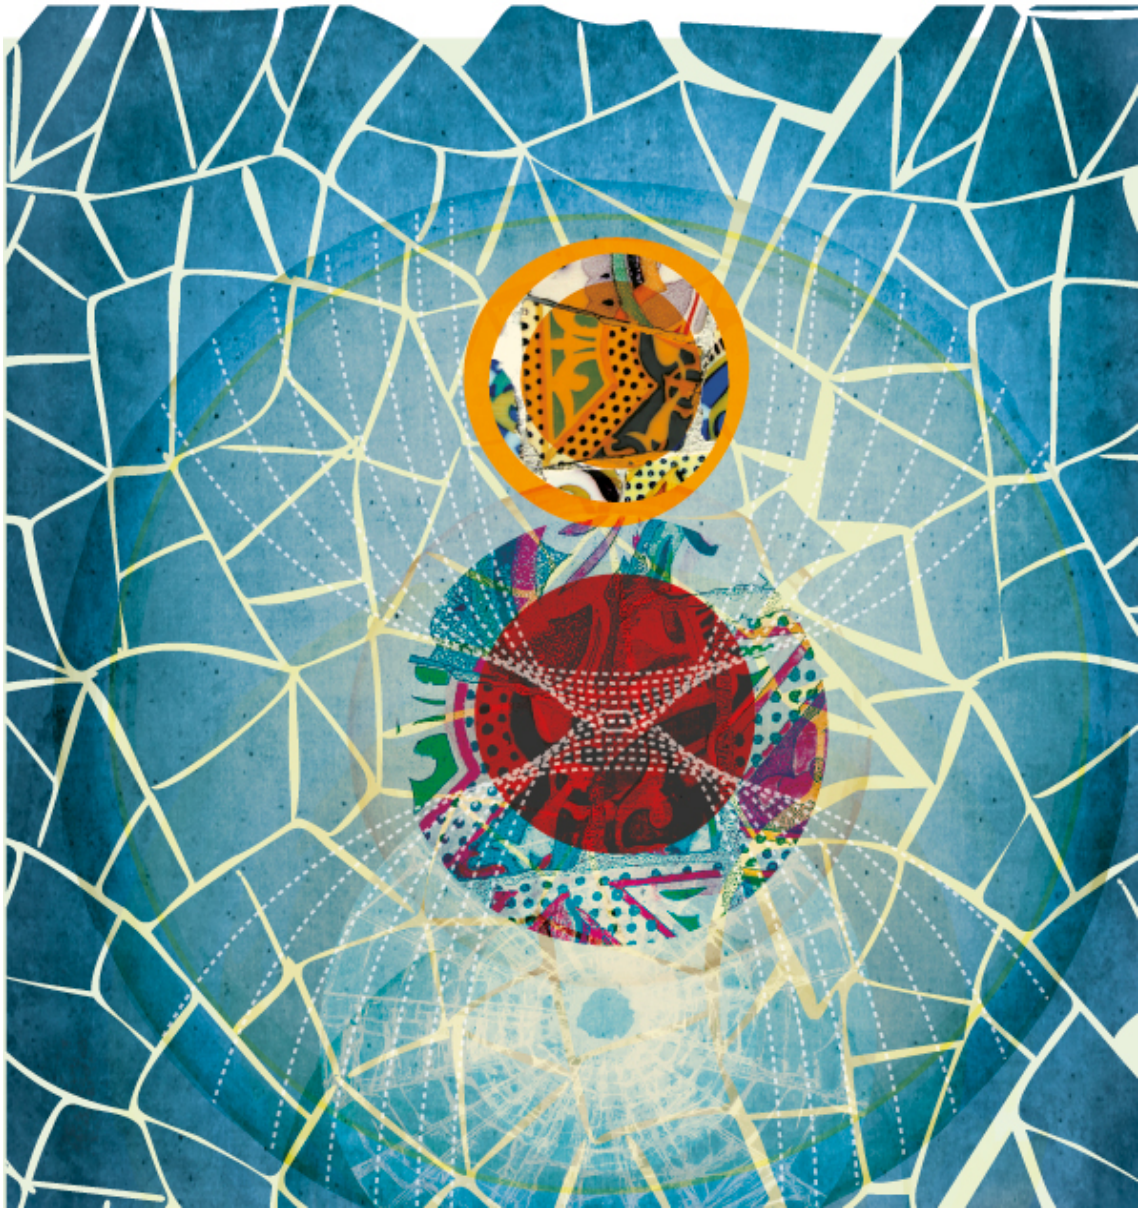
Plenary Lectures



PLENARY 1 - Continuous time quantum monte carlo methods: from quantum impurity models to real materials

