaction.
Furthermore, both the in-plane and out-of-plane components of the intrinsic spin susceptibility show a maximum for a finite value of wavevector. We complete our study by calculating the edge-state contribution to the spin-susceptibility tensor.

Kondo insulators are materials in which an energy gap in the electronic density of states (DOS) opens at the Fermi level as a consequence of strong electronic correlations. The gap is thought to arize from a half-filled conduction band hybridizing with a localized f level (cf hybridization). Since correlations renormalize energy scales the gap width of Kondo insulators is of the order of 1 to 100 meV [1]. The tetragonal compound $CeRu_4Sn_6$ shows pronounced anisotropy between the crystallographic c axis and the directions within the tetragonal plane (a and c' directions) [2,3]: characteristics of a Kondo insulator are seen within the tetragonal plane but heavy fermion metal behaviour dominates along the c axis [3]. Thermopower is extremely sensitive to details in the electronic DOS near the Fermi level. Thus, measurements on single crystals along different crystallographic axes may shed light on the underlying electronic correlation phenomena. Here we present our investigations of the thermopower and Nernst effect of single crystalline CeRu4Sn6 at low temperatures and in magnetic fields, with the aim to reveal the topology of the Fermi surface and its relation to the anisotropy of the energy gap. This work was supported by the European Research Council (ERC Advanced Researcher Grant 227378), the Austrian Science Fund (projects I623-N16 and W1243), the FRC/URC of the University of Johannesburg, the European Commission (EuroMagNET II n. 22804), and the U.S. Army Research Office (grant W911NF-14-1-0496). The participation in this conference was partially supported by the Brazilian CNPq (project 401108/2014-7).

Spin torque diode effect provides an efficient tool to access the resonant properties of magnetic nanostructures [1]. Indeed, injecting a microwave current through a magneto-resistive structure gives access to dynamic parameters of magnetization vibration modes like the frequency, damping or even the spin torques amplitude. While the quasi-uniform resonant mode has been largely studied, few spin torque diode experiments have concentrated on localized magnetic modes like Domain Wall (DW) resonance. Moreover, no quantitative parameters, except frequency, have ever been extracted from the rectified signals. In this study, we take advantage of the large magneto-resistance effects in MgO-based Magnetic Tunnel Junctions to perform for the first time a quantitative study of the spin torque induced resonance of a transverse DW and its adjacent domains. From the measured spectra we can clearly distinguish the signal of the DW from the signal due to domains. This allows us to extract simultaneously the dynamic parameters of the two probed vibration modes. By using a theoretical model we derive from the experimental linewidths that their damping is twice increased compared to the measured damping value of their host magnetic layer. In literature such an increase of the damping associated to localized magnetic modes has already been reported [2,3]. Several effects can be involved to explain the increase of effective damping, like transverse spin diffusion or surface roughness. In a multilayer system, the dipolar coupling between the magnetic object in one layer and its magnetic shadow projected on the bottom layer has been predicted [3] and can lead to an increase of the measured damping. We have performed micromagnetic simulations to evaluate the damping enhancement due to this dipolar coupling. Based on these results, we will discuss the contribution of the different effects to the observed damping increase in our system. This research was partly funded by the French Ministry of Defense (DGA) and the European Research Council (Stg 259068).

FR.A-P52 - anomalous quasiparticles on the domain wall between topological insulators and spin ice compounds

I. Kanazawa [1], T. Sasaki [1]

1. Department of Physics, Tokyo Gakugei University, Tokyo, Japan

Recently, one of present authors has proposed exotic quasiparticles with fractional charges in semiconductor-dot from collectively induced-charge effect on a domain wall shell[1]. In this study, we propose that there might be emergent quasiparticles with fractionalized electric charge on the domain wall between topological insulator and spin ice compounds, through the interaction between the Dirac fermions and excited magnetic monopoles.

Rare-earth nickelates ($RNiO_3$ with R=rare earth cation) are well known to reveal a metal-insulator transition (MIT). In this series $LaNiO_3$ bulk shows interesting behavior for electronic devices such as paramagnetic metallic properties at all temperature and no MIT with temperature [1]. However, MIT in $LaNiO_{3-d}$ can be triggered by several parameters (e.g. cation substitution, substrate strain and oxygen stoichiometry [2,3]) including by lowering the dimensionality [4,5]. Furthermore, even a short time exposure of the LNO films to the air atmosphere leads to the formation of a hydroxide layer on the films surface [6]. This ageing changes the films transport's properties in observed mostly in ultrathin films. Several series of epitaxial $LaNiO_3$ films were grown by pulsed laser deposition on STO (100) substrates, with and without protection capping. Quality of LNO films were optimized by monitoring roughness, epitaxy, thickness and homogeneity by AFM, X-ray diffraction and X-ray reflectivity. Electrical resistivity, magneto-transport and Hall Effect for thin and ultrathin LNO films were done in the range 5 - 300 K and 0 - 9 T , and after de/re-oxygenating annealing treatments. This study reveals by comparison how to disentangle effects of desorder associated to weak localisation, and of doping.

The transition from a metallic to a correlated, or Mott, insulating state is a long-standing theme of fundamental interest in condensed matter research. The nature of the Mott metal-insulator transition, the properties of the metallic and insulating state on either side of the transition, and the emergence of novel phenomena - such as high temperature superconductivity - in its vicinity have all motivated comprehensive experimental and theoretical studies.
Using quantum oscillation measurements in high magnetic fields to probe the electronic Fermi surface and effective carrier mass on the metallic side of the transition could provide much needed microscopic information. In the cuprates, such studies in samples doped into the metallic state have identified the Fermi surface structure in underdoped and overdoped regimes. Because the quantum oscillation signal is strongly suppressed in the presence of disorder, pressure rather than doping should ideally be used to reach the metallic state. We present the first observation of quantum oscillations from a pressure-metallised 3D Mott insulator. NiS_2 can be tuned through the Mott transition at a modest pressure of ~30kbar. Quantum oscillations near the Mott transition are observed with the tunnel diode oscillator technique in magnetic fields up to 31T. The main observed oscillation frequency is consistent with the Fermi surface obtained within density functional theory, whereas the effective mass is significantly enhanced over the band mass.

FR.A-P57 - Magnetic ion doping on the surface of Bi_2Se_3 topological insulators

R. Chatterjee [1], Bushra Irfan [1]

1. Indian Institute of Technology Delhi, New Delhi, India

The effect of magnetic impurities and ferromagnetism on Dirac like conducting surface states in three dimensional topological insulators (TIs) such as Bi_2Se_3 or Bi_2Te_3 have attracted a lot of attention. The introduction of magnetic impurities breaks the time reversal symmetry and thus destroys the robust metallicity of the surface of TIs. Studies in these transition metal ion-doped TIs are usually motivated by various interesting phenomenon like quantized anomalous Hall effect, spin current, inverse spin-galvanic effect, all of which critically depend upon finding a way to break time reversal (TR) symmetry on the surface and thus use the unique TR broken spin texture for applications. In this work, we investigate the effect of Co doping (~5% to 10%) in Bi_2Se_3. We mainly focus on the result obtained on $Bi_{1.8}Co_{0.2}Se_3$ single crystal sample and the device prepared on mechanically exfoliated ~70 nm flake obtained from the crystal (with a technique similar to the one used for graphene). The bulk crystal resistivity measurements reveal metallic behavior, as noted by other researcher for doped Bi_2Se_3. With increasing Co-doping, the resistivities of $Bi_{2-x}Co_xSe_3$ (x= 0.1, 0.15, 0.2) decrease maintaining the overall metallic behavior for T > 50 K, for all samples. It is interesting to note that the crystal with high (~10%, x = 0.2) concentration of Co doping i.e. $Bi_{1.8}Co_{0.2}Se_3$, shows a logarithmic increase in resistivity with decreasing temperature for T <= 50 K. Although no weak antilocalization (WAL) effect is observed in this bulk $Bi_{1.8}Co_{0.2}Se_3$ crystal, the device prepared on nano-flake from the crystal of $Bi_{1.8}Co_{0.2}Se_3$, reveals a WAL feature. Above 40 K a crossover to weak localization behavior is observed in the device. Resistivity measurement on this nano-device shows a Kondo like peak at 40 K and a clear semiconducting behavior over the whole range of temperature up to 300 K is noted in the device.

FR.A-P58 - Magnetotransport and magnetic properties of single crystals of $BaNiS_2$: a two-dimensional semimetal with highly mobile carriers

Y. Klein [1], D. Santos-Cottin [1], M. Verseils [1], A. Gauzzi [1]

1. IMPMC, University Pierre and Marie Curie, Paris, France

$BaCo_{1-x}Ni_xS_2$ is a two-dimensional Mott system, where electron doping drives the antiferromagnetic and insulating phase at x = 0 to a metallic and paramagnetic one at the critical value x_cr = 0.22 [1]. Previous studies have been mostly focused on the region near x_cr, whilst the metallic phase, $BaNiS_2$, has been relatively little studied. In particular, the available data on transport properties are limited and the carrier density and the scattering mechanism remain to be determined. For instance, the question arises whether the electron-electron or the electron-phonon scattering dominates. In order to address this point, we performed a detailed study of the magnetotransport properties, magnetic susceptibility and specific heat on high-quality single crystals. The conductivity tensor is quantitatively analyzed in terms of a three-carrier model, from which it can be stated that $BaNiS_2$ is a semimetal very close to the compensation. On one hand, two majority channels exhibit moderately high carrier motilities. On the other hand, the third one is due to highly mobile holes that are attributed to strongly curved bands with a conic-like dispersion at the Fermi level. While the electronic part of the specific heat indicates weakly correlated carriers, the magnetic susceptibility is enhanced by one order of magnitude if compared to the density of state, and exhibit non-negligible temperature dependence. The supplementary paramagnetic contribution may be explained by the recently discovered and strong spin-orbit interactions in $BaNiS_2$ [2].

3. Laboratoire Pierre Aigrain, Ecole Normale Supérieure - University Pierre and Marie Curie – Paris, France

By a combined study of Shubnikov de Haas and de Haas van Alphen effects on high-quality single crystals of the $BaNiS_2$ semimetal, the Fermi surface of the latter quasi two-dimensional system is investigated. The experimental electronic properties deduced from the present paper are in accordance with recent band calculations that take into account spin-orbit coupling and Coulomb repulsion effects [1]. The analyse of quantum oscillations by the generalized Lifshitz-Kosevich formula shows the occurrence of three extremal orbits. The angular and temperature dependencies of these frequencies suggest the presence of only two pockets at the Fermi surface: a quasi two-dimensional electron-like one at the centre of the Brillouin zone compensated by a hole-like one situated at approximatively mid-distance along the GM (ZA) direction. The latter pocket is made of two highly dispersed bands and contains very mobile charge carriers. The different symmetries of these two bands is an obstacle to the realisation of a Dirac symmetry.

3. Institut für Halbleiter und Festkörperphysik, Johannes Kepler Universitõt, Linz, Austria

Topological insulators (TIs) have attracted increasing attention as a class of materials combining new fundamental physicals and potentials for applications in the field of spintronics[1]. An essential property of 3D TIs like e.g. Bi_2Se_3 is time reversal symmetry and a strong spin-orbit coupling, leading to topologically protected surface states (TSSs) and a suppression of backscattering processes in surface electronic transport. It has been predicted that magnetic atoms in the vicinity of the TSS can break time-reversal symmetry and opens efficient spin-flip channels for backscattering processes. We have shown earlier that single magnetic adatom spins situated on TI surfaces randomly fluctuate at temperatures T~4K[2]. In order to achieve stable exchange fields, our present work focuses on MBE-grown TI heterostructures consisting of thin surface layers of pure Bi_2Se_3 and a buried, remanently magnetized Mn-doped Bi_2Se_3 layer. The heterostructure is sealed by a protective Se capping layer. In this contribution we present an optimized Se capping and decapping procedure of Mn-doped samples under UHV conditions. Surface properties before and after decapping are controlled by EDX, PEEM and XPS measurements, and the TSS state is monitored in situ by k-PEEM. The important question of potential changes of the magnetic properties of Mn-doped layers (1 - 10%) due to diffusion effects during decapping process at elevated temperatures is addressed via extensive measurements of the bulk magnetization using SQUID. These showed no significant difference of the magnetic coupling caused by decapping process.

FR.A-P63 - Metal-insulator transitions in elemental Yb and $SrTiO_3$

C. Enderlein [1,2], S. Rowley [1,2], J. Olivera [1], M. Fontes [1], S. Saxena [2], G. Lonzarich [2], E. Saitovitch [1]

1. CBPF, Urca, Rio de Janeiro, Brasil
2. Cavendish Laboratory, Cambridge, United Kingdom

We present results of a study in two systems Yb and $SrTiO_3$ which may both be readily tuned through an insulator to metal transition resulting in the formation or destruction of tiny Fermi surface pockets. In the case of Yb, ~12 kbars of pressure is enough to transform its metallic state into an insulator through a quantum critical Lifshitz transition, the point where the size of the Fermi surface is tuned continuously to zero. We study the novel transport properties around this point as a function of temperature and magnetic field and present ideas of possible new states of matter that may form at low temperatures. Pure insulating $SrTiO_3$ is close to a ferroelectric quantum critical point which is well understood by the quantum self-consistent phonon model and exhibits striking dielectric behaviour. By tuning with chemical substitution or gate voltages, insulating $SrTiO_3$ and related materials undergo a transition into the metallic state and then become superconducting. Superconductivity appears to arise in the anti-adiabatic limit where the Fermi energy is smaller than the energy scales of the pairing bosons. We discuss how the polar optical phonons present close the quantum critical point can lead to a strong binding energy for electrons over a range of carrier concentrations and present new experimental data on $SrTiO_3$ in its metallic and superconducting states.

Fr.A-P64 - Semi-epitaxial SmB_6 thin films prepared by the molecular beam epitaxy

H. Shishido [1,2], Y. Yoneda [1], T. Yoshida [1], S. Noguchi [1,2,3], T. Ishida [1,2]

1. Department of Physics and Electronics, Graduate School of Engineering, Osaka Prefecture University, Osaka, Japan
2. Institute of Nanofabrication Research, Osaka Prefecture University, Osaka, Japan
3. Nanoscience and Nanotechnology Research Center, Osaka Prefecture University, Osaka, Japan

Rare-earth hexaboride compounds have been studied extensively for their various interesting properties. Although SmB_6 is known as a prototypical Kondo insulator [1], it has recently attracted a great deal of attention as a possible candidate of a 3D topological Kondo insulator [2]. Both theoretical and experimental works are suggestive of the appearance of topologically-protected metallic surface states at low temperatures in SmB_6 while the bulk is kept as an insulator. It is of crucial importance to realize epitaxial SmB_6 films for extending the researches. We grow thin films of SmB_6 by molecular beam epitaxy (MBE). Depositions were performed under ultra-high vacuum of below 10-6 Pa. Sm and B were evaporated by Knudsen cells with the atomic ratio of B/Sm ~ 6 on a MgO (100) substrate at temperatures from 750 to 1000 C .
Reflection high energy electron diffraction (RHEED) patterns show spotted ones indicating a relatively flat film surfaces. There are in good agreement with the surface roughness measured by the atomic force microscope (AFM). Interplane X-ray diffraction (XRD) patterns show only (00l) peaks of SmB_6, except substrate peaks. The (100) peak of SmB_6 appears as a main peak at inplane XRD patterns, while other (h k 0) peaks also observed. The phi-scan of the (100) peak shows 4 peaks in every 90 degrees, which corresponds to the four-fold symmetry of SmB_6. These results indicate that our SmB6 thin films partly grow epitaxially. The electrical resistivity increases with decreasing temperature as a semiconductor, and becomes constant at low temperatures. These features well reproduce the tendency of the resistivity observed in bulk samples.

FR.B-P01 - The influence of Coulomb correlations on the tunneling transport through multi-electrons states in strongly coupled quantum dots

V. Mantsevich [1,2], N. Maslova [1,2], P. Arseyev [1,2]

1. Moscow State University, Moscow, Russia
2. P.N. Lebedev Physical Institute, Moscow, Russia

We investigated tunneling processes in the system of two strongly coupled quantum dots with Coulomb correlations between localized electrons weakly interacting with the reservoirs. In the considered system the electrons number changing due to the tunneling processes leads to the modification of the energy spectrum, which is not reduced to the simple adding of Coulomb interaction value per electron. One, two, three or four electrons can be localized in the coupled QDs at the same moment, each state with fixed total charge and spin projection has it's own energy. Transitions between these states were analyzed in terms of pseudo-particle operators with constraint on the possible physical states of the system. Filling numbers of different multi-electron states, total electron occupation of quantum dots and I-V characteristics were investigated for different single electron levels positions relative to the sample Fermi level and various tunneling transfer rates.
It was shown that due to the presence of strong Coulomb correlations total electron occupation of the system can significantly decrease with increasing of applied bias when both single electron energy levels are situated below the Fermi level contrary to the situation with no correlations. Tunneling electron changes multi-particle states of QDs and pushes out electrons from the state below the Fermi level. We demonstrated that for some parameter range, the system demonstrates negative tunneling conductivity in certain ranges of the applied bias voltage due to the Coulomb correlations. We also revealed spin blockade effects in I-V characteristics of asymmetrical tunneling contact with two correlated coupled QDs. The spin blockade effect in our model manifests in the absence of a number of steps in the I-V characteristics, when asymmetrical tunneling contact is considered. We demonstrated, that correlated QDs can be used as an effective current switch key by changing the intensity of the external field.

FR.B-P02 - New state of matter

V. Shaginyan [1,2,3], M. Amusia [1,2,3], V. Stephanowich [1,2,3]

1. Petersburg Nuclear Physics Institute, National Research Center 'Kurchatov Institute', Moscow, Russia
2. Racah Institute of Physics, Hebrew University, Jerusalem, Israel
3. Institute of Physics, Opole University, Opole, Poland

In many Fermi systems and compounds at zero temperature a phase transition happens that leads to a quite specific state called fermion condensation. As a signal of such a fermion condensation quantum phase transition serves unlimited increase of the effective mass of quasiparticles that determines the excitation spectrum and creates flat bands [1]. We have theoretically carried out a systematic study of the phase diagrams of strongly correlated heavy-fermion compounds, including heavy-fermion metals, high temperature superconductors, insulators with strongly correlated quantum spin liquid, quasicrystals, and two dimensional Fermi systems (like 3He), and have demonstrated that these diagrams have universal features. The obtained results are in good agreement with experimental facts. We have shown both analytically and using arguments based entirely on the experimental grounds that the data collected on these very different heavy-fermion compounds have a universal scaling behavior, and these materials with strongly correlated fermions can unexpectedly have a uniform behavior in spite of their microscopic diversity. Thus, the quantum critical physics of different heavy-fermion compounds is universal, and emerges regardless of the underlying microscopic details of compounds. This uniform behavior, induced by the universal quantum critical physics, allows us to view it as the main manifestation of the new state of matter. Our theoretical analysis of numerous experimental facts shows that the theory of fermion condensation develops completely good description of the non-Fermi liquid behavior of heavy-fermion compounds. Moreover, the fermion condensate can be considered as the universal reason for the non-Fermi liquid behavior observed in various heavy-fermion compounds [1].

FR.B-P03 - Orbital-selective behavior and suppression of double exchange in dimerized systems

S. Streltsov [1,2], D. Khomskii [3]

1. Institute of Metal Physics, Kiev, Ukraine
2. Ural Federal University, Sverdlovsk Oblast, Russia
3. University of Cologne, Köln, Germany

We show that in transition metal compounds containing structural metal dimers there may exist in the presence of different orbitals a special state with partial formation of singlets by electrons on one orbital, while others are effectively decoupled and may give e.g. long-range magnetic order or stay paramagnetic. Similar situation can be realized in dimers spontaneously formed at structural phase transitions, which can be called orbital-selective Peierls transition. This can occur in case of strongly nonuniform hopping integrals for different orbitals and small intra-atomic Hund's rule coupling JH. Yet another consequence of this picture is that for odd number of electrons per dimer there exist competition between double exchange mechanism of ferromagnetism, and the formation of singlet dimer by electron on one orbital, with remaining electrons giving a net spin of a dimer. The first case is realized for strong Hund's rule coupling, typical for 3d compounds, whereas the second is more plausible for 4d-5d compounds. We discuss some implications of these phenomena, and consider examples of real systems, in which orbital-selective phase seems to be realized.

FR.B-P04 - Strong coupling theory for the hubbard model

A. Sherman [1]

1. Institute of Physics, University of Tartu, Tartu, Estonia

In recent years, in connection with the discovery of iron-based superconductors and investigations of the influence of electron correlations on topological insulators, the interest has increased in the multi-band generalizations of the Hubbard model. For these model Hamiltonians it would be desirable to find an approach, which, being comparatively simple computationally, yields at least qualitatively correct results. As a possible candidate for such an approach the strong coupling diagram technique is considered in this work. The method is based on the expansion in powers of the kinetic energy. The elements of diagrams are on-site cumulants of creation and annihilation operators and hopping lines connecting cumulants on different sites. Despite the fact that by the construction the approach is intended for the strong coupling case, it gives the correct result for vanishing Hubbard repulsions *U*. The approach leads to a set of equations for the electron Green's function, which can be self-consistently solved. At half-filling, for the semi-elliptical density of states (DOS) as well as for the two-dimensional *t-U* and *t-t'-U* models these equations describe the Mott transition, which occurs at $U_c \approx 7\Delta/8$ with Δ the bandwidth. This value is close (identical for the semi-elliptical DOS) to that obtained in the Hubbard-III approximation. By the positions of maxima, shapes and their variation with momentum and electron concentration *n* the calculated spectral functions are close to results of Monte Carlo simulations in the range $0.7<n<1.3$. Also the variation of the momentum dependence of occupation numbers with *U* is in satisfactory agreement with Monte Carlo data at half-filling. The behavior of the Mott gap is different in the *t-U* and *t-t'-U* models [1].

FR.B-P05 - First-principles theory of momentum-dependent local ansatz for correlated electrons system

S. Chandra [1], Y. Kakehashi [1]

1. University of The Ryukyus

Variational approach is a simple and useful method to describe the ground state properties of strongly correlated electron system. We have recently developed the momentum dependent local ansatz wavefunction method (MLA) [1]. The method describes electron correlations from the weak to strong Coulomb interaction regime by making use of the two particle correlators with momentum dependent variational parameters and a hybrid starting wavefunction. The MLA describes the momentum dependence of physical quantities and therefore describes well those associated with the low energy excitations such as the effective mass, going beyond the Gutzwiller wavefunction. In order to describe the realistic system and to go beyond the first-principles Gutzwiller method [2], we have extended the MLA to the first-principles version using the tight-binding LDA+U Hamiltonian [3]. We present here the first-principles MLA and some numerical results on the correlation energy, momentum distribution function, charge fluctuations, amplitude of local moments, as well as quasiparticle weight for Fe and Fe compounds. We found the distinct momentum dependence of the momentum distribution function, and that the jump at the Fermi level is monotonically decreased with increasing Coulomb and exchange interactions, indicating mass enhancement.

FR.B-P06 - Thermodynamic properties of solid oxide fuel cell (SOFC) cathode material- $Nd_{1-x}Sr_xCoO_{3-\delta}$

R. Thakur [1], R.K. Thakur [1], N.K. Gaur [1]

1. Barkatullah University, Bhopal

Mixed ionic-electronic conductors (MIECs) containing Co with the capability to conduct oxygen ions and electrons simultaneously have been identified as strong potential IT-SOFC cathode candidates in recent years. The fact that rare-earth perovskite-type cobaltate are most suitable as a cathode material in solid oxide fuel cells (SOFC), makes the thermal behavior of these compounds highly important. As these compounds are predominantly ionic in nature hence the lattice contributions to the specific heat at constant volume ($C_{v(lattice)}$) of $Nd_{1-x}Sr_xCoO_{3-\delta}$ ($0.1 \leq x \leq 0.8$) has been studied and thereby thermal expansion is computed as function of temperature by means of Modified Rigid Ion Model (MRIM) and found to be in good agreement with experimental values. We have systematically investigated the effect of phonons on thermal properties, Debye temperature (θ_D), molecular force constant (*f*), Reststrahlen frequency (υ), cohesive energy (ϕ), and Gruneisen parameter (γ) for $Nd_{1-x}Sr_xCoO_{3-\delta}$ ($0.1 \leq x \leq 0.8$). Also the effect of phonons on the bulk modulus is studied using the atoms in molecules (AIM) theory for $Nd_{1-x}Sr_xCoO_{3-\delta}$ ($0.1 \leq x \leq 0.8$). We have found that the computed properties reproduce well with the available experimental data, implying that MRIM represents properly the perovskite cobaltate $Nd_{1-x}Sr_xCoO_{3-\delta}$ ($0.1 \leq x \leq 0.8$). To our knowledge some of the properties for these complicated compounds are reported for the first time.

FR.B-P07 - Metal-Insulator Transition in 1T-TaS_2:: A real-space dynamical mean-field study

Y.Y. Zhao [1], J. Sun [1], L.J. Zou [2], Y. Song [1]

1. Department of Physics, Beijing Normal University
2. Key Laboratory of materials Physics, Institute of Solid State Physics, Chinese Academy of Science, P. O. Box 1129, Hefei 230031, China

The experimental observation of an abnormal Mott insulator to metal transition in $1\mathrm{T}-\mathrm{Ta}S_2$ was assumed to be generated by the interplay between correlation and disorder[1]. Considering the stacking disorder in this compound, we take a theoretical analysis of the interplay of interactions and off-diagonal disorder in the one-dimensional extended Anderson-Hubbard model. We employ the real-space dynamical mean-field theory[2], which can treat correlation and disorder on an equal footing, to study the competition among the hopping disorder (W'), on-site interaction U , and on-site disorder W. We find that when $\mathrm{U}=\mathrm{W}=0$, the density of states has a peak at $\mathrm{E}=0$ with increasing hopping disorder. We use the generalized inverse participation ratio (GIPR) as a measure of the localization [2,3], and find that the system is localized at finite W'. We also find that when W=0 and $\mathrm{U}\neq 0$, the density of states has a Mott gap, but also has a peak at the half of the band width at large W'. The lattice size scaling of the GIPR indicates that the localization effect of the off-diagonal disorder is much weaker than that of the on-site disorder. As a result, the Mott gap cannot be closed by the off-diagonal disorder, differing significantly from the diagonal disorder. With this method, we also discuss the dependences of the optical conductivity $\sigma(\omega=0,\mathrm{T})$ with U, W and W'.

FR.B-P08 - NMR relaxation in the topological kondo insulator SmB_6

P. Schlottmann [1]

1. Florida State University, Tallahassee, United States

SmB_6 has been predicted to be a strong topological Kondo insulator and experimentally it has been confirmed that at low temperatures the electrical conductivity only takes place at the surfaces of the crystal. We study the temperature and magnetic field dependence of the NMR Knight shift and relaxation rate arising from the topological conduction states. For the clean surface the Landau quantization of the surface states gives rise to highly degenerate discrete levels for which the Knight shift is proportional to the magnetic field B and inversely proportional to the temperature T. The relaxation rate, 1/T_1, is not Korringa-like. For the more realistic case of a surface with a low concentration of defects (dirty limit) the scattering of the electrons leads to a broadening of the Landau levels and hence to a finite density of states. The mildly dirty surface case leads to a T-independent Knight shift proportional to B and a Korringa-like 1/T_1 at low T [1]. The wave functions of the surface states are expected to fall off exponentially with distance from the surface giving rise to a superposition of relaxation times, i.e. a stretched exponential. It is questionable that the experimental boron 11 Knight shift and relaxation rate [2] arise from the surface states of the TKI. An alternative explanation is that the bulk susceptibility and the boron 11 NMR properties are the consequence of the in-gap bulk states originating from magnetic exciton bound states proposed by Riseborough [3].

FR.B-P09 - Magnetic hyperfine field at a Cd impurity diluted in RCo_2 at finite temperatures

A.L. de Oliveira [1], C. M. Chaves [2], N.A. de Oliveira [3], A. Troper [2]

1. Instituto Federal de Educacao, Ciencia e Tecnologia do Rio de Janeiro, Campus Nilopolis, Rio de Janeiro, Brazil
2. Centro Brasileiro de Pesquisas Físicas, Rio de Janeiro, Brazil
3. Instituto de Fisica, Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil

The local magnetic moments and the magnetic hyperfine fields at an {s-p} Cd impurity diluted in inter-metallic Laves phase compounds RCo_2 (R = Gd, Tb) at finite temperatures are calculated. For other rare earth elements (light or heavy) the pure compounds display a magnetic first order transition and are not describable by our formalism.
The host has two coupled lattices (R and Co) both having itinerant d electrons but only the rare earth lattice has localized f electrons. They all contribute to the magnetization of the host and also to the local moment and to the magnetic hyperfine field at the impurity which occupies an R site. The investigation of magnetic hyperfine field in these materials then provides valuable information on the d itinerant electrons and also on the localized 4f magnetic moments.
For the d-d electronic interaction we use the Hubbard-Stratonovich identity thus allowing the employment of functional integral; the static saddle point approximation is also used. Our model reproduces quite well the experimental data.

FR.B-P10 - Magnetism in the three-dimensional layered Lieb lattice: Higher transition temperatures via flat-band and Van Hove singularities

K. Noda [1], K. Inaba [1], M. Yamashita [1]

1. NTT Basic Research Laboratories, Kanagawa, Japan

Realizations of two-dimensional complex optical lattices, such as the honeycomb and Kagome lattices, provide new research fields of quantum magnetism. Here, we focus on the Lieb lattice (i.e., line-centered square lattice), which was created quite recently by the Kyoto group [1]. In this lattice, the flat-band, which leads to a delta-functional divergence of the density of states (DOS), induces exotic phenomena (i.e., magnetism, superconductivity, and topological properties). However, in 2D systems, strong quantum fluctuations rule out finite temperature transitions. This fact naturally turns our attention to the three-dimensional (3D) layered Lieb lattice [1], where we addressed the ground state properties [2].
In this study, we investigate magnetism with two-component fermions in the 3D layered Lieb lattice at half-filling and finite temperatures using the dynamical mean-field theory and an analytical method. In this lattice, when the ratio of the interlayer to intra-layer hoppings changes, there appear several types of divergent DOSs, such as the delta-functional flat-band singularity (FBS) and logarithmic Van Hove singularity (VHS). First, we numerically elucidate that these two singularities change the interaction U dependence of transition temperature T_C, which drastically raise T_C. To investigate this singularity effect in detail, next we offer an analytical framework. We obtain a characteristic transition temperature specific to the FBS: $T_C/W \propto U/W$ with bandwidth W. Furthermore, using this framework, we can describe T_C in the universal form represented with the Lambert function, which includes both the characteristic and conventional dependence: $T_C/W \propto e^{-1/\rho(E_F)U}$ with the DOS at the Fermi energy $\rho(E_F)$. We also reveal that the FBS induces an anomaly of double occupancy even in the paramagnetic state above T_C, which is a precursor phenomenon to the flat-band magnetic transition.

FR.B-P11 - Steady state dynamics in a model system of strongly correlated electrons: effective temperatures near local quantum criticality

F. Zamani [1], P. Ribeiro [2], S. Kirchner [3]

1. Max Planck Institute for Physics of Complex Systems, Dresden, Germany
2. Russian Quantum Center, Business-center "Ural", Skolkovo village, Odintsovo district, Moscow, Russia
3. Center for Correlated Matter, Zhejiang University, Zhejiang, China

Strongly correlated systems far from equilibrium have recently generated considerable interest. This interest has mainly been spurred by experimental progress in preparing and characterizing such systems out of equilibrium. The theoretical understanding on the other hand suffers from a lack of methods that can reliably treat strongly correlated systems in and out of equilibrium at an equal footing. Here, we present our results for the thermal and non-thermal steady-state scaling functions and steady-state dynamics in a model of local quantum criticality. Our model, the pseudogap Kondo model, allows us to obtain full scaling functions in and out of equilibrium. We also study the concept of effective temperatures for correlations far from equilibrium near fully interacting as well as weak coupling fixed points. In the vicinity of each fixed point we establish the existence of an effective temperature - different at each fixed point-such that the equilibrium fluctuation-dissipation theorem is recovered. Most interestingly, steady-state scaling functions in terms of the effective temperatures coincide with the equilibrium scaling functions in terms of the equilibrium temperature. This result extends to higher correlation functions as will be explicitly demonstrated.

FR.B-P12 - Pinball liquid phase from Hund's coupling in frustrated triangular geometry

A. Ralko [1], J. Merino [2], S. Fratini [1]

1. Neel Institute, Grenoble, France
2. Universidad Autónoma de Madrid, Madrid, Spain

Materials with competing electronic interactions on triangular lattices are a fertile ground for novel phenomena and original quantum phases, such as the spin liquid behavior observed in organic (κ-(BEDT-TTF)2Cu2(CN)3, Me3EtSb[Pd(dmit)2]2) and inorganic (Cs2CuCl4) quasi-two-dimensional materials. Geometrical frustration can play a similar role in charge ordering phenomena leading to poorly understood unconventional metallic and superconducting states. Remarkable examples are found in the quarter-filled organic salts, the layered cobaltates and the transition metal dichalcogenide 1T-TaS2.
Motivated by AgNiO2, a layered oxide compound with a triangular planar lattice structure, whose properties reflect a rich interplay between magnetic, orbital and charge degrees of freedom exhibiting exotic symmetry broken phases, we have analyzed a multiband microscopic model which takes explicit account of electronic correlations to demonstrate that the emergence of charge ordered phases with unconventional metallic properties is a natural outcome in frustrated triangular oxides with both strong Coulomb interactions and Hund's coupling. By using complementary technics such as DMFT, Exact Diagonalizations and Generalized Hartree-Fock, we how that the combination of on-site and off-site repulsion and Hund exchange lead to the stabilization of a robust pinball liquid phase [1,2], a quantum phase where the charges spontaneously separate into coexisting localized (pins) exhibiting Mott physics and band-like itinerant electrons (balls) moving on a honeycomb lattice. We argue that the charge ordered metallic phase of AgNiO2 is a neat experimental realization of such pinball liquid, which explains many of the observed experimental features such as the 3-fold ordering pattern, the strong charge disproportionation, the presence of large local moments and the 'bad' metallic behavior.

FR.B-P13 - A phenomenological approach to the metamagnetism in heavy fermion compounds

K. Matsumoto [1], S. Kosaka [1], S. Murayama [1]

1. Muroran Institute of Technology, Hokkaido, Japan

A phenomenological theory is developed for the metamagnetism of heavy fermion compounds by the extension of the Landau theory for phase transitions. Firstly, we write down the extended Landau free energy density for the two sub-lattice Ising antiferromagnet. In this free energy density, the higher order terms of the sub-lattice magnetizations are also included. Secondary, by minimizing this free energy density with respect to the sub-lattice magnetizations, we can determine the equilibrium quantities as the functions of the applied magnetic field.

From this analysis the crossover behavior in the high magnetic field is indicated for the extended Landau free energy density. We regard some parameters of the extended Landau free energy density as the functions of temperature. Then, we can draw the magnetic phase diagrams resemble to the observed ones for $CeRu_2Si_2$ and $Ce(Ru_{0.92}Rh_{0.08})_2Si_2$.[1),2),3)] The possibility of the first order transition for the metamagnetism is discussed.

FR.B-P14 - Novel spin and orbital orderings in the layered perovskite Sr_2CrO_4

T. Ishikawa [1], T. Toriyama [1], T. Konishi [1], H. Sakurai [2], Y. Ohta [1]

1. Chiba University, Chiba, Japan
2. National Institute for Materials Science, Ibaraki, Japan

Recently, successive phase transitions were observed in Sr_2CrO_4 with the $K_2NiF_{4\text{-type}}$ crystal structure, where the lower-temperature transition at 112 K was attributed to the Néel antiferromagnetic ordering but the higher-temperature transition at 140 K remained a mystery [1]. Since the CrO_6 octahedra in this layered perovskite are elongated along the c-axis and the Cr ions are in the Cr4+ (3d2) oxidation state, the simple crystal-field theory predicts that there should be no orbital degrees of freedom in this system and thus this material is to be an antiferromagnetic Mott insulator with spin S = 1. The discovery of the successive phase transitions is therefore quite a big surprise.
We carried out the density-functional-theory-based electronic structure calculations to elucidate the origin of the observed successive phase transitions. We then obtained the electronic structure that exhibits the spin and orbital orderings in the ground state. From the analysis of the state, we found that this material consists of two subsystems: (i) a Kugel-Khomskii-type spin-orbital subsystem consisting of the dxz and dyz orbitals of Cr and (ii) an antiferromagnetic Heisenberg subsystem consisting of the dxy orbitals of Cr.
The two subsystems then couple via the Hund's ferromagnetic exchange interaction on the two-dimensional CrO_2 plane, and thus the novel spin-antiferro and orbital-antiferro state is realized in its ground state. We argue that the higher (lower) temperature phase transition is explained to be due to the ordering of the orbital (spin) degrees of freedom.

FR.B-P15 - Quantum disordered phase in the frustrated honeycomb Hubbard model

H. Nishida [1], K. Misumi [1], T. Kaneko [1], Y. Ohta [1]

1. Chiba Univercity, Chiba, Japan

The metal-insulator transition of Dirac fermions and possible occurrence of the quantum disordered (or spin-liquid) phase are studied for the frustrated honeycomb Hubbard model at half filling by means of the variational cluster approximation (VCA). The frustration in the spin degrees of freedom is introduced by the next-nearest-neighbor hopping parameters. We show that the antiferromagnetism in the Mott insulator phase is suppressed by the effects of spin frustrations in the intermediate and strong coupling regions, resulting in a possible realization of the quantum disordered (or spin-liquid) phase in the vicinity of the Dirac semimetallic phase.
This disordered phase is discussed in relation to that of the frustrated honeycomb Heisenberg model achieved in the strong-coupling region of our model.

FR.B-P16 - Charge-density wave and exciton condensation induced by Coulomb interaction and electron-phonon interaction in 1T-TiSe_2

H. Watanabe [1], K. Seki [2], S. Yunoki [1,2]

1. RIKEN CEMS, Saitama, Japan
2. RIKEN, Saitama, Japan

Transition metal dichalcogenides (TMDCs) exhibit various quantum phases and have been extensively studied for more than forty years. However, the origin of these quantum phases such as charge-density wave (CDW) and superconductivity has not been fully understood because of the complicated competition among Coulomb interaction, electron-phonon interaction, and spin-orbit interaction, which are believed to be important in TMDCs. Recently, 1T-TiSe_2, one of the typical examples of TMDCs, has attracted much interests in the context of exciton condensation. The exciton condensation is a quantum phenomenon, where bound electron-hole pairs (excitons) are macroscopically condensed in a semimetal or a semiconductor. Although the exciton condensation has been proposed to be the origin of the CDW in 1T-TiSe_2, the static lattice distortion observed in CDW phase indicates a strong coupling between electron and lattice degrees of freedom and thus the band Jahn-Teller effect is also a possible origin of the CDW.
To clarify the origin of the CDW in 1T-TiSe_2, we study the two-band Hubbard model in a triangular lattice with the electron-phonon interaction. By using the variational Monte Carlo method, both the electronic and lattice degrees of freedom are treated beyond the mean-field approximation. We show that the cooperation between the Coulomb interaction and the electron-phonon interaction is essential to induce the exciton condensation and the resulting CDW phase in the model for 1T-TiSe_2. The strong-coupling BEC-type exciton condensation is proposed for 1T-TiSe_2 by investigating the nature of an electron-hole pair of the exciton. We also study the same model in a square lattice and discuss the importance of lattice structure and Fermi surface nesting on the stability of excition condensation.

FR.B-P17 - Anomalous influence of an external magnetic field on the electron energy spectrum of ferromagnetic semiconductors with strong p,d-hybridization

A. Povzner [1], A. Volkov [1], K. Shumikhina [1]

1. Ural Federal University, Sverdlovsk Oblast, Russia

Anomalous influence of an external magnetic field on the electron energy spectrum of ferromagnetic semiconductors with strong p,d-hybridization. A. A. Povzner, A. G. Volkov, K. A. Shumikhina Ural Federal University, Russia a.a.povzner@urfu.ru, agvolkov@yandex.ru.
The influence of magnetic field on properties of the hybridized pd-electrons studied for thin films of ferromagnetic semiconductors. The initial states of p-electrons were describe by model of nearly free electrons, and strongly correlated d-electrons - by Hubbard model. The total Hamiltonian includes the term electron hopping between the p- and d-states at different sites. It was show that hybridization of p- and d-electrons leads to a picture of bands, separated by hybridization gap, the states of which are splitted and shifted in energy by stochastic internal exchange and charge fields. As a result, a narrow band of heavy fermions appears in hybridization gap. The scattering of electrons by the electron density fluctuations leads to appearance strong damping of the electron states in heavy fermions band. The energy width of these states can be expressed as , where is amplitudy of spin fluctuation, M and h are homogeny magnetization and magnetic field, T is temperature, is mode-mode coupling constant. The influence of magnetic field on the spectrum explains negative magnetoresistive and magnetorefractive effects. The temperature dependence of mode-mode coupling constant has a maximum in the ferromagnetic vicinity of the Curie point . This fact stipulates an anomalously strong suppression of spin fluctuations by the magnetic field that leads to sharp decrease of . Temperature and field dependences of simultaneously describes colossal magnetoresistive and magnetorefractive effects, as well as the red shift of fundamental absorption edge. At the amplitude of the spin fluctuations increases slightly. Therefore the fundamental absorption edge is almost unchanged compared to the ferromagnetic region. However, its field dependence is not anomalous.

FR.B-P18 - Quantum disordered phase in the triangular-lattice Hubbard model with next-nearest-neighbor hopping

K. Misumi [1], T. Kaneko [1], Y. Ohta [1]

1. Chiba University, Chiba, Japan

Magnetic ordering and metal-insulator transition (MIT) in the triangular-lattice Hubbard model have been one of the central issues in physics of frustrated strongly-correlated electron systems. In the isotropic triangular-lattice Hubbard model, it is known that a 120˚ Néel order appears in the strong-coupling region and a quantum disordered state exists near the MIT phase boundary [1,2]. Recently, the magnetic orders of the triangular-lattice J1-J2 Heisenberg model with the nearest-neighbor (J1) and next-nearest-neighbor (J2) interactions were studied by the many-variable variational Monte Carlo method, whereby the change from the 120˚ Néel order to the collinear order with increasing J2, as well as the quantum disordered state in-between, was predicted [3].
Motivated by such developments in the field, we here study the frustration and magnetic orders in the triangular-lattice Hubbard model at half filling with the nearest-neighbor (t1) and next-nearest-neighbor (t2) hopping parameters. We employ the variational cluster approach [4], which takes into account the short-range electron correlations exactly, and thus is very useful for studying the magnetic orders in the frustrated Hubbard model. We will thereby present the magnetic phase diagram of this model at zero temperature by calculating the magnetic order parameters. We will moreover show the appearance of the quantum disordered state between these two states. We will also discuss the MIT of this model by calculating the parameter dependence of the single-particle spectral function, and show that the quantum disordered state also appears in the vicinity of the MIT phase boundary.

FR.B-P19 - The Hubbard model beyond the two-pole approximation: a composite operator method study

A. Avella [1]

1. Università Degli Studi Di Salerno - Dipartimento Di Fisica, Milan, Italy

Within the framework of the Composite Operator Method, a three-pole solution for the two-dimensional Hubbard model is presented and analyzed in detail [1]. In addition to the two Hubbard operators, the operatorial basis comprises a third operator describing electronic transitions dressed by nearest-neighbor spin fluctuations. These latter, compared to charge and pair fluctuations, are assumed to be preeminent in the region of model-parameter space - small doping, low temperature and large on-site Coulomb repulsion - where one expects strong electronic correlations to dominate the physics of the system. This assumption and the consequent choice for the basic field, as well as the whole analytical approximation framework, have been validated through a comprehensive comparison with data for local and single-particle properties obtained by different numerical methods on varying all model parameters. The results systematically agree, both quantitatively and qualitatively, up to coincide in many cases. Many relevant features of the model, reflected by the numerical data, are exactly caught by the proposed solution and, in particular, the crossover between weak and intermediate-strong correlations as well as the shape of the occupied portion of the dispersion. A comprehensive comparison with other n-pole solutions is also reported in order to explore and possibly understand the reasons of such good performance. [Eur. Phys. J. B 87, 45 (2014)]

FR.B-P21 - The influence of the interband Coulomb interaction and the f-electron hopping on excitonic correlations in the extended Falicov Kimball model

P. Farkasovsky [1]

1. Institute of Experimental Physics, Slovak Academy of Sciences, Bratislava, Slovakia

The density-matrix-renormalization-group method (DMRG) is used to ex-amine effects of the interband Coulomb interaction between f and d electrons as well as the f-electron hopping on the stability of the excitonic phase in the one-dimensional Falicov-Kimball model (FKM) with local hybridization. It is found that the interband Coulomb interaction dramatically enhances the excitonic P_{df} = hd+fi average and that this effect is especially strong in the limit of small hybridization, where the interacting P_{df} (U) excitonic value is en-hanced several hundred times in comparison to its non-interacting P_{df} (U = 0) value. The further increase in Pdf is observed due to the non-zero f-electron hopping, but these changes are considerable only if the d and f bands have the opposite parity. In addition, the examination of the interplay between the excitonic effects and the charge density wave (CDW) instability showed that the CDW and excitonic phase coexist up to relatively large values of local hybridization ($V \sim 0.12$). The complete phase diagram of the model in the $V - U$ plane is presented.

FR.B-P22 - Microscopic model of full magnetic phase-diagram of itinerant ferromagnet UGe_2

We provide [1, 2] the microscopic model which provides a fairly complete description of the electronic and magnetic properties of UGe_2. It is based on the Anderson-lattice model treated in the modified Gutzwiller approximation (SGA) [3]. We explain the appearance of the experimentally observed magnetic phases, namely strong-ferromagnetism, weak-ferromagnetism, as well as the transition to paramagnetism. We show that the sequence and evolution of those phases in the applied magnetic field can be explained in a natural manner as an effect of the competition between the Coulomb repulsion of the uranium 5*f* electrons and the hybridization of f-electrons with the conduction elections [1]. We track the evolution of classical and quantum critical points in applied field, as a function of pressure, and of the total electron concentration [2]. We simulate the effect of the pressure applied to the real system. We argue, that the main effect of pressure is to change the hybridization strength. We discuss also the effect of the f-level position with the increasing pressure, as well as the possibility of crossing the Hill limit when the overlap between f-orbitals turns out to be nonzero. Our approach explains in a semiquantitative manner the recent experimental results [4].

FR.B-P23 - Theoretical study of charge-spin-orbital fluctuations in mixed valence spinels: AlV_2O_4 and LiV_2O_4

A. Uehara [1], H. Shinaoka [2], Y. Motome [1]

1. The University of Tokyo, Tokyo, Japan
2. ETH Zürich, Zürich, Switzerland

We theoretically investigate the fluctuations in charge, spin, and orbital degrees of freedom in spinel oxides AB_2O_4. As the B cations comprise a pyrochlore lattice, the mixed valence spinels are a good playground for the interplay of multiple degrees of freedom on the geometrically frustrated lattice structure. In the present study, we focus on two spinels, AlV_2O_4 and LiV_2O_4, which show puzzling, contrasting behavior despite the common structure: AlV_2O_4 exhibits a peculiar structural phase transition with a self-organization of seven V clusters (heptamers) at 700 K, while LiV_2O_4 does not show any transition down to the lowest temperature except for crossover to an unconventional heavy fermion state at 20-30 K. In order to clarify the origin of the contrasting behavior, we adopt the combined method between the first-principles calculation and the perturbation in terms of electron correlations. Specifically, we construct the multiband Hubbard model by the maximally-localized Wannier function analysis for the LDA band structure. We then calculate the generalized susceptibility, which includes all the information of fluctuations in charge, spin, and orbital sectors, by the random phase approximation. For AlV_2O_4, we find that the dominant fluctuations appear in the vicinity of the center of the Brillouin zone. We unveil that peculiar charge fluctuations are sensitively enhanced by the inter-site Coulomb interaction. The enhanced fluctuations are of sigma-bonding type with strong orbital dependence. The importance of similar sigma-bonding states in the hepmater formation was suggested in the previous studies. Hence, our results provide a key for understanding of the self-organization in AlV_2O_4. In contrast, for LiV_2O_4, we find that the on-site interaction enhances the optical-type spin fluctuations at an incommensurate wave number. This fluctuation is enhanced at very low temperature, in the order of 10 K, which is suggestive of the peculiar heavy fermion behavior in LiV_2O_4.

FR.B-P24 - Dynamical characteristics of the Mott transition: examination of doublon dynamics in a triangular-lattice Hubbard model

T. Sato [1], H. Tsunetsugu [2]

1. RIKEN, Tokyo, Japan
2. The Institute for Solid State Physics, The University of Tokyo, Tokyo, Japan

Mott transition has been understood theoretically as the singularity in the density of doublon or holon. Correlations between doublon and holon have also been studied theoretically, and it was suggested that they form a bound state in the insulating phase and the Mott transition is characterized by its binding and unbinding. Recent studies of the Mott transition include dynamical characteristics. Some theoretical groups examined dynamical spin and charge susceptibilities as optical conductivity and reported a clear difference in the spin and charge dynamics between in the metallic and in the insulating phases. However, dynamics of doublons has not been well understood. We have numerically studied dynamics of doublons near the Mott transition in the half-filled Hubbard model on a triangular lattice. By means of a cluster dynamical mean field theory with a continuous-time quantum Monte Carlo solver, we examine the change in the nearest-neighbor (NN) and on-site (OS) dynamical correlations of doublon with varying the Coulomb repulsion at a fixed temperature. Our results for the dynamical correlations show clear differences between in the metallic and in the insulating phases. We demonstrate that a NN doublon-holon pair shows a strong attractive correlation, particularly in the insulating phase, while the NN pairs of doublons or holons show a repulsive correlation. The short-time dynamics of the NN doublon and holon in the metallic phase show larger fluctuations than in the insulating phase. In the long-time region, the metallic phase has persistent fluctuations in NN configurations, while the fluctuations quickly vanish in the insulating phase. Investigating the OS dynamical correlation of doublon, we have found that the lifetime of doublon is longer in the metallic phase than in the insulating phase [Phys. Rev. B {\bf 90}, 115114 (2014)].

FR.B-P26 - Theoretical study of non-fermi liquid behavior in Pr 1-2-20 compounds

A. Tsuruta [1], K. Miyake [2]

1. Osaka University, Osaka, Japan
2. Toyota Physical and Chemical Research Institute, Aichi, Japan

Non-Fermi liquid behaviors in the resistivity have been reported in PrV_2Al_20 [1] and PrIr_2Zn_20 [2]. Namely, the electrical resistivity is proportional to T^0.5. The Specific heat increases like C_0-C_1T^0.5 as T decreases. The ground state of the crystalline-electrical field (CEF) of the local f-electron is considered to be the Gamma_3 non-Kramers doublet in 4f^2 configuration. Such a system with the Gamma_3 CEF ground state in f^2 configuration is expected to exhibit an anomalous behavior associated with the two-channel Kondo effect. Tsuruta et al. investigated electronic states in the M-channel Anderson lattice model using the expansion from the limit of large spin-orbital degeneracy N (1/N-expansion) [3]. The inclusion of the self-energy in O((1/N)^0) leads to heavy electrons with degeneracy of channel and spin-orbit. In the single channel case, the imaginary part of the self-energy of conduction electrons (ISE) shows the Fermi liquid behavior: i.e. ISE is given by a form proportional to T^2 owing the inter-site correlation effects in higher order terms in power of 1/N. In the two-channel case, however, a T-linear term in ISE at the Fermi level, in contrast to a T^2 -term in the Fermi liquid is found. However, the T-linear dependence of ISE is restricted in the asymptotic region of T=0, but a T^0.5-dependence appears in a rather wide temperature region.
Because of the anomalous T-dependence of ISE, the chemical potential is given by mu_0-mu_1T^0.5, and the specific heat is given by C_0-C_1T^0.5. We also obtain the scaling behavior f(T/T_K), T_K is the quadrupole Kondo temperature, in electrical resistivity, chemical potential, specific heat and magnetic susceptibility, explaining non-Fermi liquid properties observed in Pr 1-2-20 compounds.

FR.B-P27 - Theory of dilution effect in orbital kondo systems

T. Mutou [1], Y. Miyamoto [1], H. Kusunose [2]

1. Shimane University, Shimane, Japan
2. Ehime University, Ehime, Japan

To clarify the origin of characteristic behavior in temperature dependence of transport properties observed in Pr 1-2-20 systems, the periodic Anderson model (PAM) with orbital degeneracy is investigated by the dynamical mean-field approach. In Pr 1-2-20 systems, it is considered that the characteristic behavior that is different from usual Fermi-liquid behavior arises from the orbital degrees of freedom of f electrons in Pr ions. Since there is the Coulomb repulsive interaction between these f electrons, it is also important to treat the electron correlation appropriately. In the present study, we adopt the dynamical mean-field theory (DMFT) to treat the electron correlation and use the non-crossing approximation (NCA) as an impurity solver in the DMFT scheme. The NCA is based on the perturbation theory with respect to the hybridization energy between f electrons and conduction electrons, and it is applicable to the system with orbital degeneracy. Moreover, magnetic-ion-dilution effects on the strongly correlated electron system with orbital degeneracy are also investigated. To treat dilution effects, the coherence potential approximation (CPA) is adopted. By the hybrid scheme of the DMFT and the CPA, correlation effects and dilution effects on thermodynamic properties and transport properties of the PAM with orbital degeneracy are studied.

FR.B-P28 - Excitonic phases in the two-band Hubbard model with electron-phonon coupling

T. Kaneko [1], Y. Ohta [1]

1. Department of Physics, Chiba University, Chiba, Japan

The excitonic phases often referred to as the excitonic insulators were predicted half a century ago to occur in a small band-gap semiconductor or a small band-overlap semimetal and were described by the quantum condensation of excitons [1]. Recently, a number of candidate mate-rials for the excitonic phases have been suggested [2-4]. From the theoretical standpoint, if we take into account the electron-electron interactions only, the spin-triplet excitonic phase is stabi-lized due to Hundüfs rule coupling [5]. However, the excitonic phase in the candidate materials 1T-TiSe2 and Ta_2NiSe_5 was described in terms of the spin-singlet excitons and the importance of electron-phonon coupling was pointed out.
Motivated by the above development in the field, we investigate the stability of the spin-singlet excitonic phase in the two-band Hubbard model with electron-phonon coupling. To discuss the stability of the spin-singlet excitonic state, we use the mean field theory and variational cluster approximation. We first show that inter-band (excitonic) Coulomb interaction and electron-phonon interaction cooperatively stabilize the charge density wave (CDW) state. How-ever, if we introduce the Hundüfs rule coupling, we find that the excitonic spin-density-wave (SDW) state competes with the CDW state obtained, and becomes the most stable state. The ground state phase diagram of the CDW and SDW states is drawn in the parameter space.

FR.B-P29 - Nonequilibrium dynamics of a periodically-driven impurity spin coupled to the bath of ultracold fermions by Kondo coupling

K. Iwahori [1], N. Kawakami [1]

1. Department of Physics, Kyoto University, Kyoto, Japan

The dynamics of a single impurity in a fermionic or bosonic bath is one of the fundamental problems in condensed matter physics, and plays an important role in the polaronic systems, X-ray absorption problem, Kondo effect and so on. Recently, these impurity problems are studied in the ultracold atomic systems. For example, a polaronic system is experimentally realized[1], and the realization of Kondo effect is theoretically proposed[2]. By utilizing their high controllability, dynamics of impurity driven by the time-dependent external field is also studied[3,4].
In this presentation, we study the periodically-driven impurity spin dynamics coupled to an ultracold fermionic bath by Kondo coupling. In general, it is difficult to solve the dynamics of the quantum system with periodic driving analytically. Thus we consider the case that the external field changes values discretely in time and the Hamiltonian is at the special point in the parameter space at which we can solve each time-step analytically, and thereby treat the full dynamics exactly.
We calculate the time-dependence of the impurity spin and the magnetization of bath fermions in the cases of rectangular field and sinusoidal field. As a result, we find that their characteristic behavior changes with the field-intensity, the field-frequency, and the Kondo temperature. For example, when the field-intensity is very large, the time-dependence of the impurity spin shows an oscillation whose period is inversely proportional to the field-intensity. We also find that another time scale, which is given by the inverse of the Kondo temperature, governs the response of the system to the external field.

FR.B-P30 - Asymmetric thermal lineshape broadening in the dimerised antiferromagnet $BaCu_2V_2O_8$

E. Klyushina [1,2], B. Lake [1,2], N. Islam [1], E. Wheeler [3], J. Park [4], B. Klemke [1]

1. Helmholtz-Zentrum Berlin, Berlín, Germany
2. Technischen Universitõt Berlin, Berlín, Germany

Despite the conventional picture which suggests symmetric Lorentzian broadening of magnetic excitations as temperature is increased, the magnets, where the excitations strongly interact with each other, display asymmetric thermal lineshape broadening [1,2]. In present work we investigate the highly dimerised one-dimensional (1D) antiferromagnet $BaCu_2V_2O_8$ which is a potential candidate for the observation of asymmetric thermal line shape broadening. $BaCu_2V_2O_8$ has a tetragonal symmetry where the magnetic Cu2+ ions (spin-1/2) form alternating spiral chains along the c-axis. Our inelastic neutron scattering measurements on a single crystal of $BaCu_2V_2O_8$ reveal that the magnetic excitations consist of two excitation branches, which have a gap of 36meV and disperse along the L direction over the energy range 36-46 meV. Both modes are dispersionless in the H and K directions implying that the dimers are coupled together one-dimensionally along the c-direction, but with negligible coupling within the a-b plane. The large ratio of gap to bandwidth (=3.6) in $BaCu_2V_2O_8$ make this a candidate compound for detailed observation of asymmetric thermal lineshape broadening over a wide temperature range. The analysis of the high resolution energy scans, which were measured at the dispersion minima at different temperatures, reveals that the line shape becomes asymmetry with increasing temperature which can be attributed to strong correlations between the excitations and confirms that the excitations in highly dimerised 1D magnetic systems behave as a 1D strongly correlated gas of Bosons[2].

FR.B-P32 - Metal-insulator transition in the two-dimensional Hubbard model studied by the dual-fermion method

A. Tanaka 1,

1. Hiroshima University, Hiroshima, Japan

Although numbers of studies have been devoted to the metal-insulator transition in the two-dimensional Hubbard mode, it is still a subject of debate. The difficulty mainly arises from the fact that long-range antiferromagnetic order cannot be stable at finite T in two dimension because of the Mermin-Wagner theorem. Therefore, to describe the electronic state of the model, the theory must be taken into account not only the effects of the on-site Coulomb repulsion but also the long-range antiferromagnetic fluctuation properly. Unfortunately, the state-of-art dynamical mean field theory (DMFT) and its extension to the clusters are only capable for short-range correlation. However, the dual fermion approach (DFA), which is recently developed perturbative extension of DMFT, can incorporate the effects of long-range correlation.
The purpose of this study is to clarify the feature of the metal-insulator transition in the square-lattice Hubbard model at half-filling in relation to the spectral function by means of DFA. Unlike all other DFA calculations, where the continuous-time quantum Mote Carlo method is used to solve the effective Anderson impurity problem, the Lanczos exact-diagonalization technique is applied. This technique is advantageous to access low temperatures and obtain accurate spectral functions on the real axis.
The U-T phase diagram obtained in this study is completely different from that of DMFT. For large U (U/t 6.5-8.0), a drastic change in spectral shape is occurs at the metal-insulator transition and a clear pseudo-gap ~0.6 is appeared. On the other hand, the change is more gentle for smaller U, and the temperature at which clear gap opens is rapidly decrease with decreasing U from T/t ~0.12 and is reached T/t < 0.01 at U/t=2.5. Above this temperature non-Fermi liquid phase is present within the area where paramagnons prevail.

FR.B-P33 - Phase diagrams and phase transformations in S=1 spin- and pseudospin systems

A. Moskvin [1], Y. Panov [1], F. Rybakov [2], V. Konev [1], E. Vasinovich [1], V. Ulitko [1], A. Borisov [2]

1. Ural Federal University, Ekaterinburg, Russia
2. Institute of Metal Physics UD RAS, Ekaterinburg, Russia

At variance with quantum s=1/2 systems the Hamiltonian of S=1 spin lattices in general is characterized by several additional terms such as a single ion anisotropy, biquadratic isotropic and anisotropic exchange couplings, that results in their reach phase diagrams. Interestingly, the S=1 pseudospin formalism can be used to study an extended Bose-Hubbard model (EHBM) with truncation of the on-site Hilbert space to the three lowest occupation states n = 0, 1, 2 (semi-hard bosons). The EHBM Hamiltonian includes the on-site density-density interaction (the on-site pseudospin axial anisotropy), inter-site density-density interactions (the Ising pseudospin term), the one- and two-particle bosonic transport terms (the inter-site XY pseudospin anisotropy), and the chemical potential term (the pseudospin Zeeman coupling). Generalized non-Heisenberg effective S=1 pseudospin Hamiltonian does provide a physically clear description of different phases from uniform Mott insulating phases and density waves to two types of superfluids and supersolids. In the strong on-site attraction limit of the model we arrive at the Hamiltonian of the hard-core bosons which was earlier considered to explain the cuprate high-Tc superconductivity. Here we report results of the analysis of a simplified S=1 (pseudo)spin Hamiltonian with a two-particle transport term (inter-site biquadratic anisotropy) in frames of a generalized mean-field approximation (MFA), which takes into account the quantum description of the S=1 on-site states, as well as classical and quantum Monte-Carlo (QMC) technique. Using the MFA and two different QMC methods, the standard stochastic series expansion (SSE) with loop updates and a continuous time world-line QMC, we have obtained the ground-state and finite-temperature phase diagrams of the (pseudo)spin systems given different values of the coupling parameters. Making use of a special algorithm for CUDA architecture for NVIDIA graphics cards, a nonlinear conjugate-gradient method to minimize energy functional, and Monte-Carlo technique, we directly observed forming of the ground state configuration with lowering the temperature, allowing us to look upon the nucleation of the odd domain structure and vortex-like topological defects.

FR.C-P01 - Imaging of condensed quantum states in the quantum hall effect regime

J. Oswald [1], R. Römer [2]

1. Institute of Physics, Montanuniversity Leoben, Leoben, Austria
2. Department of Physics, University of Warwick, Coventry, United Kingdom

It has been proposed already some time ago that Wigner crystallization in the tails of the Landau levels may play an important role in the quantum Hall regime [1]. Here we use numerical simulations for modelling condensed quantum states and propose real space imaging of such highly correlated electron states by scanning gate microscopy (SGM). The ingredients for our modelling are a many particle model, that combines a self-consistent Hartree Fock calculation for the steady state with a non-equilibrium network model for the electron transport, as introduced in Ref. 2.
When there exists a condensed many particle quantum state in our electronic model system, our model shows that the response pattern of the total sample current as a function of the SGM tip position delivers detailed information about the geometry of the underlying quantum state. For the case of a ring shaped dot potential in the few electron limit it is possible to find regimes with a rigid (crystalline) charge distribution in the ring, where the SGM pattern corresponds to the probability density of the many body quantum states. The existence of the SGM image can be interpreted as the manifestation of an electron solid, since the pattern generation of the charge distribution requires a certain stability against the moving tip potential.

FR.C-P05 - Electronic structures and the spin-splittings in ullmannite-type structure compounds

H. Harima [1]

1. Kobe University, Kobe, Japan

A variety of physical properties in crystals are produced by the interplay between electrons on the specific atomic arrangement. A mineral ullmannite NiSbS belongs to the tetrahedral class T. This is the lowest symmetry class of the isometric (cubic) system. Other ternary compound minerals called changchengite, (IrBiS) gersdosffite (NiAsS) and michenerite ((Pd, Pt)BiTe) belong to the same space group #198 (P213, T4), which is the same as for the famous MnSi. In contrast to the unique magnetic properties realized in MnSi, most of the ternary ullmannite-type compounds are known to be superconducting. This space group contains only 4 three fold and 3 two fold screw axes without space inversion symmetry, so it may be called as a non-symmorphic cubic chiral structure. Such the unique symmetry brings both the extra degeneracy and the spin-splitting in electronic band structure. The screw axes cause the supplementary degeneracy on the Brillouin zone boundary. On the contrary, the lack of the space inversion symmetry lifts the degeneracy due to the spin degree of freedom in each electronic state. Recently, very good single crystals of ullmannite-type structure, PdBiSe and NiSbS are synthesized and the Fermi surface properties are investigated by de Haas-van Alphen (dHvA) effect by Y. Onuki et al. Therefore, the electronic structure and the Fermi surfaces for both the compounds are calculated by using a full potential linearized plane wave method based on the local density approximation, including the relativistic spin-orbit interactions. The dHvA results are well reproduced by the calculated Fermi surfaces. The topology of the Fermi surfaces of both compounds is very similar, but the magnitudes of the splitting of the Fermi surfaces are very different. The large spin-splitting in PdBiSe can be understood by the strong spin-orbit interaction in Bi 6p electrons.

FR.C-P07 - Correlation-induced structural transition in one-dimensional molecular hydrogen crystal

A.P. Kądzielawa [1], Andrzej Biborski [2], J. Spałek [1,2]

1. Marian Smoluchowski Institute of Physics, Jagiellonian University, Kraków, Poland
2. Academic Centre for Materials and Nanotechnology, AGH University of Science and Technology, Kraków, Poland

Proper inclusion of electronic correlations plays an essential role in the hydrogen systems, especially under high pressures. It contributes to the Mott transition [1], but may also influence the crystal structure. We describe the molecular chain within the extended Hubbard model with microscopic parameters obtained via ab-initio calculations. As the framework of the computation, we use Exact Diagonalization ab Initio (EDABI) approach - a method of the wave-function renormalization, proved to be efficient for describing hydrogen systems [2], as it avoids the double-counting problem (present in LDA+U and GGA+U methods) and allows a straightforward inclusion of the long-range electronic correlations. We discuss the electronic properties of different phases by means of sampling the space of structural parameters. We observe a first-order structural transition for intermolecular distance (-- Bohr radius), between the molecular and the two separated atomic-chain configurations and discuss the impact of the electronic correlations on this transition.

FR.C-P08 - Chemical pressure effect in $SmNiC_2$

T. Klimczuk [1], G. Prathiba [2], J. Strychalska [1], T. Park [2]

1. Gdansk University of Technology, Gdańsk, Polonia
2. Sungkyunkwan University(SKKU), Seoul, South Korea

A series of $Sm_{1-x}Ln_xNiC_2$, where Ln=La and Lu, were synthesized by arc-melting method and annealed for 2 weeks at 850^{o}C. Powder x-ray diffraction was used to analyze sample purity and the lattice parameters were calculated using LeBail refinement method. Physical properties were measured by means of magnetic susceptibility, electrical resistivity and heat capacity.
$SmNiC_2$ is a ferromagnet with relatively high Curie temperature (T_C = 17 K). Since Sm is located almost in the middle of the lanthanides, it gives unique opportunity of chemical doping by large La as well as small Lu metal. This way increase (La doping) or decrease (Lu doping) in the unit cell volume is expected, which might be seen as negative or positive “chemical” pressure.
The phase diagram reveals a sudden decrease of the charge density wave formation temperature (T_{CDW}) from 150K for $SmNiC_2$ to 55K for $Sm_{0.75}La_{0.25}NiC_2$. Such a decrease is not observed for $Sm_{0.8}Lu_{0.2}NiC_2$.
The Curie temperature decreases with both La and Lu substitution in $Sm_{1-x}Ln_xNiC_2$. Interestingly ferromagnetism is observed for $Sm_{0.13}La_{0.87}NiC_2$ and Curie temperature T_C = 3.5K was estimated from the Arrot plot. Further increase of La reveals superconductivity and the highest T_{sc} ~3K is obtained for pure $LaNiC_2$.

FR.D-P05 - Magnetic properties of the Ruddlesden-Popper phases $Sr_{3-x}Y_xFe_{1.25}Ni_{0.75}O_{7-\delta}$

S. Kontos [1], K. Gunnarsson [1], J. Grins [2], D. Wardecki [2], G. Svensson [2], P. Svedlindh [1]

1. Uppsala University, Uppsala, Sweden
2. Stockholm University, Stockholm, Sweden

Ruddlesden-Popper n = 2 member phases $Sr_{3-x}Y_xFe_{1.25}Ni_{0.75}O_{7-\delta}$, $0 \leq x \leq 0.75$, have been investigated by X-ray (XRD) and neutron powder diffraction (NPD), Mössbauer spectroscopy, magnetometry and AC susceptometry. The samples were prepared at 1300 °C under nitrogen flow and subsequently air-annealed at 900 °C. The Mössbauer results show that the air-annealed samples in addition to Ni^{3+} contain both Fe^{3+} and Fe^{5+} and that the amount of Fe^{5+} increases with decreasing Y concentration. Moreover, the XRD and NPD results show that the transition metal ions exhibit octahedral (Fe^{3+}, Fe^{5+} and Ni^{3+}) and square pyramidal oxygen coordination (Fe^{3+} and Ni^{3+}), where the latter is a consequence of oxygen vacancies. The amount of octahedrally coordinated Fe/Ni cations increases with decreasing Y concentration. AC susceptibility results show that all samples exhibit properties characteristic of spin glasses. The spin glass properties are a consequence of frustrated superexchange interactions, including antiferromagnetic Fe^{3+} - Fe^{3+}, Fe^{3+} - Ni^{3+} and Ni^{3+} - Ni^{3+} interactions as well as ferromagnetic Fe^{5+} - Fe^{3+} and Fe^{5+} - Ni^{3+} interactions. Magnetic interactions exist in-plane of a perovskite layer, between perovskite layers in a perovskite block and between neighboring perovskite blocks. The spin glass freezing temperature shows a minimum for an yttrium concentration of x=0.4. The high temperature magnetization versus temperature data indicate a predominance of low-spin states for the transition metal ions at large Y concentration, while high-spin states are observed for small Y concentration. The transition between low- and high-spin states with Y concentration correlates well with the variation of the Fe/Ni-O1 bond length, where O1 corresponds to the oxygen forming bonds along the c-axis between transition metal cations in a perovskite block.

FR.D-P07 - Hidden magnetic order in P2-$Na_{0.5}VO_2$ found by muon-spin spectroscopy

The microscopic magnetic nature of a novel Na battery material, P_2-$Na_{0.5}VO_2$, in which V ions form a two-dimensional (2D) triangular lattice [1], has been investigated with muon-spin rotation and relaxation measurements down to 50 mK [2]. Although magnetization measurements indicated the presence of an antiferromagnetic transition at 13 K [1], the internal magnetic field due to the formation of magnetic order appears not at 13 K but at 2 K. This suggests that the magnetic anomaly at 13 K corresponds to the evolution of 2D AF correlation. Furthermore, the magnetic order observed below 2 K is found to have a wide field distribution even at 50 mK. Such wide field distribution is reasonably explained by a combination of multiple muon sites and the formation of a long-range magnetic order, as for $Na_{0.75}CoO_2$ [3,4,5] or $Na_{0.5}CoO_2$ [6], although the AF spin structure is still unknown.

1T-CrSe2 belongs to a layered transition-metal dichalcogenides 1T-MX_2 family with a two dimensional triangular lattice (2DTL), where M is a transition metal and X is a chalcogen (S, Se, and Te). 1T means the phase with the layered CdI2 structure, in which M ions form the 2DTL by the connection of edge-sharing MX_6 octahedra.
According to an early report in 1980 [1], 1T-$CrSe_2$ was found to undergo successive phase transitions at 180 and 160 K. That is, as temperature decreases from 300 K, magnetization increases abruptly at T_t_1=186 K and T_t_2=164 K, while the change in resistivity at these temperatures is less drastic [1,2]. Furthermore, very recent magnetization measurements on 1T-Cr1-x$VxSe_2$ and 1T-Cr1-x$TixSe_2$ indicated that the phase below 186 K is not a charge density wave state, which was proposed for TiSe2 [3] and VSe2 [4], but an antiferromagnetic (AF) ordered state [5], although there is no direct evidence for the presence of magnetic order.
We have therefore measured muon-spin rotation and relaxation (\muSR) spectra down to 1.8 K using powder and single crystal samples of 1T-CrSe2. As a result, it is found that 1T-CrSe2 enters into a static AF order phase below T_t2. The anisotropy of the internal magnetic field suggests that the ordered moments align in the 2DTL plane.

The spin-1/2 Ising-Heisenberg model on the Shastry-Sutherland lattice with Heisenberg intra-dimer and Ising inter-dimer couplings exhibits five different ground states: the singlet-dimer state, the classical antiferromagnetic state, the fully polarized state, the stripe order of singlet-like states with the polarized triplet states and the checkerboard order of singlet-dimer states with the polarized triplet states. The most remarkable ground state represents a stripe order of singlet-like states and polarized triplet states, which corresponds to the one-third plateau in a zero-temperature magnetization curve. To quantify strength of the bipartite entanglement and quantum correlations between two spins coupled by the Heisenberg intra-dimer interaction, we have exactly calculated the concurrence, von Neumann entropy, Bell function and negativity. It is found that a size of entanglement measures does not depend on the magnetic field, but it basically depends on a relative ratio between the Heisenberg and Ising couplings, and respectively, whether or not a spontaneous breaking of the corresponding eigenvector is taken into account. In the former case the entanglement measures correctly reproduce a quantum nature of the stripe one-third magnetization plateau in a full range of the interaction parameters, while in the latter case the entanglement measures vanish for strong enough values of the ratio between the Ising inter-dimer and Heisenberg intra-dimer couplings.

Magnetic excitations in Cs_2CuBr_4, a spin-1/2 Heisenberg antiferromagnet with a distorted triangular lattice, are studied by means of high-frequency electron spin resonance (ESR) spectroscopy in magnetic fields up to 25 T. The presence of a substantial zero-field gap, Δ~10 K, observed above T_N, is interpreted in the frame of a triangular-lattice antiferromagnet model, indicating good agreement with results of spin-wave calculations. The excitation spectrum is found stable against the magnetic order, suggesting the presence of strong in-plane correlations in Cs_2CuBr_4 in the 3D magnetically ordered state. The peculiarities of the ESR spectrum are discussed taking into account the effect of staggered Dzyaloshinskii-Moriya interactions and two-magnon decay processes. This work was partially supported by Deutsche Forschungsgemeinschaft (DFG, Germany).

FR.D-P12 - Amorphous ferromagnetism and re-entrant magnetic glassiness in $Sm_2Mo_2O_7$

We report on the investigation of a high-quality single crystal of Sm2Mo2O7 by means of dc magnetometry, muon spin spectroscopy and high-harmonics ac susceptibility [1]. The magnetic phase of the Mo^{4+} sublattice develops below TC ~ 78 K and is typically discussed in the literature as a conventional itinerant ferromagnetic state. However, our results clearly detect a complicated superposition of conventional and highly disordered magnetic behaviors below 78 K sharing several common features with amorphous ferromagnetic alloys and with other insulating spin-glass pyrochlore molybdates. As typical for amorphous ferromagnets, a freezing of the transverse XY spin components of Mo^{4+} below T ~ 25 K is evidenced, an effect otherwise known as re-entrant spin-glass phase. Our results shed new light on the overall electronic phase diagram commonly accepted for pyrochlore molybdates.

S=1/2 Kagome antiferromagnet has attracted much attention because of its strong frustration effect. Especially the search for the ideal model substance is very important for the experimental studies. As Cu2+ ions (S=1/2) in [Cu3(CO3)2(bpe)3]2ClO4 form Kagome lattice structure with 180 degrees Cu-O-Cu superexchange, [Cu3(CO3)2(bpe)3]2ClO4 is a strong candidate. Kanoo et al. also suggested the small antiferromagnetic interaction from the Weiss temperature [1]. On the other hand, its ferromagnetic behaviors at low temperature are suggested from the magnetic susceptibility and NMR [2]. In order to understand these mismatches and get microscopic information of the system, we have performed high frequency ESR. Although only powder sample is available, we are able to identify the anisotropy of g-values as gper=2.150 and g//=2.056 by the advantages of high frequency ESR. By the detailed analyses of g-values considering the crystal fields of 3 non-equivalent Cu sites and the exchange narrowing effect, we are able to identify the mixed orbital states at each Cu site and concluded that the Goodenough-Kanamori rule cannot be applied in this case. Therefore, the Cu-O-Cu superexchange path in the system may be ferromagnetic instead of antiferromagnetic interaction. This conclusion was also supported by our high frequency ESR results below 10 K, where the abrupt rise of magnetic susceptibility is observed. There is a shift of ESR below 10 K suggesting the existence of the internal field. Our multi-frequency ESR results at 4.2 K are well explained by the ferromagnetic resonance (FMR) rather than the antiferromagnetic resonance (AFMR). In conclusion our high frequency ESR results suggest that [Cu3(CO3)2(bpe)3]2ClO4 is more likely the ferromagnet rather than the antiferromagnet.

FR.D-P14 - New spin glass material, $KV_{14}Ge_2O_{27}$

K. Harada [1]

1. Department of Physics, Chuo University, Hachioji, Japan

We discovered a new SG material whose origin is attributed to a geometric frustration. After a hydrothermal reaction, black, polyhedral-shaped single crystals were obtained. It was determined that the composition of this material is $KV_{14}Ge_2O_{27}$ using single-crystal X-ray diffraction and EDS. The X-ray diffraction revealed a trigonal unit cell with space group *P*-3. Its lattice parameters are a = 7.6309 Å and c = 9.2195 Å. In this structure, octahedra of VO_6 form two kinds of planes (plane A and B). The plane A contains also GeO_4 tetrahedral and the plane B contains also K atoms. These planes stack along the c axis in AABB sequence. A magnetic frustration is expected in this material, because V atoms form a triangle-based lattice in each plane. The field-cooled (FC) magnetic susceptibility doesn't agree with the zero-field-cooled (ZFC) susceptibility below 16 K. The ZFC susceptibility shows a cusp at 16 K. In addition, we observed a slow relaxation phenomenon of the remnant magnetization at low temperature. These behaviors indicate that a SG state appears in this material. The Weiss temperature is estimated at -370 K suggesting that this material has strong antiferromagnetic interactions. This indicates that the geometric frustration disturbs development of a long-range antiferromagnetic order.

FR.D-P15 - Single-crystal growth and magnetic properties of new frustrated magnet, $Rb_2Mn_3V_2O_{10}$

D. Otsuka [1], H. Sato [1]

1. Department of Physics, Chuo University, Hachioji, Japan

We succeeded in synthesizing a new frustrated magnet, $Rb_2Mn_3V_2O_{10}$ using a hydrothermal method. It has an interesting Mn^{2+} network, composed of hexagons connected to each other sharing their corners along the *b* axis and their edges along the *c* axis. From another viewpoint, it can be regarded as a combination of honeycomb chains and diamond chains elongated along the *c* axis. If the nearest neighbor exchange interaction is antiferromagnetic, we can expect interesting magnetism because of the geometric frustration. $Rb_2Mn_3V_2O_{10}$ crystallizes in a monoclinic lattice with a space group *C*2/*m*. The lattice parameters are a = 15.586(2) Å, b = 6.1855(5) Å, c = 5.4660(4) Å, β = 105.188(3)° and Z = 2.

We measured the temperature dependence of the magnetic susceptibility of **$Rb_2Mn_3V_2O_{10}$**. The Weiss temperature is about -250 K, indicating strong antiferromagnetic interactions. This compound has an antiferromagnetic transition at T_N = 40 K. The frustration factor $f = |\theta| / T_N$ is as large as 6.25. The susceptibility has a broad maximum at about 65 K. This also suggests existence of strong frustration. Our result is in contrast with the magnetism of the isostructural compound, $Na_2Ni_3(OH)_2(PO_4)_2$, which exhibits an ordinary antiferromagnetic transition.[1]

FR.D-P16 - Exact solutions on the ground states of ferro- and antiferromagnetic ising models in magnetic fields with frustration on a diamond hierarchical lattice

Y. Hirose [1], A. Oguchi [1], Y. Fukumoto [1]

1. Tokyo University of Science, Tokyo, Japan

Magnetization processes of frustrated Ising models on diamond hierarchical lattices, which contain vertices with high coordination numbers, are exactly obtained at zero temperature. In antiferromagnetic systems, the magnetization cannot saturate under finite magnetic fields owing to the competition between the antiferromagnetic and Zeeman interactions and the intrinsic long-range nature of hierarchical lattices. For the zero-field classical spin-liquid phase found in [Kobayashi et al., J. Phys. Soc. Jpn. 78, 074004 (2009)], an infinitely small applied magnetic field can induce an infinitely small magnetization, despite classical Ising models that have discrete energy levels. We examine the structure of the partition function in order to obtain ground state spin-configurations and to clarify the mechanism of the “gapless spin-liquid “behabior.

FR.D-P17 - Magnetodielectric coupling behavior of single crystalline form of the geometrically frustrated spin-chain compound, $Ca_3Co_2O_6$

T. Basu [1], K.K. Iyer [1], K. Singh [1,2], P.L. Paulose [1], E.V. Sampathkumaran [1]

1. Tata Institute of Fundamental Research, Mumbai, India
2. UGC-DAE Consortium for Scientific Research, Indore, India

We report some fascinating magnetodielectric (MDE) behaviors of a geometrically frustrated spin-chain compound $Ca_3Co_2O_6$, which undergoes (partially disordered) antiferromagnetic ordering (T_N) around 25 K followed additional magnetic phase transitions at lower temperatures (T < 12K). We find that the magnetic field (H) dependent dielectric constant at low T (<10 K) exhibits the fascinating "magnetodielectric phase coexistence" (a partial arrest of the high magnetic field dielectric phase on returning the magnetic-field to zero after the H-induced metamagnetic transition) for H//c only, irrespective of the direction of applied electric field (E); this feature is not observed for *H//c.* It is surprising that such a high-field-phase arrest could not be observed in isothermal magnetization data for any orientation. The T-dependence of ac susceptibility (as known in the past literature) for H//c exhibits a strong frequency (ν) dependence with a suppression under the application of H, but this ν-dependence is completely absent for the perpendicular orientation. However the strong ν-dependence in dielectric is surprisingly present for both the crystallographic directions (E//c and E//c) with a negligible influence of H, despite the existence of strong MDE coupling. The present results indicate complex relaxation behavior and/or different dynamics of electric and magnetic dipoles, although these are coupled as evidenced by MDE coupling. Another uncommon report of great interest is that, as observed in polycrystals [1], MDE coupling arising from short-range magnetic correlation within spin-chain persists even above T_N; that is, a broad peak in dielectric constant is observed around 60-130 K when the electric-field (E) is applied along the spin (c-direction). Single crystal studies thus confirm that this geometrically frustrated compound exhibits exotic MDE coupling behavior not only below T_N, but also well above T_N due to intra-chain interactions.

FR.D-P18 - Magnetization process of pyrochlore-slub SrCr_{9p}Ga_{12-9p}O_{19} in ultra-high magnetic fields of up to 150 T

D. Nakamura [1], S. Lee [2], J. Yang [2], H. Ueda [3], K. Penc [4], S. Takeyama [1]

1. ISSP, the University of Tokyo, Tokyo, Japan
2. University of Virginia, Virginia, USA
3. Kyoto University, Kyoto, Japan
4. Hungarian Academy of Sciences, Budapest, Hungria

Pyrochlore-slub compound SrCr_{9p}Ga_{12-9p}O_{19} (SCGO) posseses a spin system of Cr^{3+} (S=3/2), which is mainly composed by the tri-layer of Kagome lattice and triangular lattice. Therefore, SCGO is considered as a spin frustration material. The spin-glass-like behavior was observed at temperatures below 3.5 K [1]. However, the specific heat at low temperature is proportional to the square of temperature, unlike the case for other spin glass materials. A recent model calculation for SCGO shows that the quantum fluctuation induces a new glassy state called as “spin jam”, which can explain the temperature dependence of specific heat [2]. We expect that the magnetization process of SCGO also contains novel phenomena involving the quantum fluctuation.
We prepared an SCGO (p=0.7) crystal with 0.03 mm thickness. From the optical absorption spectra, a crystal field transition (d-d transition) was observed at 2.0 eV in the absence of magnetic field. The Faraday rotation (FR) measurement was performed in magnetic fields up to 150 T with the incident laser light setting at the edge of this absorption spectra. The obtained FR angle reflects well the magnetization curve of SCGO. The ultra-high magnetic fields are generated by the single-turn coil method. A small plateau in FR was observed at 80 T followed by the transition to the 3/7 plateau at around 120 T. The magnetization curve is well reproduced by a numerical calculation based on the classical Heisenberg model incorporating the biquadratic interaction.

FR.D-P19 - Ultrasound velocity measurements in orbital-degenerate frustrated spinel CoV_2O_4

T. Watanabe [1], S. Yamada [1], R. Koborinai [2], T. Katsufuji [2]

1. Department of Physics, College of Science and Technology (CST), Nihon University, Tokyo, Japan
2. Department of Physics, Waseda University, Tokyo, Japan

Vanadate spinels AV_2O_4 with divalent A_2+ ions such as Mg^{2+}, Zn^{2+}, Cd^{2+}, Mn^{2+}, Fe^{2+}, and Co_2+ have attracted considerable interest as orbitally degenerate frustrated magnets, where the trivalent magnetic V3+ ions are characterized by double occupancy of the triply degenerate t2g orbitals, and form a sublattice of corner-sharing tetrahedra. CoV_2O_4 is one of the vanadium spinel family which undergoes a ferrimagnetic transition at Tc1 = 142 K and another phase transition at Tc2 = 59 K. CoV_2O_4 is the only vanadate spinel which exhibits the absence of structural phase transition. Recent studies of structural, magnetic, and electric properties under pressure in CoV_2O_4 revealed that this compound resides closest to the itinerant electron limit in AV_2O_4, which is due to the shortest V-V distance in AV_2O_4. We performed ultrasound velocity measurements in CoV_2O_4 single crystal to study the spin and orbital states. The measurements were performed in all the symmetrically-independent elastic moduli of the cubic spinel, compression modulus C11, tetragonal shear modulus (C11-C12)/2, and trigonal shear modulus C44. In temperature dependence of the elastic moduli, a discontinuous change occurs at Tc1 in C11, (C11-C12)/2, and C_{44}, and at Tc_2 in Ct. Additionally, and more interestingly, the elastic moduli exhibit elastic-mode-dependent anomalous temperature variations. In the paramagnetic phase (T > Tc1), (C11-C12)/2 and C44 exhibit softening with decreasing temperature. In the ferrimagnetic phase (Tc2 < T < Tc1), C11, (C11-C12)/2, and C44 exhibit nonmonotonic temperature dependence. In the low-temperature phase (T < Tc2), C11 and (C11-C12)/2 exhibit softening with a characteristic minimum with decreasing temperature. These anomalous temperature variations of the elastic moduli should originate from the coupling of lattice to the magnetic fluctuations and/or the magnetic gapped excitations. In the presentation in the conference, we would also like to report the magnetic-field effects on the elastic properties of CoV_2O_4.

FR.D-P21 - Exploring new magnetic phases in artificial spin ices with perpendicular spin moments

I.A. Chioar [1,2], N. Rougemaille [1,2], A. Grimm [1,2], O. Fruchart [1,2], E. Wagner [1,2], M. Hehn [3], D. Lacour [3], F. Montaigne [3], B. Canals [1,2]

3. Institut Jean Lamour, Université de Lorraine and CNRS, Vandoeuvre lès Nancy, France

Frustration is a ubiquitous concept in physics. In some cases, frustration can lead to an extensively degenerate ground state of the considered system. Pauling's description of the low-temperature proton disorder in water ice is probably the first example of frustration in condensed-matter physics and remains its paradigm [1]. At the end of the 1990s, new magnetic compounds were synthesized in which the disorder of the magnetic moments at low temperatures was analogous to the proton disorder in water ice [2]. Since then, intense work has been devoted to these frustrated spin systems. This correspondence between the physics of water ice and its magnetic counterparts has been recently extended to artificial realizations of frustrated spin systems [3].
In this contribution, magnetic frustration effects in lithographically patterned artificial kagome arrays of nanomagnets with out-of-plane magnetization are investigated using magnetic force microscopy and Monte Carlo simulations. In addition to the observation of how each individual spin locally accommodates frustration, experimental and theoretical results are compared to those found for the artificial kagome spin ice in which the nanomagnets have in-plane magnetization. In contrast with what has been recently reported [4], we demonstrate that the system with out-of-plane magnetization is characterized by a new magnetic phase [5]. However, the ground-state configuration still remains unknown.