A.J. Millis [1]

1. Department of Physics, Columbia Universit, New York, United States

Continuous-time quantum Monte Carlo methods have revolutionized manu-body physics by providing direct and accurate access to the real and imaginary time Green functions of a wide variety of quantum impurity models over wide temperature and parameter ranges. The ability to obtain results over wide spectral ranges makes the methods particularly useful as ``solvers" for dynamical mean field theory. After a brief review of the history of the methods and the connection to dynamical mean field theory, this talk will explain what the methods really do, why they work wellùand in what situations they fail and where other method are preferable. The methods will be illustrated with examples including magnetization dynamics and the splitting of the Kondo resonance in the nonequilibrium Anderson impurity model, properties of spin crossover molecules, and the dynamical mean field theory of correlated materials such as the rare earth nickelates and the copper - oxide high temperature superconductors.
My work in this area has been performed in collaboration with many scientists, including Philipp Werner, Emanuel Gull, Chris Marianetti and Hyowon Park and has been supported by the US National Science Foundation Division of Materials Research under grants 1006282 and 1308236 and the Basic Energy Sciences Division of the US Department of Energy under grant 046169.

PLENARY 2 - Golden era of modern magnetism

C.L. Chien [1]

1. Johns Hopkins University, Baltimore, United States

Few could envision in the mid-1980' that, magnetism, by then a well-established and mature field, would enter a golden era in which so many new phenomena could be realized in rapid succession, and some expeditiously exploited in new technologies. Beginning with the discovery of interlayer coupling and GMR, we had spin-valves, magnetic tunnel junctions, half-metals, spin transfer torque, spin Hall effect, domain wall motion, and countless other new subjects. In this talk, some recent examples in pure spin current phenomena and materials with Dzyaloshinskii-Moriya (DM) interaction will be given. We are truly blessed that after three decades the golden era continues unabated.

PLENARY 3 - Spin current generators

E. Saitoh [1,2,3,4]

1. ERATO-SQR, JST, Saitama, Japan
2. WPI-AIMR, Tohoku University, Miyagi, Japan
3. Institute for Materials Research, Tohoku University, Miyagi, Japan
4. ASRC, JAEA, Ibaraki, Japan

Generation and utilization of a flow of spin angular momentum of electrons in condensed matter, called spin current, are the key challenge of todayüfs nano-scale magnetism and spintronics. The discovery of the inverse spin Hall effect (ISHE) [1-3], the conversion of spin current into electric voltage via spin-orbit interaction, has allowed researchers to detect and utilize spin current directly, and, since then, many spin-current driven effects have been discovered by exploiting the ISHE. Here, such newly discovered spin-current effects will be

outlined, including light-spin conversion [1,4], plasmon-spin conversion, sound-spin conversion, and heat-spin conversion [5-6], and their common mechanism and future possible application will be discussed. Among them, a typical conversion effect is the spin Seebeck effect (SSE) [5], spin current generation from a temperature gradient. SSE has attracted a great deal of interest since it may realize new type thermo-electric convertors which make full use of the characteristic feature of spins: the non-reciprocal dynamics. This non-reciprocity allows a spin to rectify thermal fluctuation into unidirectional spin current via the spin pumping mechanism, which can be converted into electric power via the ISHE. Spins, working as a natural rectifier in magnets, may thus provide a versatile mechanism of energy conversion in condensed matter. I will show also that the rectification mechanism underlies various spin related phenomena which were found recently. At the end of my talk, spin current generation from mechanical motion of condensed matter will be discussed.

PLENARY 4 - Molecular spintronics

E. Coronado [1]

1. ICMol. University of Valencia, Valencia, Spain

So far spintronics has been based on conventional materials like inorganic metals and semiconductors. A current trend in this area is that of incorporating molecules in the game. The resulting emergent field - namely molecular spintronics - is propelled by the possibility of preparing a second generation of spintronic devices based on molecular materials (organic spintronics) and by the possibility to manipulate the molecular spin individually (single-molecule nanospintronics). In this talk these trends will be illustrated with several examples taken from my own research: I) the fabrication of multifunctional molecular devices in which the light emission can be tuned through a magnetic field; II) The electrical addressing of the spin in molecular nanoobjects; III) the use of single-molecule nanomagnets as spin qubits.