FR.D-P22 - Spin glass field theory with replica Fourier transforms

I. Pimentel [1], C. De Dominicis [2]

1. Departamento de Física e CFTC, Faculdade de Ciências, Universidade de Lisboa, Lisboa, Portugal
2. CEA Saclay Orme des Merisiers, Inst Phys Theor, Gif Sur Yvette, France

We develop a field theory for spin glasses using replica Fourier transforms (RFT). We present the formalism for the case of replica symmetry and the case of replica symmetry breaking on an ultrametric tree, with the number of replicas n and the number of replica symmetry breaking steps R generic integers. We show how the RFT applied to the two-replica fields allows one to construct a new basis which block-diagonalizes the four-replica mass-matrix, into the replicon, anomalous and longitudinal modes. The eigenvalues are given in terms of the mass RFT and the propagators in the RFT space are obtained by inversion of the block-diagonal matrix. The formalism allows one to express any i-replica vertex in the new RFT basis and hence enables one to perform a standard perturbation expansion. We apply the formalism to calculate the contribution of the Gaussian fluctuations around the Parisi solution for the free-energy of an Ising spin glass.

FR.D-P23 - Nematic phases in the bilinear biquadratic Heisenberg model on the honeycomb lattice.

A. Pires [1]

1. Universidade Federal de Minas Gerais, Belo Horizonte, Brazil

As it is well known, quantum spin liquids are characterized by the absence of any symmetry-breaking long-range order. In contrast to this states, spin nematic states exhibit long-range quadrupolar correlations which has no magnetic order. One interesting example where spin nematic phases could appear is the spin-1 bilinear biquadratic Heisenberg model. This model can present several interesting phases and spontaneously develop a columnar dimer order with a non-bipartite structure. In this work I will study this model in the honeycomb lattice. This lattice has the smallest coordination number in two dimensions and the effect of quantum fluctuations is the strongest.
A very convenient analytical technique to study this model (and other frustrated systems which present disordered phases and possibly new materials synthesized in the future) is the SU(3) Schwinger boson formalism (also called flavor-wave theory). I will discuss this formalism and show how it can be used to study different phases of the model and to calculate its phase diagram. I will give special attention to the ferroquadrupolar phase, which is characterized by a uniform alignment of the directors. Since quadrupolar/nematic ordering has not yet been identified unambiguously in real materials, I will present the dynamical quadrupolar structure factor, which could be, in principle, measured using resonant techniques, such as resonant inelastic x-ray scattering. This type of experiment could provide evidence for the existence of spin-nematic order.

FR.D-P24 - Magnetic field dependence of magnetoelastic interactions in $Tb_2Ti_2O_7$

M. Ruminy [1], T. Fennell [1], M. Kenzelmann [2]

1. Laboratory for Neutron Scattering and Imaging, Paul Scherrer Institut, Villigen, Switzerland
2. Laboratory for Developments and Methods, Paul Scherrer Institut,Villigen, Switzerland

The highly frustrated rare earth magnet $Tb_2Ti_2O_7$ enters a spin liquid regime at low temperatures which supports spin ice-like power-law correlations and a wealth of magnetoelastic effects [1-4]. These experimental observations are in stark contrast to the classically expected long-range magnetic order and/or structural phase transition - a long-standing challenge in frustrated magnetism. Recently we have discovered a microscopic coupling mechanism between the magnetic and lattice fluctuations, which forms hybrid, magnetoelastic propagating excitations via quadrupolar transition moments between the doublet groundstate and the low-lying first excited crystal field level [5,6]. Using inelastic neutron scattering, we have now studied in detail the effect of an applied magnetic field on the magnetoelastic excitation spectrum of $Tb_2Ti_2O_7$. I will show how these experiments not only boost our understanding of the coupling between spins and phonons in $Tb_2Ti_2O_7$ but also enlighten how a shift of the first crystal field excitation drives the hitherto unexplained field induced long-range antiferromagnetic ordering transition [7].

FR.D-P25 - Unstable magnetic properties of $Pd_{99}Fe_{01}$ nanofilms.

L.S. Uspenskaya [1], V. Bolginov [1], I.N. Khlustikov [2]

1. Institute of Solid State Physics RAS, Chernogolovka, Russia
2. P.L. Kapitza Institute for Physical Problems RAS, Moscow, Russia

Bulk $Pd_{1-x}Fex$ alloy is known as the material which gains the ferromagnetic properties because of high magnetic polarization of Pd already at the doping level about 0.1 - 1 %. The effective magnetic moment per Fe atom grows inversely proportional to x and reaches 12 Bohr magnetons at x ~ 0.01 [1]. Depending on x, ferromagnetic or antiferromagnetic arrangement of magnetization takes place [2]. The spontaneous magnetization of the alloys and the Curie temperature are reduced with the doping decrease and with the reduction of magnetic material volume [3,4]. The interest to the magnetic properties of weak ferromagnet nanofilms appears a few years ago with the development of cryoelectronics where such a films are suggested to be used as the layer governing electromagnetic properties of hybrid superconductor-ferromagnet-superconductor structures [5].
Herewith we report on the properties of 20 to 40 nanometers thick $Pd_{1-x}Fex$ films fabricated by rf magnetron sputtering. The experiments were performed by SQUID maghetometery in temperature range 1.4 - 40 K. Temperature dependences of magnetization, coercitivity and magnetic permeability were determined. Two types of magnetization loops were found depending on the range of magnetic field sweeping with the threshold value as low as 20 Oe. Large shift of Curie temperature under the applied magnetic field was observed. Huge relaxation of magnetization in all temperature range was revealed.
The results are explained taking into account the magnetic nanocluster arrangement of weak ferromagnet film which was proven by the experiments on magnetic flux penetration in Nb-PdFe bilayer films.

Spin-1/2 J1-J2 Heisenberg antiferromagnet on the square lattice has attracted a lot of interest for a long time. One of the reasons is the relevance to cuprates, Fe-based superconductors and other materials. It has been found recently numerically [1] that this model has a singlet ground state in the range $0.41J1<J2<0.62J1$ that is separated from the first excited (singlet) level by a gap. It is argued in [1] that a topological quantum spin liquid phase (QSLP) is realized in the range $0.41J1<J2<0.62J1$. Values of the ground state energy and the gap are found numerically in [1] but the problem remains open of the low-energy sector quantitative description in QSLP. We give a physical picture of the low-energy sector in QSLP. Using a series expansion, we find an effective Hamiltonian describing an anisotropic spin-1/2 ferromagnet on the square lattice in magnetic field, which low-energy sector is fully equivalent to that of J1-J2 model in QSLP. Remarkably, this effective model possesses a long-range magnetic order. Thus, we show that QSLP in J1-J_2 antiferromagnet is equivalent to the magnet with the local order parameter. This situation is similar to that found in [2] for topological phases in Kitaev model. We discuss the effective model numerically and using the standard 1/S expansion and find the value of the order parameter and the elementary excitation spectrum. In particular, our results for the ground state energy and the gap values are in quantitative agreement with previous numerical findings [1].

FR.D-P27 - Novel magnetic phase transition and spin-lattice effects in the frustrated magnet $CdCr_2O_4$

Frustrated magnetic systems manifest a number of fascinating properties often with novel magnetic phases accompanied by magneto-structural transformations. Ultrasound studies are a powerful method to probe spin-lattice interactions and possible lattice instabilities in the frustrated magnetic systems. We present results of ultrasound investigations of the frustrated antiferromagnet $CdCr_2O_4$. A new magnetic phase transition has been observed below the Neel temperature, TN = 7.8 K. This transition renormalizes the velocity and amplitude of the transverse acoustic mode cT propagating along the crystallographic [111] direction whereas the longitudinal mode cL propagating along the same direction is not affected. The specific heat does not show any significant change of the entropy at this transition. We argue that the magnetic transition separates two different spiral structures within the antiferromagnetic state. Furthermore, in an applied magnetic field we have observed extended metastable magneto-structural states neighboring the one-half magnetization plateau which exists in $CdCr_2O_4$ between 28 and 58 T. By applying an exchange-striction model we can quantitatively describe the field dependence of the sound velocity below and above the one-half magnetization plateau. Moreover, we notice a much stronger renormalization of the sound velocity in approaching TN for the transverse mode, cT, than for the longitudinal one, cL, signaling that the leading contribution to the exchange-striction coupling comes from the transversal polarization of the cT mode. The low-temperature H - T phase diagram of $CdCr_2O_4$ is extracted from the ultrasound experiments. Our work shows that the spin-strain coupling is crucial and determines the underlying physics of this frustrated magnetic material.
The research has been partly supported by the DFG via TRR 80 (Augsburg-Munich) and SFB 1143 (Dresden).

FR.D-P28 - Order by disorder or energetic selection of the ground state in the XY pyrochlore antiferromagnet $Er_2Ti_2O_7$ a neutron scattering study

S. Petit [1], J. Robert [1], S. Guitteny [1], I. Mirebeau [1], C. Decorse [2], J. Ollivier [3], H. Mutka [3], M. Gingras [4]

4. Department of Physics and Astronomy, Univ of Waterloo, Waterloo, Canada.

Examples of materials where an ``order by quantum disorder' mechanism is at play to select a particular ground state are scarce [1,2]. It has been recently proposed that the anti-ferromagnetic XY pyrochlore $Er_2Ti_2O_7$, reveals a most convincing case of this mechanism [3,4,5]. Observation of a spin gap at zone centers was interpreted as a definitive proof of this physics [6]. We argue, however, that the magnetic anisotropy provided by the interaction-induced admixing between the crystal-field ground and excited levels gives an alternative energetic mechanism [7,8]. Random phase approximation RPA calculations based on a mean field model taking into account explicitly the crystal-electric field anisotropy reproduce quite well new high resolution inelastic neutron scattering data. These experiments point out the existence of a spin gap of 43 μeV which can be well understood within this scenario: in this energetic selection mechanism, the gap originates from the anisotropy rather than quantum fluctuations effects. The present study revives the issue of the physical origin of the experimentally broken discrete symmetry ground state in $Er_2Ti_2O_7$. It raises the question of the quantum order by disorder as the sole or even principal mechanism for the selection of the magnetic ground state in this material.

FR.D-P29 - "Half-moon" excitations in the magneto-elastic spin liquid $Tb_2Ti_2O_7$

S. Petit [1], S. Guitteny [1], J. Robert [1], I. Mirebeau [1], J. Ollivier [2], H. Mutka [2], C. Decorse [3]

3. LPCES, Université Paris-Sud, Orsay, France

Geometrical magnetic frustration is a central concept in condensed matter physics. In this field, rare earth pyrochlore magnets $R_2Ti_2O_7$ (R is a rare earth) play a prominent role, as they form model systems showing a rich variety of ground states, depending on the balance between dipolar, exchange interactions and crystal field [1]. The Terbium compound $Tb_2Ti_2O_7$ remains a cooperative paramagnet, or a "quantum spin ice", with strongly correlated moments still fluctuating at 50 mK [2]. Recent time of flight neutron and triple-axis neutron scattering experiments have recently shed light in this puzzle, revealing a complex "magneto-elastic" ground state [3,4] characterized by a local constraint resulting in "pinch points" [5], analogous to the ice rule in spin ices, and supporting a low energy (bosonic) excitation [4]. Under applied field, a complex antiferromagnetic structure sets in, while the low energy excitations transform into a spin wave like mode whose dynamical structure factor is highly anisotropic, showing "half-moons" in reciprocal space [6]. This peculiar form indeed casts light on the underlying "ice rule" of $Tb_2Ti_2O_7$.

FR.D-P30 - Spin-1/2 Heisenberg ferromagnet on the pyrochlore lattice

O. Menchyshyn [1], O. Derzhko [1], J. Richter [2]

1. Institute for Condensed Matter Physics of NAS, Lviv, Ukraine
2. Institut für theoretische Physik, Magdeburg, Germany

We investigate the spin-1/2 Heisenberg model on the pyrochlore lattice (three-dimensional lattice made of corner-sharing tetrahedra) with ferromagnetic nearest-neighbor interaction within 1) the linear spin-wave theory, 2) the two-time Green-function method, and 3) the quantum Monte Carlo approach. Though the pyrochlore ferromagnet has the same coordination number as the simple cubic ferromagnet (i.e., six nearest neighbors), the results for both models beyond the mean-field theory differ substantially. For example, the quantum Monte Carlo simulations yield a critical temperature of the simple cubic model of Tc=0.839(1) [1], while for the pyrochlore model only Tc=0.718(6) is obtained. Furthermore, we compare our findings for the pyrochlore ferromagnet with the high-temperature-expansion predictions [2] and the experimental data for $Lu_2V_2O_7$ [3].

The presence of qualitatively new ground states brings quantum magnets with frustrated exchange interactions into a focus of modern magnetism. A high degree of degeneracy in the ground state of frustrated magnets provides an opportunity for studying quantum phase transitions. For example, the magnetic-field-induced plateau phase at one-third of the saturation magnetization in frustrated antiferromagnets with a triangular arrangement of spins was predicted as a field-induced ground state stabilized by quantum fluctuations [1]. Cs_2CuBr_4 is an example of a frustrated magnet on a distorted triangular lattice where the plateau has been observed [2]. We report on a far infrared and magnetic torque investigation of Cs_2CuBr_4 at high magnetic fields and temperatures down to 300 mK. We observed two vibrational modes at 25.4 and 29.3 cm^{-1} by means of far-infrared spectroscopy. High-field experiments reveal a splitting of the phonon mode between 24 and 26 T, which coincides with an anomaly observed in magnetic torque. We associate these findings with a field-induced distortion of the tetrahedral environment of Cu^{2+} ions due to the competition between Jahn-Teller and spin-orbit interactions. The external magnetic field shifts the energetic balance between those two interactions. Our findings and previous theoretical investigations [3] suggest that a wide class of quantum magnets can exhibit field-induced quantum phase transitions. Such investigations were limited in the past by the lack of sufficiently strong magnetic fields, but now the availability of continuous fields above 35 T and pulsed fields above 90T opens new possibilities.

4. Helmholtz Zentrum Berlin für Materialien und Energie, Berlin, Germany

Unusual spin structure of double perovskite and re-entrant spin-glass (RSG) compound Lu_2MnNiO_6 has been investigated using conventional magnetometry and neutron diffraction. System possesses a ferromagnetic (FM) ordering below T_C = 40 K and undergoes a RSG transition at, T_g = 20 K. Interestingly, the system retains the memory effect above T_g, till spins sustain ordering. It is found that as system cools below T_C, spins cant ferromagnetically with respect to the crystallographic 'c' axis, resulting a novel critical behavior whose exponents (β = 0.241 and γ = 1.142) doesn't match with any of the conventional model. Comprehensive study of temperature dependent neutron diffraction and first principle-based computation divulges that octahedral tilting induced structural transition and an imprinting spin-orbit interaction results this novel canted spin structure below T_C, which might be the intrinsic scenario for all RSG compounds.

FR.D-P35 - High-field raman spectroscopy measurement of the geometrically frustrated chromium spinel oxide $CdCr_2O_4$

Y. Sawada [1], S. Kimura [1], K. Watanabe [1], H. Ueda [2]

1. Institute for Materials Research, Tohoku University, Sendai, Japan
2. Graduate School of Science, Kyoto University, Kyoto, Japan

The chromium spinel oxide $CdCr_2O_4$ remains the paramagnetic state down to low temperature due to the strong geometrical frustration. It is known that this material undergoes the magnetic phase transition to the magnetically ordered phase at TN = 7.8 K. By applying a magnetic field at low temperature, the 1/2 magnetization plateau phase that is stable in a wide range of the magnetic field, appears at Hc = 28 T, accompanied by a large magnetostriction [1]. It is considered that the stability of the plateau phase originates from the lattice deformation that stems from the spin-lattice coupling. Therefore, we have performed a high field Raman spectroscopy measurement in order to clarify the lattice dynamics in the 1/2 magnetization plateau phase.
The experiment using a single crystal of $CdCr_2O_4$ has been done by the high field Raman spectroscopy system utilizing the 31 T hybrid magnet in our laboratory. At zero field, three Raman peaks were observed at 131, 501, and 602 cm-1 below TN. These peaks correspond to the phonon triplets of T2g symmetry, for which oxygen ions displace whereas chromium is not in motion [2]. In the high field experiment, we found that the T2g phonon peaks do not show clear shift at Hc. In this material, the nearest-neighbor exchange interaction between chromium ions is considered to be a sum of the antiferromagnetic direct exchange interaction and the ferromagnetic superexchange interaction through non-magnetic oxygen ions. Since our result indicates that T2g modes, which involve only the vibration of oxygen and cadmium ions, is not changed by the transition to the 1/2 magnetization plateau phase. We conclude that the direct-exchange interaction is dominant in the nearest-neighbor interaction of $CdCr_2O_4$.

FR.D-P36 - Critical properties of a triangular lattice Ising AF/FM bilayer

M. Zukovic [1], A. Bobak [1]

1. Institute of Physics, Faculty of Science, P.J. Šafárik University, Košice, Slovakia

We study by Monte Carlo simulation an Ising spin system consisting of one antiferromagnetic (AF) and one ferromagnetic (FM) triangular plane, with the respective intralayer couplings of equal strengths but opposite signs, which are coupled by a varying FM interlayer exchange. The critical behavior of the decoupled planes is notoriously well-known. The AF one shows no long-range ordered (LRO) phase down to zero temperature due to high geometrical frustration, while the FM one displays a single standard Ising universality class phase transition to the FM LRO phase. We show that introduction of a finite interlayer exchange induces drastic changes to this critical behavior. Namely, when the interlayer coupling is relatively small or comparable with the intralayer coupling we identify two separate phase transitions. The one occurring at higher temperatures is related to the transition from the paramagnetic to FM state and is of standard Ising universality class. At lower temperatures there is another phase transition that takes place only in the AF plane. At this transition spins rearrange into a ferrimagnetic state with spins on two sublattices pointing parallel and on one sublattice antiparallel to the spins on the FM plane. Finite size scaling indicates that the critical indices governing this phase transition take non-universal (not even weakly universal) values that vary with the interlayer to intralayer coupling strength ratio. Nevertheless, if the interlayer coupling becomes sufficiently strong both phase transitions disappear and the AF/FM bilayer effectively behaves as a single AF layer, showing only a noncritical anomaly in thermodynamic quantities. Thus, while a relatively weak interlayer coupling to the FM plane induces even two phase transitions in the frustrated noncritical AF plane, a sufficiently strong coupling to the AF plane impedes any LRO in the standard FM Ising model.

FR.D-P37 - Single crystal growth of tunable Cu-based quantum spin systems

P. Puphal [1], N. Van Well [1], F. Ritter [1], D.V. Sheptyakov [2], C. Rüegg [2,3], C. Krellner [1]

1. Goethe University Frankfurt, Frankfurt, Germany
2. Laboratory for Neutron Scattering and Imaging, Paul Scherrer Institute, Villigen, Switzerland
3. Department of Quantum Matter Physics, University of Geneva, Geneva, Switzerland

We present crystal growth and analysis of the spin liquid candidate $(Zn,Ga)Cu_3(OH)_6Cl_2$ and the dimersystem $(Ba,Sr)CuSi_2O_6$.
Herbertsmithite the spin ½ Heisenberg antiferromagnet with a kagome lattice was proposed and proven to have a spin-liquid ground state due to the high degree of frustration. We have synthesised powder of $Ga_xCu_{4-x}(OH)_6Cl_2$, in which a doping of x = 1 was proposed to give a correlated Dirac metal (I. I. Mazin et. al., Nature Communications 5, 4261 (2014)). We have confirmed with EDX and magnetic measurements that Ga is built into the structure with values of. $Ga_xCu_{4-x}(OH)_6Cl_2$ shows long-range magnetic order similar to Zn-Paratacamite and with increasing x the ordering temperature decreases.
In $BaCuSi_2O_6$ triplons condense in a 2D Bose-Einstein-Condensate (BEC) at magnetic fields above 23.15 T at low temperatures accompanied by a dimensional crossover from 3D to 2D, when lowering temperature (S. E. Sebastian, et al., Phys. Rev. B 74, 180401(R) (2006)). A structural phase transition below 100 K leads to two different Cu-dimer layers, making the Hamiltonian describing the system complex (D. V. Sheptyakov et. al., Phys. Rev. B 86 014433 (2012)).
Results for strontium substitution on the barium side and investigation of the structural transition with specific heat measurements, low temperature x-ray and neutron powder diffraction surprisingly show that already small amounts of Sr (x = 0.05) lead to a suppression of the structural phase transition. Crystal growth in a tube furnace with a flow of oxygen was successfully employed and gave rise to Sr substituted crystals of up to 3 x 4 x 1 mm^3 and 18 mg. With increasing Sr-content the unit cell volume decreases and the intra-dimer spacing increases. The role of frustration and the dimensionality of the BEC in this system might be clarified by studying the substituted system.

FR.D-P38 - Spin -glass magnetism in $RFeTi_2O_7$ (R=Lu and Tb) compounds

T. Drokina [1], G. Petrakovskii [1], M. Molokeev [1], D.i Velikanov [1], A. Arauzo [2], J. Bartolomé [2]

1. L.V. Kirensky Institute of Physics, SB RAS, Tomsk, Russia
2. Instituto de Ciencia de Materiales de Aragón (ICMA) and Departamento de Física Condensada, Zaragoza, Spain

The compounds $RFeTi_2O_7$ (R=Lu and Tb) crystallize at room temperature in centrosymmetric orthorhombic space group Pcnb. There are five nonequivalent positions of the iron ions: the Fe ions occupy the two positions of Fe, Fe (Fe) - in the octahedron consisting of the Fe tetrahedron and Fe (Fe) five-vertex, and the three positions of Fe in the mixed octahedron Fe - Ti positions1. The populations of the mixed Fe-Ti sites are different. The crystal structure features lead to the atomic disorder in the distribution of the magnetic ions in this compound. From low temperature heat capacity, magnetization and frequency dependent ac susceptibility we conclude that both compounds undergo a spin glass transition at TSG=4.5 and 6 K for Ln=Lu and Tb, respectively. Since Lu is not magnetic, in $RFeTi_2O_7$ the spin glass behavior is caused by the disordered distribution of the magnetic Fe^{3+} ions in the different crystallographic positions. The substitution of the magnetic and highly anisotropic Tb ion instead of Lu increases TSG because of the additional Tb-Fe exchange interaction, while the critical exponent of the frequency dependence on temperature hardly varies. The spin glass behavior in these crystalline compounds is caused by the presence of competitive interactions that lead to frustration.

FR.D-P39 - Tricritical behavior in the Ising honeycomb lattice with competing interactions

A. Bobak [1], T. Lucivjansky [1], M. Zukovic [1], M. Borovsky [1], T. Balcerzak [1]

1. Institute of Physics, Faculty of Science, P.J. Safarik University, Košice, Slovakia

We study the phase diagram of the Ising antiferromagnet on the honeycomb lattice with competing interactions $J_1 < 0$ on nearest neighbor and $J_2 < 0$ on next-nearest neighbor bonds within the framework of the effective-field theory with correlations. The theory is based on different cluster sizes and allows us to treat large clusters in a simpler and more efficient computational manner. We determine the ground-state energy as a function of the frustration parameter $R = J_2 / |J_1|$. We find that the ground state is the Néel antiferromagnet for $R > -1/4$ and in the case of $R < -1/4$ the system orders in the anti-Néel states. The critical point separating these two phases lies at $R = -1/4$, where the transition temperature is suppressed to zero and the ground-state is highly degenerate. In order to determine the phase diagram of the J_1–J_2 model and take into account effects of frustration within the present effective-field theory, it is necessary to consider at least a two-spin cluster. In particular, we have found that the critical temperature $k_B T_N / |J_1|$ versus R between the antiferromagnetic and paramagnetic phases changes from second to first order at a tricritical point. To get a more convincing evidence of the existence of a tricritical point in the phase diagram, we also consider four- and six-spin clusters. In this case, the clusters contain more information about lattice topology. On the other hand, our observations suggest that the transition line between the anti-Néel antiferromagnet and paramagnetic phases is first order for entire range of $R < -1/4$.

FR.D-P40 - Thermodynamic properties in the Kitaev spin liquids

J. Nasu [1], M. Udagawa [2], Y. Motome [2]

1. Tokyo Institute of Technology, Tokyo, Japan
2. University of Tokyo, Tokyo, Japan

Quantum spin liquid (QSL) is an exotic quantum state of matter in insulating magnets, where long-range ordering is suppressed down to the lowest temperature. Several experimental candidates of QSL have been recently nominated thus far. In their characterization, the absence of thermodynamic anomalies is experimentally regarded as a hallmark of QSL. On the other hand, the finite-temperature properties theoretically have not been well known due to the difficulty in the analysis for models with a QSL ground state such as the negative sign problem in quantum Monte Carlo (QMC) simulations. To clarify this problem, we address three kinds of Kitaev models on a honeycomb, a decorated honeycomb, and a three-dimensional hyperhonycomb lattices. The Kitaev model is one of the solvable quantum spin models, where the ground state is given by QSLs. In addition, the Kitaev-type interaction is relevant to the recently found Ir oxides Li2IrO3. Here, we investigate the finite-temperature properties in these Kitaev models by using the QMC simulation in the Majorana representation that we developed. Our method is free from any biased approximation as well as the negative sign problem. We find that these models commonly exhibit a two-stage entropy release, indicating thermal fractionalization of the quantum spins into two kinds of Majorana fermions. Moreover, there is no phase transition at nonzero temperature in the Kitaev model on the honeycomb lattice, but we find that the models on the decorated honeycomb and the hyperhoneycomb lattices exhibit the finite-temperature phase transitions. In the former case, the transition is associated with the time reversal symmetry breaking in the chiral QSL. On the other hand, in the latter case, the transition cannot be characterized within the Ginzbrg-Landau-Wilson framework. We find the difference between QSL and paramagnet comes from the topological nature of the excitations.

FR.D-P41 - Dimer-dimer correlations and magnetothermodynamics of S=1/2 spherical kagome clusters in W$_{72}$V$_{30}$ and Mo$_{72}$V$_{30}$

Y. Fukumoto [1], N. Kunisada [1]

1. Tokyo University of Science, Tokyo, Japan

Quantum-spin icosidodecahedrons are realized in W$_{72}$V$_{30}$ and Mo$_{72}$V$_{30}$. The former is expected to have the ideal symmetry I_h and exchange coupling of 115 K, and the latter is a little distorted. Icosidodecahedron can be considered as a kagome on a sphere, so the observation of resonating-valence-bond (RVB) states in W$_{72}$V$_{30}$ is of great interest. We present dimer-dimer correlation functions and show that the feature is similar to the kagome system. We also calculate the specific heat under magnetic fields below the spin-gap energy. It is found that there appears a low-temperature structure below 10 K, which has substantial magnetic-field dependence. The low-temperature structure comes from about 800 states, which consists of 360 non-magnetic and 440 magnetic ones. The existence of massive singlet and triplet low-energy excitations is consistent with the RVB picture. Calculated results for the distorted system Mo$_{72}$V$_{30}$ are also presented for comparison.

FR.D-P44 - Monte Carlo study of heisenberg antiferromagnets on breathing pyrochlore lattices

K. Aoyama [1], H. Kawamura [1]

1. Department of Earth and Space Science, Graduate School of Science, Osaka University, Osaka, Japan

Geometrical frustration plays an important role in magnetism. One typical example of frustrated systems is antiferromagnets on a pyrochlore lattice which is a three dimensional network of corner-sharing tetrahedra. Due to a dominant nearest-neighbor antiferromagnetic interaction, classical Heisenberg spins on the tetrahedra cannot orient in certain fixed directions, and as a result, do not show any long range order at nonzero temperatures [1]. Recently, a new type of the pyrochlore lattice has been found in the spinel oxides, $LiGaCr_4O_8$ and $LiInCr_4O_8$ [2]. In contrast to the regular pyrochlore lattice in transition metal oxides AB_2O_4, these materials have a 'breathing' structure consisting of an alternating array of small and large tetrahedra, because of the large size mismatch between Li+ and Ga^{3+}/In^{3+} ions at the A site. Although the geometrical frustration should still exist even in this nonuniform structure, specific heat measurements suggest a phase transition at T= 13.8 and 15.9 K for $LiGaCr_4O_8$ and $LiInCr_4O_8$, respectively.
Motivated by the experimental result, we theoretically investigate classical antiferromagnets on the breathing pyrochlore lattice. The results of our Monte Carlo simulations suggest that a breathing nearest-neighbor interaction does not lead to a long range order and that other intrinsic interactions are also essential in the above materials. In the presentation, we will discuss spin-lattice coupling effects on the spin ordering in this system.

FR.D-P45 - Ice-rule violation and magnetic monopoles hopping in artificial spin ice

S. Krishnia [1], I. Purnama [1] N, C. Sheng Soh [1] N, W. Siang Lew [1] N, R. Maddu [1]

1. Nanyang Technological University, Singapore, Maylasia

Isolated elementary particles with a net magnetic charge have yet to be observed since the prediction by Dirac[1]. However, recent observations of mobile quasiparticles that emerge in frustrated bulk magnetic materials when the ice rule is violated, has renewed the interest in uncovering the existence of magnetic monopoles[2]. To direct the visualization of these monopoles and ice rule violation at macroscopic level, a set of magnetic nanostructures can be arranged in hexagonal geometry to create artificial spin ice systems[3].

Fig.1(a) shows the magnetic charge configuration of ordered and monopole defects in static state of honeycomb artificial spin ice. Each vertex of the structure has a finite magnetic charge whose sign depends on the magnetization directions of the interacting single domain nanowires, as shown in Fig.1(b). The ordered ground state[4] (no ice rule violation), which shows alternate dark and bright spots of equal intensity in magnetic force microscopy (MFM), is achieved by saturating the structure in *-x* direction. Our MFM results show that it is possible to break the ice rule by applying external magnetic field to flip the magnetization of one of the nanowire. As shown in dotted area of Fig2(a), after the application of +630Oe, a new magnetic particle at point *A* has emerged in the lattice. The MFM phase shift that corresponds to that magnetic particle is found to be three times higher than the rest of the magnetic charges (Fig.2(b)). All three spins around point *A* converge towards it, and thus point *A* can be said to behave as a magnetic sink. The emergent magnetic particle is stable at room temperature and can be termed as a "magnetic monopole defect" ($Q = \pm 3$). In conclusion, with the support of micromagnetic simulations a coherent picture of monopole creation and motion (1D Dirac strings) is studied.

Geometrically frustrated magnets attract much interest recently because several new magnetic phases including quantum liquid state are expected to occur in these systems. If the frustrated lattice is formed by S=1/2 magnetic moments, the combination of the frustration and quantum effects will lead to novel phenomena. In Cu3(OH)5(NO3)·2H2O (mineral name; likasite), tetrahedra composed by Cu2+ (S=1/2) ions are coupled by corner-sharing manner to make one dimensional (1D) chain along crystallographic b axis. Each 1D chains are interconnected by Cu2+-Cu2+ bonds to form two dimensional spin lattice. This spin lattice (likasite lattice) is a novel frustrated lattice which has not been studied so far. We synthesized powder sample of likasite and studied its magnetic properties using magnetic susceptibility, specific heat and high field magnetization measurements. Weiss temperature estimated form magnetic susceptibility was -16 K, and a dominant magnetic interaction in likasite is found to be antiferromagnetic. The magnetic susceptibility had a round maximum at around 12 K, which is characteristic of low dimensional antiferromagnets. No long range magnetic order was observed down to 2 K, suggesting the good low-dimensionality of likasite. We measured the high field magnetization up to about 75 T at 1.3 K and 4.2 K. Below about 30 T, magnetization curve showed downward convex form, reflecting the low dimensional nature of this compound. The magnetization curve appeared to saturate above 40 T but the 'saturation' value was only 2/3 of the expected saturation magnetization. This result will be discussed in terms of a 2/3 magnetization plateau, which was theoretically pointed out to be stabilized in the frustrated diamond chain spin model with monomer interactions.

FR.D-P49 - Critical phenomena in two-dimensional frustrated Heisenberg models

S. Tanaka [1], R. Tamura [2], N. Kawashima [3]

1. Waseda Institute for Advanced Study, Waseda University, Tokyo, Japan

3. Institute for Solid State Physics, The University of Tokyo, Tokyo, Japan

To quest novel phase transition behavior in frustrated systems with order parameter spaces described by direct product SO(3) \times Zn, we consider the classical Heisenberg model on a distorted triangular lattice with the first nearest-neighbor and the third nearest-neighbor interactions. The order parameter space can be tuned by changing the model parameters. We focus on the case that the order parameter space is described by SO(3) \times Z2. Using the Monte Carlo simulations, we found that a second-order phase transition occurs at a finite temperature, though the system we considered is two dimension. The second-order phase transition is associated with Z2 symmetry breaking. In addition, the Z2 vortex dissociation originated by SO(3) is observed at the second-order phase transition temperature. To confirm whether the Z2 vortex dissociation affects the critical phenomena, we perform the finite-size scaling. As a result, we confirm that the phase transition belongs to the universality class of the two-dimensional Ising model. Thus, we conclude that the Z2 vortex dissociation does not influence the critical phenomena in the model. To our best knowledge, this is the first example that the simultaneous emergence of the Z2 vortex dissociation at the critical point.

FR.D-P50 - Magnetic and thermal properties of an s=1/2 triangular lattice antiferromagnet Ba_2CoTeO_6

P. Chanlert [1], N. Kurita [1], H. Tanaka [1]

1. Tokyo Institute of Technology, Tokyo, Japan

S=1/2 Heisenberg Triangular Lattice Antiferromagnetic (TLAF) has been attracting considerable attention. This system exhibits quantum phase transitions such as magnetization plateau under magnetic field due to the strong frustration and the quantum fluctuation. This subject has been studied theoretically for a long time. However, experimental realization of S=1/2 Heisenberg TLAF is a little. Recently $Ba_3CoSb_2O_9$ was shown to be the best realization of S=1/2 Heisenberg TLAF [1,2].
Ba_2CoTeO_6 is considered to be other S=1/2 Heisenberg TLAF. Ba_2CoTeO_6 has a hexagonal structure with space group P-3m1 [3] in which Co^2+ with effective spin 1/2 is surrounded octahedrally by six O^2- ions. There are two Co^2+ sites, Co(1) and Co(2). When considering cobalt atoms in the structure, they form a two-dimensional (2D) triangular lattice parallel to the ab-plane. In this study, we have synthesized Ba_2CoTeO_6 powder. By using X-ray powder diffraction technique, the sample was identified to be Ba_2CoTeO_6. Magnetic properties were studied by magnetic susceptibility and specific heat measurements. The temperature dependence of magnetic susceptibility was measured at H = 0.1 T. With decreasing temperature, the susceptibility has a rounded maximum at about 19 K and decreases. Two susceptibility anomalies are observed at T_{N1} = 12.0 K and T_{N2} = 3.2 K. T_{N1} coincides with that reported previously. The second transition at T_{N2} was also observed in this study. Because T_{N2} is close to the ordering temperature T_N = 3.8 K in $Ba_3CoSb_2O_9$, and the configuration of $Co(1)O_6$ octahedra is similar to that in $Ba_3CoSb_2O_9$, we infer that spins on the Co(2) sites order first at T_{N1} and then spins on the Co(1) sites order next. From the specific heat measurements in magnetic fields, it was found that the low-temperature transition splits into two transitions in the field above 7 T, although the high-temperature transition is not largely affected.

3. ANSTO, Lucas Heights, Australia

Triangular-lattice antiferromagnets have attracted many experimentalists and theorists in the field of geometrically frustrated magnets. Small perturbation such as interlayer interaction, anisotropy, etc., lifts the macroscopic degeneracy of the ground, leading to an exotic magnetic state. Ba_2NiTeO_6 is a rare experimental realization of the bilayer equilateral triangular lattice of Ni^{2+} ions (S = 1). Meanwhile $Ba_3NiTa_2O_9$ is a conventional triangular antiferromagnet. Comparative study would be important for the understanding of the unique lattice in Ba2NiTeO6. Recently, bulk properties were studied in Ba_2NiTeO_6 and $Ba_3NiTa_2O_9$ by heat capacity and magnetic susceptibility measurements, and phase transitions were identified in both materials [1,2].
In order to investigate the magnetic states, we carried out powder neutron diffraction measurements at ECHIDNA in ANSTO. We observed magnetic Bragg peaks below the transition temperatures, and identified the magnetic propagation vectors for these oxides. The representation analyses lead to a 120 degree structure for $Ba_3NiTa_2O_9$ and collinear magnetic ordering for Ba_2NiTeO_6. We discuss the interlayer interactions and single-ion anisotropy of Ni^{2+} ion for Ba_2NiTeO_6 in terms of the crystal structure in order to clarify the origin of the difference for the magnetic structures.

We report dc and ac magnetic susceptibility, magnetic specific heat, and ZF- and LF-muon spin relaxation (muSR) measurements of the stacked triangular antiferromagnets Ba3Ru1-xIrxTi2O9, which combine geometrical frustration and strong spin-orbit coupling [1,2]. The emerging issue is whether a ground state can be tuned by controlling the strength of spin-orbit coupling. The magnetic susceptibility of Ba3Ru1-xIrxTi2O9 show that with increasing x a Curie-Weiss temperature increases systematically from Θ_{CW}= -161 K to - 86 K while the effect magnetic moment decreases from μ_{eff} ~ 2.5 μ_B for x=0 (Ru4+;S=1) to μ_{eff} ~ 1.0 μ_B for x=1 (Ir4+;Jeff=1/2). ac magnetic susceptibility exhibits a spin freezing-like transition at T=100 mK for x=0 whereas no signature for frozen magnetic moment is observed down to 20 mK for x=0. The ZF- and LF-¦ìSR spectra reveal the development of no static magnetic moments down to 23 mK and show a persisting spin dynamics for temperatures below 1 K for all x. Taken together with ac susceptibility, we conclude that a fraction of spin freezing at x=0 is completely melted to a dynamically fluctuating state at x=1. This result suggests that strong spin-orbit coupling provides a control parameter of stabilizing spin liquid in a triangle lattice owing to extended 5d orbitals.

FR.D-P53 - Substitution effect on S=1/2 frustrated magnetic cluster system $Li_2AMo_3O_8$ (A=In, Sc)

Y. Haraguchi [1], C. Michioka [1], H. Ueda [1], K. Yoshimura [1,2]

1. Department of Chemistry, Graduate School of Science, Kyoto University, Kyoto, Japan
2. Research Center for Low Temperature and Materials Sciences, Kyoto University, Kyoto, Japan

Frustrated cluster magnets are expected to produce competition between spin frustration effects and charge fluctuation within a cluster, which possibly produces novel physics. We investigated the substitution effects on S=1/2 frustrated magnetic cluster system $Li_2AMo_3O_8$ (A=In, Sc) for the purpose of revealing details of the effect of charge fluctuations on cluster magnets. For the non-substituted compounds $Li_2AMo_3O_8$ (A=In, Sc), although their magnetic properties are attributed to the same magnetic cluster lattice, their ground states are completely different from each other; while $Li_2InMo_3O_8$ exhibits a conventional magnetic ordering with 120-degree structure, $Li_2ScMo_3O_8$ shows a spin liquid like condensation. From the 115In- and 45Sc-NMR studies, charge fluctuations are found to play a key role for suppression of a magnetic ordering.
For substituted compounds Li_2In_1-xScxMo$_3$O8, XRD patterns of the 0<x<1 samples demonstrated successful synthesis, and suggest monotonic-decrease of cell parameters from $Li_2InMo_3O_8$ to $Li_2ScMo_3O_8$.
The effective magnetic moment for Li2In1-xScxMo_3O_8 obtained from the high temperature Curie-Weiss fitting to magnetic susceptibility does not show the linear relation against x value and take a minimum at x=0.5. Moreover, it was observed that Li_2In_1-xScxMo_3O_8 with 0.3<x<0.9 exhibits the disappearance of partial paramagnetic spins without magnetic orderings. Such the disappearance is also observed in the cluster magnet $LiZn_2Mo_3O_8$ with the same magnetic lattice of $Li_2AMo_3O_8$.
These facts suggest that cation-disordering suppress the low-temperature magnetic moment which comes from local dimerizations or constructions of VBS on honeycomb sublattice among cluster spins.

FR.D-P55 - Magnetic characterization of single crystalline barlowite - a structurally perfect spin-1/2 kagome system

M. Lang [1], E. Gati [1], N. Hieu Hoang [1], B. Wolf [1], H. Jeschke [2], F. Salvat-Pujol [2], R. Valenti [2], J.A. Schlueter [3]

1. Physics Institute, Goethe University Frankfurt, Frankfurt, Germany
2. Institute for Theoretical Physics, Goethe-University Frankfurt, Frankfurt, Germany
3. Division of Materials Research, National Science Foundation, Arlington, Virginia, United States

Quantum-spin-liquid (QSL) candidates based on spin-1/2 kagome lattices have been of high interest in recent years [1-3]. The natural mineral herbertsmithite ZnCu_3(OH)_6Cl_2 has been considered one of the best QSL candidate systems although some ambiguities remain. Since chemical modifications of this kagome system are difficult to realize, new design strategies are necessary for synthesizing novel spin-liquid materials. The mineral barlowite Cu_4(OH)_6FBr reflects such a novel approach [4,5]. It contains Cu^2+ ions in a structurally perfect kagome arrangement due to the different bonding environments adopted by the F^- and Br^- ions. Here we present a detailed magnetic characterization of small single crystals of barlowite Cu_4(OH)_6FBr. Measurements of the magnetization and susceptibility down to 2 K and up to 5 T reveal indications for two dominant magnetic couplings of different sign and an antiferromagnetic transition at T_N = 15 K. The experimental findings are in good agreement with the results of density functional theory (DFT) calculations from which the Heisenberg Hamiltonian parameters are derived. By using a high temperature series expansion and the DFT-derived intra- as well as inter-kagome-plane exchange couplings, a very good fit to the susceptibility data for T > T_N is obtained. The magnetic coupling between the kagome layers together with the Dzyaloshinskii-Moriya interaction, implied by the crystal's symmetry, provide a natural explanation for the canted nature of the antiferromagnetic ordering at T_N = 15 K giving rise to a weak ferromagnetic component.

FR.D-P56 - Single-crystal high-temperature pyrochlore antiferromagnetic $NaCaCo_2F_7$: An NMR investigation

R. Sarkar [1], J. Krizan [2], F. Brückner [1], R.J. Cava [2], H.H. Klauss [1]

1. Technical University of Dresden, Dresden, Germany
2. Department of Chemistry, Princeton University, Princeton, United States

The fluoride pyrochlore $NaCaCo_2F_7$ is a newly discovered frustrated pyrochlore. This possesses the large Curie Weiss theta (-140 K) albeit there is no magnetic ordering down to low temperature. The resulting frustration index of $f = \theta_{CW}/T_f \sim 56$ indicates that $NaCaCo_2F_7$ is highly frustrated. The small entropy loss at the freezing transition suggests magnetic entropy remains present in $NaCaCo_2F_7$ at 0.6 K [1]. We performed ^{19}F and ^{23}Na NMR investigations on a large single crystalline sample of $NaCaCo_2F_7$. While ^{23}Na NMR -spectra reveals the presence of two inequivalent Na sites, in accordance with the local disorder of the system, below ~3.7 K both the ^{23}Na -and ^{19}F spectra broadens considerably. Reduction of the ^{23}Na NMR signal intensity hints at a spin-glass state or a quasi-static field distribution in $NaCaCo_2F_7$. On the other hand, ^{19}F spin-lattice relaxation rate $^{19}(1/T_1)$ exhibits a peak at around ~3 K, at the same temperature range where ac and dc susceptibility data show a broad maximum. The overall temperature dependence of $^{19}(1/T_1)$ can be modeled by the BPP theory considering a fluctuating hyperfine field with an autocorrelation function. The correlation time of the autocorrelation function exhibits an activation behavior further indicating the spin-glass state in $NaCaCo_2F_7$.

FR.D-P58 - Magnetic properties in a frustrated spin ladder

Takanori Sugimoto [1], M. Mori [2], T. Tohyama [1], S. Maekawa [2]

1. Department of Applied Physics, Tokyo University of Science, Tokyo, Japan
2. Advanced Science Research Center, Japan Atomic Energy Agency, Ibaraki, Japan

Recently, a new type of low-dimensional quantum spin model has attracted much attention due to successive magnetic phase transitions in a corresponding compound BiCu2PO6 [1]. The magnetic behaviors of the compound are well understood as a frustrated two-leg spin-ladder system, which bridges between the frustrated spin chain and the non-frustrated spin ladder with 1/2 spins [2]. A pile of studies on the frustrated spin chain and non-frustrated spin ladder has insisted that number of chains and magnitude of frustration strongly affect spin gaps in excitation spectrum. For instance, the non-frustrated spin ladder exhibits a finite spin gap, although the spin chain has no gaps without frustrations. On the other hand, a strong frustration in the spin chain causes not only a spin gap over the ground state but also another gap above 1/3 magnetized state. Therefore, the bridging model of these is worthy of study in order to clarify mechanisms of spin gaps in terms of frustration and number of chains.
We firstly investigate magnetic excitations in the frustrated two-leg spin ladder without magnetic fields by using the dynamical density-matrix renormalization-group method. We find some differences in excitation spectrum between two possible ground-state phases. The qualitative features can be understood by two different elementary excitations. Additionally, we examine magnetization processes and magnetic phase transitions. The numerical results show that magnetization plateaux emerge at M=1/2 and 2/3, in addition to 1/3 plateau and some cusps [2]. We also find out an analytical correspondence between effective models in weak and strong rung-coupling limits, which gives an explanation of the plateaux and cusps. Our study is useful to analyze experimental data of $BiCu_2PO_6$.

FR.D-P59 - Atomic layer deposition and characterization of triangular lattice antiferromagnetic oxide $CuCrO_2$

T. S. Tripathi [1], M. Karppinen [1]

1. Inorganic Chemistry Department, Aalto University, Espoo, Finland

In this study, we report the atomic layer deposition (ALD) of antiferromagnetic ternary copper chromium oxide: $CuCrO_2$. Copper tetramethyl heptanedionate (Cu(thd)2) has been used as the precursor for copper source, chromium acetyl acetonate (Cr(acac)3) for chromium source and ozone as the oxygen source. The growth was investigated at deposition temperatures from as low as 200 0C up to 350 0C. The effect of the process conditions and post-deposition annealing on the film structure was investigated. Atomic force microscopy revealed that the films were smooth (surface roughness ~ 0.5 nm) and uniform. The composition and stoichiometry of the films were determined by X-ray photoelectron spectroscopy and inductively coupled plasma mass spectrometry (ICP-MS).

FR.D-P60 - Specific heat of triangular spin tubes in magnetic fields

H. Manaka [1], M. Hagihala [2], S. Hayashida [2], M. Soda [2], T. Masuda [2], Y. Miura [3]

1. Graduate School of Science and Engineering, Kagoshima University, Kagoshima, Japan
2. Neutron Scattering Laboratory, Institute for Solid State Physics, The University of Tokyo, Tokyo, Japan
3. Suzuka National College of Technology, Suzuka, Japan

Triangular spin tubes belong to a new category of one-dimensional Heisenberg antiferromagnets along the tubes coexisting with geometrically frustrated spin systems in the triangular plane. We discovered that chromium fluoride $CsCrF_4$ forms ideal equilateral triangular spin tubes with $S = 3/2$[1]. All Cr ions are at equivalent sites, and each angle of Cr-Cr-Cr in the triangular plane is 60 deg. Because superexchange interactions through the three Cr-F-Cr paths in each equilateral triangle may be kept in equilibrium at 0 K, we propose resonating spin-singlet pairs in each equilateral triangle. To clarify ground state of the spin-liquid ground state, we performed temperature dependence of specific heat $C(T)$ measurements in magnetic fields on $CsCrF_4$. As a result, there is no anomaly which indicates magnetic long-range order above 0.3 K. But temperature dependence of $C(T)/T$, after exhibiting the minimum at around 1 K, exhibits
steep monotonic increase toward 0 K. The increase of $C(T)/T$ disappears, while a broad peak appears above $B = 1$T. We found that magnetic entropy is restored above $B = 1$ T because spin frustration effect is suppressed by magnetic fields.

FR.D-P61 - Low temperature spin-glass behavior in nonmagnetic atom disorder compound Pr_2CuIn_3

D. X. Li [1], Y. Homma [1], F. Honda [1], T. Yamamura [2], D. Aoki [1]

1. Institute for Materials Research, Tohoku University, Oarai, Japan
2. Institute for Materials Research, Tohoku University, Senda, Japan

Ternary intermetallic compounds with the formula R_2TX_3 (R=U or rare-earth element, T=transition element, X = Ga, In, Si, Ge) have been the subjects of intensive studies during the past years because of their intriguing physical properties. The interest in these compounds stems from the characteristic NMAD (nonmagnetic atom disorder) crystal structure, i.e., completely or partly disordered distribution of the T and X atoms on the crystallographic sites, which is expected to cause some anomalous magnetic properties. Recently, we have been paying special attention to the ternary copper indides R_2CuIn_3. Except for the early susceptibility measurements between 4.2 and 160 K, no other magnetic properties are reported for the compounds of this family.
We present the experimental results of ac and dc susceptibility, magnetization, magnetic relaxation, specific heat, electrical resistivity and magnetic memory effect for hexagonal CaIn2-type polycrystalline Pr_2CuIn_3. It is found that the ac susceptibility shows an evident peak near Tf~5.4 K, which shifts to high temperature with increasing frequency, while irreversible magnetism manifesting as the separation between FC and ZFC dc susceptibilities, long-time magnetic relaxation behavior and ZFC magnetic memory effect can be clearly observed below Tf. These features are considered as evidence for the formation of spin-glass (SG) state in Pr_2CuIn_3. This conclusion is further confirmed by the specific heat and electrical resistivity measurements that suggest the absence of long-range magnetic ordering in this system. As important parameters characterizing the SG state, static spin freezing temperature, critical exponent and activation energy are determined from the dynamical analyses of the ac susceptibility data and compared with those obtained for other 2:1:3 compounds. We conclude that Pr_2CuIn_3 could be classified as a NMAD spin glass. The SG state in Pr_2CuIn_3 seems to originate from the continued site randomness of the non-magnetic elements, which introduce the random distribution of RKKY interactions.

FR.D-P62 - Frustrations in a mixed spin-1/2 and spin-1 Ising model with multispin exchange interactions and single-ion anisotropy on a bipartite honeycomb lattice

V. Stubna [1], M. Jascur [1]

1. Department of Theoretical Physics and Astrophysics, Institute of Physics, P.J. Safarik University In Kosice, Košice, Slovakia

This work is devoted to the study of a mixed spin-1/2 and spin-1 Ising model on the honeycomb lattice. In addition to the standard pair exchange interactions and single ion-anisotropy term, we have also included into Hamiltonian unconventional three-site interactions between spin residing on the sublattice A and its nearest neighbors located on the sublattice B.

Applying the generalized form of star-triangle transformation, we have obtained an exact expression for the partition function of the system under investigation. Then, using standard relations of thermodynamics and statistical physics, we have derived exact results for the ground-state and finite temperature phase diagrams, thermal variations of the sublattice and total magnetization, correlation functions, internal energy, Helmholtz free energy, specific heat and entropy of the system. Our results clearly illustrate that due to the presence of three-site interaction term, the system exhibits very interesting physical behavior.

We have observed that the inclusion of three-site interaction causes strong competitive effects in the system, that in turn generate novel disordered phases. In particular, we have found several disordered frustrated phases exhibiting non-zero ground-state entropy. On basis of our analysis one can definitely state that the multispin interactions in magnetic systems are of extraordinary importance and deserve further investigation.

This work has been supported under grant VEGA No. 1/0331/15.

FR.D-P63 - Exact results of a mixed spin-1/2 and spin-3/2 Ising model with multispin exchange interactions and single-ion anisotropy on a decorated triangular lattice

V. Stubna [1], M. Jascur [1], K. Szaowski [2], T. Balcerzak [2]

1. Department of Theoretical Physics and Astrophysics, Institute of Physics, P.J. Safarik University In Kosice, Kosice, Slovakia
2. Department of Solid State Physics, Faculty of Physics and Applied Informatics, University of Lodz, Lodz, Poland

In this work we have obtained exact results for a mixed spin-1/2 and spin-3/2 Ising model in which, in addition to the standard pair exchange interactions, we have also considered unconventional three-site interactions between each decorating spin and its nearest neighbors. Applying the generalized decoration-iteration transformation, we have obtained an exact expression for the partition function of the decorated triangular lattice. Then, using standard relations of thermodynamics and statistical physics, we have calculated the ground-state and finite temperature phase diagrams, thermal variations of the sublattice and total magnetization, correlation functions, internal energy, Helmholtz free energy, specific heat and entropy of the system. Our results clearly indicate extraordinarily interesting influence of the three-site interaction term on physical properties of planar Ising spin systems. In particular, we have found that in the case of pure three-site interactions, the system becomes frustrated and exhibits non-zero ground-state entropy. Our results also clarify the role of coordination number and the spin value in the systems with multispin interactions. This work has been supported under grant VEGA No. 1/0234/12.

FR.D-P66 - Neutron scattering study of the quantum spin ice candidate $Pr_2Zr_2O_7$

7. Institut Laué Langevin, Grenoble, France

The pyrochlore compound $Pr_2Zr_2O_7$ is suggested to be a good candidate for displaying quantum spin ice phenomenology [1]. This is supported by recent measurements by Kimura et al showing that the elastic magnetic pattern displays a large pinch point broadening and fast fluctuations down to 50 mK. They also showed that the crystal electric field of the non-Kramers ion Pr^{3+} is consistent with an Ising anisotropy [2]. In this work, we report local susceptibility measurements carried out with polarised neutrons revealing the strong Ising-like anisotropy of the magnetic moments of the Pr^{3+} ions along the <111> axis. We also investigate the field induced magnetic ordering of this compound using neutron diffraction and inelastic scattering. Our neutron experiments support the existence of ferromagnetic correlations between the magnetic moments despite a negative Θ_{CW}. These, together with the magnetization measurements, indicate a mixing of the two wave functions of the non-Kramers ground state which leads to fluctuations within the doublet. It is of great interest to compare these results with another quantum spin ice candidate with Ising-like non Kramers ions, namely $Tb_2Ti_2O_7$. In this compound, the coupling with the lattice written in terms of quadrupoles is likely at play involving the existence of a magneto-elastic excitation [3, 4]. However, in $Pr_2Zr_2O_7$, although we have clues for a coupling to the lattice, such features have not been observed. Moreover, one has to take into account the importance of defects which do play a role in the physics of this compound

6. Inst. for Problems of Mat Science, Ukraine Acad. of Science, Kiev, Ukraine

We investigate the dynamics of the frustrated FCC - magnet HoB12 with inelastic neutron diffraction in the paramagnetic state. Distinct regions in q - space are identified where the dynamics shows different behaviour above TN: These are, first, so called “pinch points” of the reciprocal lattice which show static spin correlation that diverge only in the limit T-> 0, second, general lattice points and third nodal lines that connect reciprocal lattice points. Correlations from general lattice points show power law like temperature dependence that finally drives the antiferromagnetic (afm) ordering. The data are compared with results from classical Monte Carlo simulations as well as simulations of the dynamic behaviour in the paramagnetic and the afm ordered phase.

FR.D-P69 - Re-investigation of low-temperature magnetic phase transitions of the geometrically frustrated isosceles triangular Ising antiferromagnet CoNb2O6

S. Mitsuda [1], S. Hosaka [1], H. Tamatsukuri [1], H. Koorikawa [1], S. Kobayashi [2], T. Nakajima [3], K. Prokes [4], K. Kiefer [4]

4. Helmholtz-Zentrum Berlin, Berlin, Germany

A columbite niobate, $CoNb_2O_6$ is one of the model material of isosceles-triangular lattice Ising antiferromagnet, where magnetic Co^{2+} ions form quasi-one-dimensional ferromagnetic zigzag chains running along the orthorhombic c axis and form an antiferromagnetic isosceles-triangular lattice in the a-b plane. Extensive neutron diffraction measurements have demonstrated rich magnetic field (H) versus temperature (T) phase diagrams which are attributed to the competing interchain exchange interactions on the isosceles-triangular lattice.
While the H//c-T magnetic phase diagram is well studied down to 0.2K [1], neutron diffraction study of the H//a-T magnetic phase diagram is limited down to 1.8K [2]. In present study, we performed neutron diffraction and magnetization experiments down to 0.5 K on a single crystal of $CoNb_2O_6$ with an external magnetic field applied along the a axis, in order to investigate (i) how field-induced ferrimagnetic phase characterized by the propagation wave vectors Q=(0,1/4,0) which has been suggested by H. Weitzel et al.[2] is extended to lower temperature region in the H(//a)-T magnetic phase diagram and (ii) how it connected with 1/2 magnetization plateau reported by T. Hanawa et al. [3] from which three up and one down spin arrangement is inferred.
As a result, we found that the field-induced ferrimagnetic phase does not exist in zero temperature limit, being consistent with that the ferrimagnetic state is degenerate at the transition magnetic field between antiferromagnetic ground state and field-induced paramagnetic state.

4. Department of Applied Chemistry, Faculty of Science and Engineering, Chuo University, Tokyo, Japan

Magnetism of the spinel-type magnetically frustrated antiferromagnetic $CoAl_2O_4$ and its magnetically diluted system, $Co_{1-x}M_xAl_2O_4$; (M = Mg and Zn), are reported. These systems are partially inverted spinel oxides with magnetic cobalt ions (spin S = 3/2) predominately in the tetrahedral A-site. The effects of inversion and dilution were revealed when the system is field-cooled from the paramagnetic region. After the field cooling, a small ferromagnetic component was quenched at low temperatures. Magnetic anomalies associated with magnetic transitions were observed in magnetic susceptibility and specific heat. We proposed x-temperature phase diagrams in the range of $0 \leq x \leq 1$ for $Co_{1-x}M_xAl_2O_4$ (M = Mg and Zn). For the Zn-substituted system a multicritical point was indicated at T = 3.4 K and x = 0.12, where the antiferromagnetic, spin glass-like, and paramagnetic phases met. The quenched ferromagnetic moment was sharply enhanced at x = 0.12. While for the Mg-substituted system a phase boundary was also indicated at $x \sim 0.1$, the critical singularities observed in magnetization and specific heat were quantitatively different from those in the Zn substituted system.

FR.D-P72 - Exotic Field Induced Quantum Phase Transition of the Kagome Lattice Antiferromagnet

T. Sakai [1], H. Nakano [2]

1. JAEA, SPring-8, Hyogo, Japan
2. University of Hyogo, Hyogo, Japan

The kagome-lattice antiferromagnets have attracted a lot of interest in the field of the low-temperature physics. It exhibits some exotic field-induced phenomena, like a magnetization plateau, jump etc. Our previous large-scale yumerical exact diagonalization study on the S=1/2 kagome-lattice antiferromagnet revealed that a novel field-induced phenomenon, 'the magnetization ramp', occurs at 1/3 of the saturation magnetization[1]. It is characterized by different critical exponents between the lower-field and higher-field sides of the magnetization curve[2]. In order to clarify unconventional properties around the 1/3 magnetization, we considered some extended lattice models; a distorted kagome lattice and distorted triangular lattice etc[3]. The ground-state magnetization curve recently obtained by the numerical exact diagonalization up to 42-spin clusters is also presented to estimate the shape in the thermodynamic limit. Our numerical exact diagonalization study also indicates that the ground state of the kagome-lattice antiferromagnet is gapless quantum spin liquid.

6. Institut Max von Laue-Paul Langevin, Grenoble , France

The search for new states of matter is a fundamental theme of condensed matter science. Frustrated magnetic materials are promising candidates for new states because lattice geometry suppresses conventional magnetic dipole order. Frustration thus drives novel emergent states.
$Gd_3Ga_5O_{12}$ is the canonical frustrated magnet as the compound that does not order via the pervasive "order by disorder" mechanism down to the lowest temperatures probed, 25 mK [1 and ref. therein]. Short-range correlations, determined via neutron diffraction, have long been assumed to originate from near neighbour short-range interactions.
A non-dipole ("hidden") order has been uncovered via recent developments in Reverse Monte Carlo techniques [2] in conjunction with optimised neutron scattering instrumentation that enabled S(Q) of non-isotope enriched $Gd_3Ga_5O_{12}$ to be probed. The hidden-order state of $Gd_3Ga_5O_{12}$, the only known example of a magnetic multipole crystal in a spin liquid, does not break the crystal symmetry and is built from individually fluctuating groups of spins. Indeed the multipolar order creates loops that are long-range ordered while individual spins show only short-range correlations.

FR.D-P74 - Study of the frustrated Ising antiferromagnet on the stacked triangular lattice in the field

M. Borovsky [1], M. Zukovic [1]

1. Institute of Physics, P.J. Safarik University, Kosice, Slovakia

Ising triangular antiferromagnet (J1 < 0) on the stacked lattice is one of the simplest three-dimensional geometrically frustrated spin models. Several theoretical studies have been performed to analyse this model for the case of a ferromagnetic interlayer interaction (J2 > 0) and these are in a very good agreement with the experimental results for the quasi-one-dimensional frustrated magnetic compound $Ca_3Co_2O_6$. However, the model with an antiferromagnetic interlayer interaction (J2 < 0) has been studied much less. Such a model is a suitable choice for description of the material $CsCoX_3$, where X = Cl and Br. An applied magnetic field yields interesting new ground state phases in the system. For a weak external magnetic field ($h/|J1| < - 2J2/|J1|$) the nature of the exchange couplings arranges spins in the layers ferrimagnetically, while the adjacent layers are ordered antiferromagnetically. Macroscopically this phase is non-magnetic (total magnetization m = 0). Larger fields ($-2J2/|J1| < h/|J1| < 6 - 2J2/|J1|$) allow ferromagnetic rearranging of the spins in one third of the chains while the ferrimagnetic ordering in the layers is preserved. This phase exhibits a plateau with m = 1/3 in the ground state. Above $h/|J1| = 6 - 2J2/|J1|$ the system is in a paramagnetic phase (m = 1). This behaviour could correspond to the magnetization measurements of $CsCoX_3$. The effective-field theory with correlations is applied in order to study this case. In order to verify the most interesting results we implement some progressive parallel algorithms such as population annealing, which is suitable for studying the systems with rough free-energy landscapes.

FR.D-P76 - Magnetothermal properties of the local xy-antiferromagnet $Er_2Ti_2O_7$

B. Wolf [1], W. Assmus [1], R. Schindler [1], S. Dörschug [1], M. Lang [1]

1. Physikalisches Institut, Goethe University Frankfurt, Frankfurt, Germany

The magnetocaloric effect (MCE), i.e., temperature changes of a magnetic material in response to an adiabatic change of the magnetic field, has been successfully applied for reaching temperatures significantly below 1 K. Such a magnetic cooling is used in low-temperature laboratory experiments as a cost-efficient alternative to dilution refrigerators, and represents the cooling technique of choice in present space applications. No doubt, there is a demand on magnetic coolants exhibiting an enhanced MCE combined with a high cooling efficiency. The MCE of a material depends on the distribution of the magnetic entropy with respect to temperature and magnetic field. In a proof-of-principle-experiment we have demonstrated that the accumulation of magnetic entropy near a field-induced quantum-critical point (QCP) can be used for an efficient magnetic cooling [1]. Moreover, it has been shown that the cooling efficiency can be further increased significantly by employing materials with magnetic frustration [2]. Here we present magnetothermal data for $Er_2Ti_2O_7$ obtained on single crystalline as well as powder samples for 0.3 K< T <. 4.5 K and magnetic fields up to 7 T. $Er_2Ti_2O_7$ is distinct among the family of geometrically frustrated rare-earth pyrochlores as it is the only pyrochlore antiferromagnet known so far that exhibits a strong easy-plane anisotropy. The system orders antiferromagnetically below TN = 1.2 K into an unusual noncoplanar structure and exhibits a QCP around 1.5 T [3]. These characteristics make $Er_2Ti_2O_7$ particularly interesting for magnetic cooling. Especially the dT/dB-rate of $Er_2Ti_2O_7$ exceeds considerably that of Gadoliniun Gallium Garnet, a material used for magnetic cooling in space applications.

4. Max Planck Institute for Solid State Research, Stuttgart, Germany

We present the phase diagram K(J) for 8 – sites cluster within Kitaev – Heisenberg (KH) model. Above system is studied by means of cluster mean field method. Detailed examination of order parameters, two point correlation functions and ground state energies leads to the said phase diagram. While the diagram confirms part of recently published results for Γ=0 [1] (zigzag, stripy, spin liquid, ferromagnetic and antiferromagnetic phases) we argue that minor differences in the boundaries of the phases appear due to the shape of 8-sites cluster and specifics of cluster mean field method.
The results of [1] and [2] are compared with a recently developed analysis for N=24 cluster which preserves the lattice symmetry and also find the above phases, with somewhat extended range of Kitaev spin liquid phase. Furthermore the examination of Γ≠0 (extended KH model) region [1],[3] in phase space is presented.

FR.D-P79 - Spiral-spin-liquid state in spinel $MnSc_2S_4$

S. Gao [1], O. Zaharko [1], M. Ruminy [1], T. Fennell [1], T. Vladimir [2], Y. Su [3], D. Chernyshov [4], C. Rüegg [1]

4. Swiss-Norwegian Beam Lines, European Synchrotron Radiation Facility, France

The spinel $MnSc_2S_4$ was predicted to host a special spiral-spin-liquid state above the magnetic phase transition temperature of 2.1 K. In this state, Mn^{2+} spins (S = 5/2) at the spinel A-sites tend to fluctuate together as spirals with propagating k-vectors distributed around the Brillouin zone boundary. Here we present the first neutron diffraction and diffuse scattering study on $MnSc_2S_4$ single crystals. Our diffuse scattering results strongly corroborate the proposed spiral-spin-liquid picture but the diffraction results call for some further modification of the proposed model Hamiltonian. Our crystals were grown using chemical transport reaction methods (typical size 1/1/0.5 mm). Synchrotron diffraction (BM-01A beamline at ESRF) on single crystals of the same batch didn't show any Mn/Sc anti-site disorder, confirming the high quality of our sample. Neutron diffuse scattering experiments were performed on DNS at FRM2 at selected temperatures from 1.5 to 50 K. Below 2 K, strong magnetic reflections for LRO with k vector of [3/4 3/4 0] is observed; while above 2.9 K, these strong reflections are replaced by broad diffuse scattering intensity near the Brillouin zone boundary, just as theoretically predicted. Using Monte Carlo simulation, the main feature for the diffuse scattering can be reproduced with a model Hamiltonian with $|J2/J1| = 0.85$.
Neutron diffraction experiments measured on TriCS at PSI came as a surprise: the previously proposed ab-planar chiral based upon powder refinement cannot fit the single crystal data. With simulated annealing technique, we present here a new magnetic structure. It should be noted that Monte Carlo simulation with previous Hamiltonian prefers a parallel spin configuration along [1-10] direction, which is not the case for our new magnetic structure. Further modification for the Hamiltonian is needed to explain the formation of our proposed structure.

FR.D-P81 - Nonfrustrated Interlayer Order and its Relevance to the Bose-Einstein Condensation of Magnons in $BaCuSi_2O_6$ - an NMR, x-ray and neutron scattering, and DFT study

R. Stern [1], A. Tsirlin [1], I. Heinmaa [1], E. Joon [1], S. Krõmer [2], M. Horvatic [2], C. Berthier [2], V. Mazurenko [3], M. Valentyuk [3], D. Sheptyakov [4]

4. Laboratory of Neutron Scattering, Villigen PSI, Switzerland
5. Osaka University, Japan

Han purple ($BaCuSi_2O_6$) is not only an ancient pigment, but also a valuable model material for studying Bose-Einstein condensation (BEC) of magnons in high magnetic fields. In order to understand the nature of the two-dimensional BEC phase in $BaCuSi_2O_6$, we performed detailed ^{63}Cu and ^{29}Si NMR above the critical magnetic field, H_{c1} = 23.4 T.
We investigated the low-temperature crystal structure of $BaCuSi_2O_6$ with high-resolution synchrotron x-ray and neutron powder diffraction techniques and found it to be on average (ignoring the incommensurate modulation) orthorhombic, with the most probable space group *Ibam*. The Cu-Cu dimers in this material are forming two types of layers with distinctly different interatomic distances. Subtle changes also modify the partially frustrated interlayer Cu-Cu exchange paths. The two different alternating layers present in the system have very different local magnetizations close to H_{c1}; one is very weak, and its size and field dependence are highly sensitive to the nature of inter-layer coupling. Its precise value could only be determined by "on-site" ^{63}Cu NMR, and the data are fully reproduced by a model of interacting hard-core bosons in which the frustration associated to tetragonal symmetry is lifted, leading to the conclusion that the population of the less populated layers is not fully incoherent but must be partially condensed.
Using precise low-temperature structural data and extensive density-functional calculations, we elucidate magnetic couplings in this compound. The resulting magnetic model comprises two types of nonequivalent spin dimers, in excellent agreement with the $^{63,65}Cu$ nuclear magnetic resonance data. We further argue that leading inter-dimer couplings connect the upper site of one dimer to the bottom site of the contiguous dimer, and not the upper-to-upper and bottom- to-bottom sites, as assumed previously. This finding is verified by inelastic neutron scattering data and implies the lack of frustration between the layers of spin dimers in $BaCuSi_2O_6$, thus challenging existing theories of the two-dimensional-like BEC of magnons in this compound.

FR.D-P82 - Investigation into the magnetic properties of pyrochlore-type rare-earth hafnates

J.H. Chun [1], R.K. Kremer [1], C. Lin [1]

1. MPI for Solid State Research, Suttgart, Germany

Cubic rare-earths transition metal pyrochlores with composition $R_2TM_2O_7$ have attracted broad attention because of their unusual magnetic ground state properties related to geometrical frustration of the pyrochlores lattice. So far, the investigation focused mainly on 3d and 4d transition metal systems. The magnetic properties of rare-earths 5d TM pyrochlores are comparatively less well studied. Here we report on the single-crystal growth and the magnetic properties of some rare-earth hafnates (R =Nd, Gd, Dy; TM = Hf) of composition $R_2TM_2O_7$. $Nd_2Hf_2O_7$ and $Gd_2Hf_2O_7$ crystallize with the cubic pyrochlores structure whereas diverging reports on the structure of $Dy_2Hf_2O_7$ are available in literature. Crystals of $Gd_2Hf_2O_7$ and $Gd_2Hf_2O_7$ have been grown and their structural and magnetic properties have been investigated. Our investigations confirm $Gd_2Hf_2O_7$ and $Gd_2Hf_2O_7$ to crystallize in the cubic pyrochlores structure. Magnetic ordering below ~ 0.5 K has been observed by magnetic susceptibility and heat capacity measurements for both compounds.

FR.D-P83 - Magnetic order in pyrochlore hafnate $Nd_2Hf_2O_7$

V. Kumar Anand [1], A. Kumar Bera [1], J. Xu [1], T. Herrmannsdörfer [2], C. Ritter [3], A. Nazmul Islam [1], B. Lake [1]

2. Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany
3. Institut Laue-Langevin, Grenoble, France

The observation of spin-ice behavior and magnetic monopoles in pyrochlore titanates have created great interest in rare earth pyrochlore oxides $(R^{3+})_2(T^{4+})_2O_7$ (R = rare earth ion, T = transition metal). In the search for novel pyrochlore oxides we have investigated a pyroclore hafnate, namely $Nd_2Hf_2O_7$ in which magnetic ion is Nd3+ in 4f3 electronic configuration having ground state 4I9/2 (S=3/2, L=6, J=9/2). Both polycrystalline and single crystals of $Nd_2Hf_2O_7$ have been synthesized and investigated by ac and dc magnetic susceptibilities, isothermal magnetization and heat capacity measurements. The heat capacity data show an upturn in Cp/T below 6 K with a value of Cp/T = 0.53 J/mol K2 at 1.8 K. The ac susceptibility measurements reveal an anomaly below 0.55 K associated with a magnetic phase transition to a long range ordered state. The long range ordering is further confirmed by a neutron powder diffraction investigation. An antiferromagnetic ground state with an ordering wavevector k = 0 is inferred from the neutron data. The Fullprof refinement of the data reveals the magnetic structure to be all-in-all-out (where for successive tetrahedra, the four magnetic ions point alternatively all-into or all-out-of the tetrahedron) which implies antiferromagnetic interactions between the Nd^{3+} ions. The ordered state magnetic moment of 0.6 Bohr magneton at 0.1 K is much lower than the fully ordered value of 3.3 Bohr magneton for Nd^{3+} ions suggesting the persistence of dynamic correlations down to the lowest temperatures.

FR.D-P84 - Determination of critical exponents in a metallic glass: FeCrCuNbSiB

A. Rosales-Rivera [1], J. Hernadez-Parra [1], J. Lopez-Tabares [1], J. Hincapie-Bedoya [1], A. Velasquez-Salazar [1], D. Gomez-Montoya [1], F. Saccone [2]

1. Universidad Nacional de Colombia, Sede Manziales, Caldas, Colombia
2. Universidad de Buenos Aires, Buenos Aires, Argentina

In this work, we investigate the universality class of the $Fe_{73.5-x}Cr_xCu_1Nb_3Si_{13.5}B_9$ metallic glasses by determining the critical exponents for the zero-field magnetization (β) and critical isotherm (δ) and critical temperatures from magnetization measurements. Furthermore, to obtain qualitative information on the possible magnetic interactions that are active in previous materials and to gain understanding of their effects on the critical exponents, we employ the Hall effect and Mössbauer spectroscopy. These metallic glasses were prepared as amorphous alloy ribbons of $Fe_{73.5-x}Cr_xCu_1Nb_3Si_{13.5}B_9$ with x = 0, 2, 4, 6, 8, and 10 by means of the melt spinning technique. The magnetization as a function of temperature of each sample was measured in the range 300–950 K using a vibrating sample magnetometer (VSM-VersaLab by Quantum Design) at fixed external magnetic fields (H). The Hall effect measurements were carried out in the field range $-10 < H < 10$ kOe for several *dc* electrical currents applied to the samples at room temperature. Mössbauer spectra data were collected at room temperature and at zero-field. The radiative source was a ^{57}Co in an Rh matrix with 5 mCi. It is found that the β value shows a quasi-linear dependence on the Chromium content and, interestingly goes through values that belong to the Ising (sample with x = 0), XY (sample with x = 2) and Heisenberg (sample with x = 4) models, respectively, before finally deviating of any of these models in the high x region (samples with x = 6, 8 and 10). The δ value found varies between 3.8 and 6.1. The possible mechanisms leading to such universality classes including the spin-orbit interaction, shape anisotropies, direct exchange and itinerant exchange are analyzed.

Fr.D-P87 - Polarised neutron scattering studies of magnetic correlations in pyrochlore iridates

E. Feng [1], Y. Su [1], T. Wolf [2], T. Brueckel [3,1]

1. Jülich Centre for Neutron Science JCNS, Forschungszentrum Jülich GmbH, Outstation at MLZ, Garching, Germany
2. Institut für Festkörperphysik, Karlsruhe Institute of Technology KIT, Karlsruhe, Germany
3. Jülich Centre for Neutron Science JCNS and Peter Grünberg Institut PGI, JARA-FIT, Forschungszentrum Jülich GmbH, Jülich, Germany

The metallic pyrochlore iridate compounds $A_2Ir_2O_7$, where the A sites are occupied by rare-earth local moments and the B sites by 5d transition metal Ir ions with strongly spin-orbit coupled (SOC) itinerant electrons, have attracted tremendous interests because they sit in the intersection of the two emerging research fields in condensed matter physics: quantum spin ice in frustrated magnets [1] and strongly SOC correlated phenomena [2]. For instance, due to the presence of both local ice-rule constraint and quantum fluctuation at the rare-earth A-site, a quantum spin ice ground state carrying exotic quasi-particles and fractionalized excitations could appear. On the other hand, novel topological states such as Weyl semimetals may emerge as a consequence of the strong spin-orbit coupling of the B-site 5d conduction electrons. Exotic ground states and novel magnetic phases can be resulted from complex interplay of these two phenomena. However, neutron scattering, a powerful microscopic probe to magnetism, has hardly been performed on pyrochlore iridates due to strong neutron absorption and small magnetic moment of Ir. We have recently carried out comprehensive polarized neutron scattering studies of magnetic correlations of high-quality $Nd_2Ir_2O_7$ and $Pr_2Ir_2O_7$ powder samples synthesized by solid-state reaction [3]. In $Nd_2Ir_2O_7$, a q=0 long-range antiferromagnetic order has been observed below T_N~20 K, in consistence with “all-in-all-out” spin configuration as proposed in an earlier neutron diffraction investigation [4]. In $Pr_2Ir_2O_7$, magnetic diffuse scattering, a signature of short-range magnetic correlations, has been observed below 1 K. The polarized neutron scattering data has been analysed within the context of both quantum spin ice [1] and chiral spin liquid [5]. The important role of the RKKY interaction mediated by the itinerant Ir electrons will be discussed as well.

FR.E-P01 - Classical spin relaxation via spin-bath interaction: longitudinal vs. transverse spin-bath-coupling

S. Kun Oh [1], S.C. Yu

1. Chungbuk National University, Chungcheongbuk-do, South Korea

The system of noninteracting classical spins coupled to a heat bath consisting of one-dimensional harmonic oscillators is examined with an aim of understanding spin relaxation mechanism. Both the cases of longitudinal and transverse spin-component coupled to the modes of harmonic oscillators are studied. For the case of the longitudinal spin-component coupled to the harmonic oscillators, it is exactly solved but it does not show relaxation toward equilibrium. For the case of transverse spin-component coupled to the harmonic oscillators, it is numerically solved via geometric algorithm, and it does show some relaxation but it has nothing to do with equilibrium.

FR.E-P02 - Magnetic properties of the SPIN-1 J1-J3 heisenberg model on a triangular lattice

A. Sherman [1], P. Rubin [1], M. Schreiber [2]

1. Institute of Physics, University of Tartu, Tartu, Estonia
2. Institute für Physik, Technische Universität, Chemnitz, Germany

Motivated by the experimental data for $NiGa_2S_4$, the spin-1 Heisenberg model on a triangular lattice with the ferromagnetic nearest- and antiferromagnetic third-nearest-neigh-bor exchange interactions, $J_1 = -(1-p)J$ and $J_3 = pJ$, $J > 0$, is studied in the range of the parameter $0 \le p \le 1$. Mori's projection operator technique is used as a method which retains the rotation symmetry of spin components and does not anticipate any magnetic ordering. For zero temperature several phase transitions are observed.
At $p \approx 0.2$ the ground state is transformed from the ferromagnetic spin structure into a disordered state, which in its turn is changed to an antiferromagnetic long-range ordered state with the incommensurate ordering vector $Q \approx (1.16, 0)$ at $p \approx 0.31$. With growing p the ordering vector moves along the line $Q - Q_1$ to the commensurate point $Q_1 = (2\pi/3, 0)$ which is reached at $p = 1$. The final state with an antiferromagnetic long-range order can be conceived as four interpenetrating sublattices with the 120˚ spin structure on each of them. The model is able to describe the state with the incommensurate short-range order observed in $NiGa_2S_4$. Also our approach is able to reproduce a quadratic temperature dependence of the specific heat and dependence of the uniform spin susceptibility on T in $NiGa_2S_4$.
To verify the used approach the ground state energy and corresponding spin-spin correlations for small lattices are compared with exact-diagonalization results obtained with the SPINPACK code (the Lanczos exact diagonalization). The Mori's and the Lanzcos results are in qualitative agreement.

FR.E-P03 - Effect of doping on magnetic properties of magnetocaloric series (Fe1-xMnx)2P1-ySiy

J. Goraus [1], Łukasz Hawełek [2], A. Kolano-Burian [2]

1. University of Silesia, Institute of Physics, Uniwersytecka 4, Katowice
2. Insitute of Non-Ferrous Metals, Gliwice, Poland

We have calculated the magnetic quantities such as local and total magnetic moments and exchange integrals for the Fe_2P type series where iron was substituted by manganese and phosphorus was substituted by silicon. In Fe_2P type structure transition metals can occupy two Wyckoff sites - *3f* and *3g*. We considered three structural models, where substituting the iron for the manganese lead to preference in occupation of one of the sites, as well as the model where the concentration of manganese was equal across these two sites. It is clear from our calculations, which these structural models lead to different behaviour of considered series with respect to absolute doping with the transition metal and also with respect to the silicon concentration.

FR.E-P04 - Breaking symmetry in one dimensional random chain

O. Kryvchikov [1], V. Slavin

1. ILTPE - B.Verkin Institute for Low Temperature Physics and Engineering of The National Academy of Sciences of Ukraine, Kyev, Ukraine

The ground state of interacting particles on a disordered one-dimensional host-lattice is studied by new method, using Lapunov central theorem, and verified by a direct numerical method. It is shown that if the concentration of particles is small, then randomnes of the host-lattice sites positions breaks the long-range order of Generalized Wigner Crystal, replacing it by the sequence of blocks (domains) of particles with random lengths. The mean domains length as a function of the host-lattice disorder parameter is also found by both methods.

FR.E-P05 - dynamical properties of honeycomb lattice iridate Na_2IrO_3

S.I. Suga [1], T. Yamada [1], T. Suzuki [1]

1. University of Hyogo, Hyogo, Japan

Honeycomb lattice iridate Na2IrO3 has attracted much attention, since the system can be described by a Kitaev-Heisenberg model, in which the Kitaev spin-liquid state is a possible ground state [1,2]. Several models including further neighbor interactions and/or anisotropic interactions have been proposed to explain the observed zigzag order and thermodynamic properties. However, its dynamical properties have not been fully investigated yet. In this study, we calculate dynamical spin structure factors for proposed four models [2-5] using exact numerical diagonalization. By comparing our numerical results with inelastic neutron scattering (INS) experiments [3], we find that the models in Refs. 3 and 5 well reproduce qualitative features of the experiments. However, when we focus on the scattering 'boundary' and the scattering intensity of the low energy region at the \Gamma' symmetric point, we confirm better agreement between the numerical results for the model in Ref. 5 and the INS experiments. We thus consider that the model in Ref. 5 is most adequate to describe the INS experiments. We further perform spin-wave analyses for both models. The difference appears at the M symmetric point. The low-lying excitation is gapless there for the model in Ref. 5, while it is gapped for the model in Ref. 3. This notable difference helps us to conclude the adequate model for Na2IrO3, which may pave a way for realizing quantum spin liquids.

FR.E-P06 - Hybrid molecular and spin dynamics simulations of gel-based Co nanoparticle dispersions

L. Teich [1], C. Schröder [1]

1. Bielefeld Institute for Applied Materials Research, University of Applied Sciences Bielefeld, Bielefeld, Germany

Dispersions of magnetic nanoparticles in conductive gel matrices exhibit promising magnetoresistive characteristics [1-3] which makes them suitable for a rational design of magnetoresistive sensor devices. This approach needs detailed knowledge of the viscous and magnetic parameters that influence the structuring processes of the nanoparticles within the dispersion and hence their magnetoresistive properties. In this regard, time-resolved simultaneous spin dynamics and molecular dynamics simulations provide crucial information which is not accessible experimentally. Here, we present a hybrid approach, which combines a modified version of HOOMD-blue [4] for molecular dynamics and a stochastic spin dynamics method that involves solving the Landau-Lifshitz equation [5]. We have applied our approach to the simulation of an ensemble of 192 monodisperse Cobalt nanoparticles. The time development of the structuring process results in the formation of vortices and chain fragments. This is in agreement with previous investigations [2].

FR.E-P07 - Magnetic simulation of nano-granular thin films

J.D. Agudelo Giraldo [1], J. Restrepo [2], E. Restrepo Parra [1]

1. Universidad Nacional de Colombia, Bogotá, Colombia
2. Universidad de Antioquia, Medellín, Colombia

A new methodology for generating thin granular films was obtained according with reports of magnetic materials. The growth considered periodic boundary conditions. The Monte Carlo Method was used for a randomly grow from different seeds and subsequently for to compute magnetic properties. Metropolis algorithm was implemented for relaxation purposes. The grain boundary relaxation was obtained with Morse Potential. The Magnetic Hamiltonian was based in Heisenberg model. The sums included exchange interaction with cut radius, cubic magnetocrystalline anisotropy with temperature dependence, external magnetic field in different directions and dipolar interactions with cut radius until six times the sample length. Parallelization was necessary. The results show changes on transition temperature as function of computational thread numbers, grain size, magnetocrystalline anisotropy and cut radius. Magnetization decreases at low temperatures by cubic anisotropy effects. As a result of grain orientation, cut radius and intergranular boundaries were observed magnetic vortex formation in different points of the sample.

FR.E-P08 - Frustrated spatially anisotropic spin-1/2 Heisenberg antiferromagnet on a square lattice

V. Ilkovic [1]

1. Joint Institute for Nuclear Reserch-JINR, Moscow, Russia

Frustrated spatially anisotropic spin-1/2 Heisenberg antiferromagnet on a square lattice Vladimir IlkoviÞ Bogoliubov Laboratory of Theoretical Physics, JINR, 141980 Dubna, Moscow region, Russia Permanent address: Institute of Experimental Physics, Slovak Academy of Sciences, Watsonova 47, 040 01 Kosice, Slovak Republic . The new magnetic materials such as the layered oxide high-temperature superconductor can be well described by the Heisenberg spin model with nearest-neighbor (NN) antiferromagnetic coupling J1 and next-nearest-neighbor (NNN) antiferromagnetic coupling J2. It is now well accepted that the model J1-J2 exhibits two phases displaying magnetic order at small J2, separated by an intermediate paramagnetic phase in the interval Jc1<J2<Jc2. The ground state for J2<Jc1 exhibits Neél magnetic order, whereas for J2>Jc1 it exhibits collinear stripe order. A generalization of the frustrated J1-J2 model is the J1-J1'-J2 model where J1' is the directional anisotropy parameter. The nearest-neighbor bonds have different strength J1 and J1' in the x and y directions, respectively. The effect of the coupling J1' on the Neél and stripe states is investigated. The spin-wave excitation spectrum, the magnetization and the antiferromagnetic Neél and collinear antiferromagnetic stripe order for frustrated J1-J1'-J2 Heisenberg model are calculated within the quantum many-body Green function method.

FR.E-P09 - Spontaneous magnetizationá and specific heat of a coupled spin-electron model on doubly decorated planar lattices

H. Cencarikova [1], J. Strecka [2], M. Lyra [3]

1. Institute of Experimental Physics, Slovak Academy of Sciences, Bratislava, Slovakia
2. Faculty of Science, P. J. Safarik University, Kosice, Slovakia
3. Instituto de Fisica, Universidade Federal de Alagoas, Maceió, Brazil

The generalized decoration-iteration transformation is adopted for an exact study of a coupled spin-electron model on 2D lattices, in whichálocalized Ising spins reside nodal lattice sites and mobile electrons are delocalizedá over pairs of decorating sites. The model takes into accountáa hopping term for mobile electrons, the Ising coupling between mobile electrons and localized spins, as well as, the Ising coupling between localized spins (J'). The ground state, spontaneous magnetization and specific heat are examined for both ferromagnetic (J'>0) and antiferromagnetic (J'<0) interaction between the localized spins. Besides reentrant transitions with only two consecutive critical points between the paramagnetic (P) and the antiferromagnetic (AF) or ferromagnetic (F) phase (P-AF/F-P) observed for J'=0, one may also found more peculiaráreentrant transitions with three successive critical points AF/F-P-F/AF-P for a non-zero value of J'. Moreover, very interesting thermal variations of spontaneous magnetizations were found, which exhibit for the convenientááelectron concentration <n>á simultaneous presence of the spin/electron magnetization and staggeredá spin/electron magnetization, respectively. It is shown that the specific heatámay also display diverse thermal dependences,á which include singularities of various type for non-zero values of <n> and J'.

FR.E-P10 - Short-range order above the Curie temperature in the dynamic spin-fluctuation theory

N. Melnikov [1], B. Reser [2]

1. Lomonosov Moscow State University, Moscow, Russia
2. Institute of Metal Physics, Russian Academy of Sciences, Ekaterinburg, Russia

Existing theories of metallic magnetism all postulate that local magnetization remains above the Curie temperature, but there is no agreement about the extent of the short-range order in the paramagnetic phase. We study the paramagnetic spin density correlations of strong ferromagnetic metals using the dynamic spin-fluctuation theory (DSFT) [1]. Unlike the dynamic mean-field theory [2] and dynamical coherent potential approximation [3], based on the single-site approximation, the DSFT takes into account both single-site and nonlocal interactions. We obtain computational formulas for the correlation function and short-range radius in different approximations of the DSFT. Using these formulas, we calculate the short-range order above the Curie temperature in the bcc iron. Results of the calculation confirm our theoretical prediction that the inverse correlation radius increase linearly with temperature for T sufficiently large. We compare the results with other theoretical work and neutron scattering experiments.