PLENARY 5 - Magnetic materials for green technologies

O. Gutfleisch [1,2]

1. TU Darmstadt, Material Science, Darmstadt, Germany
2. Fraunhofer Project Group Materials Recycling and Resource Strategy IWKS, Hanau, Germany

Due to their ubiquity, magnetic materials play an important role in improving the efficiency and performance of devices in electric power generation, conversion and transportation [1]. Permanent magnets are essential components in motors and generators of hybrid and electric cars, wind turbines, etc. Magnetocaloric materials could be the basis for a new solid state energy efficient cooling technique alternative to compressor based refrigeration [2]. Any improvements in magnetic materials will have a significant impact in these areas, on par with many “hot” energy materials (e.g. hydrogen storage, batteries, thermoelectrics, etc.). The talk focuses on rare earth and rare earth free permanent magnet and magnetocaloric materials with an emphasis on their optimization for energy and resource efficiency in terms of the usage of critical elements. The concept of criticality of strategic metals will be explained by

looking at demand, sustainability and the reality of alternatives of rare earths. Synthesis, characterization, and property evaluation of the materials will be examined considering their micromagnetic length scales and phase transition characteristics.

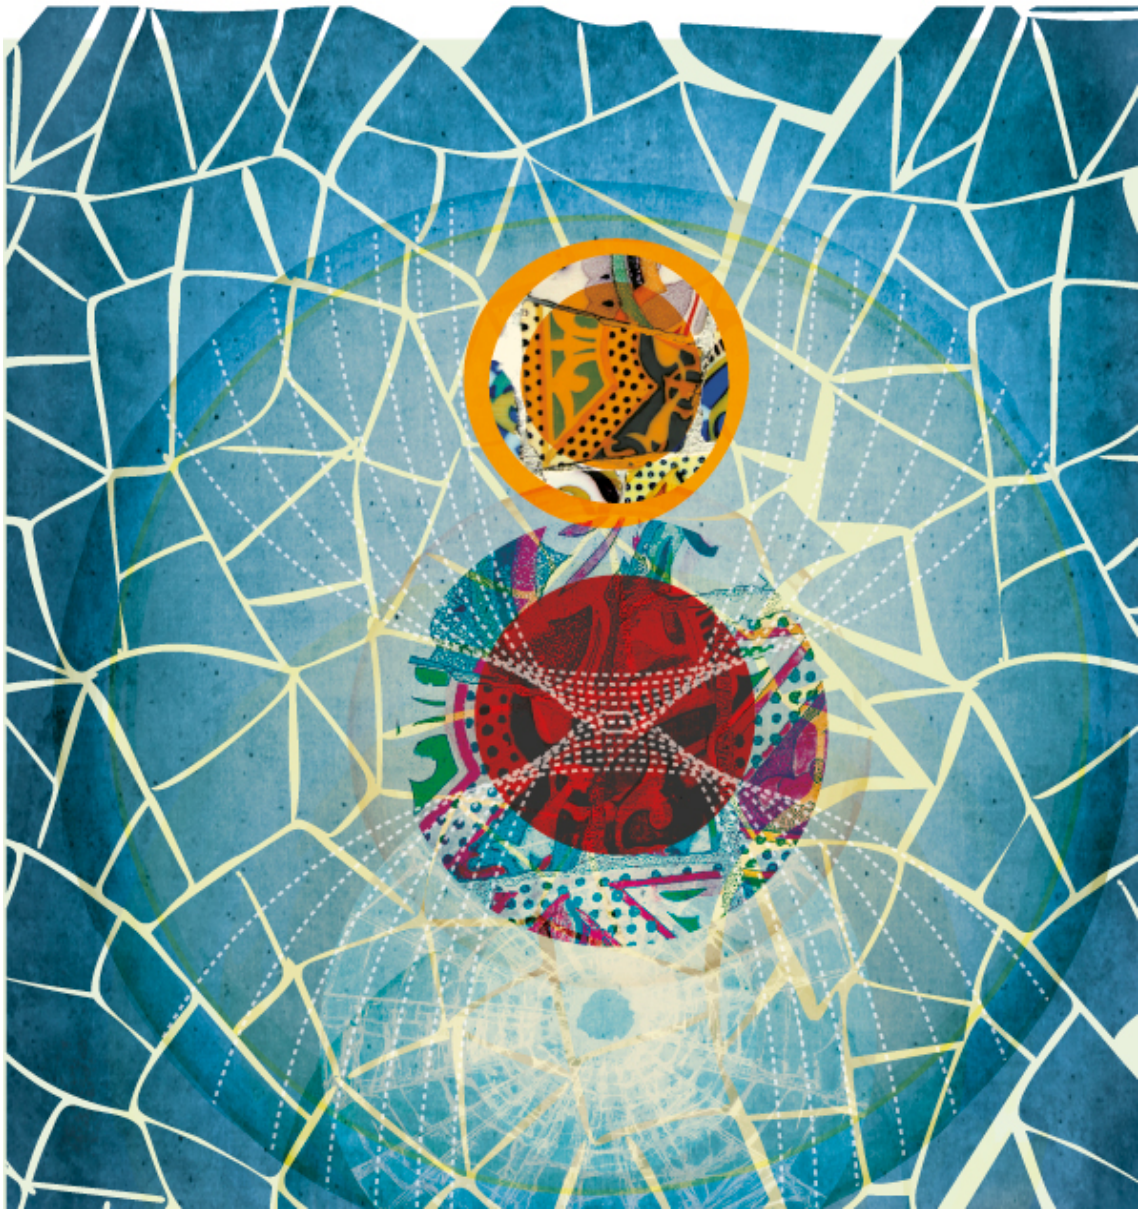
Semi-plenary Lectures



MO.SP-1 - Adding magnetic functionalities to epitaxial graphene

R. Miranda [1,2]

1. IMDEA Nanociencia, Madrid, Spain
2. Dep. Física de la Materia Condensada, Universidad Autónoma de Madrid, Madrid, Spain

The development of all-graphene spintronic devices requires that in addition to its capability to passively transmit spins over long distances, new magnetic functionalities are added to graphene. By growing epitaxially graphene on single crystal metal surfaces under UHV conditions [1] and either adsorbing molecules on it or intercalating heavy atoms below it, we show how to incorporate long range magnetic order or giant spin-orbit coupling, respectively, to graphene. I) Achieving long range magnetic order by a monolayer of electron acceptor molecules adsorbed on graphene /Ru(0001). Epitaxial graphene is spontaneously nanostructured forming an hexagonal array of 100 pm high nanodomes with a periodicity of 3 nm [2]. Cryogenic STM and Spectroscopy and DFT simulations show that TCNQ molecules deposited on gr/Ru(0001) acquire charge from the (doped) gr substrate and develop a sizeable magnetic moment revealed by a prominent Kondo resonance. The self-assembled molecular