FR.E-P11 - Magnetic phase transition in the spin-fluctuation theory

N. Melnikov [1], G. Paradezhenko [1]

1. Lomonosov Moscow State University, Moscow, Russia

The first-order phase transition is a characteristic feature of the Gaussian approximation in the spin-fluctuation theory [1]. We present a method that takes into account the fourth-order terms in the expansion of the free energy and thus leads to a renormalization of the magnetic susceptibility [2]. To deal with the higher-order terms, we introduce partial averaging of the fluctuating fields, which is based on the Wick theorem, and is different from the decoupling of operators in mean-field theories and the Green functions in equations of motion. By example of the Ising model, we show that the renormalization of the magnetic susceptibility leads to continuous second-order phase transition, which is experimentally observed in metals. We explain the mechanism of the renormalization and show that the spin-rotational invariance is not the reason for the first-order phase transition in the spin-fluctuation theory, as it was speculated in [3].

FR.E-P12 - Generalized flavor-wave expansion for softcore bose-hubbard systems

K. Masuda [1], S. Kurihara [1], D. Yamamoto [2]

1. Waseda University, Tokyo, Japan
2. Waseda Institute for Advanced Study, Tokyo, Japan

We propose a systematic perturbative approach to study softcore Bose-Hubbard models by generalizing the flavor-wave theory for quantum spin systems. In previous studies, the Gutzwiller approximation has succeeded in qualitatively describing various phenomena of the Bose-Hubbard models, including the superfluid-Mott-insulator transition. On the other hand, this site-decoupled mean-field theory cannot take into account the effect of intersite correlations and quantum fluctuations, which are essential for the systems with classically degenerate ground states, e.g., strongly frustrated systems. In order to describe the fluctuation effects that are absent in the Gutzwiller approximation, we introduce auxiliary Bose fields, called the ``flavor bosons,'' and expand the Bose-Hubbard model in powers of the flavor-boson operator. While the zeroth-order term represents the site-decoupled mean-field energy, the higher-order terms give the quantum corrections due to intersite correlations. We apply this systematic flavor-wave expansion to the Bose-Hubbard model on the square lattice and demonstrate that the quantum corrections suppress the superfluid order. The critical ratio of the hopping amplitude and the onsite interaction strength at the superfluid-Mott-insulater phase boundary asymptotically approaches the value obtained by the quantum Monte Carlo simulations as higher-order corrections are included. Building upon this result, we study several issues of current interest, including magnetic structures in spin-1 Bose gases and the ground state of frustrated Bose-Hubbard models.

FR.E-P14 - Realization of the Green's function approach for calculation of inter-atomic exchange interactions in real compounds within full-potential and pseudopotential methods based on the plane-wave basis

Z. Pchelkina [1,2], D. Korotin [1], S. Streltsov [1,2], V. Anisimov [1]

1. M N Miheev Institute of Metal Physics of Ural Branch of Russian Academy of Science, Ekaterinburg, Russia
2. Ural Federal University, Ekaterinburg , Russia

The value of inter-atomic exchange interactions is one of the main characteristics of magnetic systems. In the mean-field approximation it could be extracted from the Curie-Weiss fit of experimental magnetic susceptibility data. Such estimation strongly depends on the underlying model, which is often based on structural considerations. In this regard, theoretical calculation of the exchange interactions in the real materials is hardly needed.
The exchange parameters could be calculated by mapping the Heisenberg model to the total energy difference of several magnetic configurations. To get N exchange parameters one needs to calculate the total energy for N^{+1} magnetic configurations and as a result one obtains the number without a clear physical picture (e.g. which particular orbitals are responsible for exchange processes; what is the mechanism of exchange interaction etc.).
A more general approach to derive the exchange interactions is a Green's function method, which was developed by Liechtenstein et al. in 90s. It allows to calculate the inter-atomic magnetic interactions corresponding to infinitesimal rotations of spin magnetic moments near equilibrium. Basically the calculation for one magnetic configuration will produce all exchange interactions as well as their orbital components. The Green's function approach was performed for the methods with the localised orbitals basis sets. However, nowadays in the most accurate schemes for the band structure calculations the plane-waves basis is used, e.g. full-potential (linearized) augmented plane-wave (LAPW) or pseudopotential methods.
Here we reformulate the Green's function approach to the plane-wave based electronic structure calculation methods using Wannier functions formalism. This calculation scheme is implemented in the full-potential WIEN2k and pseudopotential Quantum-ESSPRESSO codes and tested on NiO compound.
The work was supported by the Russian Science Foundation through the project no. 14-22-00004.

FR.E-P15 - Spontaneous symmetry breaking in variational wave functions: When is it possible?

R. Kaneko [1], F. Becca [2], R. Valenti [1], C. Gros [1]

1. Institut Fuer Theoretische Physik, Goethe-Universitaet Frankfurt, Frankfurt, Germany
2. CNR-IOM-Democritos National Simulation Centre and International School for Advanced Studies, Trieste, Italy

The resonating valence bond (RVB) theory has been used to study and predict novel phenomena in strongly correlated electron systems. Especially, Bosonic- [Liang-Doucot-Anderson (LDA)] and Fermionic-type singlet RVB wave function are often used to investigate quantum magnetism. The LDA wave function with slowly power decaying amplitudes is shown to reproduce the magnetic long-ranged ordered state on the square Heisenberg model with accurate energy. On the other hand, the Fermionic-type singlet RVB wave function has also been extensively used to study unconventional quantum states, such as the superconducting and spin liquid states. Although there might exist a mapping between two wave functions for some special cases, it is still elusive whether the best singlet Fermionic wave functions generally allow the spontaneous symmetry breaking. To understand what kind of Fermionic RVB wave functions are possible to induce the spontaneous symmetry breaking, we investigate the magnetic properties of the Heisenberg model on the one-dimensional (1d) chain and two-dimensional (2d) square lattice. In 1d, singlet wave functions are shown to reproduce the short-range order irrespective of the power-law exponent of amplitudes. In 2d, the projected Fermi sea reproduces the long-range magnetic order, although the energy is much higher than the disordered d-wave state. To find a best wave function, which reproduces accurate energy and magnetization, we employ more flexible RVB wave functions, including general pairings and additional long-range spin Jastrow correlators. Optimized best wave function is much more improved in energy with less than 1% error from the exact result, however, the spontaneous symmetry breaking is shown to require the spin rotational SU(2) symmetry breaking.

FR.E-P16 - Functional integral calculation on the temperature depndence of the magnetic hyperfine field at a Cd impurity diluted in RZn (R = Gd, Tb, and Dy)

A.L. De Oliveira [1], C.M. Chaves [2], N.A. De Oliveira [3], A. Troper [2]

1. Intituto Federal do Rio de Janeiro, Campus Nilópolis, Rio de Janeiro, Brazil
2. Centro Brasileiro de Pesquisas Físicas, Rio de Janeiro, Brazil
3. Instituto de Física Armando Dias Tavares, Universidade do Estado do Rio de Janeiro, Brazil

The study of the local magnetic moment formation and the related magnetic hyperfine fields at a s-p, noble and nd impurities diluted in GdZn and GdCd compounds at 0K have been studied both experimentally and theoretically [1]. In this work we discuss the temperature dependence of the local magnetic moment and the related magnetic hyperfine field at a non-magnetic s-p impurity, namely Cd, diluted in RZn (R = Gd, Tb, and Dy) compound. We adopt here a functional integral approach in the static approximation, which is an extension of conventional mean field calculation [2]. The temperatures ranges from 0K up to the critical temperatures Tc of these compounds, when they become paramagnetic. We calculate the perturbed densities of states and the local magnetic moments at the Cd impurity site, in each temperature. The self-consistently calculated magnetic hyperfine fields as a function of temperature are in good agreement with the available experimental data [3,4].

FR.E-P17 - Hysteresis behavior of magnetic nanotubes with radial anisotropy component

V.A. Hurtado Marín [1], S. Morales Rojas [1], J.D. Agudelo Giraldo [1,2], E. Restrepo Parra [1]

1. PCM Computational Application, Universidad Nacional de Colombia, Manizales, Colombia
2. Escuela de Materiales, Facultad de Minas, Universidad Nacional de Colombia, Medellin, Colombia

Hysteresis properties of single wall ferromagnetic nanotubes were studied on the basis of a classical Heisenberg model and Metropolis dynamics using the Monte Carlo method. The Hamiltonian involved nearest neighbor interactions for exchange energy; radial and tangential magneto-crystalline anisotropy was considered with the purpose of establish vector component correlations. The diameter of the nanotubes was selected taking into account particular observations of size effects over the critical temperature made in previous works. Our results show a typical decrease of coercive field as temperature increases at low anisotropy constant. As anisotropy increases, effects of competition with exchange interaction are observed and coercive field suddenly decreases at low temperatures. Hysteresis disappears if the applied magnetic field is not sufficient to eliminate the influence of the anisotropy over the moments configuration, even above the remanence.

FR.E-P18 - Orbital magnetism in multi-band systems

M. Ogata [1]

1. Depertment of Physics, University of Tokyo, Tokyo, Japan

The effects of a magnetic field on electrons in solids are very complicated because of the matrix elements between different Bloch bands. This is called as the interband effects of a magnetic field. One of the typical problems for this interband effect is the orbital diamagnetism which has been discussed since Landau. We develop a general and rigorous theory of susceptibility for orbital magnetism which includes Landau-Peierls susceptibility, interband effects, and susceptibility from the core electrons. We find that a new additional contribution called Fermi-surface term exists in the susceptibility formalism. This general theory is applied to tight-binding models including triangular lattice and honeycomb lattice (or two-dimensional graphene). The results are compared with those obtained by using the Peierls phase. The effects of spin-orbit interaction are also studied.

FR.E-P20 - First principles investigation of magnetic properties of Fe-Ni-Mn-Al heusler alloys

M. Zagrebin [1,2], M. Klyuchnikova [1], V. Buchelnikov [1], V. Sokolovskiy [1]

1. Chelyabinsk State University, Oblast, Russia
2. National Research South Ural State University, Oblast, Russia

The Fe-Ni-Mn-Al alloys system is beginning to gain a great interest due to many of its mechanical and magnetic properties and the possibility to be applied as a stainless steel and as a semisoft magnetic material. In engineering applications, they are offered as cryogenic materials, presenting high strength with low density, goodtoughness, good oxidation resistance and strength, and as cheap substitutes for some stainless steels. In this context, the Fe-Ni-Mn-Al alloys particularly have attracted much attention considering its promising technological applications. This has encouraged the experimental research to improve alloys performance in a large variety of applications [1,2]. The aim of this work is obtaining information of the magnetic properties (magnetic moment and magnetic exchange parameters) of the $Fe_{8-x}NixMn_4Al_4$ and $Fe_7Ni_1Mn_6Al_2$ and $Fe_7Ni_1Mn_5Al_3$ alloys. The $Fe_7Ni_1Mn_6Al_2$ and $Fe_7Ni_1Mn_5Al_3$ composition are closed to $Fe_{43.5}Ni_{7.5}Mn_{34}Al_{15}$ experimental composition with giant superelastic effect [3]. All calculations were performed using the density functional theory as part of the spin-polarized relativistic Korringa-Kohn-Rostoker (SPR-KKR) band structure code [4]. For our calculation we used the equilibrium lattice parameters. For $Fe_{8-x}Ni_xMn_4Al_4$ alloys maximal value have Mn-Ni interactions. This interaction is FM and decreases with increasing of Ni concentration from 8.5 to 7.5 meV. The Fe-Mn interaction increases with increasing of Ni concentration approximately to 4 times. It is follow from our calculations that Fe-Ni-Mn-Al alloys are very interesting compounds and theoretical study of them allows to predict the new features of Heusler alloys.

FR.E-P21 - Low temperature properites of chiral magnets with defects

O. Utesov [1], A. Syromyatnikov [1, 2]

1. Petersburg Nuclear Physics Institute NRC "Kurchatov Institute"
2. Department of Physics, Saint Petersburg State University, Saint Petersburg, Russia

We address the present study to magnets without inversion symmetry, which leads to appearance of Dzyaloshinskii-Moriya interaction (DMI). This work was motivated by the recent experimental activity in the study of noncentrosymmetric cubic magnets $Mn_{1-x}Fe_xSi$, $Fe_{1-x}Co_xGe$ etc. [1] In that research was found that magnetic chirality changes it's sign at some point x_c and also helical vector x-dependence was measured.
Solid solutions at small x can be treated as system with small amount of defects. So our aim was to describe theoretically low temperature properties of chiral magnets with a small amount of defects. It consists of two parts - determine new classical ground state and calculate corrections to elementary excitations spectra and damping due to scattering on the defects. For theoretical description we used two different spin models - a cubic magnet with ferromagnetic interaction between nearest neighbors and DMI between neighbors along one of the axes and a B20 system with interactions from paper [2]. Defects were considered changing interactions constants locally.
We found that defects have a long-range impact on the spin system. All spins obeys additional to pure systems rotation due to the defects, which describes by the same equations as for electrostatic dipole field. So after averaging on the disorder configurations we have a linear growth of spin rotation along one of the axes. That is equivalent to a linear in x changing of pure system helical vector. Also we study a defects impact on elementary excitations spectra and damping.

FR.E-P23 - Manipulation of magnetic order in antiferromagnets by strong magnetic field

L. Smejkal [1], K. Vyborny [1]

1. Institute of Physics ASCR, V. V. I., Prague, Czech Republic

Control of magnetic moment orientation in antiferromagnets (AFM) is much more involved than in ferromagnets (FM). One option to induce switching is to employ the spin-orbit torques [1], however, this remains only a theoretical proposal up to date and the approach common in experiments is to apply strong external magnetic field. Despite the fact that the consequent orientation of magnetic moments is not straightforward to infer [2], the situation is usually still more transparent than in FM/AFM multilayers where the magnetic field primarily manipulates the FM and the AFM magnetic moments follow because of the exchange spring effect [3]. In order to determine the orientation of magnetic moments as a function of the applied external field in several topical antiferromagnets including Mn_2Au, FeRh and MnTe, we generalize the Stoner-Wohlfarth model of single-domain ferromagnets. The magnetocrystalline anisotropy needed as an input to the model is determined by the first principles calculations. Experimentally, results of this analysis can be confirmed employing the anisotropic magnetoresistance in these materials.

FR.E-P25 - Novel chiral metastable states in the discrete finite-size classical one-dimensional planar spin model with competing exchange interactions

M.G. Pini [1], A. Rettori [2], A.P. Popov [3]

1. Istituto Dei Sistemi Complessi Del CNR (CNR-ISC), Unità Di Firenze, Florence, Italy

2. Dipartimento di Fisica ed Astronomia, Università degli Studi di Firenze, Sesto Fiorentino, Italy
3. Department of Molecular Physics, National Research Nuclear University MEPhI, Moscow, Russia

Driven by the interest for artificially created nanoscale magnetic structures displaying a helical or spiral magnetic order (such as ultrathin films of rare-earth elements, or Fe chains deposited on a reconstructed surface [1]), we investigated the effect of finite size and open boundary conditions on the equilibrium states of a one-dimensional (1D) model of N classical planar spins with competing nearest neighbor (nn) and next nearest neighbor (nnn) intrachain exchange interactions. Using a theoretical method recently developed [2], the non-collinear magnetization profile was calculated up to N=16 in a systematic and accurate way [3] by finding the (N-1) roots of a function in the 1D space of the first relative orientation angle. The roots were then analyzed in order to determine which of them correspond to stable, metastable or unstable states. In addition to the ground state, symmetric with respect to the center of the chain, we found metastable states of two kinds: either antisymmetric or without a definite symmetry ('ugly' states). In the ground state, the modulated configuration is non uniform along the finite chain, but the chirality of the helix does not change. In contrast, the metastable states present a change of chirality, located either in the middle of the chain (antisymmetric state) or away from it ('ugly' state). 'Ugly' states are always metastable. Antisymmetric states are metastable (unstable) for even (odd) values of N. As N grows the difference between even-N and odd-N configurations is found to decrease, and for N tending to infinity is expected to vanish.

FR.E-P26 - Monte Carlo investigation of magnetic properties of anisotropic transition-metal oxides

D. Ledue [1], A. Al Baalbaky [1], R. Patte [1]

1. GPM UMR 6634 CNRS-Université & INSA de Rouen, Rouen, France

The delafossite $CuCrO_2$ is of particular interest, especially because it enters the multiferroic state in zero field with the magnetic transition [1]. In this compound, the magnetic structure below TN = 24 - 26 K [2,3] is an incommensurate proper-screw magnetic structure with a propagation vector equal to (0.3298,0.3298,0) [4] very close to the commensurate value (1/3,1/3,0). Since several sets of exchange interactions up to the 4th neighbours have been recently proposed for $CuCrO_2$ [4,5] and because its magnetic properties have been widely investigated experimentally [6], we aimed here to investigate by means of Monte Carlo simulations the equilibrium magnetic properties of $CuCrO_2$ using the proposed exchange interaction sets. Our simulations provide the thermal variation of the internal energy $U(T)$, the specific heat $C(T)$, the order parameter $\eta(T)$, and the chiral susceptibility $\chi'(T)$ from which we can deduce the transition temperature T_N. In addition, we have calculated the linear susceptibility $\chi(T)$ at small applied field ($\chi(T) = M(T)/H$, where $M(T)$ is the magnetization) in order to estimate the Curie-Weiss temperature θ_{CW}. Finally, note that if the cooling is slow enough during the simulation, the final magnetic configuration corresponds to one of the ground states. All these results are compared to the experimental ones [6] to discuss the validity of the proposed exchange interactions sets. Our results indicate that there are differences between the final configurations obtained with the set of interactions proposed by Xue-Fan and those proposed by Frontsek et al.

FR.E-P27 - Longitudinal Spin fluctuations studies on magnetic properties of transition medal random-alloys at finite temperatures

F. Pan [1], J. Chico [2], A. Bergman [2], L. Bergqvist [1]

1. Dept. of Nanomaterial Physics, Royal Institute of Technology (KTH), Stockholm, Sweden
2. Dept. of physics and astronomy, Uppsala university, Uppsala, Sweden

Using a combination of ab-initio and MC(Monte Carlo) simulations, a method that includes both transversal and longitudinal fluctuations of the magnetic moments has been developed for calculating the magnetic properties of random alloys at finite temperatures. Results demonstrates that the longitudinal fluctuations contributes to the phase transition are non-trivial, e.g. the individual moment size is reduced by about 10\% up to the Curie temperature for iron. Although the standard Heisenberg model which includes the transversal fluctuation only, is sufficient for describing the critical properties of iron, the longitudinal fluctuation can play an essential role at exploring the phase transitions in Permalloy and other transition metal alloys with induced moments. We parametrized the exchange coupling for different magnetic configurations, which was calculated using the Korringa-Kohn-Rostoker (KKR) method within the coherent potential approximation (CPA) framework and fix spin moment (FSM). Our method provides a broadening insight on the investigation of magnetic behaviour up to the Curie temperature, particularly on estimating the suppression of the atomic moments length. This extended Heisenberg model is flexible to study various magnetic systems. The method is easily extended to atomistic spin dynamics simulations.

FR.E-P28 - Magnetic moment properties of an arbitrary quantum ring contour in the presence of a magnetic field

P. Dahan [1], P. Malits [1]

1. School of Engineering at Ruppin Academic Center, Emek-Hefer, Israel

The influence of an arbitrary contour of a quantum ring (QR) on the ring's magnetic moment properties is studied. The magnetic moment properties of QRs are not only of fundamental interest, but are also important due to their potential applications. The magnetic moment and oscillations are formulated in the framework of a one-dimensional model for a non-circular quantum ring [1]. In our theoretical model, the ring curvature is introduced into the orbital magnetic moment equation by means of the conformal mapping that maps the unit circle onto the QR contour.

We show that the magnetic moment, as well as other characteristics of the non-circular ring, is a periodic function of the flux, Φ/Φ_0 , and its properties are depending on the shape and order of symmetry.

We study three specific non-circular shapes of different symmetries. In the case of an elliptical QR (two axes of symmetry), our analytical results based on the conformal mapping and method of asymptotic perturbations are in good agreement with those of earlier numerical studies. To the best of our knowledge, this is the first time that explicit formulae allowing study of electronic effects are established for this contour. In particular, as the ellipse eccentricity, ε, and Φ/Φ_0 are satisfy the conditions $\varepsilon \leq 0.6$ and $|\Phi/\Phi_0 - k| > 0.05$, k is a natural number, we have derived very simple approximate formulae for the magnetic moment, as well as for the persistent and total currents.

FR.E-P31 - Emergence of quasi-two-dimensional ordered phase in anisotropically coupled spin ladders

S. Furuya [1], T. Giamarchi [1]

1. Department of Quantum Matter Physics, University of Geneva, Geneve, France

The dimensionality plays a decisive role in the spontaneous magnetic ordering. Having severe quantum fluctuations, one-dimensional quantum antiferromagnetic systems exhibit the Tomonaga-Luttinger liquid phase that is unavailable in higher dimensional systems.
Among one-dimensional quantum antiferromagnets, the spin ladder compound is of particular interest because of controllability of the dimensionality with the temperature and the magnetic field. The spin ladder system goes through the field-induced Tomonaga-Luttinger liquid phase and reaches the three-dimensional Neel ordered phases as the temperature is decreased under the strong magnetic field. For realizing the Neel ordered phase, the interladder interaction is crucial. If the spin-spin interaction respects the rotational symmetry, the Neel ordered state breaks the U(1) symmetry around the magnetic field spontaneously. Such an ordered phase can exist only when spin ladders are coupled three-dimensionally. If spin ladders are coupled two-dimensionally, the Neel order is allowed only at zero temperature. The highly anisotropically coupled spin ladder system is placed in an intermediate situation between those two limits, whose ordered phase is yet to be understood.
In this presentation, keeping in mind a recently synthesized compound (C7H10N)2CuBr4, we investigate anisotropically coupled spin ladders and discuss emergence of a quasi-two-dimensional Neel ordered phase in that system with the aid of several complementary analytical approaches: the bosonization, the variational analysis and the renormalization group analysis. We point out that the quasi-two-dimensional ordered phase has suppressed but nonzero Neel order, yielding a stepwise curve of the order parameter against the temperature.

FR.E-P34 - An extension of the Neel-Brown model of magnetization reversal

A. Roy [1], A.P.S. Kumar [1]

1. Indian Institute of Science, Karnataka, India

The popular Neel-Brown model of magnetization reversal describes magnetization reversal of a sample by thermal excitation over an energy barrier. It uses two parameters that characterize the barrier, an energy (height) E_B, and a field H_K. The interpretation of H_K depends on the mode of reversal and it may represent an anisotropy field or a domain wall pinning field. This model predicts a decreasing coercivity and an increasing width ΔH of switching field distribution as the temperature is increased, and has been found to hold good on several occasions particularly for nano-scale systems.

Our experiment constitutes the study of switching field statistics of Permalloy ($Ni_{80}Fe_{20}$) thin films on Si(100) grown by PLD. Temperature dependence of the switching field distribution showed that the mean switching field (coercivity) increased as a function of temperature, as expected. However, ΔH increased as the temperature was lowered, contrary to the Neel-Brown model.

We have attempted to explain this anomalous behaviour by realizing that for a large system (100μm) several magnetization reversal pathways are possible, corresponding to different domain structures. Keeping the framework of the Neel-Brown model intact, we incorporated a multitude of reversal pathways in the form of a Gaussian distribution in the values of H_k (FWHM σ_{Hk}). Calculations based on this model for different values of σ_{Hk} show two distinct regimes. At low values of σ_{Hk}, ΔH is limited by thermal broadening according to the traditional Neel-Brown expression. This regime is characterized by an increasing ΔH with temperature. For high σ_{Hk}, the broadening is dominated by σ_{Hk}, which masks thermal broadening. Decrease of the effective barrier E_B/k_BT at increasing temperature causes the mean switching field to lie far below H_K, causing a rescaling of the distribution widths, producing temperature dependence of ΔH as observed.

FR.E-P35 - Resonating valence bond physics is not always controlled by the shortest tunneling loops

A. Ralko [1], I. Rousochatzakis [2]

1. Neel Institute, Grenoble, France
2. School of Physics and Astronomy, University of Minnesota, Minneapolis, United States

One of the central aspects of the nearest-neighbor valence bond (NNVB) description of magnetically disordered phases is that the dynamics is controlled by the shortest tunneling loops. Here we show that this intuitive quantum-mechanical notion can be completely wrong on account of renormalization effects that stem from virtual longer-range singlet fluctuations outside the NNVB basis.
The aim of this presentation is twofold. First, we want to unravel and establish precisely the importance of such virtual longer-range singlets in describing RVB physics, and show how the quantum dimer model (QDM) needs to become non-local in order to accurately describe the Heisenberg physics. Second, by focusing on the so-called square-kagome, a 2D spin-1/2 Heisenberg AFM with corner sharing triangles, closely related to the Kagome, we study the nature of the disordered ground state by deriving a weighted-amplitude QDM that counts for defect triangles around the loops.
As in the kagome [1], virtual singlets affect the nature of the ground state qualitatively, stabilizing an exotic valence bond crystal (VBC) that maximizes the tunneling events on the second shortest loops [2].

FR.E-P36 - Meron crystals with spin scalar chiral stripes

R. Ozawa [1], S. Hayami [1], M. Udagawa [1], Y. Motome [1], K. Barros [2], G.W. Chern [2], C. Batista [2]

1. Univ. of Tokyo, Tokyo, Japan
2. Los Alamos National Laboratory, New Mexico, United States

Noncoplanar spin textures, such as skyrmion crystals, have been extensively studied not only for their intriguing transport phenomena but also their potential for applications. In most cases, the relativistic spin-orbit coupling plays an important role in the stabilization of the noncoplanar spin states. Recently, another class of noncoplanar spin textures has been found in spin-charge coupled systems in the absence of the spin-orbit coupling. These nonco-planar states are induced by the instability originating in the Fermi surface structure, which exists ubiquitously in itinerant electron systems. In this new class, a rich variety of exotic magnetism as well as peculiar transport properties is expected, depending on the band struc-ture and electron filling.
Motivated by these new findings, we explore a further possibility for unconventional noncoplanar orders, focusing on the Fermi surface instability. Specifically, we consider the Kondo lattice model with the nearest- and third-neighbor hoppings on a square lattice. In this model, the band structure has four saddle points at the Lifshitz transition point, which give the van Hove singularity in the density of states. Such singular behavior is expected to enhance the instability of the Fermi surface. Performing an efficient numerical simulation based on the Langevin dynamics, we find that the system exhibits a new type of noncoplanar spin orders accompanied by spin scalar chiral stripes. The obtained stripes are regarded as crystals of fractionalized topological objects --- merons (half of the skyrmions). We also investigate the stabilizing mechanism by both the analytical perturbation approach with respect to the spin-charge coupling and the numerical variational calculations for the ground state.

FR.E-P39 - Volume dependence of magnetic properties in $Co_2Cr_{1-x}Y_xGa$ (Y = Ti, V, Mn, Fe) alloys by first-principles

J. Gonþalves [1], J. Amaral [1,2], N. Fortunato [1], V. Amaral [1]

1. Departamento de Física and CICECO, Universidade de Aveiro, Aveiro, Portugal
2. Instituto de Física dos Materiais da Universidade do Porto, Institute of Nanoscience and Nanotechnology, Porto, Portugal

A Curie temperature (T_C) close to room temperature, a high magnetic moment and a steep T_C dependence with volume are favorable properties for magnetocaloric applications. The latter is usually not studied in detail in Heusler alloys, and these provide a rich variety of compositions for optimization via first-principles calculations. In a previous work [1] we have examined these properties in a number of Heusler compounds of the general formula Co_2YZ. Co_2CrGa (T_C=370 K, m=3 μ_B, and dT_C/dV=-4.5 K/Å^3) was taken as the starting point for this work. A detailed exploration of quaternary alloys is presented, with Cr site substitution by neighbor elements (Ti, V, Mn, Fe). We use the density functional KKR method and the coherent potential approximation for disorder. Heisenberg exchange constants are calculated with the magnetic force theorem, and the mean-field Curie temperature is obtained. For several concentrations, in steps of Δx=0.1 the volume change is simultaneously explored around the theoretical lattice parameters, and the change of magnetic properties is detailed, including the magnetic moments (local and total) and T_C.
Iron substitution increases the spin moment, and increases T_C away from RT, in agreement with previous studies [2]. Manganese substitution also results in increase of T_C and spin moment. The addition of vanadium decreases T_C closer to RT, although dT_C/dV becomes less negative. However, dT_C/dV can become positive and increase by application of moderate compressive strains, reaching 8 K/ Å^3 for high concentrations of vanadium and 3% compression. This variability of dT_C/dV with dopant concentration is also found with titanium doping, where dT_C/dV similarly changes from negative to positive with increasing concentration, but is not found in iron or manganese doping, wherein dT_C/dV remains relatively constant for all concentrations and in the few percent volume changes studied, generally becoming slightly more negative with increasing volume.

FR.E-P40 - Fast computational magnetic materials design via DFT calculations and a novel Monte-Carlo sampling method

N.M. Fortunato [1], C. de Oliveira Amorim [1], J.S. Amaral [1,2]

1. Departamento de Física and CICECO, Universidade de Aveiro, Aveiro, Portugal
2. IFIMUP and IN-Institute of Nanoscience and Nanotechnology, Rua do Campo Alegre, Porto, Portugal

The end game of computational material design is to replace the high-cost and labor associated with the exhaustive experimental search for new materials, with quantum mechanical and thermodynamical modeling [1].
A common approach for predicting the magnetic properties of materials is to consider an Ising or Heisenberg-like model, solved via a Monte-Carlo method, typically by the Metropolis algorithm [2]. The required magnetic required exchange parameters (J) values can be readily obtained via Density Functional Theory (DFT) methods.
While the Metropolis algorithm is the go-to method in this kind of studies, mainly due to its ease of implementation and flexibility, there are considerable drawbacks to its generalized use to determine applied magnetic field (H) and temperature (T) dependent properties. In terms of computational requirements, independent converged calculations are required for each T and H values, which can become overwhelming for detailed studies, particularly near phase transitions. Additionally, magnetovolume coupling effects, which are an important performance parameter of magnetocaloric materials, are difficult to consider, even for a simplified Domb model approach [3].
We here present an overview of the recently proposed Random Path Method (RPS) [4]. This method allows an unbiased statistical sampling of spin configurations, energy and degeneracy values of Ising and Heisenberg-like systems, leading to an approximation of the partition function coefficients. As such, the partition function obtained is generalized in terms of system parameters, such as exchange constants, external field, temperature, volume, or other homogeneous contributions to the energy.
We show a generalization of the RPS methodology to three-dimensional Ising and discretized Heisenberg-like vector models, exploring the effects of magnetic anisotropy energy (MAE), in-plane and out-of-plane exchange parameters and magnetovolume coupling. Computational performance and convergence criteria are discussed, together with finite-size effects in thermodynamic properties, obtained both via free-energy minimization and average values calculated from the partition function.

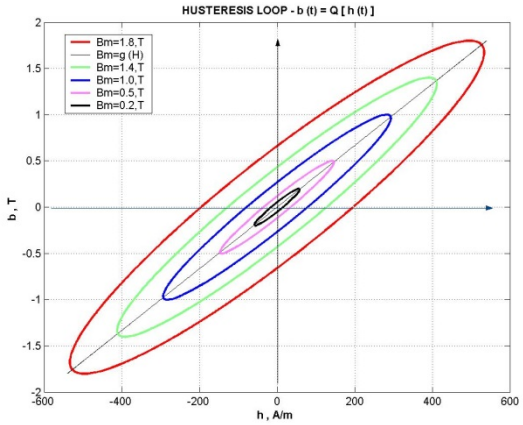
FR.E-P42 - Simulation of established linear and nonlinear hysteretic loops in coil with an iron core

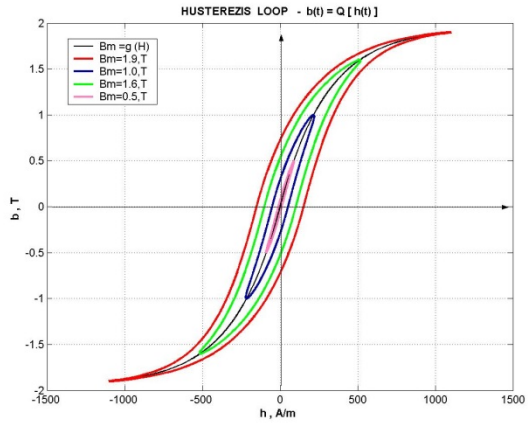
D. Danailov [1]

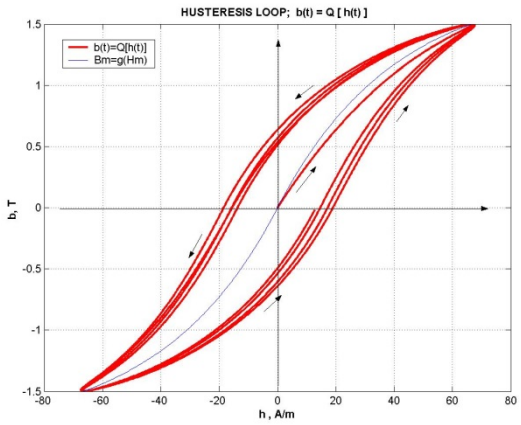
1. Todor Kableshkov University of Transport, Sofia, Bulgary

The paper considers a model for the simulation of an established linear and nonlinear symmetric hysteretic loop. The base magnetic material curve $B_\mu(H_\mu)$, as well as magnetic chain active resistance, assigned by the $B_r(H_r)$ curve, are used in its construction. It is possible to determine remagnetization and iron losses. Hysteresis is presented by means of pulsing functions of the type $\overset{*(p)}{b} = \vartheta[\overset{*(p)}{h}]$, where flux density $\overset{*(p)}{b}[t, b_r(t), b_\mu(t)]$ and magnetic field strength $\overset{*(p)}{h}[t, h_r(t), h_\mu(t)]$ are preliminarily expanded into two components $(b_r(t); b_\mu(t))$ and $(h_r(t); h_\mu(t))$. Parametric functions $b_r(t), b_\mu(t)$, $h_r(t), h_\mu(t)$ are trigonometric.

A software product for the assignment of symmetric loop family has been created according to the mathematical model of hysteretic process description. Fig. 1 and fig. 2 show obtained hysteretic loop families, of linear and nonlinear hysteretic loops. The model can be also applied in dynamic hysteretic process research (fig. 3).







FR.F-P02 - Magnetism of GaSb-MnSb granular films controlled by charge carriers tunneling through the cluster-matrix Schottky barrier

A. Talantsev [1], R. Morgunov [1]

1. Institute of Problems of Chemical Physics RAS, Chernogolovka, Russia

Ferromagnetic clusters incorporated in semiconductor crystal lattice attract significant attention because interplay between their electrical and magnetic properties is possible in the wide temperature range [1]. In our work, we have studied series of GaSb(59 %) - MnSb(41 %) thin films with different carrier concentrations from Nh = 4*10^18 to Nh = 4*10^20 cm^(-3) at 300 K. Clear concentration dependence of saturation magnetization Msat(Nh) was observed. At lower carrier concentrations (~ 4*10^18) the Msat(Nh) dependence is linear corresponding to spin-dependent tunneling under the Shottky barriers on the cluster-matrix bounds. At higher carrier concentration Msat(Nh) dependence becomes non-linear and magnetization saturates at Nh = 2*10^20 cm^(-3) reaching the value Msat = 3.6 Bohr's magnetons, which is in good agreement with the highest saturation magnetization, obtained from electronic calculations for MnSb [2]. At higher carrier concentrations the width of Schottky barrier becomes comparable with charge carrier wavelength. This fact allows over-barrier transitions of charge carriers from matrix into clusters. These transitions are responsible to non-linear Msat(Nh) dependence. To investigate tunneling conductivity separately from over-barrier motion, we have carried out magnetization and carrier concentration measurements at 2 K. At this temperature carrier concentrations were decreased down to 2*10^17 cm^(-3), and only linear part of Msat(Nh) was observed.

FR.F-P03 - Magnetically induced transition from hopping-type to band-type conduction in Mn-doped ZnO

A. Ruotolo [1], X. Wang [2], S. Qi [1], R. Lortz [3], J. Wang [3]

1. City University of Hong Kong, Tat Chee Ave, Hong Kong
2. Chinese Academy of Science, Beijing, China
3. Hong Kong University of Science and technology, Clear Water Bay, Hong Kong

We here show that a negative magnetoresistance as large as several hundreds percent can be induced in simple zinc oxide (ZnO) doped with manganese (Mn). This anomalous effect was found to appear in oxygen-deficient films and to increase with the concentration of dopant. By combining magnetoresistive measurements with magneto-photoluminescence, we demonstrate that the effect can be explained as the result of a magnetically induced transition from hopping-type to band-type conduction where the activation energy is caused by the sp-d exchange interaction. The study was carried out on films of $Zn_{1-x}Mn_xO$ with x = 0 (pure ZnO), 0.02, 0.04 and 0.08 grown by pulsed laser deposition on sapphire substrates. The films showed n-type conductivity, regardless temperature. Oxygen vacancies (VO's) were introduced in the films by increasing the temperature of the substrate and decreasing the oxygen partial pressure during growth. As the temperature is reduced, the resistivity of the films increases with distinct signatures of a transition from band- to hopping-conduction. A sharp decrease of resistance of the Mn-substituted films was measured when an external magnetic field was applied. The change of resistivity was found to increase with the concentration of Mn. The magnetic activation of electrons to the band conduction was probed by resorting to magneto-photoluminescence measurements.

FR.F-P04 - The magnetic phase diagram of Mn-Doped GeTe crystals

M. Kriener [1], Y. Kaneko [1], X.Z. Yu [1], Y. Tokura [1,2], Y. Taguchi [1]

1. RIKEN Center for Emergent Matter Science (CEMS), Wako, Saitama, Japan
2. Department of Applied Physics and Quantum-Phase Electronics Center (QPEC), University of Tokyo, Hongo, Tokyo, Japan

GeTe has attracted huge interest for decades: It is one of the first examples among the many-valley semiconductors in which superconductivity was found [1]. Later it came into the focus of research as an ingredient for thermoelectrical materials [2] and more recently due to its large Rashba-spin splitting [3]. Moreover, GeTe exhibits a ferroelectric distortion. Since Mn doping leads to the formation of a diluted magnetic semiconductor [4], the system is also discussed as a possible multiferroic material [5]. The polar distortion is suppressed with increasing Mn concentration x and eventually disappears above approximately x ± 0.15 where the high-temperature cubic structure is retained down to low temperatures. Here we investigate the magnetic phase diagram of bulk $Ge_{1-x}Mn_xTe$ (x ² 0.25) with respect to the polar distortion by means of high-resolution transport, thermodynamic, and microscopic measurements. The magnetic exchange interaction is found to strongly depend on the crystal-growth method. One can get control of it by carefully varying the growth recipe of stoichiometrically mixed powders. Such modifications lead to deviations from the previously reported linear dependence of the ordering temperature on x [4].

FR.F-P06 - Systematic study of AMR in (Ga,Mn)As

Z. Kaspar [1], K. Olejnik [1], K. Vyborny [1], V. Novak [1], T. Jungwirth [1]

1. Institute of Physics ASCR, V.V.I., Prague, Czech Republic

We systematically study the anisotropic magnetoresistance (AMR) on a series of optimized (Ga,Mn)As samples [1]. The crystalline and non-crystalline contributions to the AMR were separated [2] and an apparent higher-order term (of six-fold symmetry) was dentified to be an artefact resulting from the presence of magnetic anisotropy of the material and of the residual fields of external superconducting magnets. In the broad range of nominal Mn concentrations from 2 to 11%, we find the non-crystalline contribution to dominate, although the crystalline terms become relatively more important for higher doping levels. We compare these findings with the Boltzmann transport calculations based on the k.p mean-field kinetic-exchange model [3] and discuss the level of agreement of AMR components term by term. For some terms, the model turns out to be very sensitive to the input Luttinger parameters (taken from the clean GaAs host material), yet the dominant non-crystalline term is largely independent of the model details demonstrating the applicability of this model to the highly disordered dilute magnetic semiconductor.

FR.F-P07 - Magnetic properties of the CeO_2-Co system

M. Paulin [1], A. Leyva [1], J. Sacanell [1]

1. Departamento de Física de la Materia Condensada, Gerencia de Investigación y Aplicaciones, Centro Atómico Constituyentes, Comisión Nacional de Energía Atómica, Río Negro, Argentina

The development of spintronics has promoted the study of materials with strong coupling between their electric and magnetic properties. For that kind of applications, the materials should have a high spin polarization and also present structural compatibility with existing semiconductors. Among materials that meet these requirements are the diluted magnetic oxides such as Co doped CeO_2. The pure compound is a diamagnetic insulator, but on doping with magnetic ions like, the system can become paramagnetic or ferromagnetic. The great capability to accomodate oxygen vacancies in its structure can be the responsible for this particular behavior however, some results could also been explained in terms of small segregation of magnetic impurities. In order to determine the contribution of each of them, we performed X-ray absorption near edge structure (XANES) and Magnetization measurements in oxidizing and reducing conditions as we observed that the FM contribution is enhanced as we increase the time of the thermal treatments in vacuum. Those systematic experiments allows us to establish a relation between ferromagnetism and oxygen content of the samples.

FR.F-P08 - Spin correlations in the lightly doped semiconductor oxide Mn:ZnO

A. Wildes [1], D. Lanþon [1,2], G. Nilsen [1], H. Rønnow [2], A. Magrez [2]

1. Institut Laue-Langevin, Grenoble, France

2. ╔cole Polytechnique Fédérale de Lausanne, Lausanne, Switzerland

ZnO is a wide-gap semiconductor that, on light doping with another transition metal for the zinc, is reported to have room temperature ferromagnetism. These reports have resulted in a flurry of interest, as such a material would have applications in spintronic materials. It is possible to manufacture some of these materials in bulk, although the processes used can result in phase segregation and clustering. We have used magnetometry and neutron scattering with polarization analysis to determine the spin correlations in ZnO lightly doped with manganese. The samples were manufactured via a solid-state synthesis method, or via a thermal decomposition of hydrozincite. Our results show clear evidence for ferromagnetism in 3% doped samples made by solid-state synthesis, however there is also clear phase segregation of the manganese into MnO and $ZnMn_2O_4$. The decomposed hydrozincite samples also showed clear ferromagnetism at 3% doping, however they also showed the formation of MnO nanoparticles. Lower doping of Mn in the decomposed hydrozincite samples resulted in superparamagnetic behaviour with no evidence of phase segregation and with indications of ferromagnetic short-ranged order.

FR.F-P09 - Magnetic band splitting of $Ga_{1-x}Mn_xAs$ estimated by magnetic circular dichroism spectroscopy

K. Ando [1], H. Tanaka [2], V. Zayets [1], H. Saito [1]

1. National Institute of Advanced Industrial Science and Technology (AIST), Japan
2. Ohio University, Athens, United States

$Ga_{1-x}Mn_xAs$ is a canonical III-V diluted magnetic semiconductor (DMS). In spite of intensive studies reported in nearly two decades from its discovery, its band structure is still under heated debate. Because Mn-related impurity bands makes the interpretation of the optical spectroscopic date extremely difficult [1], even the most important characteristic parameter of DMS, i.e. magnetic band splitting (Zeeman splitting), had not been reported until quite recently [2]. In this study, we report the band splitting of high quality $Ga_{1-x}Mn_xAs$ samples by using magnetic circular dichroism (MCD) spectroscopy. $Ga_{1-x}Mn_xAs$ thin films were grown by MBE method. The InP substrates were removed by chemical etching. MCD spectra were measured between 0.62 eV and 4.0 eV. Around 3 eV, which corresponds to the L critical points (c.p.) optical transitions of GaAs, strong and characteristic MCD structures were observed. Analyses of the MCD spectral shape clearly indicated that E1-c.p. is magnetically split with at least 7 meV at 6 K in a x = 0.03 sample. The Zeeman splitting at E0-c.p., which is known to be typically 16 times larger than that at E1-c.p. in zinc-blend type DMS, was thus estimated to be larger than 110 meV. With Mn concentration, the MCD structures showed a shift to the lower energy which quickly saturated with Mn concentration far below x=0.01. This red-shift with quick saturation suggests that the s, p-d exchange interaction of $Ga_{1-x}Mn_xAs$ has a very localized nature.

FR.F-P10 - Magnetic properties of Mn doped crystalline and amorphous Ge thin film grown on Si(111)

A.C. Önel [1], L. Çolakerol Arslan, B. Toydemir, M. Ertas

1. Gebze Technical University, Kocaeli, Turkey

We report on the structural and magnetic properties of Mn-doped Ge thin films grown by thermal diffusion. X-ray diffraction, X-ray photoelectron (XPS), and electron spin resonance (ESR) spectroscopies were applied to investigate crystallinity, the local structure and magnetism of the Mn doped Ge films grown on Si (111) by molecular beam epitaxy in monocrystalline and amorphous forms. We have found out that the distribution of Mn atoms inside the Ge layer and resulting properties are affected by the thickness, crystal quality and roughness of the Ge layer. The results show that for Mn doped crystalline Ge film, most of the Mn atoms diffused into the deep region of Ge without forming any secondary phase. Both magnetic and structural investigations indicate that only few percent of Mn atoms are in the ionic form with a valency of +2 and Mn atoms in crystalline Ge ferromagnetically interact. When a thin highly strained monocrystalline Ge film is formed on Si (111), Mn atoms travel through the Ge layer and form ferromagnetic MnSi nanodots at the interface. For amorphous film, on the other hand, both chemical shift in the Mn 2p peak positon and changes in the core level line-shape reveal the formation of Ge-Mn phase in the surface region. ZFC and FC curves of amorphous film exhibits low temperature irreversibility just below Tc=300K, indicating the existence of ferromagnetic nanoparticles of Mn_5Ge_3 incorporated into the amorphous film. Similar to the thin Mn_5Ge_3 films, amorphous film shows uniaxial magnetic anisotropy with easy axis parallel to the film surface. Thermal diffusion doping strategy on thin crystalline Ge is a reachable path toward Si based DMS for future semiconductor spintronics devices.

FR.F-P11 - Femtosecond optical excitation of spin resonances in the easy-plane antiferromagnet semiconductor EuTe

4. LAS-INPE, Sao Jose dos Campos, Brazil

Understanding laser-induced spin dynamics in magnetic materials is a cornerstone for high-speed spintronics and magnetic recording. Here we investigated the ultrafast spin dynamics in the model Heisenberg antiferromagnetic semiconductor EuTe. We employed a time-resolved all-optical pump-probe technique at a temperature of 1.7 K and magnetic fields up to 70 kG applied in the plane of the sample. We demonstrate that the optically excited electrons from the 4f to 5d EuTe band trigger antiferromagnetic spin precession consisting of two modes, in accordance with the theoretical model for an easy plane antiferromagnet.
Analyzing the efficiency of the excitation of the modes as a function of the applied magnetic field we found that the antiferromagnetic spin precession is induced by the ferromagnetic 5d-4f exchange interaction, which is high in comparison with the antiferromagnetic f-f exchange. The d-f exchange in EuTe, in particular, gives rise to the isotropic magneto refractive effect.
It is manifested as a modulation of the bandgap of EuTe at the antiferromagnetic resonance frequency and can be monitored by measuring the pump induced reflectivity changes in the probe beam. We found that the antiferromagnetic s precession is triggered at magnetic fields higher than that of the spin flop transition at ~1 kG, and lower than that of spin flip transition at ~70 kG. We found that at magnetic fields, corresponding to the crossing of the two modes, the amplitudes of both modes are strongly enhanced; meanwhile the damping is strongly suppressed. The amplitude enhancement can be explained by a weak coupling of the two antiferromagnetic modes, which can be due to a small non-collinearity of the external magnetic field to the sample plane. We show that the damping suppression can be explained by accounting possible modification of the damping by the 5d electrons.

3. Advanced Photon Source, Argonne National Laboratory, Argonne, United States

$Zn_{0.95}Co_{0.05}O$ films have been prepared by pulsed laser deposition, PLD, using three different solid state targets formed from different precursors; ZnO and metallic Co, CoO and Co_2O_3 to investigate if the amount of oxygen in the precursor material is important and mimics the well-studied effects of changing the oxygen content in the PLD chamber. Films of thickness 700nm were grown at base pressure using each of the targets; we found that all the films contained a fraction of the Co ions in metallic Co and the rest as Co^{2+}. The film grown with CoO was the most ordered and contained the smallest fraction of Co ions in metallic Co (9%). Its magnetic circular dichroism signal, MCD, showed no evidence of inclusions of CoO. The film grown with metallic Co in the target contained the largest fraction of Co ions in metallic Co (24%). All three films showed ferromagnetic behavior at low temperatures with small coercive fields (~ 100Oe). However this magnetization had vanished by room temperature. In all cases the size of the magnetization measured at low temperatures was larger than the amount that would be expected from the measured amount of metallic cobalt. Films were also deposited using the target made from metallic Co in 10mTorr and 100mTorr of O_2, of thickness 300nm and 100nm respectively, and x-ray and optical MCD measurements showed that the metallic fraction had vanished, the crystal quality dramatically improved. Furthermore the substantial ferromagnetic signal (~10emu/cm3) had become almost independent of temperature. Hence a conclusion of this work is that the choice of precursor is important and that adding oxygen in the growth chamber does not appear to be equivalent to including more oxygen in the target. Furthermore the highest quality and most useful films may be made by using metallic cobalt in the preparation of the target and including some oxygen in the growth chamber. This result disagrees strongly with what is found when the target was made using Co_2O_3. when including oxygen in the growth chamber reduces the magnetization.

FR.F-P13 - Direct observation of Dresselhaus effect in zinc blend structure InSb

W. Jung [1], J. Hong [2], S. Cho [1], B. Kim [1], M. Leandersson [3], T. Balasubramanian [3], S. Kimura [4], J. Shim [2], C. Kim [1]

4. UVSOR Facility, Institute for Molecular Science and The Graduate University for Advanced Studies, Okazaki, Japan

We have performed circular dichroism angle-resolved photoemission spectroscopy (ARPES) experiments on InSb. Our results show that InSb surface has very strong circular dichroism (CD) signal, indicating probable existence of orbital angular momentum (OAM). In nonmagnetic semi-conductor samples, net OAM in the bulk should be normally zero because of the symmetric electric potential. However, non-zero OAM can appear when there is an inversion symmetry reaking (ISB) which is caused of zinc blend structure and cleaved surface. We find that the dichroism has momentum dependence which, in our view, comes from modulation in the internal electric field in InSb. Heavy hole band shows a Rashba type OAM modulation and warping effects. Light hole band has a the Dresselhaus type OAM modulation. Rashba and Dresselhaus type OAM chiralities coexist in each hole bands. From these results, we suggest new effective Hamiltonians in the form of HLD and HLRD for the Dresselhaus and rst order of RashbaDresselhaus Hamiltonian.

FR.F-P15 - Effect of Ge layer thickness on formation of Mn_5Ge_3 Thin Film on Si (111)

B. Toydemir [1], A. Can Önel [1], M. Ertaþ [1], L. Çolakerol Arslan [1]

1. Gebze Technical University, Kocaeli, Turkey

Injection of spin polarized current via ferromagnetic materials into the Si based semiconductors is the most important requirement to develop such spin-based devices. For this purpose, a lot of attention has been devoted to the development of epitaxial ferromagnetic compounds due to their high Curie temperature, high spin polarization and compatibility with the recent technology. Among these materials, Mn_5Ge_3 is an appealing candidate with its high spin injection efficiency, high spin polarization and room temperature ferromagnetism. Numerous investigations on the fabrication of epitaxial Mn_5Ge_3 films directly grown on Ge showed that growth conditions play a significant role in the magnetic and structural properties of this material. However, a detailed investigation of the growth of thin Mn_5Ge_3 film on the Si substrate has not been carried out so far, although such information is crucial for such a system to be combined with the existing Si technology.
Epitaxial ferromagnetic Mn_5Ge_3 thin films were deposited on Ge/Si (111) substrates by molecular beam epitaxy using solid phase epitaxy. The role of Ge layer thickness and surface morphology on the formation of epitaxial Mn_5Ge_3 films and their magnetic properties were examined. Both structural and magnetic investigation results indicate that Mn_5Ge_3 thin film is formed above a critical Ge layer thickness and it shows perpendicular magnetic anisotropy with magnetic anisotropy increased with decreasing temperature. On the other hand, below critical thickness, Mn atoms directly diffuse into Si underlayer and form a ferromagnetic MnSi phase below a Curie point of about 250K. X-ray photoelectron spectroscopy (XPS) measurements also confirm the diffusion of Mn atoms from Ge towards Si. These results show that high crystallinity and defect free Mn_5Ge_3 can be epitaxially grown on Si substrate, despite an 8% lattice mismatch between Mn_5Ge_3 and Si (111).

FR.F-P16 - Defect-induced magnetism in graphite through neutron irradiation

4. Helmholtz-Zentrum Berlin fur Materialien und Energie, Lise-Meitner-Campus, Berlin, Germany

We have investigated the variation in the magnetization of highly ordered pyrolytic graphite (HOPG) after neutron irradiation, which introduces defects in the bulk sample and consequently gives rise to a large magnetic signal. We observe strong paramagnetism in HOPG, increasing with the neutron fluence. The induced paramagnetism can be well correlated with structural defects by comparison with density-functional theory calculations. In addition to the in-plane vacancies, the transplanar defects also contribute to the magnetization. The lack of any magnetic order between the local moments is possibly due to the absence of hydrogen/nitrogen chemisorption, or the magnetic order cannot be established at all in the bulk form.

FR.F-P19 - Influence of manganese ions environment in octahedral sublattice on the properties of triple-substituted manganites

V. Karpasyuk [1], A. Badelin [1], D. Merkulov [1], S. Estemirova [2], I. Derzhavin [1]

2. Institute for Metallurgy, Ural Division of RAS

The purpose of present research is to establish the regularities in dependencies of unite cell volume (v), magnetization (σ) and Curie temperature (T_c) upon concentration and electron configuration of substituent Me^{2+} in manganites $La_{1-c}Sr_cMn^{3+}_{1-c-x-2\gamma}Mn^{4+}_{c+2\gamma}Me^{2+}_{0.5x}Ge^{4+}_{0.5x}O_{3+\gamma}$, where Me^{2+}=$Mg^{2+}(2p^6)$, $Zn^{2+}(3d^{10})$, $Ni^{2+}(3d^8)$, c=0.2+x (x=0.05; 0.10; 0.15).

Polycrystalline samples were prepared by traditional ceramic processing. The final sintering step was performed in air at 1473 K. In order to provide stoichiometric oxygen content (γ=0), obtained samples were annealed in vacuum (partial oxygen pressure 10^{-1} Pa) at 1223 K.

It was found that T_c of all samples increases as a functions of "x", but v and σ decrease. Magnetization of Mg-contained manganites decreases most sharply.

After annealing, characteristics of manganites changed in the following way: the values of v of all Ni-substituted manganites diminished, while v of Mg- and Zn-contained samples with x=0.05 increased; magnetization of all manganites and T_c of compositions with 3d substituents did not practically alter, while Curie point of Mg-contained compositions with x=0.15 greatly lowered.

Interpretation of experimental results is based on the assumption that, owing to Coulomb interaction, Me^{2+} ions shield Mn^{4+}, breaking double-exchange bonds, and Ge^{4+} dilutes sublattice of Jahn-Teller ions Mn^{3+}. These processes are associated with the formation of clusters enriched with the pairs of different valence cations. Besides that, competing exchange interactions, interionic distances and the effect of composition on the value of γ are taken into account.

This research was supported by the Ministry of Education and Science of Russian Federation (State order project 334).

FR.F-P20 - Low temperature magnetization and Electron Spin Resonance studies in $SrSn_{1-x}Fe_xO_3$ (x=0.05 to 0.1)

H. Kumar N. [1], Radhika K. [1]

1. Department of Physics,IIT MADRAS, Tamil Nadu, India

Oxide Dilute magnetic semiconductors (DMS) continue to be attractive due to the possibility of realizing room temperature ferromagnetism required for spintronic device applications [1, 2]. Perovskite oxides exhibit many interesting physical phenomenon such as superconductivity, colossal magnetoresistance etc. Perovskite based DMS can lead to the fabrication of novel devices, with hetero junction of materials with dissimilar properties [3]. Hence it is interesting to explore possibilities of inducing magnetic interaction by suitable substitutions of ferromagnetic elements. Fe substituted SrSnO3 gives rise to room temperature (RT) ferromagnetic response for concentrations above 4% with Curie temperature around 600 K. However the low temperature magnetic measurement exhibit anomalous characteristics. In order to understand the nature of magnetic interactions in this system and the dependence of it on Fe concentration we have synthesized compounds with Fe concentration in the range 5% - 10 % and investigated their properties. The M-H isotherms recorded at 5K and 13K differs from the ones recorded at 100 K, 200 K and 300 K. The magnetization shows saturation in the isothermal field sweep measured at room temperature. Lack of saturation is observed in the low temperature regime which may arise from either magnetic anisotropy or due to the presence of mixed magnetic phases. Zero field cooled (ZFC) and field cooled (FC) measurements were carried out in the temperature range 5 K - 300 K at an applied field of 100 Oe. As the concentration of Fe increases, drastic changes are observed in the shape of the ZFC and FC curves. Electron spin resonance (ESR) spectra for all samples have shown broad asymmetric spectra at room temperature. A slight shift towards left in the spectra is observed at 77 K and a change in line shape can also be seen for samples. These observations indicate the presence of strong magnetic interactions in the material.

FR.F-P21 - Complex magnetic response of SrSn1-xFexO3-δ (x=0, 0.05 and 0.08) nano sticks

H. Kumar N. [1], Radhika K. [1]

1. Department of Physics,IIT MADRAS, Tamil Nadu, India

In $SrSnO_3$ substitution of 5% Fe not only induces ferromagnetism but also reduces resistivity by a few orders of magnitude. But in the nanocrystalline form a substantial reduction in the magnetic moment was observed. In order to strengthen the magnetic interactions without altering its semiconducting and optical characteristics the Fe concentration was increased to 8% and the magnetic properties were investigated by DC magnetization and electron spin resonance measurements. Nanocrystalline $SrSn_{1-x}Fe_xO_{3-\delta}$ (x=0, 0.05 and 0.08) were prepared by co precipitation method. The X-ray Diffraction analysis showed that the samples have crystallized in nearly single phase. Scanning electron microscope images showed stick shaped grains with average width 50 nm. The 5% Fe sample exhibits paramagnetism at room temperature (RT) but shows nonlinear magnetic response below 50K with increase in magnetic moment and anisotropy while ferromagnetic response is observed at room temperature in the 8% Fe sample. The magnetization is hysteretic at 5K and the magnetization curve looks distinctly different than that of 5% Fe sample. For the 8% Fe sample Zero field cooled and Field cooled curves show a large bifurcation from low temperature to RT which confirms that the sample retains its ferromagnetic characteristics upto room temperature. Magnetic phase transition with Curie temperatures 725 K and 848 K respectively is observed for 5% and 8% Fe samples with sharper transition for the latter. The broad electron spin resonance spectra at RT indicate the presence of strong magnetic interactions among the dipoles in both the samples. The spectra of 5% Fe doped sample looks more symmetric. A small peak is observed with g= 4.3 which may originate from Fe^{3+} ions having paramagnetic behavior. At 77 K, the spectrum of 8% Fe sample is broader but for 5% Fe sample it is sharper and highly asymmetric suggesting complex magnetic interactions in the latter.

FR.F-P22 - Large magnetoresistance in diluted magnetic semiconductors in quasi-two dimensional geometry

I. Kanazawa [1], T. Sasaki [1]

1. Department of Physics, Tokyo Gakugei University, Tokyo, Japan

Large magnetoresistance effects in diluted magnetic semiconductors(DMS) have been reported [1]. In addition, interesting phenomena such as the photo-induced magnetic polaron in DMS has been discovered [2]. These works stimulated us to the study of the carrier-induced magnetic solotons, which is an interesting and challenging subject. Kanazawa [3] has discussed the localization mechanism in the metal-insulator transition, using the gauge-invariant Lagrangian density for the hole-induced magnetic solitons. In this study, we have discussed the large magnetoresistance effects in DMS in quasi-two dimensional geometry, extending the previous formula[4]

FR.F-P24 - Mössbauer and magnetic study of $Ni_xCo_{1-x}Fe_2O_4$ nanoferrites

J. Msomi [1], B. Ndlovu [1], T. Moyo [1]

1. University of Kwazulu-Natal, Durban, South Africa

Ni-Co nano crystalline ferrites having the general formula $Ni_xCo_{1-x}Fe_2O_4$ ($0 \leq x \leq 1.0$, in steps of 0.1) were synthesized by glycol-thermal route. X-ray powder diffraction (XRD) and Fourier transform infrared (FTIR) spectroscopy were carried out to investigate the structural properties of the samples. XRD patterns indicate the formation of spinel structure of the prepared compounds. FTIR data confirmed the XRD results. ^{57}Fe Mössbauer spectroscopy and SQUID measurements were used to investigate the magnetic properties. The Mössbauer spectra indicate ordered magnetic spin state in all the compounds. The 'S' shaped hysteresis curves with almost zero coercive recorded at 300 K is characteristic of the superparamagnetic nature of the fine particles. The changes in the saturation magnetization and coercive fields as a function of composition or sample measuring temperature were observed.

FR.F-P26 - Magnetic properties of V- and Ta-doped alpha-Fe_2O_3 films

S.J. Liu [1], L.W. Juang [1], Y.Z. Lin [2], J.H. Hsieh [2]

1. Thin Film Laboratory, National Taiwan Normal University, Taipei City, Taiwan
2. Department of Materials Engineering, Mingchi University of Technology, Taipei City, Taiwan

V- and Ta-doped alpha-Fe_2O_3 films were fabricated by using magnetron co-sputtering technique. The valence state of both V and Ta doped in the films is 5+, which is higher than that of Fe^{3+}. Moreover, the ionic radii of V^{5+} and Ta^{5+} ions are respectively smaller and larger than that of Fe^{3+} ions. The effects of electron doping and lattice strains induced by impurity doping on the magnetic properties of the doped Fe_2O_3 films were investigated, as well as electrical and optical properties. Density functional theory calculations were performed to further clarify the mechanism causing the variation of physical properties of doped alpha-Fe_2O_3.

FR.F-P28 - Nanoscale tin oxide undoped and doped by 3-d elements: Synthesis and magnetic properties

D. Nazarov [1], P. Matveeva [1], N. Bobrysheva [1], O. Osmolowskaya [1], V. Smirnov [1], M. Osmolowsky [1]

1. Saint Petersburg State University, Institute of Chemistry, Saint Petersburg, Russia

SnO_2 attracts enormous interest caused by a variety of areas of its application, such as a gas sensors, catalysts, solar cells, optoelectronics, Li-ion batteries. Presence of the room temperature ferromagnetism (RTF) in the nanosized doped and pristine SnO_2 causes concern to this oxide as the material for spintronic. In spite of extensively theoretical and experimental studying of the RTF in the diluted magnetic semiconductors the nature and cause of the ferromagnetism in the tin dioxide is still not fully elucidated.
In this work we have investigated the influence of the size, dimension, composition, nature and concentrations of dopants on the magnetic properties of undoped and chromium, iron, copper doped SnO_2 nanoparticles and nanofilms.
Undoped and doped nanoparticles were obtained by sol-gel method. $SnCl_4$, $FeCl_3$, $Cr_2(SO_4)_3$ and $Cu(NO_3)_2$ were used as tin, iron, chromium and copper sources, respectively. Doping element concentration varied from 1 to 20%. Pristine tin oxide nanofilms (4-32 nm) were deposited on silicon (100) and quartz substrate by Atomic Layer Deposition (ALD) method using tetraethyl tin (IV) and ozone or hydrogen peroxide.
The nanopowders were characterized by XRD, TEM, BET, TGA, DTA, Mossbauer, Raman and luminescence spectroscopy. Ellipsometry, AFM, SEM, XPS and XRD methods were used to characterize nanofilms. Magnetic properties for all samples were studied by Vibrating Sample Magnetometry (VSM) method.
Presence of RTF was found in both undoped and doped samples. It has been found that the formation of RTF mainly determined by the postprocessing (calcination, vacuum treatment) and concentration of dopants for the nanoparticles and for the films the thickness performs a crucial role.

The reported study was supported by RFBR, research project № 14-03-31053 mol_a. Scientific research were performed at the "Center for optical and laser materials research", "X-ray Diffraction Studies", "Physical Methods of Surface Investigation" and "Nanocomposite" Centers of St. Petersburg State University.

FR.F-P29 - Magnetic anisotropy energy studies in highly Co-doped ZnO by ab initio calculations

A. Lusakowski [1], W. Szuszkiewicz [1]

1. Institute of Physics Polish Academy of Sciences, Warsaw, Poland

ZnO is well known and intensively investigated wide-gap semiconductor with the wurtzite type crystal structure. Both the transition-metal doped thin layers and bulk crystals of this compound or diluted magnetic semiconductors (DMS) grown on the basis of ZnO attract still a lot of attention due to continuous interest in materials for possible future applications in the area of spintronics. In particular, the ZnO crystals containing Co exhibit interesting magnetic properties and have been the topic of several recent papers.
The aim of the present work is the theoretical analysis of the magnetic anisotropy energy (MAE) for a Co-doped ZnO crystal. In the paper we discuss the results of extensive ab initio calculations of the MAE for 2x2x2 ZnO supercell containing 32 atoms with one Zn ion replaced by the Co ion. It is demonstrated that the effect of spin polarization of the surrounding atoms caused by the Co ion is almost limited to the four nearest oxygen neigbours only. As it could be expected, the influence of the Zn and O spin-orbit coupling on the MAE magnitude is very weak and one may claim that the magnetic anisotropy of Co is a single ion type anisotropy. On the contrary, the MAE is extremely sensitive to the lattice geometry and to the nearest neighbourhood of Co ion. The direction of magnetization easy axis is well reproduced by the calculations performed for the ZnO lattice parameter values. However, there exists a significant discrepancy between experimental and theoretical MAE value, the latter one is about one order of magnitude smaller than the former.

This work was supported in part by the Grant No UMO-2011/03/B/ST3/02664 from the National Science Centre (Poland) and by PL-Grid Infrastructure.

FR.F-P30 - Magnetic properties of the MOVPE and implanted GaN:Mn films

M. Marysko [1], Z. Sofer [2], D. Sedmidubsk² [2], J. Hejtmánek [1], K. Jurek [1], V. Laguta [1], J. Stejskal [2], P. èimek [2], A. Macková [3], V. Havránek [3]

5. Faculty pf Mathematics and Physics, Charles University, Prague,Czech Republic
6. Peter Grunberg Institute (PG1-9), Julich, Germany

The metal-organic vapour phase epitaxy (MOVPE) and implantation process were used to prepare GaN:Mnx (x=0.1-0.4) thin films on the sapphire substrates. The samples were characterized by the SIMS, disorder density analysis and the Mn content was determined by the electron microprobe method. The EPR measurement at the X band yielded information on the absence of Mn^{2+} ions in the films. The detailed SQUID measurements showed the zero ferromagnetic and, in the low temperature region, relatively large paramagnetic (PM) moment of the samples. The magnetization curves at T=2 K and temperature dependence of the PM susceptibility were measured for the parallel and perpendicular orientation of the magnetic field with respect to the film plane. The results were interpreted in terms of the molecular field approximation starting from the spin Hamiltonian for the Mn^{3+} ion [1],[2]. In contrast to nearly single crystal character of the MOVPE films, for which the m(H) curves exhibit a clearly pronounced anisotropy with the easy axis in the plane, the anisotropy of the implanted films is very small which suggests that the Mn^{3+} ions are in a disordered state. The PM susceptibility follows the Curie-Weiss law and a special attention was given to the Weiss temperature giving information on the possible exchange interaction between the Mn^{3+} ions. The evaluated value of the Weiss temperature was found to depend on the applied field and the value extrapolated to zero field approaches zero which would point to the ensemble of non-interacting Mn^{3+}ions. On the other hand, the dependence on the applied field could be ascribed to a part of the Mn^{3+} ions exhibiting ferromagnetic and antiferromagnetic exchange interactions.

FR.F-P31 - Transport properties in the ferromagnetic semiconductor gadolinium nitride

B. Ruck [1], T. Maity [1], H. Warring [1], E.M. Anton [1], C.M. Lee [1], J. Chan [1], S. Granville [1], F. Natali [1], J. Trodahl [1]

1. Victoria University of Wellington, Wellington, New Zeland

Gadolinium nitride is one of the rare examples of an intrinsic magnetic semiconductor [1], which makes it of particular interest for use in spintronics studies. As a semiconductor its conductivity is controlled by doping, with most GdN samples being heavily n-type doped by large concentrations of nitrogen vacancies. The concentration of such vacancies can be controlled by varying the growth conditions [2], and we have recently shown that Mg doping can passivate the donors to give semi-insulating GdN [3]. However, fundamental questions regarding the nature of the dopant levels and their influence on the electrical transport remain unanswered. Here we will present the transport properties, including temperature dependent resistivity, magnetoresistance, anisotropic magnetoresistance, and Hall effect, from a series of samples that span the range from insulating to degenerately doped. The data can be understood in terms of an evolution from isolated impurity levels in the insulating material to an impurity band that merges with the conduction band at heavy doping levels. The overall behaviour is reminiscent of that seen in dilute magnetic semiconductor such as (Ga,Mn)As.

FR.H-P01 - Magnetoresistive memory with recording by the electric field

A. Morosov [1], A. Sigov [2], D. Vinokurov [2]

1. Moscow Institute of Physics and Technology (State University), Moscow, Russia
2. Moscow State Technical University of Radioengineering, Electronics and Automation, Moscow, Russia

To realize a magnetoresistive random-access memory cell with recording by the electric field one needs to turn by 90° the magnetization of one of ferromagnetic layers entering the magnetic tunnel junction that consists of two conducting ferromagnetic layers separated by the dielectric interlayer. The parallel orientation of magnetizations of these layers serves to write “zero”, while the mutually perpendicular orientation of magnetizations is used to write “unity”. To switch the magnetization of one of ferromagnetic layers, the additional electrosensitive layer neighboring with the selected ferromagnetic layer is used. One possible mechanism of interaction between these layers is the interaction due to the elastic deformations transferred from one layer to another. If the reorientation occurs between two equilibrium positions existed in the absence of the interaction with the electrosensitive layer (two easy axes in the layer plane caused by the crystalline symmetry), there is the lower limit of about 100 nm for the bit size because of the occurrence of the superparamagnetic threshold. Promising directions for the development of the magnetoresistive memory switched by the electric field are the memory based on the exchange interaction between the ferromagnetic layer and multiferroic BiFeO3 layer [1], as well as the memory based on the elastic interaction between the ferromagnetic layer and the layer of ferroelectric-ferroelastic (the “long-leg” memory [2]), in which the magnetization direction of the ferromagnetic layer is determined by the deformation direction of the electrosensitive layer in the absence of the electric field.

FR.H-P02 - Intrinsic magnetoresistance in metal films on ferromagnetic insulators

V. Grigoryan [1], W. Guo [1], J. Xiao [1], G. Bauer [2,3]

1. Department of Physics and State Key Laboratory of Surface Physics, Fudan University, Shanghai, China
2. Kavli Institute of NanoScience, Delft University of Technology, Delft, The Netherlands
3. Institute for Materials Research and WPI-AIMR, Tohoku University, Sendai, Japan

We predict a magnetoresistance induced by the interfacial Rashba spin orbit coupling in a normal metal-ferromagnetic insulator bilayer system. This new magnetoresistance depends on the angle between current and magnetization directions as the recent discovered 'spin Hall magnetoresistance' mechanism caused by a combined action of spin Hall and inverse spin Hall effects. Due to the identical phenomenology we question the true origin of the spin Hall magnetoresistance and propose that a normal metal film thickness dependence measurement can clarify which effect, the interfacial Rashba or the bulk spin Hall effect, is responsible for the new magnetoresistance.

FR.H-P03 - Interface influence on the properties of $Co_{90}Fe_{10}$ films on soft magnetic underlayers - magnetostrictive and Mössbauer spectrometry studies

T. Szumiata [1], M. Gzik-Szumiata [1], K. Brzózka [1], B. Górka [1], M. Gawroński [1], A. Caruana Finkel [2], N. Reeves-McLaren [2], N.A. Morley [2]

1. Department of Physics, Faculty of Mechanical Engineering, University of Technology and Humanities in Radom, Radom, Poland
2. Department of Materials Science and Engineering, University of Sheffield, Sheffield, United Kingdom

The main aim of the work was to understand the correlation between magnetostrictive properties and microstructure of 25 nm thick $Co_{90}Fe_{10}$ films deposited on soft magnetic underlayers. The investigated magnetic bilayers were grown on silicon substrates using a RF sputtering deposition system with 3 targets: $Co_{90}Fe_{10}$, $Ni_{81}Fe_{19}$ (permalloy), and METGLAS 2605SC of $Fe_{81}B_{13.5}Si_{3.5}C_2$ composition [1]. The magnetostriction constant was measured by the Villari Effect using a magneto-optic Kerr effect (MOKE) magnetometer. Crystalline and magnetic microstructure has been examined with 57Fe-based conversion electrons Mössbauer spectrometry (CEMS). In the case of $Co_{90}Fe_{10}$ on 25 nm and 35 nm thick METGLAS underlayers one can resolve in Mössbauer spectra two hyperfine field distributions (high-field and medium-field ones) corresponding to these two constituents of bilayers. Analogical distributions describe the spectra of $Co_{90}Fe_{10}$ bilayers on 25nm and 35 nm thick $Ni_{81}Fe_{19}$ underlayers, however an additional low-field, smeared component has been observed. It has been attributed to the interface layer (of partially disordered structure) between magnetostrictive and soft magnetic layer. Such interpretation is backed up by the obtained linear correlation between mean hyperfine field value and magnetostriction constant of the films. The investigated bilayers are good candidates for MagMEMS devices, like FeGa-based films [2].

FR.H-P07 - Interfacial-scattering-induced enhancement of the anomalous Hall effect in uniform Fe nanocluster-assembled films

D. Peng [1], J. Wang [1], W. Mi [2], L. Wang [1]

1. Department of Materials Science and Engineering, College of Materials, Xiamen University, Xiamen, China
2. Department of Applied Physics, Tianjin University, Tianjin, China

More than a century ago, the anomalous Hall effect (AHE) in ferromagnets was found. The large AHE made them become the potential candidates for the practical applications in the field of Hall sensors, magnetic logic devices, etc [1, 2]. But the AHE mechanisms are still a controversial issue. Recently, extensive studies have been devoted to understand the influence factors of AHE [3-5]. However, so far, there has been no report on the granular size effects on AHE. Although the AHE is strongly related to the granular size, it is difficult to investigate the size effect on the AHE in the granular films due to their wide size distribution. In this work, we studied the cluster size (d=4.3-16.1 nm) dependence of the anomalous Hall effect in uniform Fe nanocluster-assembled films prepared by the plasma-gas-condensation method. In particular, a large enhancement of AHE is observed at d=4.3 nm, which is almost four orders of magnitude larger than bulk Fe. The saturated anomalous Hall resistivity (RA xy) shows a sharp decrease as d increases from 4.3 to 10.1 nm and a slight decrease with further increasing d to 16.1 nm. Moreover, the relations between the RA xy and longitudinal resistivity (Rxx) were also discussed in details. Results show that in double-logarithmic scales, RA xy decreases with the increase of Rxx, obeying a new scaling relation of log(RA xy/Rxx) = a0+b0logRxx, which originates from the interfacial scattering to the AHE and longitudinal resistivity.

FR.H-P08 - Thermal stability of an interface-stabilized skyrmion lattice

S. Krause [1], A. Sonntag [1], J. Hermenau [1], R. Wiesendanger [1]

1. University of Hamburg, Hamburg, Germany

Skyrmions are topologically protected field configurations with particle-like properties. They are in the focus of many ongoing investigations due to their potential application for future spintronic devices. Using spin-polarized scanning tunneling microscopy (SP-STM) at low temperature (T = 11 K), a lattice of nanoskyrmions has been shown to be the ground state of the one-atomic-layer thick Fe/Ir(111) surface [1]. In our recent SP-STM studies we investigated the influence of temperature onto the Fe/Ir(111) nanoskyrmionic lattice. The experiments reveal that the lattice is stable against thermal agitation up to T = 27.4 K. Further elevating T to 28.0 K results in a fading of the magnetic SP-STM contrast, indicating a phase transition into the paramagnetic state. By slowly varying T we elaborate a very sharp phase transition at T = 27.8 K. [2] At second monolayer Fe step edges the skyrmionic lattice is found to persist even to higher T, which is attributed to pinning. The experimental results will be presented and discussed in terms of magnetic corrugation amplitude of the skyrmion lattice and pinning decay length.

3. Department of Applied Physics and Materials Research Centre, The Hong Kong Polytechnic University, Hung Hom, Kowloon, Hong Kong, China

A magnetically dead layer exists at the surface of manganites. This dead layer can be used as a non-magnetic natural barrier at the interface of manganite/magnetic-metal bilayers for space-less pseudo spin-valves [1,2]. Ideally, magnetism should be completely suppressed at the interface of the bilayer to achieve maximum magnetoresisitve effect. This can be achieved by ion bombardment. We investigated the effect of Ar+ ion bombardment on the magnetic and magneto-transport properties of $La_{0.7}Sr_{0.3}MnO_3$/Permalloy (LSMO/Py) bilayers. LSMO films were grown by pulsed laser deposition (PLD) on (100) $SrTiO_3$ single crystal substrates. The LSMO films showed a Curie temperature larger than room temperature, as measured by a vibrating sample magnetometer. The surface of the LSMO films was bombarded by Ar ion-beam for different periods (tbomb = 1 to 10 mins.) with an End Hall ion source. Py was subsequently deposited by a Kaufmann ion source using the ion-beam sputtering deposition technique. Atomic Force Microscope (AFM) measurements show that, for the power used here, the bombardment did not significantly increase surface roughness. Magnetization versus temperature (M vs T) measurements showed that the magnetic layers could be independently reversed. Low dose bombardment was effective in increasing decoupling between the layers as compared to the case of untreated interface. This could lead to enhanced giant magnetoresistive effect in patterned devices.

FR.H-P10 - Ferromagnetic resonance measurements in sub-nanometer Fe films

H. Mizuno [1], T. Moriyama [1], M. Kawaguchi [1], M. Nagata [1], K. Tanaka [1], T. Koyama [2], D. Chiba [2], T. Ono [1]

2. The University of Tokyo, Tokyo, Japan

Interfacial effects in magnetic multilayers are a key phenomenology for the recent spintronic research developments involving the spin Hall effect, the Rashba effect, voltage-induced magnetism, and the Dzyaloshinskii-Moriya interaction. Since the interfacial effects become more and more pronounced as the ferromagnetic films get thinner, it is desirable to measure the magnetic properties in the thinnest limit of magnetic films. In this study, we show that our ferromagnetic resonance (FMR) measurement technique is sensitive enough to characterize the various static and dynamic magnetic properties of the sub-nanometers (~0.56 nm) Fe films. We prepare Ta 3.0 nm/Pt 1.5 nm /Fe *x* nm/MgO 2.0 nm (*x*=0.56-0.86) films grown on a GaAs(001) substrate. The film is patterned into the 40 μm wide strip. A microwave current is applied along the strip and a rectified dc voltage across the strip is measured akin to the spin torque FMR technique [1]. With the frequency bandwidth of 40 GHz, we extract the Landé g-factor, the Gilbert damping constant α, and the effective demagnetizing field $4\pi M_{\mathrm{eff}}$ from which the perpendicular magnetic anisotropy (PMA) is estimated.
It is found that both the g-factor and the PMA linearly decrease with increasing the reciprocal of *x*, implying the PMA correlates with the anisotropy of the orbital moment at the Pt/Fe interface [2]. The measurement results clearly capture the magnetic properties of sub-nanometer ferromagnetic films where the interface effects dominate. Especially, the capability of the g-factor extraction in our measurement will be very helpful for characterizing ultra-thin films with various interfacial effects perturbed by spin-orbit interactions.

FR.H-P11 - Study on spin-orbit interaction in an MgO/Co/Pd trilayer with annealing

S. Kim [1,2], M. Kim [1], J. Ko [1], J. Hong [1]

1. Department of Material Science and Engineering, Yonsei University, Seoul, South Korea
2. Institute for Chemical Research, Kyoto University, Tokyo, Japan

The spin-orbit interaction (SOI) is well known to depend on the atomic environment. Crystalline and chemical structures are critical to observe the spin-orbit coupled phenomena, such as perpendicular magnetic anisotropy (PMA), spin-orbit torque (SOT) and Dzyaloshinskii-Moriya interaction (DMI). Magnetic trilayers composed of non-magnetic metal/ferromagnet/oxide have been intensively studied during the last five years since they have shown the SOT effect due to strong SOI. Because the thickness of ferromagnets was on a nanometer scale, the interfacial structure can dominate the behavior of the ferromagnets in the trilayer. Essential to understand is a quantitative study about how the interfacial state in the structure affects the spin-orbit coupled phenomena, which has not been fully explored before. In this talk, we present that a thermal treatment changed the chemical and structural states in an MgO/Co/Pd trilayer and as a result, both volumetric and interfacial magnetic anisotropy changed accordingly. Varying the annealing temperature, two important phenomena were discovered: 1) the metallic Co/Pd interface contributes more to magnetic anisotropy than the MgO/Co one does, and 2) the stress developed in the MgO/Co layer during annealing induces magnetoelastic anisotropy of the trilayer. X-ray magnetic circular dichroism (XMCD) study proves that the spin-orbit interaction was significantly enhanced due to atomic intermixing and lattice strain in the trilayer induced during annealing, which led to strong PMA in the trilayer. Our experimental results will make it clear how spin-orbit interaction is affected by chemical and structural modification through thermal annealing.

FR.H-P12 - Anomalous hall conductivity at uncompensated antiferromagnetic interfaces

K. Nakamura [1], M. Ikuta [1], T. Akiyama [1], T. Ito [1]

1. Mie University, Tsu, Japan

Interest in antiferromagnets has increased towards atomic-scale data storage/spintronic applications that may overcome a surperparamagnetic issue [1] while a key challenge remains in understanding magnetocrystalline anisotropy (MCA) and sensing ways of the magnetic states since the lack of net magnetic moment in the antiferomagnets make measurements difficult. Here, we demonstrate from first principles calculations that an anomalous Hall conductivity, being proportional to the magnetization of uncompensated spins at antiferromagnetic film surfaces/interfaces, enables a characterization of the magnetic states. Calculations were carried out by using the full-potential linearized augmented plane wave method [2], in which the anomalous Hall conductivity was obtained by applying the Kubo formula of the linear response theory. We confirmed that the MCA energy in a prototype Cr_2O_3(0001) thin film shows the magnetic easy axis along perpendicular to the film plane with the MCA energy of 0.45 meV, which arises from the surface Cr 3d states appeared in the bulk band gap. By capping a nonmagnetic metallic layer (Au) on the Cr_2O_3(0001) surface, the magnetic easy axis remains along the perpendicular and the anomalous Hall conductivity results in 0.1×10^{15} s^{-1}; the magnitude predicted is enough for experimental measurements. The uncompensated spin alignment at the Cr_2O_3(0001) interface plays an important role where the interface Cr d states highly couple to the conduction electrons in the Au layer.

FR.H-P13 - Influence of roughness in ultrathin Co/Ni multilayered films with perpendicular magnetic anisotropy: reduction or enhancement?

D. Gopman [1], A. Chen [1], L. Chen [2], G. Rowlands [3], R. Shull[1]

1. Materials Science and Engineering Division, NIST, Gaithersburg, United States
2. Center for Nanoscale Science and Technology, NIST, Gaithersburg, United States
3. Applied and Engineering Physics, Cornell Univeristy, Ithaca, New York, United States

The perpendicular magnetic anisotropy (PMA) of thin films is sensitive to surface and interfacial roughness. Established roughness anisotropy models are limited to films much thicker than the roughness amplitude (low roughness limit), and may not be applicable to technologically-relevant magnetic films of several monolayer thickness. To better understand the evolution of PMA in the low and high roughness limit, we grew films on substrates displaying a range of roughness amplitudes. We observe distinct roughness amplitude regimes: low and high roughness characterized by decreasing PMA, and an intermediate range associated with increasing PMA. We present magnetic and morphological measurements on Co/Ni multilayered films grown on SiO_2/Si substrates with designed roughness amplitudes. By controlling the duration of a reactive ion etch, we tuned the roughness amplitude from 0.3 nm to 12 nm. Using sputtering, we grew a magnetic thin film of Ta(3)/Pt(2)/[Co(0.15)/Ni(0.6)]x8/Co(0.3)/Pt(2)/Ta(3), simultaneously on the series of substrates. (Numbers in parentheses indicate thicknesses in nm.) Using ferromagnetic resonance spectroscopy, vibrating sample magnetometry and atomic force microscopy, we present the evolution of the effective perpendicular anisotropy field (H_eff) and saturation magnetization (M_S) with roughness. The H_eff of the film series decreases slightly from 184.4 ± 0.3 mT with increasing roughness (Rq) at the lowest roughness amplitudes, but for Rq>3.5 nm H_eff begins systematically increasing at a fast rate with roughness, reaching a maximum of 240 ± 2.4 mT near Rq=8 nm. Substrates in the series exceeding 8 nm roughness exhibit lower H_eff, presumably a ramification of changes in the film growth process as it develops into a combination of discontinuous island growth and interstitial filling as the substrate roughness becomes comparable and larger than the film thickness. M_S decreases continuously with roughness, perhaps due to increased chemical reactivity/disorder. These results could suggest distinct roughness contributions to surface and volume anisotropies.

FR.H-P14 - Probing Co/Pd interfaces by the extraordinary hall effect.

A. Gerber [1], A. Segal [1], G. Winer [1]

1. Tel Aviv University, Tel Aviv-Yafo, Israel

We used measurements of the magnitude and polarity of the extraordinary Hall effect to identify and characterize the alloyed interfaces in Co/Pd bi-layer and multi-layer structures. As far as the EHE is concerned, Co/Pd multilayers with monoatomic thickness of Co layers behave as alloys with an effective concentration corresponding to the thickness ratio between the Co and Pd layers. Intermixing leading to formation of interfacial alloys occurs during the deposition and continues either as a natural aging or due to post-deposition annealing. An effective natural alloying time at room temperature is about 100 days while thickness of the intermixed layer is of order of 1 nm. Multilayers and homogeneous Co-Pd alloys demonstrate positive or negative EHE polarity when an effective Pd content is respectively below or above the mark of about 75%. We found a direct correlation between changes in the EHE signal occurring due to a gradual alloying of the interface and coercivity of the hysteresis loops in Co/Pd bi-layers. This is a straightforward evidence that perpendicular magnetic anisotropy in heterogeneous Co/Pd systems is due to formation of strained interfacial CoPd alloys. As a general note, our results put in doubt the very existence of sharp alloy-free interfaces between Co and Pd or other miscible elements.

FR.H-P15 - Mechanism and control of antiferromagnetic coupling in Fe/Fe3O4 junctions

J. Inoue [1], S. Honda [1], H. Yanagihara [1], E. Kita [1], H. Itoh [2], K. Mibu [3]

1. Faculty of Pure and Applied Sciences, University of Tsukuba, Tsukuba, Japan
2. Department of Pure and Applied Physics, Kansai University, Osaka, Japan
3. Graduate School of Engineering, Nagoya Institute of Technology, Aichi, Japan

The antiferromagnetic (AF) exchange coupling between two ferromagnetic layers in trilayers is an essential feature for spintronics applications such as hard-disk drive and spin-valve sensors. Recently, a rather strong AF coupling, ~1 erg/cm2, has been observed in Fe(001)/Fe_3O_4 junctions [1], which may have potential applicability to spintronics devices. It has been proposed theoretically that control of the magnitude of the AF coupling is possible by inserting thin Co or Mn layers between Fe and Fe_3O_4 layers [2]. The mechanism of the AF coupling, however, remains to be clarified. Purposes of present study are to confirm the theoretical prediction experimentally, and to clarify the mechanism of the AF coupling in Fe/Fe_3O_4 junctions.
Magnetization curve (M-H loop) was measured for Fe/Fe_3O_4 junctions in which a thin Co (Mn) film is inserted, and the M-H loops are analyzed by adopting several models which include bilinear, biquadratic, and magnetization twisting near the interface. The analyses indicate that the bilinear term is dominant in AF coupling and rather independent of the Mn layer thickness while it decreases with increasing Co layer thickness, in agreement with the theoretical prediction. The analyses further show that the magnetization twisting is crucial for the M-H loop fitting, and that the biquadratic term may not be neglected completely, suggesting an importance of roughness at the interface.
We performed first-principles calculations to clarify possible mechanism of the AF coupling. It was found that ideally epitaxial junctions give always ferromagnetic (F) coupling, while extra Fe atoms located on hollow sites of Fe_3O_4 mediate AF coupling between Fe and Fe_3O_4 layers. Coexistence of the F and AF couplings may produce frustration in alignment of Fe and Fe_3O_4 magnetizations resulting in the biquadratic exchange interaction.