monolayer develops spatially-extended spin-split electronic bands. The predicted spin alignment in the ground state is visualized by spin-polarized STM at 4.6 K [3]. The system shows promising perspectives to become an effective spin filter device. II) Introducing a giant spin-orbit interaction on graphene/Ir(111) by intercalation of Pb. The intercalation of an ordered array of Pb atoms below graphene results in the appearance a series of sharp pseudo-Landau levels in the differential conductance revealed by STS at 4.6 K. The vicinity of Pb enhances by orders of magnitude the, usually negligible, spin-orbit interaction of graphene. The spatial variation of the spin-orbit coupling creates a pseudo-magnetic field that originates the observed pseudo-Landau levels [4].

MO.SP-2 - Magnetization dynamics of nanodots and fundamental limits of minimum energy dissipation during switching

G. Carlotti [1]

1. University Of Perugia - Dipartimento di Fisica E Geologia, Perugia, Italy

In this talk I will review recent results achieved by means of both micromagnetic simulations and Brillouin light scattering experiments at GHOST Laboratory, Perugia University, about the dynamical properties of either isolated or coupled magnetic nanodots [1,2,3]. The character of their spin-wave eigenmodes (frequency and spatial profile) exhibits peculiar properties when the lateral size D of the dots decreases below a critical value of about 150 nm. For in-plane magnetization, the inhomogeneity of the internal field and exchange-energy effects cause qualitative and quantitative differences in the spin wave spectrum, if compared to larger dots. For instance, the fundamental mode lies at the bottom of the spectrum and exhibits a maximum amplitude at the edges. This mode softens at an applied switching field with magnitude comparable to the coercive field, determining the initial steps of magnetization reversal. Therefore, a detailed knowledge of the eigenmodes spectrum of nanodots is also crucial to understand the switching process. To this respect, careful analysis of the fundamental limits of minimum energy consumption, during either conventional (irreversible)

[4] or adiabatic (reversible) switching [5], shows that dissipationless reversal is achievable, provided that both dynamic (arbitrarily slow application of external fields) and entropic reversibility (no free entropy increase) are insured [6]. These results can be relevant for the exploitation of deep-submicrometric magnetic dots as elemental switches in magnetic memory or storage devices, as well as in nano-magnetic logic applications and spin-torque oscillators.