FR.H-P16 - Reversed behavior studies of angle-dependent magneto-optical Kerr rotation in magnetic/optical birefringent system

C. Su [1], C. Lin [1], G. Chern [1]

1. National Chiayi University, Chiayi City, Taiwan

In a magnetic/optical spin material system, the interface problem always directly reflects its structural character from the magnetic layer or the beneath optical layer. We used a common magneto-optic Kerr effect (MOKE) magnetometry method through angle-dependent detection in the incident plane. The low-vibration homemade horizontal optical platform is suitable for studying a perpendicular spin system, ultrathin magnetic structure Ta/CoFeB/MgO film, (3)/(1.5)/(1) in nanometer thick. The experimental result for this sample is interesting that we found a reversed hysteresis loop behavior between 69 and 70 degrees. The angle of hysteresis flipping is dependent of the covering thickness of Ta. The direction of Kerr rotation is reversed from clockwise to counterclockwise only in the out-of-plane MOKE configuration. The reason of the reversed hysteresis loop originates from the optical properties of the interface structure between the magnetic film and optical underlayer. We use an equation considering anisotropic birefringence of the optical material, and compare the data by simulation of the polar magneto-optical Kerr effect. The ordering thickness of the anisotropic optical layer plays an important role in the reversed character of magneto-optic effects. This finding is very important for future spintronics application of any ultrathin device which is already fabricated and can be examined without any structural destruction.

FR.H-P17 - Reduction of the mean magnetic moment of Ni clusters embedded in Ag

Magnetic properties of materials change drastically from the bulk size to the nanoscale [1]. This is due to surface effects, which become increasingly important and need to be taken into account when analyzing the magnetic properties at the nanoscale.
In this work we combine experimental results with Density Functional Theory (DFT) calculations to show that Ni clusters embedded in an Ag matrix become non-magnetic below a cluster size of around 6 atoms. Experimental measurements have been performed on a DC-sputtered Ni_6Ag_{94} nanogranular thin film. The film structure investigated by means of Extended X-ray Absorption Fine Structure (EXAFS) confirms that the film is composed of sub-nanometre sized Ni particles. The magnetic analysis highlights a strongly reduced magnetic signal that is 62% lower than the bulk value. DFT calculations performed on Nim clusters of selected sizes (m=1 to 6, 10 and 13) embedded in an Ag bulk matrix confirm that Ni clusters below 6 atoms become non-magnetic due to charge transfer between the Ni sp and d orbitals. This explains the loss of magnetic signal observed experimentally as being due to the coexistence of small non-magnetic Ni clusters together with slightly larger ones that do hold a full magnetic moment.

FR.H-P18 - First-principles study on the vertical spin texture of anomalous rashba effect in Tl/Si(111) and Tl/Si(110)

H. Nakano [1], H. Kato [1], M. Obata [1], D. Yoshikawa [1], N. Kitagawa [1], K. Sakamoto [2], T. Oda [1,3]

1. Graduate School of Natural Science and Technology, Kanazawa University, Kanazawa, Japan
2. Department of Nanomaterials Science, Chiba University, Chiba, Japan
3. Institute of Science and Engineering, Kanazawa University, Kanazawa, Japan

The heavy-element-covered semiconductor surfaces show a giant Rashba-type spin splitting and many experiments have been reported for spintronics applications. In particular, the surface of Tl/Si(111) has been known to show out-of-plane spin textures in the surface bands [1,2]. This is novel, compared with a normal Rashba spin texture, in which the spin lies within the surface plane. However, the vertical spin configuration may be useful, because of the suppressed spin scattering. The silicon based materials are still recommended as a new material in the next generation electronics (spintronics). In these contexts, it is important to clarify electronic structures in the surface electronic structure. In this work, we studied the surface systems of Tl/Si(111) and Tl/Si(110), in which the system has a triangular lattice network of Tl atoms on the respective silicon substrate. The systems have a single Tl monolayer (ML), and 16 Si MLs, and is terminated with the hydrogen. We carried out a fully relativistic first-principles computation based on the density functional theory. The Rashba effect is taken into account through the bi-spinor wavefunctions and fully relativistic ultrasoft pseudopotentials. The artificial surface electric polarization was excluded by using an effective screened medium method.
We revealed that the surface in Tl/Si(110) has vertical spin textures at around the parts of momentum space, which corresponds to the K-bar points of Tl/Si(111). We calculated the distribution of the surface states given at a constant energy. This result agreed well with the corresponding experimental result. In the presentation, we explain the electronic structures and the spin textures, and discuss the similarity between two surface electronic structures and doping effect for realizing surface current carriers.

Strain is the most important linker in multiferroic devices that utilize magnetoelectric coupling [1-3]. It links piezoelectricity of one material with magnetoelasticity (usually magnetostriction) of another material. Strain in ferromagnetic layer affects magnetocrystalline anisotropy and may change the axis of easy magnetization. Magnetoelectric coupling in multiferroic heterostructures has been frequently reported experimentally and theoretical model for a monodomain magnetic layer has been proposed [4]. Recently a magnetoelectric cells with resistive readout have been demonstrated [5] as a new step towards designing of magnetoelectric random access memory. The purpose of this research was a comprehensive investigation of magnetoelastic effect in multiferroic heterostructures and it's quantitative description with the use of existing theory of magnetism. Magnetoelastic coupling between ferroelastic substrates ($LiCsSO_4$, KH_2PO_4 and $Gd_2(MoO_4))_3$) and thin $Ni_{85}Fe_{15}$ layer has been studied by different techniques. Measurements revealed strong influence of a strain onto magnetic properties of a layer. Significant, continuous and reversible drop of longitudinal magnetization in NiFe film cooled below substrate phase transition temperature has been observed by SQUID magnetometry. As imaged by Kerr microscope, magnetic domains strictly copy the pattern of elastic domains of a substrate. This also affects the frequency of magnetostatic surface spin waves, which were investigated by Brillouin spectroscopy. Results have been quantitatively compared with micromagnetic simulations, which describe observed effects as a strain-driven reorientations of magnetic moments, taking into account peculiar multidomain pattern of a substrate. Thus, we have successfully linked theoretical predictions of spin-reorientation transitions [4] with experiment.

5. Centro Atómico Bariloche- Comisión Nacional Energía Atómica, Río Negro, Argentina

The perovskite-like compound $LaFe_{0.5}Co_{0.5}O_3$ have attracted significant attention for more than a decade, mainly because of their magnetoelectric and multiferroic properties.[1,2] In this work we present the synthesis, structure, magnetism and electric transport properties of different grain size $LaFe_{0.5}Co_{0.5}O_3$ perovskites.
Different compounds have been synthesized by citrate method and then annealed 12 hours at different temperatures (T_{anneal}) between 600 and 1200 °C. The crystallographic characterization was performed by X-ray powder diffraction, the best Rietveld refinement was obtained with a rhombohedral structure ($R\bar{3}c$) at room temperature. Also from the X-ray data, we observe the increase of the grain size increasing T_{anneal}. The temperature and field dependence of the magnetization evidences a ferrimagnetic transition (T_C) around 250 K in all cases. Differences in field cooled cooling, field cooled warming and zero-field cooled magnetization suggest the presence of different magnetic states (Ferri and Antiferro) below T_C whose ratio change with temperature. Impedance and DC resistivity were characterized as a function of temperature. The resistivity shows a semiconducting-like or thermally activated behavior. From impedance spectroscopy (IS) characterization, we calculated different complex functions as: impedance (Z*), dielectric modulus (M*), permittivity (ε*); and loss tangent (tan δ). The conduction process is dominated by a long-range mechanism in all samples. This process is related to a single relaxations peak in tan δ plots. However, imaginary part of Z* and M* functions show two different relaxations process, which are linked to the grain and grain boundary effects. From this behavior we found the increase of the grain boundary effect as the T_{anneal} decreases. On the other hand, we observed a subtle effect of T_{anneal} on the studied magnetic properties. However, differences on the contact between ceramic grains becomes much more important on the transport properties (IS and DC resistivity). As a final remark, our work shows how the synthesis protocol is a powerful tool in the search of specific properties of these kinds of oxides.

FR.H-P22 - First-principles studies on the electronic and magnetic properties of (001) surfaces of half-heusler X(X=Li and Na)CaB

D. Kim [1], B. Bialek [2], J. Il Lee [2]

1. Halla University, Wonju-si, South Korea
2. Inha University, Incheon, South Korea

Half-metals, substances that act as conductors to electrons with one spin orientation, but as insulators or semiconductors to electrons in the other spin orientation, have been attracted much attention as candidates for application to spintronics as, for example, multilayer spin valves systems, spin injectors, and/or spin transistors. Recently, an exotic class of half-metals not containing a transition metal element in their structure emerged due to results of computational study with the use of first-principles methods. Specifically, half-Heusler compounds, XCaB, (X=Li, Na, and K) were found to be half-metallic [1]. It is crucial to have information on the surface properties of materials for the spintronics application. In this study, we investigated the electronic and the magnetic properties of (001) surfaces of two of the mentioned half-Heusler compounds, namely LiCaB and NaCaB. The full-potental linearized augmented plane wave method [2] with the generalized gradient approximation [3] was used to calculate the surface electronic properties. We considered two possible terminations of the (001) surfaces, i.e., alkali metal terminattion and CaB-termination. From the calculated local densitis of states, we found that the half-metallicity is not retained at all the surfaces. The magnetic moments of the Li or Na atom at the (001) surface decrease to nearly zero. The magnetic moments of B atom of CaB-terminated surface in LiCaB is 0.51 bohr magneton, and that of NaCaB compound is 0.05 bohr magneton. Due to a delocalization of p-electrons at the surfaces the values of magnetic moments on Ca atoms in both systems are close to zero, even though in the bulk structures Ca atoms exhibit noticeable magnetization.

In this study, the effect of the surface electric field over the optical and electrical properties of quantum Hall effect (QHE) devices were analyzed using photoreflectance and QHE measurements. AlGaAs/GaAs heteroestructures were grown by MBE with a GaAs cap layer passivated by one and two silicon monolayers. Photoreflectance spectra show wide-period Franz-Keldysh oscillations between 1.42 and 1.70 eV originated by the surface electric field. For sample without silicon monolayer the surface electric field is near to 5x107 V/m whilst sample with 1 Si-ML has 2.9x107 V/m and 1.7x107 V/m for the sample with 2 ML. the electric field decreases near to 66%. By QHE measurements we have found the electron density varied between 5.3 and 9 x10-11 cm-2, which increases as the surface electric field decreases. Furthermore, Raman measurements have been used to study the passivated surface.

4. ALBA Synchrotron Light Source, Cerdanyola del Valles, Barcelona, Spain

The emergent physical properties displayed by transition-metal oxide (TMO) heterostructures are originated by the charge, spin and orbital reconstructions occurring at interfaces [1]. However, the mechanisms driving these reconstructions, largely discussed in the last years, are still under debate. Manganites represent a prototypical system to explore oxides interface phenomena. In manganite thin films it is now understood that, at free surfaces, the reduced coordination of Mn ions leads to an imbalance of the orbital population in the surface layers [2], which is expected to originate the commonly found electrically and magnetically inert character of ultrathin films. However, at interfaces with other oxides, the transition metal crystal field will be modified in a different manner dependent upon the component layers.
By means of X-ray absorption linear dichroism we study the influence of oxide epitaxial capping layers on the Mn-3d orbital occupancy of manganite films with composition $La_{0.7}Sr_{0.3}MnO_3$. Probing with different capping materials ($SrTiO_3$, $LaAlO_3$, $SrZrO_3$) and thicknesses we find a clear dependence of the Mn electron distribution on the structural characteristics of the capping layers. We also demonstrate the correlation of these electronic reconstructions with the magnetic properties of the films, which is crucial for the implementation of these materials in magnetic tunnel junctions.

FR.H-P27 - Investigations on interface magnetism of Fe-containing heusler alloy films through mössbauer spectroscopic measurements

K. Mibu [1], A. Okubo [1], N. Nakatani [1], M. Tanaka [1]

1. Nagoya Institute of Technology, Nagoya, Japan

The interface magnetism of Fe-containing Heusler alloy films, such as Co_2FeGe, was examined through magnetic hyperfine fields at the interfacial Fe sites derived from ^{57}Fe Mössbauer spectra, absorption spectra of gamma-rays by the ^{57}Fe nuclei in the film. The samples were prepared on MgO(001) substrates using alternate deposition of an atomic layer (or a half an atomic layer) of the constituent elements. The Fe atoms at the interfacial regions were made of the Mössbauer-sensitive ^{57}Fe isotope, and those at the inner part of the films were of the Mössbauer-inert ^{56}Fe isotope, so that interface-sensitive measurements can be performed. To examine whether the interfacial atomic species can be controlled or not, the deposition sequence of the constituent elements was tested to be changed in four ways.
For the Co_2FeGe/MgO interfaces, the magnitude of the magnetic hyperfine field was obtained to be around 34 - 35 T at room temperature, which was almost the same as the value at the inner part of the Heusler alloy layer. The values were not different among the samples prepared with different deposition sequences (therefore nominally with different interfacial atomic species). The evidence of controllability of the interfacial atomic species was not obtained.
In magnetic tunnel junctions or giant magnetoresistance multilayers using Heusler alloys as ferromagnetic layers, a strong reduction in magnetoresistance is generally observed when the temperature approaches from low temperatures to room temperature. This change may have relation with some instability of the magnetization at the interfacial region, but the above result indicates that the interfacial magnetization has no special anomaly, at least for the Co_2FeGe/MgO(001) system. The results for other material combinations will also be shown in the presentation.

FR.H-P28 - Magnetism of Ru monolayer - first principles calculations -

Y. Kitaoka [1], K. Nakamura [2], H. Imamura [1]

1. National Institute of Advanced Industrial Science and Technology (AIST), Spintronics Research Center, Japan
2. Department of Physics Engineering, Mie University, Tsu, Japan

The study of magnetism in nano-structures composed of 4d transition metal elements is to pave the way for new materials sciences and technologies. It is well known that bulk 4d transition metals are non-magnetic. However, there are recent experimental and theoretical investigations showing ferromagnetism for some of these 4d transition metals thin films on noble metal substrate. For example, Y. Sun et al. demonstrated that application of an external electric field can induce and modulate ferromagnetism on an otherwise paramagnetic Pd metal thin-film surface[1]. Until now most researches are focused on Pd films since Pd is very close to fulfill the Stoner criterion of ferromagnetism. By contrast, little attention has been paid to the magnetism of the other 4d transition metals.
Here, we investigate the magnetism of the free-standing Ru monolayer and that on MgO(001) substrate by using first-principles FLAPW method [2]. Results predict that the free-standing Ru monolayer shows ferromagnetic properties with the magnetic anisotropy (MA) energy of 3.4 meV/atom, which means it has a perpendicular magnetic anisotropy. For the free-standing Ru monolayer with the same lattice constant as the bulk MgO the easy axis of magnetization changes to in-plane (planar magnetic anisotropy). For the Ru monolayer on MgO(001) substrate the magnetization remains and the MA energy is 1.52 meV/atom (perpendicular magnetic anisotropy). The change of easy axis between the free-standing Ru monolayer and Ru/MgO multilayer is explained by the hybridization between the Ru dz2 and O pz orbitals at the metal-substrate interface as discussed in Fe/MgO interface [3].

FR.H-P29 - The influence of interfacial dzyaloshinskii-moriya interaction strength on the magnetic structure of thin films under magnetic field

C. Wu [1], C. Kuo [2]

1. Department of Physics, Chung Yuan Christian University, Chungli, Taiwan
2. Department of Physics, National Sun Yat-Sen University, Kaohsiung, Taiwan

The magnetic skyrmions have attracted much attention recently due to their potential applications in spintronics. They arises from the spin-orbit coupling in non-central symmetric systems, such as the MnSi bulk material, or the interface between a magnetic thin film and a strong spin-orbit coupled adjacent layer. The coupling in such cases is called Dzyaloshinskii-Moriya interaction (D). The influence of this interaction strength on the magnetic structure of thin films plays a key role to understand the behavior of magnetic skyrmions. We study the influence of D values on the magnetic structures of thin films to obtain the phase diagram of the magnetic skyrmions under magnetic fields by using the micromagnetism simulation (OOMMF code). The skyrmion state is found to exist only when the D is larger than a certain finite value and when the magnetic field is less than the saturation field, which increases linearly with the increasing D value. In the skyrmion state, the stripe domains and isolated skyrmions can co-exist. When the magnetic field is increased, the stripe domains shrink toward skyrmions, resulting in isolated skyrmions. The diameter of the isolated skyrmions decreases with the increasing field. When the saturation field is reached, all of the skyrmions are smeared out and the sample changes to a ferromagnetic single domain state. This is provided as the guideline for designing the magnetic skyrmions for further applications in spintronics.

FR.H-P31 - Magnetic properties of ordered CoO nanostructures on Co/Fe(001)

Intriguing magnetic properties can be obtained in systems containing antiferromagnetic (AF) transition metal (TM) oxides both by low-dimensionality and by proximity to ferromagnetic (F) layers. So far, we have investigated both chemical [1] and magnetic [2] properties of a rich record of Fe/AF (NiO, CoO) layered structures [3].
One of the most critical issues concerning the interfaces between TM mono-oxides and a reactive TM is the high degree of chemical mixing at the interfaces [1]. We have observed, through scanning tunneling microscopy combined with Auger, photoemission, and X-ray absorption spectroscopies, that the layer-by-layer growth of an ultrathin (1 nm) Co buffer layer prior to CoO deposition prevents, in particular growth conditions, the different elements to react and mix at the interface. When this occurs, we also observe a dislocation-driven nanostructuration of CoO, which grows in square islands, whose lateral sizes (tens of nanometers) increase with CoO coverage.
On such samples, peculiar hysteresis loops are observed, whose reversal is characterized by the nucleation of 90° in plane domains when the magnetic field is applied along one of the Fe easy axes. On the other hand, when the field is moved away from the easy axes, jumps in the loops are seen, which interestingly resemble those observed on exchange spring multilayers, thus suggesting the presence of different magnetically active components. When performing element specific hysteresis loops by XMCD, it is revealed that the transverse component observed in the loop arise only upon CoO formation and that it can be attributed to both Fe and Co magnetic moments close to the interface.

FR.H-P33 - Magnetic properties of tetra-phenyl-porphyrins adsorbed on metal surfaces

M. Panighel [0], G. Di Santo [1], M. Caputo [1], A. Goldoni [1]

1. Elettra-Sincrotrone Trieste S.C.p.A., Trieste, Italy
2. Università degli Studi di Trieste, Trieste, Italy
3. Institut Català de Nanociþncia i Nanotecnologia (ICN2), Campus UAB, Bellaterra, Spain

Within the next few years the traditional semiconductor technology will reach its essential size limit. The use of organic molecules as single functional units in metal-organic based devices could overcome this limitation. However, the success of this approach strongly depends on the understanding of the interaction of the molecules with metallic substrates which determines the electronic and magnetic properties of these interfaces.
Organic molecules such as porphyrins can be deposited in the sub-monolayer regime on single crystal surfaces in ultra high vacuum and geometrically ordered structures can be obtained from this procedure [1]. Taking advantage of the flexibility in choosing their molecular substituents, in combination with the presence of active sites of interactions with metals [2-4], this kind of molecules can be used to fabricate two-dimensional arrays of metallic centres with nanometric spacing, making them promising candidates for applications in emerging fields like spintronics and molecular electronics.
By means of XPS, NEXAFS and XMCD techniques we studied the self-assembly, metalation and magnetic properties of tetra-phenyl-porphyrins (TPP) on metal substrate. Focusing on the magnetic coupling of two layers of molecules with a ferromagnetic thin film, we will show that, in the case of a MnTPP layer on FeTPP/Fe(110), the magnetic coupling extends to the second molecular layer, and its magnetization is opposite with respect to the substrate [5].

Magnetism at the nanoscale and especially the magnetism of the square-planar metallo-porphyrins and -phthalocyanines adsorbed on (magnetic) substrates has attracted considerable attention. Several reports showed that when adsorbed on ferromagnetic (FM) substrates such magnetic molecules possess an exchange induced magnetic moment [1, 2, 3]. Furthermore, the magnetic moment of ad-molecules can be tailored by the introduction of a non-magnetic spacer layer in between molecules and the substrate [3] or by means of a chemical stimulus (i.e. by coordination with ligands like NO, NH3, CO) [3,4,5]. In this contribution we use X-ray Photo-Emission Electron Microscopy (X-PEEM) combined with X-ray Magnetic Circular Dichroism (XMCD) to investigate the magnetic exchange coupling between Mn-porphyrin molecules and (1) native FM Co (001) substrates; (2) oxygen-terminated Co (001) substrates and (3) FM Co (001) substrates covered with a Cr spacer layer with increasing thickness. Specifically, we investigate spatial variations in the magnetic coupling of the molecules, their chemical state as well as the spatial distribution of the respective elements at the surface of the sample by combination of PEEM and XMCD in a direct spectro-microscopy correlation [5].

FR.I-P02 - Implementation of broadband magnetic susceptibility meter based on broadband lock-in amplifier techniques

J. Lu [1], C. Guo [1], X. Shao [1], B. Shen [1]

1. State Key Laboratory of Magnetism, Institute of Physics, Chinese Academy of Sciences, Beijing, China

Measuring magnetic susceptibility of spintronic materials in a wide frequency window is important for exploring high performance soft magnetic materials with high permeability in high frequency, researching magnetic resonance phenomena and understanding the order-disorder transition of superconducting vortex configuration. To fully investigate magnetic dynamics behaviors of various spin related materials, it is necessary to use broadband magnetic susceptibility measurement system. Conventionally, magnetic susceptibility meters have four types: 3-coil system, impedance measurement, cavity resonance and vector network analyzers. Unfortunately, none of them could continuously work from low frequency (below 1 Hz) to high frequency (above 1 GHz). The current poster introduces a new type of magnetic susceptibility meter, which can measure not only linear magnetic susceptibility but also higher-order magnetic susceptibility in broad frequency range from low frequency to above 1 GHz. We implement the broadband magnetic susceptibility measurement system based on broadband lock-in amplifier techniques. We have studied broadband lock-in amplifier (LIA) and its application to multifunctional electromagnetic measurement system for many years, with continuous improvement on bandwidth and precision. The magnetic susceptibility measurement system takes advantage of a specially designed sample holder compatible to high frequency coaxial cables and dynamical compensation. To enhance the convenience of physical research, our broadband measurement system can easily be connected and integrated to different types of environments,such as temperature and magnetic field.

FR.I-P03 - Controllable measurements of magnetic hysteresis and Barkhausen noise

A. Stupakov [1], O. Perevertov [1], V. Zablotskii [1]

1. Institute of Physics ASCR, Prague, Czech Republic

We developed a novel setup for accurate measurements of the magnetic hysteresis and Barkhausen noise (BN) with two distinctive features. First, the magnetic field is measured directly by an array of Hall sensors. Second, a digital feedback loop adjusts the waveform of the magnetic induction or field to the prescribed sinusoidal/triangular shape. This method gives physically accurate and repeatable results, which are independent of a specific design of the magnetizing circuit. In particular, the measurements can be performed in a magnetically open configuration, i.e. with a several mm air-gap between the ac magnet and a tested sample [1]. This provides new possibilities for further development of the measurement standards and industrial non-destructive techniques. The enhanced performance of the setup was clearly demonstrated on the measurements at constant field/induction rates allowing the physically correct study of the magnetization dynamics in ferromagnetic steels and alloys. Interesting results were obtained for the BN signal originating from a sub-surface irreversible motion of the magnetic domain walls. The shape of the BN rms profile was found to correlate with the surface field rate dH/dt; e.g., the measurements of magnetically soft materials at the constant field rate (triangular field waveform) reduce a typical two-peak profile to a usual single-peak one [2]. Similar to the hysteresis loss behavior, the BN signal was shown to follow a nearly square root dependence on the magnetizing frequency.

5. Department of Materials Science and Engineering, Iowa State University, Ames, Iowa, United States
6. Department of Physics and Astronomy, Iowa State University, Ames, Iowa, United States

The resonant scattering and diffraction beamline P09 at PETRA III at DESY is equipped with a 14 T vertical field split-pair magnet. A Helium-3 refrigerator is available that can be fitted inside the magnet's variable temperature insert. Here we present the results of a series of experiments aimed at determining the beam conditions permitting operations with the He-3 insert. By measuring the tetragonal-to-orthorombic phase transition occurring at 2.1 K in the Jahn-Teller compound TmVO_{4}, we find that the photon flux at P09 must be attenuated by 4 orders of magnitude for the sample to remain at temperatures below 800 mK. Despite such a reduction of the incident flux and the subsequent use of a Cu(111) analyzer, the resonant X-ray magnetic scattering signal at the Tm L_(III) absorption edge associated with the spin-density-wave in TmNi_{2}B_{2}C below 1.5 K is intense enough to permit for a complete study in magnetic field and at sub-Kelvin temperatures to be carried out.

FR.I-P05 - Measurement of the DC properties of permanent magnets using a Pulsed Field Magnetometer.

M. Hall [1], N. Hillier [1], S. Harmon [1], S.Turner [1]

1. National Physical Laboratory, Middlesex, United Kingdom

In the design of electric motors that use NdFeB magnets the intrinsic coercivity exhibited determines the maximum operating temperature that can be used. A convenient method for measuring this quantity and the changes exhibited with temperature is Pulsed Field Magnetometry (PFM). The pulsed magnetic field applied to the magnet allows the full BH curve to be measured in milliseconds. This is important since when determining the DC properties of permanent magnets, the increase in the magnetic field necessary for reversal of polarization should be performed quasi statically to avoid introducing dynamic errors such as magnetic viscosity.

The measured intrinsic coercivity is known to increase when the polarization reversal time (PRT), the time taken to reduce polarization from 90% to zero, is below a material dependent threshold.

Since industrial measurement systems require a high throughput of measurements, the errors that dynamic measurements, such as the PFM, introduce need to be evaluated. In this paper a detailed study is reported on magnets with intrinsic coercivities ranging from 640 kA/m to 2000 kA/m, measured using a National Measurement Institute grade electromagnetic system. For each magnet a PRT between 2 to 600 seconds was used. The dependence of the measured intrinsic coercivity on the PRT was analysed using published models and a method for correcting the dynamically measured values from a PFM to obtain the required DC value is presented. This work shows that an electromagnet measurement of DC intrinsic coercivity, where the PRT is too short, cannot be used to calibrate the PFM. The effect of saturating the electromagnet's yokes on the measured demagnetization curve will also be presented, which despite producing unphysical reversal behaviour, is shown to still yield the correct intrinsic coercivity.

FR.I-P06 - A giant magneto-impedance magnetometer for magnetic nondestructive detection of corrosion activity

I.a Bardin [1], V. Bautin [1], S. Gudoshnikov [1], B. Ljubimov [2], N. Usov [2]

1. National University of Science and Technology MISiS, Moscow, Russia
2. Pushkov Institute of Terrestrial Magnetism, Ionosphere and Radio Wave Propagation RAS, Oblast, Russia

It has recently been demonstrated [1] that the GMI magnetometer [2] with a sensitivity of approximately 10^{-6} Oe is able to measure the distribution of very weak magnetic fields, of amplitude $H \sim 10^{-4}$ Oe, of corrosion currents existing near an isolated corrosion center of diameter 0.15 cm, simulating pitting corrosion. In this paper we study the magnetic field distribution near the long zinc strip of width 0.12 cm in the copper sample placed in a weak solution of sulfuric acid, which simulates another common type of electrochemical corrosion, the so-called intergranular corrosion. In addition, we study the magnetic field distribution for two corrosion centers of small diameters, depending on the distance between them. The experimental results are compared with the corresponding numerical simulation data. The approximation of the isolated corrosion centers [1] is proved to hold for the case when the distance between the corrosion centers is more or of the order of their diameters. Consequently, the magnetic field distribution for the pitting corrosion, when the corrosion centers are typically scarce and randomly distributed, can be described with reasonable accuracy as a superposition of the magnetic fields of the individual corrosion centers.
We acknowledge funding from Russian Ministry of Education and Science (Grant RFMEF157-514X0011).

FR.I-P07 - CAMEA - Continuous angle multiple-energy analysis a novel neutron spectrometer

F. Groitl [1,2], D. Graf [3], J. Okkels Birk [2], M. Markó [4], M. Bartkowiak [3], U. Filges [3], R. Müller [3], C. Niedermayer [2], C. Rüegg [2], H. Ronnow [1]

1. Laboratory for Quantum Magnetism, ╔cole Polytechnique Fédérale de Lausanne, 1015 Lausanne, Switzerland
2. Laboratory for Neutron Scattering and Imaging, Paul Scherrer Institut, Villigen, Switzerland
3. Laboratory for Developments and Methods, Paul Scherrer Institut, Villigen, Switzerland
4. Neutron Spectroscopy Department, Wigner Research Centre for Physics, Budapest, Hungary

The novel neutron spectrometer concept CAMEA (Continous Angle Multiple Energy Analzyer), developed in collaboration between University of Copenhagen, Danish Technical University, Paul Scherrer Institute (PSI) and École Polytechnique Fédérale de Lausanne (EPFL), will be installed at SINQ at PSI, Switzerland, and will replace the cold triple-axis spectrometer RITA-II. The novelty of the CAMEA design is that it employs a series of several upwards scattering analyser arcs behind each other. This allows each analyser to collect neutrons over different energy ranges and a large solid angle that are measured simultaneously by position sensitive detectors. The result is that in a single data-acquisition an entire constant-energy line in the horizontal scattering plane is recorded for a quasi-continuous angular coverage of about 60°, where tremendous gains in data collection rates can be achieved. Combined, this will result in a state-of-the-art spectrometer, which will be particularly suited for parametric studies under extreme conditions requiring restrictive sample environments such as high magnetic field magnets or pressure cells, and for small samples of novel materials. This project is a joint venture of the Laboratory for Neutron Scattering and Imaging (LNS, PSI), Laboratory for Developments and Methods (LDM, PSI) and the Laboratory for Quantum Magnetism (LQM, EPFL) financed by the R'Equip program of the Swiss National Science Foundation (SNF) and the EPFL.
We will present the instrument concept, performance simulations, technical solutions and prototype verifications.

[1] Reports on the CAMEA projects can be found here: http://lqm.epfl.ch/page-66994-en.html

FR.I-P08 - Application of electroplated magnetic gratings for high-resolution position sensing

Z. Xu [1], B. Tseng [2], C. Hung [1], C. Chang [2], S. Wang [3], T. Chin [2], C.Sung [1]

1. Department of Power Mechanical Engineering, National Tsing Hua University, Hsinchu City, Taiwan
2. Department of Materials Science & Engineering, Feng Chia University, Taichung City, Taiwan
3. Department of Mechanical Engineering, National United University, Miaoli Country, Taiwan

Unlike optical encoders, magnetic encoders are applicable in a harsh environment involving dust, oil and splash fluids. To improve the resolution of a magnetic sensing system, the pole pitch has to be fine enough. However, conventional magnetization process requires a complicate magnetizing system and time consuming. It is difficult to achieve pole pitches finer than 1 mm. This paper proposes a new method to prepare magnetic gratings by using lithography to define grooves of photoresist then to electroplate permanent magnetic layer of CoP into grooves. The gratings are magnetized in unison by a single pulsed field in a solenoid. Magnetic gratings were designed and simulated by a commercial software Maxwell, including magnetic properties, demagnetizing factors, and magnetization directions. Then suitable shapes and thickness with respect to time were also simulated by the software Consol. CoP layers were electroplated with various power modes that included pulsed current, pulsed voltage, constant current and constant voltage. Magnetic hysteresis loops were measured by a vibrating sample magnetometer. After the magnetic grating was magnetized with a solenoid coil by a single pulse, the resultant magnetic flux density was detected by using a Hall sensor. According to experimental results, the best electroplating conditions were: pH 4.52 at 24óJ under constant current mode. The best magnetic properties in a parallel field are: Br 550 mT and Hc 76.9 kA/m at the current density 5 mA/cm2. The shapes of the gratings are well patterned by lithography and electroplating to have a 400-um-pitch and a 200-um-width. After magnetization, the peak-to-peak amplitude of Bz is 6.2 mT at parallel magnetizing, and the half periodicity of the sinusoidal magnetic flux density from the grating is 200 um. These are crucial for decoding the signal by a thousand fold to obtain a resolution approaches 200 nm for incremental positioning.

FR.I-P09 - In-situ magnetic studies on LixCoO2 battery cathodes during charging/discharging

S. Topolovec [1], H. Kren [2], G. Klinser [1], S. Koller [2], H. Krenn [3], R. Würschum [1]

1. Institute of Materials Physics, Graz University of Technology, Graz, Austria
2. VARTA Micro Innovation GmbH, Graz, Austria
3. Institute of Physics, University of Graz, Graz, Austria

In-situ magnetic measurements during electrochemical charging, with the purpose to tune magnetic properties by electrochemical processes, have recently attracted considerable attention (i.e. [1-3]). As the magnetic properties of the technologically important Li-ion battery electrode materials are sensitive to phase composition, structural disorder, defects and the oxidation state of the transition metals ions [4], such in-situ magnetic studies could also be used to provide insights into the electronic and chemical processes during charging.
Based on our recent electrochemical in-situ experiments in a SQUID [2,3] we have designed an electrochemical cell allowing in-situ measurements of the magnetic susceptibility of commercially used battery electrodes during charging/discharging. This is demonstrated by the example of Li_xCoO_2 cathodes, which show reversible variations of the magnetic susceptibility χ of up to 167% with lithium de-/intercalation. For lithium contents $1>x\geq0.77$ the susceptibility χ, which is mainly attributed to a Pauli-paramagnetic component, varies linear with charging. This indicates a linear rise of $D(E_F)$ with Li extraction. For $x<0.77$ the variation of χ can be assigned to alterations of the Co oxidation state, revealing that in addition to Co also O undergoes partial oxidation during charging. An observed further increase of χ at the beginning of the discharging process may indicate the formation of Co^{2+} during reduction. The sensitive in-situ technique opens up a new pathway for studying the kinetics of the atomic processes underlying the charging-induced property variations in solids.

FR.I-P11 - A new bench concept for measuring magnetic fields of big closed structures

J. Campmany [1], J. Marcos [1], V. Massana [1], C. Colldelram [1], L. Ribó [1], F. Becheri [1]

1. CELLS - ALBA Synchrotron, Barcelona, Spain

The measurement of big closed magnetic structures is becoming a challenge of great interest. The main reason is the tendency towards building accelerators with high magnetic fields produced by small gap magnets, as well as the development of cryogenic or superconducting narrow-gap insertion devices. Usual approach, based on side-measurements made with a Hall probe mounted on the tip of a motorized arm based on a long granite bench is no more applicable to such closed structures. So, new concepts and approaches have been developed, mainly based on complex devices that insert a Hall probe inside the magnetic structure maintaining the desired position by close-loop controls. The main problem of these devices is that they are not general-purpose oriented: they need a special vacuum chamber, require a specific geometry of the magnetic structure, or does not provide 3D field-map measurements. We present in this paper a new bench that has been built at ALBA synchrotron that is simple, multi-purpose and can be a general solution for measuring big closed structures. Motion control is done via ICEpap using the new trigger feature that has been implemented in this motor controller.

FR.I-P12 - New improvements in magnetic measurements laboratory of the ALBA synchrotron facility

J. Campmany [1], J. Marcos [1], V. Massana [1]

1. CELLS - ALBA Synchrotron, Barcelona, Spain

ALBA synchrotron facility has a complete ID laboratory to characterize and produce the insertion devices and magnetic devices needed to satisfy the requirements of ALBA user's community. The laboratory is provided with a Hall-probe bench working in on-the-fly measurement mode allowing the measurement field maps of big magnetic structures with high accuracy, both in magnetic field magnitude and position. The whole control system of this bench is based on TANGO. The Hall probe calibration range extends between sub-Gauss to 2 Tesla with an accuracy of 100 ppm. Apart from the Hall probe bench, the ID laboratory has a flipping coil bench dedicated to measure field integrals and a Helmholtz Coil bench specially designed to characterize pure permanent magnetic blocks. Also, a fixed stretched wire bench is used to measure field integrals of magnet sets. This device is specifically dedicated to insertion devices construction. Finally, the laboratory is equipped with a Rotating coil bench, specially designed for measuring multipolar devices used in accelerators, as quadrupoles, sextupoles, etc. Last improvements of the magnetic measurements laboratory of ALBA synchrotron include the design and manufacturing of very thin 3D Hall probe heads, the design and manufacturing of coil sensors for the Rotating coil bench based on multilayered PCB, and the improvement of calibration methodology in order to improve the accuracy of the measurements. ALBA magnetic measurements laboratory is open for external contractors, and has been widely used by national and international institutes as CERN, ESRF or CIEMAT, as well as magnet manufacturing companies, as ANTEC, TESLA or I3M. In this paper we will present the main features of the measurement benches as well as the last improvements made so far.

FR.I-P13 - Magnetic vector potential formulation forstress intensity factorscalculation by eddy currenttesting

S. Harzallah [1], M. Chabaat [1], S. bensaad [1]

1. University of Sciences and Technology HouariBoumediene, Bab Ezzouar, Algeria

A new method for computing the Stress Intensity Factor (SIF) by measuring and testing related Eddy currents is considered. In the process, a magnetic vector is provided on the basis offormulationstaken from thetheoretical set up.Thus, results of relevant applications are obtained to check the theoryconsistency.A simulation by a numerical approach using the finite element method is employed to detect cracks and damaged zones in Magnetic materials and eventually to study their propagation. Crucial parameter such as a SIF is determined.This method has emerged as one of the most efficient technique for prospecting cracks in materials, evaluating SIFs and analyzing crack's growth in the context of linear elastic fracture mechanics (LEFM). Crack's growth is analyzed as a model by combining the maximum circumferential stress criteria with the critical plane for predicting the direction of crack's propagationinmagnetic materials. On the other side,SIFfor these models are calculated using the domain form of the J-integral.This latest is an important parameter in LEFM for the integrity assessment of structures containing cracks. It is proven herein that these measurements givethe intensity of a stress field in the vicinity of a crack tip andalso allow the possibility of analyzing crack's growth until a catastrophic failure.

FR.I-P14 - Numerical modeling of Barkhausen magnetic noise

A. Zaoui [1], L. Cherifi [1]

1. Ecole Militaire Polytechnique, Bordj El Bahri, Algeria

In this work, a numerical modeling of Barkhausen magnetic noise (MBN) phenomenon is proposed. The developed model is based on the coupling between the quasi-static formulation of Maxwell's equations using the vector magnetic potential A and the microscopic model of BN. The resolution of this model is obtained by the finite difference method where the microscopic model of BN is introduced at the level of each discretization cells. The numerical model has enabled us first, to plot the hysteresis loop, and also to get the BN.
An experimental test bench is built and the simulated signal obtained from the numerical model is similar to measured one. The numerical model is developed for the study and the tuning parameters of the BN nondestructive evaluation technique.
The MBN signal obtained for different types of metals is presented and the effect of the different metallurgical treatment techniques is highlighted on the response of the signal.

FR.I-P15 - Radiation pressure excitation of low temperature atomic force & magnetic force microscope (LT-AFM/MFM) for imaging

O. Karc² [1], U. Celik [1], Y. Uysalli [2], H. Ozgur Ozer [3], A. Oral [2]

1. NanoMagnetics Instruments Ltd., Ivedik, Turkey
2. Orta Dogu Teknik Universitesi, Ankara, Turkey
3. Istanbul Technical University, Istanbul, Turkey

We describe a novel method for excitation of Atomic Force Microscope (AFM) cantilevers by means of radiation pressure for imaging in an AFM for the first time. Piezo excitation is the most common method for cantilever excitation. However, it has quite a few drawbacks like causing spurious resonance peaks and non-ideal Lorentzian curves. Radiation pressure excitation is an alternative method for cantilever excitation1,2,3 however it has never been used for imaging before.
A fiber optic interferometer with 1310 nm laser was used both to measure the deflection of cantilever and apply a force to the cantilever in a LT-AFM/MFM from NanoMagnetics Instruments. The laser power was modulated sinusoidally at the cantileveræs resonance frequency utilizing a digital Phase Lock Loop (PLL). The force exerted by the radiation pressure on a perfectly reflecting surface by a laser beam of power P is F = 2P/c. For 3 mW laser power, the force exerted by radiation pressure is calculated to be 20 pN for 5 N/m cantilever, which will deflect the cantilever 4 pm. Typical Q factor in air is 200 and the final amplitude of oscillation will be 8 nm. We can obtain much larger Q values, ~ 8,000 and hence larger oscillation amplitudes when we evacuate the system to 2.5x10-4 mbar. The cantilever's stiffness can be accurately calibrated by using the radiation pressure. We shall demonstrate tapping mode AFM image of a calibration grating at 300 K and MFM images of a harddisk sample with radiation pressure excitation at 300 K and 4 K.

FR.I-P16 - 1fm/√Hz Noise Level Low Temperature Atomic Force & Magnetic Force Microscope (LT-AFM/MFM) in 20mK-300K Temperature Range

O. Karc² [1], U. Celik [1], M. Dede [1], A. Oral [2]

1. NanoMagnetics Instruments Ltd. , Ivedik, Turkey
2. Orta Dogu Teknik Universitesi, Ankara, Turkey

We describe the design of a new low temperature Fabry-Perot interferometer for LT-AFM/MFM operating in 20mK-300K Temperature range. We used a multilayer dielectric mirror coated optical fiber to achieve 1fm/√Hz Noise Level, while the shot noise limit was 0.16fm/√Hz. The fibre can be brought very close to the cantilever using a dedicated 2mm stroke piezo nanopositioner integrated in the piezo tube scanner. The same nanopositioner is used to park the fibre to a safe parking location during cantilever exchange. The LT-AFM/MFM can be used between 6µW-3mW laser power. We have demonstrated performance of the LT-AFM/MFM by imaging a hard disk sample between 1.5-300K and Abrikosov vortex lattice in BSCCO single crystal at 4K.

FR.I-P17 - An ultra-low temperature scanning hall probe microscope (SHPM) for magnetic imaging below 40 mK

O. Karc² [1], J. Piatek [2], P. Jorba [2], M. Dede [1], H. Ronnow [2], A. Oral [3]

1. NanoMagnetics Instruments Ltd., Ivedik, Turkey
2. Laboratory for Quantum Magnetism, Ecole Polytechnique Federale de Lausanne (EPFL), Lausanne, Switzerland
3. Orta Dogu Teknik Universitesi, Ankara, Turkey

We describe the design of a low temperature scanning Hall probe microscope (SHPM) for a dilution refrigerator system. A detachable SHPM head with 25.4 mm OD and 200 mm length is integrated at the end of the mixing chamber base plate of the dilution refrigerator insert (Oxford Instruments, Kelvinox MX−400) by means of a dedicated docking station. It is also possible to use this detachable SHPM head with a variable temperature insert (VTI) for 2 K–300 K operations. A microfabricated 1μm size Hall sensor (GaAs/AlGaAs) with integrated scanning tunneling microscopy (STM) tip was used for magnetic imaging. The field sensitivity of the Hall sensor was better than 1 mG/√Hz at 1 kHz bandwidth at 4 K. Both the domain structure and topography of LiHoF4, which is a transverse-field Ising model ferromagnet which orders below TC=1.53 K, was imaged simultaneously below 40 mK.

FR.I-P18 - Broadband dynamic permeability measurements of a single micronic ferromagnetic flake

A. Adenot-Engelvin [1], M. Ledieu [1], J. Neige [2], N. Vukadinovic [3]

1. CEA Le Ripault, Monts, France
2. Sherbrooke OEM, Sherbrook, Canada
3. Dassault Aviation, Saint-Claud, France

Ferromagnetic flakes made of FeSiAl or of soft magnetic alloys are widely used as ferromagnetic constituents in composites for electromagnetic shielding of RFID antennas [S. Yoshida et al, J. Appl. Phys., vol. 85, n°8, pp. 4636- 4638, 1999]. The high-frequency response of such composites is usually measured by means of coaxial line or shorted microstrip techniques. In the last case, the zero-field permeability spectra measured on NiFeMo flake composites revealed a low-frequency resonance below 100 MHz, recently interpreted as an embedded vortex translation mode, and a broad high-frequency resonance above 2 GHz corresponding to the natural ferromagnetic resonance [J. Neige et al, Appl. Phys. Lett., vol. 102, p. 242401, 2013]. An open question is how to connect the permeability spectrum of such composites with that of a single flake. To tackle this issue a setup has been developed to measure the permeability measurement of a micrometric flake, free from couplings. The RF excitation is obtained by a copper micro-loop, which acts like an electrical short circuit between the inner and the outer conductors of a small diameter coaxial line. This setup allows the application of a static magnetic field in the plane of the flake. The dynamic permeability measurements of single flakes were performed in the frequency range 1 MHz-20 GHz [J. Neige et al, Appl. Phys. Lett., vol. 104, p. 162402, 2014]. The zero-field permeability spectrum shows two main contributions: a resonance at 50 MHz and the natural spin resonance at 2.8 GHz, in accordance with the composite permeability spectrum. In addition, it is shown that the edge roughness of flake affects the permeability spectrum. Permeability measurements have been performed on square-shaped samples of similar size. By analogy with these samples, a shouldering appearing at intermediate frequency in the single flake spectrum has been identified as domain wall excitations.

FR.I-P19 - Nuclear GISAXS superstructure peaks for characterization of antiferromagnetically ordered nanostripes

L. Dzemiantsova [1,2], K. Schlage [2], L. Bocklage [1,2], H. Wille [2], D. Erb [2], G. Meier [1,3], R. Roehlsberger [1,2]

1. The Hamburg Centre of Ultrafast Imaging, Hamburg, Germany
2. Deutsches Elektronen Synchrotron, Hamburg, Germany
3. Max-Planck Institute for the Structure and Dynamics of Matter, Hamburg, Germany

Magnetic superstructure reflections have been extensively used for more than twenty years to characterize the vertical spin profile in multilayer structures like antiferromagnetically coupled superlattices. To investigate the lateral spin configuration of ordered nanostructure patterns, we employ a new scattering technique based on resonant GISAXS superstructure peaks, namely grazing incidence nuclear small-angle X-ray scattering (nuclear GISAXS). This synchrotron based x-ray scattering technique is highly sensitive to the magnetic moment orientation and uniquely offers a background free nuclear signal. We perform GINSAXS at the Dynamics beamline P01 at PETRA III to study the lateral magnetic configuration in isotopically enriched permalloy nanostripes during magnetic reversal and to detect a ferro- and an antiferromagnetic state. The origin of this state is the difference in nanostripes which are with and without pads for nucleation of domain walls. We measure a conventional GISAXS pattern of the sample, exhibiting a large number of diffraction maxima, where the angular spacing is determined by the lateral distance of the stripes (250 nm). We find that the nuclear GISAXS line scan of the saturated sample is characterized by diffraction maxima at the same angular position as the electronically scattered GISAXS intensity. Additional strong nuclear superstructure peaks appear when the sample is brought into the antiferromagnetic state. The field dependent intensity of these resonant GISAXS superstructure peaks is a powerful measure of the antiferromagnetic contribution in the sample and is highly suitable to study the lateral saturation behavior. With GINSAXS, it will be possible to magnetically characterize complex ordered structures such as spin ice and skyrmions with sub-nm resolution, even under different conditions of pressure and temperature which is hardly accessible for most surface-sensitive magnetic techniques. The technique can be further developed to study spin dynamics from selected parts of a periodic sample.

FR.I-P20 - Investigation of vortex chirality via local hysteresis loops measured by magnetic force microscopy

M. Coisson [1], G. Barrera [1,2], F. Celegato [1], A. Manzin [1], F. Vinai [1], P. Tiberto [1]

1. INRIM, Torino, Italy
2. University of Torino, Chemistry Department, Torino, Italy

Magnetic force microscopy (MFM) is a valuable technique to investigate the reversal mechanisms of the magnetisation in patterned films that are not accessible to magneto-optical methods. A field-dependent MFM-derived technique has been recently exploited to measure local hysteresis loops (LHL) on sub-micrometric magnetic structures, consisting in repeatedly scanning the same profile of the sample by disabling the slow scan axis while synchronously changing the magnetic field. A suitable analysis of the phase channel in pass 2 provides a means of investigating the magnetisation reversal processes. In the present work, this technique is exploited to control and measure the vortex chirality on square dots of Ni80Fe20 (lateral size 800 nm, thickness 30 nm) prepared by EBL. LHL are significantly affected by vortex chirality: when it is inverted between the first and second loop branch, symmetric hysteresis loops are observed, whereas when the chirality is preserved the LHL turn out to be asymmetric. Micromagnetic simulations have been performed on dots having the same shape, size and composition to calculate their domain configuration as a function of the applied field, by also taking into account the tip-sample interaction. The corresponding MFM images have been calculated from the magnetisation distribution in the dot. These simulated MFM images, that correspond to the experimental ones, allow the determination of the LHL as if they were measured by the exploited MFM-derived technique. The experimental loops shape and their different symmetries have been accurately reproduced. The tip-sample interaction tourned out to have negligible effects on the magnetisation configuration of the dot, but can be exploited to induce vortex nucleation along a specific dot edge, and therefore to accurately control vortex chirality. Via LHL measurements, these effects can be observed and the results of the simulations have been experimentally confirmed.

FR.I-P21 - Transversal mapping of Gd concentration in UO_2-Gd_2O_3 nuclear fuel pellets

D. Tobia [1,2], E. L. Winkler [1], J. Milano [1], A. Butera [1], R. Kempf [3], L. Bianchi [4], F. Kaufmann [4]

2. Instituto de Física "Gleb Wataghin", UNICAMP, Campinas (SP), Brazil
3. División Caracterización de Combustibles Avanzados, Gerencia Ciclo Combustible Nuclear, Centro Atómico Constituyentes - CNEA, San Martín, Pcia. de Buenos Aires, Argentina
4. Departamento de Combustibles Avanzados, Gerencia Ciclo Combustible Nuclear, Centro Atómico Constituyentes - CNEA, San Martín, Pcia. de Buenos Aires, Argentina

One of the major challenges of the nuclear industry is the research and development of new materials in order to extend the fuel lifetime, increase the burn-up and optimize the power density distribution. With this aim Gd is usually incorporated into the UO_2 nuclear fuel as a burnable poison, due to its high cross section for neutron absorption. However, the fabrication process of the solid solution (U, Gd)O_2 and the amount of Gd incorporated could affect some physical and chemical properties, that can eventually alter the proper and safe performance of this fuel in reactors, as well as the stability in storage and disposal conditions. Within this frame, it is crucial the search of new and more precise analysis techniques that allow a better characterization of Gd content and distribution in the fuel pellets.[1] Due to its high sensitivity, electron paramagnetic resonance spectroscopy (EPR) emerges as an excellent candidate to carry out this goal. In this work we present a method to measure with a very high precision the transversal mapping of the Gd concentration in UO_2-Gd_2O_3 nuclear fuel pellets by EPR.[2]The quantification of Gd^{3+} ions in the UO_2 matrix was made from the direct comparison with a Gd_2O_3 reference sample. The simple protocol employed allows to determine the relative concentration of Gd in UO_2 with an error smaller than 5%. The nominal concentration in the pellets is UO2: 7.5% Gd_2O_3. However, a concentration gradient was found, which indicates that the Gd2O3 amount diminishes towards the edges of the pellets. The concentration varies from (9.3 ± 0.5)% in the center to (5.8 ± 0.3)% in one of the edges.

FR.I-P22 - Diffraction-limited optical imaging of ferroelectricity and magnetism

O. Vlasin [1], B. Casals [1], N. Dix [1], F. Sánchez [1], G. Herranz [1]

1. Icmab-Csic, Bellaterra, Spain

The electrical polarization in ferroelectrics as well as the magnetization in ferromagnets can be exploited for digital processing and storage. In this regard, a deep understanding of the dynamics and the local response of these materials is crucial for the comprehension of the mechanisms underlying the endurability, retention and fatigue effects in ferroelectric or magnetic devices. Optics is particularly well suited to peer noninvasively into the local responses of both ferroelectric and magnetic properties. Although the spatial lateral resolution cannot beat the ultimate nanoscale resolution of scanning proximity probes, light polarization comes along with the advantage of being sensitive to magnetism and ferroelectricity simultaneously, giving optics an edge over other experimental approaches.
Here we present a comprehensive experimental methodology that exploits electro-optics and magneto-optics as probes of ferroelectricity and magnetism, respectively. For that purpose, confocal optical microscopy was adapted to measure the rotation and ellipticity of the polarization of light with diffraction-limited lateral resolution. As a showcase study, we have imaged the birefringence of ferroelectric $BaTiO_3$ and manganite La2/3Sr1/3MnO3 thin films. In the particular case of the ferroelectric, we further disentangled the contributions arising from electro-optics -linked to ferroelectricity- as well as strain - arising from converse piezoelectricity-, so that both properties were mapped out simultaneously. Remarkably, in spite of the high quality of the films under study, the optical imaging displayed inhomogeneous spatial distributions of both ferroelectric- magnetic- and strain-related responses, so that they exhibited significant fluctuations in the scale of the micrometer. Our work underscores the relevance and impact that these variations may have when ferroelectric or magnetic materials are downscaled to small sizes.

FR.I-P24 - Magnetic classification in wet-mode: proofs of concept, and applications.

P. Augusto [1], T. Castelo-Grande [2], A. M Estevez [1], P. M Costa [1], D. Barbosa [2], C. Torrente [1]

1. APLICAMA - Dep. Chem Engineering - Fac Chem Sciences - Univ Salamanca
2. LEPABE, Departamento de Engenharia Química, Faculdade de Engenharia da Universidade do Porto, Rua Dr. Roberto Frias, Porto, PORTUGAL

We have developed recently an indirect proof of concept (POC) of magnetic classification in wet mode. This POC, was accompanied by another one, concerning fundamental background theory and simulations. Both POC's proved the feasibility of the process and specially have allowed to determine the influence of some of the force balances and some of the main parameters in fluid media. Based on the preliminary results we are now ready to develop, design and control a larger scale device for future applications, and to strength the proof of concept by direct determination.
Bearing in mind the systems and trajectories obtained we were able to conclude that magnetic classification was able to be achieved with the classes differences shown in Table 1.

Magnetic array touching the walls		$\frac{F_{m1}}{F_{m2}} = \frac{BVB_1}{BVB_2}$	$\frac{F_{m1}}{F_{m2}}$	*extrapolated* $\frac{\chi_1}{\chi_2} = \frac{F_{m1}}{F_{m2}}$

Table 1. Results obtained.

Developing this processing techniques allow us to selectively separate and purify several substances at the same step and in the same device, especially in what concerns biomedical applications (ranging from diagnostics until treatment of diseases), mineral processing, water treatment and recycling, as modern technologies are still very limited regarding this goal. The main applications and the improved given by magnetic classification will be also detailed.

FR.I-P26 - Elastic scattering of electron vortex beams through magnetic matter

A. Edström [1], A. Lubk [2], V. Grillo [0], J. Rusz [1]

1. Uppsala University, Uppsala, Sweden
2. Technische Universitõt Dresden, Dresden, Germany

4. CNR-IMEM Parco Area delle Scienze 37/A, Parma, Italy

Recently, electron vortex beams, i.e. electron beams carrying orbital angular momentum (OAM), have gained much attention as a promising route to measure magnetic properties of materials with high spatial resolution in inelastic electron scattering experiments. One challenge to still overcome is poor signal to noise ratio. Due to recent progression in producing beams with very high OAM (in the order of 100xPlanck's constant) [1], a new route to overcome this could potentially be elastic scattering of high OAM vortex beams. In order to investigate this possibility, we derive a model to describe the magnetic interaction of vortex beams with magnetic matter and, based on this model, present simulations evaluating this potential route to atomic resolution magnetic measurements.

FR.I-P27 - A firmware-defined digital direct-sampling NMR spectrometer for condensed-matter physics

M. Pikulski [1], T. Shiroka [1, 2], H. Rudolf Ott [1], J. Mesot [1,2]

1. Laboratorium für Festkörperphysik, ETH Zürich, Zürich, Switzerland
2. Paul Scherrer Institut, Villigen, Switzerland

Nuclear magnetic resonance (NMR) instrumentation employed in condensed-matter physics typically relies on purpose-built hardware, which in most cases involves analog signal-processing components. This approach implies high initial costs and/or significant constructional efforts. By contrast, modern high-performance radio- processing devices are capable of directly sampling and emitting signals throughout the NMR frequency range. In addition, they often feature field-programmable gate arrays (FPGAs), which allow for real-time control and data processing. Hence, fully soft- and firmware-defined solutions are feasible, promising unprecedented levels of flexibility. We report the implementation of a novel type of NMR spectrometer applying these techniques and demonstrate its ability to meet the special demands of condensed-matter NMR. Besides regular laboratory- applications, our approach may be interesting in situations where the number of repeated acquisitions is limited, such as low-temperature and pulsed magnetic-field experiments, since it combines large bandwidth and accurate data acquisition.

FR.I-P28 - Quantitative analysis of shadow X-ray magnetic circular dichroism photo-emission electron microscopy

S. Jamet [1,2], S. Da-Col [1, 2], N. Rougemaille [1,2], A. Wartelle [1,2], A. Locatelli [3], T. Onur Mentes [3], B. Santos Burgos [3], S. Bochmann [4], J. Bachmann [4], R. Afid [1,2]

2. CNRS, Institut NEEL, Grenoble, France
3. Elettra - Sincrotrone Trieste S.C.p.A., Trieste, Italy
4. Univ Erlangen, Department of Chemistry, Germany

Shadow X-ray Magnetic Circular Dichroism Photo-Emission Electron Microscopy (XMCD-PEEM) is a recent technique, in which the photon intensity in the shadow of an object lying on a surface, may be used to gather information about the inner magnetic structure of the object. It is attractive as both surface information (through usual photo-emission from the object) and volume information may in principle be extracted, whose combination may be crucial to identify complex three-dimensional magnetization textures. Recently we applied it to formally identify the Bloch-point domain wall in cylindrical nanowires 100nm in diameterá[PRB89, 180405 (2014)].
Our ongoing purpose is to lay the basis of a quantitative analysis for this technique. We first discuss the principle and implementation of a method to simulate the contrast expected from an arbitrary micromagnetic state. The simulation is based on finite elements micromagnetics. The intensity of X-ray beams is computed along their path in matter, depending on the dichroic contrast and the local direction of magnetization. From this, the magnetic image is simulated quantitatively both at the surface of the magnetic object, and in its shadow. An excellent agreement is shown with both test cases and experiments.
We also discuss instrumental settings having an impact on the contrast and spatial resolution. For instance, the strength of both dichroism and the absorption length may be changed through the choice of the absorption edge, and adapted to each situation. In principle the contrast in the shadow increases for higher absorption, however in practice it is limited by the S/N ratio, and also the background level of the PEEM, which we evidenced experimentally. The microscope extraction voltage and plane of focus may also be used, to enhanced the surface or the volume contrast.

FR.I-P29 - Magnetic moment measurement utilizing single magnetometer and levenberg-marquardt algorithm

M. Nowicki [1], D. Jackiewicz [2], R. Szewczyk [1]

1. Initute of Metrology and Biomedical Engineering, Warsaw University of Technology, Warsaw, Poland
2. Industrial Research Institute for Automation and Measurements, Warsaw, Poland

Helmholtz coils connected to the integrator are a well-known method of magnetic moment measurement, taking also into account the magnet geometry. The coils themselves must have proper dimensions for the measured object. Besides this, standardized magnets are often needed to calibrate the system. Therefore, it is a problematic procedure for a single measurement, or the small-scale production testing. In the paper, a procedure for magnetic moment measurement, utilizing single sensitive magnetometer is described. The object under test, for example a permanent magnet, is swept along the sensitive axis of the stationary magnetometer, and the magnetic field strength is recorded, as well as the sample's precise position. The results of measurement are then processed in the Matlab software, and the non-linear least squares curve fitting is done using the Levenberg-Marquardt algorithm. The fitting is performed for the magnetic dipole magnetic field strength versus distance equation. The important factor is that the distance of the first measurement point from the measured object is also treated as unknown, and thus not essential to perform the procedure. Therefore only the information of the magnetic field strength value in measurement points, and the distance between them, is needed for the magnetic moment measurement. To evaluate the proposed method, a laboratory test stand was constructed. The first part of the test stand consist of the Helmholtz coil and precise fluxmeter setup for the reference magnetic moment measurement. The second part consist of magnetoresistive magnetometer, and a linear table for sample manipulation. The measurements of the magnetic moment were done for the Alnico, NdFeB and SmCo permanent magnets. High reproducibility of the results was achieved, with better than 5% accuracy. Additionally, with proper scaling, the proposed method allows for magnetic moment measurement of larger and more complicated objects, for which the standard method would be impractical.

FR.I-P30 - In-situ observation for reaction sintering behavior of Bi-Mn alloy in high magnetic fields

D. Miyazaki [1], Y. Mitsui [1], K. Abematsu [1], K. Takahashi [2], S. Uda [2], K. Watanabe [2], K. Koyama [1]

1. Faculty of Science, Kagoshima University, Kagoshima, Japan
2. Institute for Materials Research, Tohoku University, Miyagi, Japan

The application of high magnetic fields for synthesizing process of magnetic material have been performed for controlling phase equilibrium, microstructure, diffusion, and so on. Recently, it was found that the reaction sintering of ferromagnetic MnBi phase is also influenced by magnetic fields [1].
For understanding the magnetic field effect on synthesizing process of MnBi, in-situ observation is one of the important techniques. Recently, we have developed an in-situ observation system with differential thermal analysis (DTA) in high magnetic fields, which is utilized by combining the cryogen-free superconducting magnet with 100 mm room temperature bore [2]. In this study, in order to investigate the magnetic field effect on reaction sintering process from Bi + Mn to ferromagnetic MnBi, in-situ observation of reaction sintering were carried out.
The pellets of Bi-50at.%Mn and Bi-20at.%Mn were prepared by pressing the mixed powder Mn and Bi. The heat treatments were carried out at 520 K for 6 hours in a zero field and 10 T. Here, the annealing temperature was just below the eutectic temperature of Bi and Mn. So that, ferromagnetic MnBi phase is synthesized by solid-state reaction.
For Bi-20at.%Mn, it is found that the surface of the sample slightly changed during the reaction in 10 T. After the heat treatment, the sample shows ferromagnetism, resulting the synthesis of ferromagnetic MnBi phase from Bi and Mn. On the other hand, reaction process is not observed clearly from DTA signal because the reaction is very slow.

FR.I-P31 - Development of a rapid temperature scanning system for pulsed magnetic fields and its applications

K. Mochidzuki [1], Y. Kohama [1], K. Kindo [1]

1. International MegaGauss Science Laboratory, The Institute For Solid State Physics, The University of Tokyo, Tokyo, Japan

A pulsed magnet provides us a way to access the extremely high magnetic field range (above 50 T) and is an effective tool to explore exotic physical properties of the strongly correlated materials such as high-Tc superconductors, heavy fermions and so on. However, owing to the short time duration of a pulsed magnet at best a few seconds, it was difficult to measure a temperature dependence of a physical property under pulsed magnetic fields. To overcome this difficulty, we have developed an apparatus that has a short relaxation time of 0.01-1 ms between the sample and the platform on which a film thermometer and a film heater are deposited, and have succeeded in measuring temperature dependencies of the specific heat and resistivity on a short time-scale of pulsed magnetic fields.[1] More recently, we have found that this apparatus also enables to measure other physical quantities (dielectric polarization) as a function of temperature. In this poster presentation, we will describe the details of our measurements and discuss an advantage (and disadvantage) of using our apparatus.

FR.I-P32 - Application of thermal expansion and magnetostriction measurements using PPMS

S. Tateno [1], N. Kishii [1], M. Ohashi [1]

1. Kanazawa University, Ishikawa, Japan

We report a bridge circuit-type detector that has a simple structure and high accuracy with a low degree of error when measuring thermal expansion and magnetostriction by a strain gage method using a commercial PPMS (physical property measurement system, Quantum Design). A compact bridge circuit is connected between a cryostat and the bridge board, which is the primary hadrware component on the Model 6000 PPMS controller. Thermal expansion and magnetostriction is calculated from the resistance of the bridge and the bridge voltage, which is measured by the operation of a standard PPMS resistivity option. Its performance is demonstrated by measuring the temperature and the magnetic field dependences of the expansion of some rare earth compounds.

FR.I-P34 - High-frequency ESR measurements of lightly phosphorous doped silicon at low temperatures and their extension to lower temperatures for high B/T ratio

Y. Fujii [1], S. Mitsudo [1], K. Morimoto [2], T. Mizusaki [1], M. Gwak [3], S. Lee [3], A. Fukuda [4], A. Matsubara [5], T. Ueno [6], S. Lee [7]

One of the most practical quantum computer designs reported so far is the system consisting of phosphorus (P) atoms in silicon (Si) crystal as proposed by B. Kane [1]. However, experimental demonstration has not been done yet. One of the remaining unknown properties of this device essential for the realization of Kane's model is spin dynamics including dynamic nuclear polarization phenomena at very low temperatures below 0.1 K and under high magnetic fields above 2 T. These conditions are required for Kane's model. In order to investigate the feasibility of Kane's model, we have been studying phosphorous-doped silicon (Si:P) by magnetic resonance [2]. In Si:P, the donor electrons are well localized around the donor ions if the donor concentration is below the critical doping concentrati on, n_c = 3.7 x 10^18 cm^-3, while they are delocalized above n_c. We have measured T1 and T2 relaxation times of donor electrons in Si:P with the concentration n = 6.5 x 10^16 cm^-3 with a W-band (94 GHz) pulsed ESR system. The spin-lattice relaxation rate 1/T1 rapidly decreases with decreasing temperature below 30 K down to approximately 4 K. Below 4 K, 1/T1 ~ T due to the phonon-direct relaxation mechanism. These behaviors are qualitatively the same as the data extrapolated from X-band ESR data and our previous data from cw-ESR measurements at 80 GHz [2], though the measured values from pulsed ESR are slightly smaller than them. In order to study the spin dynamics of 31P in the mK regime, we have constructed a magnetic resonance system with a 3He/4He dilution refrigerator and succeeded to detect ESR of Si:P with this system. We will also report the detail of this system.

2. Warsaw University of Technology, Institute of Metrology and Biomedical Engineering, Warsaw, Poland
3. Institute of Electronic Materials Technology, Warsaw, Poland

The Hall-effect sensors are used in many industrial applications and are the most common type of sensors in the market of industrial measurements of magnetic field [1]. Paper presents newly developed Hall-effect sensors made of graphene for measurements of magnetic flux density.
Graphene is a 2-dimensional crystalline allotrope of carbon, where atoms are organized into sp^2-bonded hexagonal pattern [2]. Recent studies indicates that graphene, with high electron mobility (up to 5 000 cm^2/Vs) [3] and carrier concentration, allows to obtain significantly higher sensitivity than materials used for Hall-effect sensors so far.
The investigated graphene Hall-effect structure was manufactured using new and original method based on Chemical Vapor Deposition (CVD). Graphene layer was grown on the Si face of SiC substrate in hot-wall CVD Aixtron VP508 reactor.
Digitally controlled measurement system, utilizing Helmholtz coils as a source of reference magnetic field, was developed to measure basic functional properties of graphene structures.
Investigated graphene Hall-effect structure is characterized by low value of offset voltage (3,4 mV with supply current value 10 mA) and significantly high sensitivity ($4{,}92 \cdot 10^{-1}$ V/T with 10 mA supply current). Both sensitivity and offset voltage are proportional to the supply current. Sensitivity of the structure has high stability over time. The relative deviation from the average value is lower than 0,2%. Value of offset voltage is decreasing over time at an average rate of 0,006 mV/h. Measured sheet resistance of the structure is 247 Ω/sq. The obtained results confirmed that graphene may be the good material for Hall-effect sensors.

FR.I-P37 - M-H loop tracer for low frequency measurements: ribbons, powders and wires

J.J. Suñol [4], J. Bonastre [1], I. Santandreu [2], Ll. Escoda [3]

1. University of Girona, Girona, Spain

Measurement of a hysteresis loop is a very simple and fast method to characterize ferromagnetic materials. In this work, a high-performance home-made M-H loop tracer has been developed to measure low frequency magnetic hysteresis loops of soft magnetic samples. Commercially available hysteresis loop tracers and magnetic devices are usually designed for hard magnetic materials. The measurement setup is based on digital signal processing (with data acquisition cards). Several requirements are needed in this device as: noise reduction, flux compensation and voltage integration. Sensitivity and accuracy is compared with those of home-made devices described in the literature. Equivalent or high performance is found. The system has been successfully tested in samples from: a) ribbons of crystalline ferromagnetic Heusler shape memory alloys, b) glass coated microwires of soft magnetic amorphous alloys and c) powders of amorphous and nanocrystalline samples produced by mechanical alloying. Results were compared with those obtained in the same samples in commercial equipments. Next evolution of this measuring system is the application of external forces to take into account the effect of stress on the magnetic response of these alloys. Acknowledgements: Financial support from project MAT2013-47231-C2-2-P.

FR.I-P38 - Hexapod Hall scanner for high-resolution magnetic imaging

G. K. Perkins [1], M. Kustov [1], L. F. Cohen [1]

1. Blackett Laboratory, Imperial College London, London, United Kingdom

Scanning Hall probe microscopy is a powerful magnetic quantitative imaging technique that offers a unique combination of a large scan range with a submicron lateral resolution and a large measured magnetic field range [1-3].
In this work we report the design, construction and performance of a scanning Hall probe microscope (SHPM) which uses six bending piezoelectric actuators that are arranged in a hexagonal configuration and kinematically coupled. This arrangement allows both translation and rotation of a mounted Hall probe along the three Cartesian coordinates. Keeping such general advantages of the technique as the large scan range and the submicron resolution (provided that a high-resolution Hall probe is used), the constructed SHPM offers a unique opportunity of the *in situ* adjustment of the alignment of the sensor with respect to the sample surface that enhances the lateral resolution of the imaging device. The SHPM is compact measuring 25 mm across, and is designed to be fitted into the bore of a cryogenic environment such as those equipped with a superconducting magnet for temperature- and magnetic field-dependent imaging.

FR.I-P39 - Discrete inverse transformation for eddy-current tomography based on whitney finite edge element method

P. Nowak [1], R. Szewczyk [2], M. Urbanski [2], J. Ruokolainen [3], P. Raback [3]

1. Industrial Research Institute for Automation and Measurements PIAP, Al.Jerozolimskie, Warsaw, Poland
2. Institute of Metrology and Biomedical Engineering, Warsaw University of Technology, Warsaw, Poland,
3. CSC - IT Center for Science, Espoo, Finland

Eddy current tomography is a method for non-destructive testing of ferromagnetic and non-ferromagnetic but conductive, materials. Tested element is placed between exciting and sensing coil. Alternate current in exciting coil induces eddy currents in the tested element, which affect signal picked by the sensing coil. Variation of phase and amplitude of sensed signal is caused by variation of conductivity and permeability of the tested element, which are caused by element's defects.
Forward transformation in eddy –current tomography with utilization of Whitney finite edge element method was previously reported [1]. The expected measurement results can be calculated with finite-element method, knowing only he shape, conductivity, and permeability of the sample.
On the base of measurements of exemplary elements [2] and system for calculation of forward transformation, discrete inverse tomography transformation was applied. Values of conductivity and permeability of the model elements are discretely changed, then forward transformation is applied. Calculation results were compared with the real object measurements, and proper changes were applied in the next iteration, until the assumed compliance level was achieved. Discrete optimization was performed only on the element edges, therefore calculation time was significantly faster.
The results show acceptable element shape reconstruction, with visible indentation in place of the sample discontinuity. Further research will be conducted in order to achieve higher reconstruction accuracy and lower computation time.

FR.I-P40 - Comparison of different geometries for membrane based AC calorimeters

M. Bratko [1], D. Caplin [1], L.F. Cohen [1], Y.V. Bugoslavsky [2]

1. Imperial College London, United Kingdom
2. Cryogenic Limited, London, United Kingdom

AC calorimetry is an alternative to differential scanning calorimetry and relaxation methods. One of its main advantages is the measurement speed. During the measurement the sample is excited by a heat wave from a local heater resulting in temperature oscillations in the sample. Due to the capacitive load of the sample the temperature oscillation lags between the power excitation. The heat capacity can be calculated from the temperature oscillations phase and amplitude based on a simple AC-circuit model of the thermodynamic setup. Here we study a SiN-membrane based AC calorimeter suitable for measurement of extremely small samples of the order of a few micrograms in magnetic field [1]. We compare two types of membranes with different spatial arrangements of the essential elements: heater, sample, temperature sensor. We study the system response as a function of frequency and observe that both geometries deviate from the simple thermodynamic model but in significantly different ways. By considering these deviations within the context of the spatial arrangements of the essential elements on the membrane we were able to identify the limiting assumptions in the simple model and optimise the operating conditions for accurate calibration and measurement.

FR.I-P41 - Magnetometry based on asymmetric coupled mechanical oscillators

T. Mühl [1], J. Körner [1], C. F. Reiche [1], B. Büchner [0]

1. IFW Dresden, Dresden, Germany
2. Institut für Festkörperphysik, Dresden, Germany

In cantilever magnetometry, the field-dependent frequency shift and damping of a small mechanical oscillator is used to measure magnetic moments, anisotropy fields, switching fields, and magnetic fluctuations of tiny samples that are attached to the oscillator [1]. An increase of sensitivity of such mechanical magnetometers can be achieved be decreasing their effective spring constants. This is usually accompanied by a reduction of their spatial dimensions, which may require more sophisticated detection methods. A high-sensitivity magnetometer might be based on a one-side clamped carbon nanotube [2].
By discussing the rich behavior of a simple asymmetric coupled harmonic oscillator model, we present a co-resonant sensor concept which combines a conventional cantilever oscillator and a low-stiffness nanowire oscillator. Even though the spring constants and the effective masses of the two partial systems differ by orders of magnitude, the nanowire oscillator strongly influences the cantilever oscillation if nanowire and cantilever have similar resonance frequencies. Thus, the magnetic interaction of a nanosized sample attached to the nanowire with an external field leads to a notable frequency shift of the coupled system which can be measured at the cantilever by conventional means.
We prepared a co-resonant oscillator that is composed of an iron-filled carbon nanotube (FeCNT) and a Si cantilever forming a coupled flexural oscillation system. Frequency matching of the partial oscillators has been achieved by deposition of materials at the FeCNT free end. The measured field-dependent frequency shift of the coupled oscillator system is several orders of magnitude larger than that of a corresponding single-cantilever magnetometer, which is in agreement with our calculations.

FR.I-P42 - Surface flaws detection in low conductivity titanium alloys using magnetoresistive devices

F. Franco [1], F. Cardoso [1], L. Rosado [0], R. Ferreira [4], S. Cardoso [1,2], P. Freitas [0]

1. INESC - Microsistemas E Nanotecnologias
2. Instituto Superior Técnico, Universidade de Lisboa
3. INESC - Investigaþão e Desenvolvimento
4. International Iberian Nanotechnology Laboratory

Typically inductive sensors used for Eddy current testing (ECT) display limited sensitivity in a low frequency range and poor spatial resolution, being nowadays surpassed by magnetoresistive (MR) sensors with improved spatial resolution, high sensitivity and bandwidth [1]. Therefore, MR-ECT tools are of high impact even with surface contaminations, which is impossible with common liquid penetrate testing. In particular, ECT reliability is critical for low conductivity titanium alloys broadly integrated in aerospace industries due to their high strength/weight ratio [2].
A TA6Valpha titanium mock-up with a single defect (0.6mmx100umx50um) was characterized using MR-ECT probes. Probe A consisted of 10 magnetic tunnel junctions (MTJs) in series (each 10x4um2, total area=22x96um2) for enhanced spatial resolution and Probe B is an array of 72 MTJs (each 50x50um2, total area=500x500um2) for improved detectivity, both based on IrMn/CoFe/Ru/CoFeB/MgO/CoFeB stacks [1].
Probes A and B were biased with 180µApp and 1.65mApp, respectively, at 4999kHz (fb) while the excitation line was biased with 2App at 5MHz (fH), promoting a confined and intense EC density at the surface. The magnetic information was modulated at fH-fb, avoiding the electric biasing component (fb) and electromagnetic coupling (fH). Sample topography was partially removed by assembling the probes in a differential configuration.
With enhanced sensitivity (1.5x) and larger area, Probe B revealed a maximum signal amplitude increase of 7.6x (Vout(max)=6uV). However as the sample-sensor distance increases, a compromise between number of sensors and their intrinsic noise has to be met. Finite element simulations allowed us to access the influence of the total array area versus each sensor's noise. For a width of 500um, we demonstrate that probe B is close to the total area that maximizes the signal-to-noise ratio.

FR.I-P43 - Local magnetic measurements in multi-layered nanowires observed by electron holography

D. Reyes [1], C. Gatel [1, 2], N. Biziere [1], T. Wade [3], B. Warot-Fonrose [1]

1. CEMES-CNRS , Toulouse, France
2. Université Paul Sabatier, Toulouse, France
3. LSI, Ecole Polytechnique, Palaiseau, France

Magnetic multilayered structures are studied for various applications like nano-oscillators, as multilayered nanowires can be used as a spin transfer torque system. In this kind of systems, a spin polarized current can transfer its angular momentum to a ferromagnet layer, inducing a torque on its magnetization. Thus, the magnetic moment can switch to another state or oscillate around its equilibrium position at microwave frequencies. The possibility in multilayers to couple multiple individual oscillators allows an increased power for RF signal generator. In this work we demonstrate how the advanced quantitative electron microscopy techniques allow for the complete description of magnetic nanowires, for both structural and magnetic properties that can not be achieved by standard method.
We have studied the magnetic configuration in multilayered Co/Cu nanowires. We will show that electron holography is mandatory to observe the magnetic configuration in such small magnetic volumes. The acquisition and treatment methods will be detailed. The interpretation of the magnetic states needs combined structural and chemical characterization to estimate the thickness and the crystallinity of the layers, two geometrical parameters required for meaningful simulations.
The 60 nm diameter wires are characterized by chemical imaging (EFTEM) in order to know the distribution of cobalt and copper along the wire, 24nm thick Co and 14nm thick Cu layers are observed. Detailed EELS analysis show that 15% of Cu is mixed in the cobalt layers.

FR.I-P44 - Highly sensitive very low temperature and high field faraday magnetometer

O. Florea [1], E. Lhotel [1], J. Mocellin [1], Y. Launay [1], S. Dufresnes [1]

1. Institut Neel, Grenoble, France

We present the development of a new Faraday Magnetometer, which will allow performing absolute magnetization measurements with a high sensitivity (10-8 A.m2 = 10-5 emu) in extreme conditions: at very low temperature, down to 30 mK, and high applied magnetic fields, up to 16 T.
Our objective is to be able to probe the entanglement in quantum frustrated molecules as well as exploring the field induced phases at very low temperature in exotic materials such as frustrated magnets or ferromagnetic superconductors. The principle is to use a capacitive detection to measure the Faraday force induced on a magnetized sample in presence of a field gradient.
The originality of our magnetometer compared to similar systems [1,2] is two fold : i) We have developed an electronic detection system which involves a cold amplifier stage in the 3He-4He dilution fridge to improve the sensitivity of the capacitive measurement. ii) We have designed two capacitive sensors to probe a large variety of physical systems: a 'usual' sample holder, made using a 3D printer, suitable for samples with strong magnetic signals or large samples and a MEMS (MicroElectroMechanical System) made of a suspended nanofabricated silicon membrane, able to reach a high sensitivity.

Magnetization dynamics in patterned magnetic elements is fertile ground for fundamental research that also leads to novel technological applications. In many studies of magnetization dynamics in micron-sized elements, the ultrafast magnetization processes have been investigated using time-resolved magneto-optical Kerr effect (TR-MOKE) techniques, with sub-micron spatial resolution and ~50 ps temporal resolution. The biggest drawback of TR-MOKE is its spatial resolution, which is diffraction-limited due to the use of conventional optics. With the continuing demand for faster, more compact technological applications, this limit to spatial resolution is becoming a significant problem. One way of bypassing the diffraction limit in magnetic imaging is with near-field scanning optical microscopy (NSOM), which utilises evanescent waves at sub-wavelength distances from the sample surface. In this study we combined a near-field scanning optical microscope and magneto-optical contrast and successfully developed a new magnetic microscope, i.e., time-resolved near-field scanning magneto-optical microscope (TR-NSMOM). By taking advantage of the high temporal resolution of time-resolved Kerr microscope and the sub-wavelength spatial resolution of a near-field microscope, we achieved a temporal resolution of ~50 ps and a spatial resolution of < 100 nm. In order to demonstrate the spatiotemporal magnetic imaging capability of this microscope, the magnetic field pulse induced gyrotropic vortex dynamics occurring in 1 μm diameter, 20 nm thick CoFeB circular disks has been investigated. The microscope provides sub-wavelength resolution magnetic images of the gyrotropic motion of the vortex core at a resonance frequency of ~240 MHz. The details of the vortex dynamics are reconstructed using micromagnetic modeling based on time integration of the Landau-Lifshitz-Gilbert (LLG) equation.

FR.I-P46 - Oxide wizard as a new tool to probe magnetic properties at the nanoscale.

It is well-known that the oxidation state of rare-earth and transition metals cations in different types of oxides governs its magnetic properties. Electron Energy Loss Spectroscopy (EELS), has repeatedly shown to be a technique that can acces this type of information at the nanoscale [1-2], and even with atomic resolution [3]. However, as datasets become increasingly larger, the treatment of the data can be complicated.It can even be biased as it involves arbitrary choices of values such as integrating windows, peak onsets etc. In this work we developed a new software (Oxide Wizard) that evaluates the most important parameters of rare-earth and transition metals EEL spectra that can be related with their oxidation state, and we show how this information can solve material science problems related to magnetism [4].

FR.I-P47 - Probing nano- and micro- magnetism with very small angle neutron scattering instrument KWS-3

Z. Fu [1], V. Pipich [1], K. Ono [2], S. Siegfried [3], T. Brückel [4]

1. Forschungszentrum Jülich GmbH, Jülich, Germany
2. High Energy Accelerator Research Organization (KEK), Ibaraki, Japan
3. Helmholtz Zentrum Geesthacht, Geesthacht, Japan
4. Forschungszentrum Jülich GmbH, Jülich, Germany

KWS-3 is a very small angle neutron scattering (VSANS) instrument operated at the Research Neutron Source Heinz-Maier Leibnitz (FRM-II) in Garching, Germany. The principle of this instrument is to form a one-to-one image of an entrance aperture on a 2D position sensitive detector by neutron reflection from a double-focusing toroidal mirror. The instrument has two fixed and one flexible sample position, covering a scattering vector Q range between $4 \cdot 10^{-5}$ and $2 \cdot 10^{-2}$ $Å^{-1}$. Correspondingly the structural and magnetic properties of microstructures with sizes from 10 µm to 50 nm can be investigated on KWS-3. For example, VSANS measurements at KWS-3 have been performed on sintered (Nd, Dy)-Fe-B magnets, which have grain sizes ranging from several hundred nanometers to a few micrometers. Field-dependent VSANS patterns of sintered and Dy-free magnets were measured and revealed that the sizes of the magnetic microstructures increase with the sizes of crystal grains, giving valuable information on the high coercivity mechanism in this series of permanent magnets with wide automotive applications. Another example is the field-dependent VSANS measurement on the Fe-doped CoGe alloys at various temperatures below 200 K. This experiment identifies the k-value of the helical phase in the half-doped sample and confirms the disappearance of the helical peak at a critical Co-concentration is true even down to $Q = 4 \cdot 10^{-4}$ $Å^{-1}$, which might be difficult to reach using normal SANS. Given the implementations of polarization option and more sophisticated sample environment in the near future, VSANS instrument KWS-3 is a powerful tool to investigate magnetic microstructures ranging from nanoscale to microscale.

FR.I-P48 - Software development for investigating magneto-optical and non-linear effects in nanofluids

R. Srinivasan [1], C. Pai [1], S. Mohan [1,3], N. Momin [1], Muthurajan H. [2], Nagarajan R. [3]

1. Department of Physics, University of Mumbai, Mumbai, India
2. Centre for Nanoscience and Nanotechnology, University of Mumbai, Mumbai, India
3. UM-DAE Centre for Excellence in Basic Sciences, University of Mumbai, Mumbai, India

In this paper, we present the instrumentation software developed for studying non-linear and magneto-optical effects in nanofluids. Laser beam (He-Ne, 632 nm, 10 mW) transmission studies through nanofluid samples are carried out. In-house software contains modules for control and data processing.
Laser beam transmitted through nanofluid shows thermal lensing along with higher order non-linear effects like self-diffraction and magneto-optical effects. In case of magnetic nanofluids, refractive index gradient arising due to thermal and concentration diffusion of particles is found to be tunable with external magnetic field. Control module in the software generates customized magnetic field varying with time. Self diffraction patterns show variation with magnetic field resulting into temporal variation of non-linear refractive index. Separate module has been developed for processing the images of self-diffraction patterns and storing optical transmission data.
This paper presents laser interaction studies carried out with dispersions of Fe_3O_4 nanoparticles (40 nm, 30 mg/ml in Hexane) where a non-linear optical response in form of self diffraction patterns is observed. On the other hand, laser transmission through smaller sized Fe_3O_4 particles (8-10 nm, 10 mg/ml in Water) show speckle like forward scattered patterns tunable with external magnetic field. The simple experimental set-up and associated software system is useful for understanding colloidal dynamics, non-linear, magneto-optical response of nanofluids and the possible applications for development of optofluidic sensors.

FR.I-P49 - Three axis vector magnet for low temperature magnetic imaging

Three axis vector magnet for low temperature magnetic imaging Scanning probe measurements, i.e. STM or MFM, in vectorial magnetic field systems is a growing research area, which can be used, in superconductors or magnets, to establish internal anisotropies and, for example, observe possible vortex lattice transitions in the mixed state of superconductors [1]. In this work we present a three axis vector magnet system for cryogenic scanning probe microscopy, which has been developed and successfully used in conjunction with a liquid helium temperature Magnetic Force Microscopy (MFM) [2]. We discuss the magnet support as well as the homogeneity of the fields achieved in the sample space. We obtain tilted fields in any direction of space, with a maximum field of 5T along the Z axis and 1.2T in the XY plane. We further present the evolution of (ferro)magnetic domains, first on a test sample (HDD) and subsequently on a nanostructured manganite thin film, with temperature, magnetic strength and direction.

FR.I-P50 - Using of ambient magnetic field information in diagnosis of electric motor

P. Szulim [1], S. Gontarz [1]

1. Warsaw University of Technology, Institute of Vehicles, Warsaw, Poland

In this paper, the authors present theoretical basis of using external magnetic fields surrounding electric machines like BLDC motors or generators to diagnose their technical state. Conducted analytical calculation was verified on the test stand with the BLDC motor subjected to some mechanical faults. The problem of determining the technical condition of an electric machine has not been resolved yet. Many new publications related to this topic can bear witness to this. However, the demand for reliable diagnosis can be easily observed in case of complicated technical systems which perform important functions, which takes place for example in the energy industry. It turns out, that an unambiguous statement of specified mechanical faults occurrence may not necessarily be distinguished on sufficient level, because of the lack of diagnostic methods. An interesting alternative can be using external magnetic field that comes from rotors and windings, as a source of diagnostic information. A significant part of this field is confined in the motor armature but measuring of some residual values can have diagnostic validity. In this paper, the complete analytical 2D model of the electric BLDC motor was shown, allowing for the derivation of some analytical relationships between the specified mechanical faults like eccentricity, torque pulsation, unbalanced load, demagnetization, and distribution of instantaneous values of magnetic field vector on the outside of investigated motor. The topic of analytical modeling of electric brushless motors has been an object of intensive work for the last 40 years. Achievements from this area were used in this paper. The result of analytical modeling will be verified by test stand investigations where the investigated motor works in different load conditions. Three axial magnetometer made of magneto-resistive elements was used to wide band measurements. Using these elements allows for the precise measurement of three components of vector field with high sensitivity and linearity. In this paper, the analysis of influence of chosen mechanical faults on diagnosis signal under time-frequency analysis, will be presented. The results will be compared with the classic CSA analysis where advantages of presented method will be clearly depicted.

FR.I-P51 - Passive identification of magneto-mechanical phenomena in process of fatigue of steel and cast

S. Gontarz [1], J. Dybala [1], P. Szulim [1]

1. Warsaw University of Technology, Institute of Vehicles, Warsaw, Poland

Fatigue process in steel materials leads to changes in their structure, that modify their magnetic properties also. The influence of fatigue is so large, that this material in the presence of earth magnetic field yields measurable view in the form of characteristics changes of magnetic fields near steel materials. In work one was verified abilities of identification magneto-mechanical phenomena in a fatigue process of steel and cast. To do this test stand based on MTS machine had been modified. Measurement was realized in contactless manner using FluxGate magnetometers. Analysis of signals was oriented on determination of a degree of material fatigue and quantitative characteristic of changes that had place for the analyzed materials.