MO.SP-3 - Ferromagnetism in Semiconductors and the Role of Localization

T. Dietl [1]

1. Institute of Physics, Polish Academy of Sciences, Warsaw, Poland

The recent years have witnessed a rapid progress in the understanding of puzzling and controversial origin of ferromagnetism in various families of dilute magnetic semiconductors and insulators [1]. In the talk, an overview will be given on the relative importance of the dominant spin-spin exchange mechanisms in magnetically doped semiconductors, oxides, arsenides, and topological insulators, taking into account intra-band Ruderman-Kittel- Kasuya-Yosida interaction and the inter-band Bloembergen-Rowland mechanism as well as the short-range antiferromagnetic and ferromagnetic superexchange. The role of powerful element-specific and spin-sensitive nanocharacterization tools will be emphasized underlying that they have allowed to correlate magnetic properties with the distribution and location of magnetic ions in the host lattice. At the same time, photoemission results will be presented noting that they have provided direct information on the density of states of itinerant carriers. The importance of interplay between carrier-mediated ferromagnetism and carrier localization will be discussed in the context of studies on gated structures. These investigations have demonstrated the presence of electronic and magnetic phase separations on approaching the Anderson-Mott transition, the key element accounting for colossal magnetoresistance effects, a trade mark of magnetic semiconductors.

TU.SP-1 - Overview of Ce-115 based superconductors

J. Thompson [1]

1. Los Alamos National Laboratory, New Mexico, United States

The Ce-115 heavy-fermion superconductors CeCoIn5, CeIrIn5 and CeRhIn5 under applied pressure have revealed a remarkable variety of electronic states, none of which is understood well but some of which may be similar to those in other classes of electronically correlated materials. Magnetism in general and magnetic quantum criticality in particular are fundamentally the origin of these states, including superconductivity itself. Among other recently discovered states are one of coexisting magnetism and unconventional superconductivity whose coupling may lead to an exotic order [1], a pseudogap phase with seemingly dx2-y2 symmetry [2,3], and an unconventional type of quantum-critical state that favors the development of d-wave superconductivity [4,5,6]. This overview summarizes experimental evidence for these and related states and suggests areas where future work might be beneficial.

TU.SP-2 - Phonons, Magnons and Spin Current

S. Maekawa [1]

1. Advanced Science Research Center, Japan Atomic Energy Agency, Ibaraki, Japan

Phonons and magnons are the elementary excitations in a magnet. The interaction between them gives rise to a variety of magneto-acoustic and magneto-elastic effects. Since magnons carry spin angular momenta, the interaction provides an opportunity for phonons to contribute to spin-related phenomena. Spin current is a flow of spin angular momentum, and is converted to the charge current by the (inverse) spin Hall effect. Spin current carries energy and information as well. Here, we extend the magneto-acoustic and magneto-elastic effects by introducing spin current. In particular, the effects based on spin current in a hybrid system consisting of a non-magnetic metal such as Pt and a magnet including ferromagnet, antiferromagnet and ferrimagnet are examined. The spin Seebeck effect refers to the generation of a spin voltage caused by a temperature gradient in a magnet, which enables the thermal injection of spin current from the magnet into an attached non-magnetic metal. The inverse spin Hall effect converts the injected spin current into a transverse charge voltage, thereby producing electromotive force as in the conventional charge Seebeck device. Recent theoretical and experimental efforts have shown that magnons and phonons play crucial roles in the spin Seebeck effect. We present the theoretical basis of the spin Seebeck effect and other thermal spin effects.

TU.SP-3 - Quantum tunneling of the magnetic moment: From molecules to collective effects

J. Tejada [1]

1. University Barcelona, Barcelona, Spain

Experimental work on quantum tunnelling of the magnetic moment performed at the University of Barcelona will be reviewed, starting with the discovery of quantum magnetic relaxation in nanoparticles and resonant spin tunnelling in molecular magnets. Collective quantum phenomena related to spin tunnelling will be discussed, such as quantum magnetic deflagration and superradiance. It will be argued that tunnel splitting in two-state systems introduces forces of quantum origin that can be measured in molecular magnets. Our most recent experiments with nanospheres of molecular magnets exhibiting extremely narrow quantum resonances will be reviewed.

TH.SP-1 - Novel topological phases in strongly correlated electron systems

L. Balents [1]

1. Kavli Institute For Theoretical Physics, Santa Bárbara, United States

The role of topology in electronic systems is an active subject of research. Within a non-interacting quasi-particle picture, describing both weakly correlated insulators and superconductors, a rather complete classification of possible topological phases has been achieved, and of course topological insulators have been found and studied intensively experimentally.
The problem of correlated electrons is much richer, and requires updating the quasi-particle classification.
New topological phases and phenomena can occur only when electronic interactions are present. I will discuss some of the possible novel states that might be achieved in this way. I

will describe how gapped states may exhibit two distinct classes of topology: symmetry protected topological order, and intrinsic topological order.
I will also touch upon gapless states with topologically protected bulk gapless excitations.
Finally, I will spend some time describing applications of these ideas to the iridates.

TH.SP-2 - Electric manipulation of spin textures

A. Hoffmann [1]

1. Materials Science Division, Argonne National Laboratory, Argonne, United States

Temporal and spatial magnetic spin textures have received increased interest, due to their potential for power-efficient information encoding and processing [1]. Examples of temporal spin textures are spin waves, and of spatial spin textures are magnetic skyrmions, which are stabilized by their distinct topology. Two types of electrical manipulation of these spin textures are duiscussed. First, local Oersted magnetic fields from charge currents can manipulate the propagation of spin waves. This can be used to guide spin waves through curved waveguides, where otherwise the propagation is suppressed by their inherently anisotropic dispersion in thin films [2]. This same concept is generalized for the switching of spin waves between multiple waveguides [3]. Second, magnetostatically-stabilized skyrmion bubbles can form in ferromagnet/heavy-element bilayers, where the interface gives rise to perpendicular magnetic anisotropy and a chiral Dzyaloshinskii-Moriya interaction [4]. These magnetic skyrmions are electrically manipulated utilizing spin Hall effects [5]. Furthermore, it is demonstrated that skyrmion generation via the spin Hall effect coupled to inhomogeneities in electrical charge currents occurs in a process that is similar to the droplet formation in surface-tension driven fluid flows. This provides a practical approach for skyrmion formation on demand. This work was supported by the U.S. Department of Energy, Office of Science, Materials Sciences and Engineering Division.

TH.SP-3 - High temperature nanostructured superconductors: a tool towards a new era of high field magnetism*

X. Obradors[1]

1.Institut de Ciència de Materials de Barcelona, ICMAB-CSIC, Campus de la UAB, Bellaterra, Spain

Achieving high current superconducting wires has been one of the most challenging objectives during all the High Temperature Superconductivity (HTS) era.

Extraordinary new ideas and materials developments have been demonstrated and second generation YBa2Cu3O7 conductors (coated conductors, CCs) have emerged as an outstanding practical opportunity to generate high and ultrahigh magnetic fields.
The quasi-epitaxial multilayered film structure on flexible metallic substrates of CCs can be now achieved in very long lengths without the detrimental influence of grain boundaries. Additionally, a new boost in performance at high magnetic fields is being achieved when unique nanostructures are being introduced in these epitaxial films which allow reaching very high vortex pinning strengths. All these features make nanostructured CCs an enabling technology to develop practical high field large scale power applications and so opens a new era of high field magnetism.
In this talk I will present the major recent developments of the different CC architectures and the existing bottlenecks towards understanding the complex relationship between nanostructure and vortex pinning in HTS materials. Emphasis will be made in describing the diverse nanoscale structures allowing to enhance vortex pinning based on cost-effective chemical deposition approaches. Research progress in CC development in Europe, particularly in the scope of the European research program EUROTAPES (www.eurotapes.eu), will be reported.

* Research funded from EU-FP7 NMP-LA-2012-280432 EUROTAPES project

FR.SP-1 - Magnetocaloric effect: Challenges and opportunities

V. Pecharsky [1,2], Y. Mudryk [1], D. Paudyal [1], K. Gschneidner, jr. [1,2]

1. Ames Laboratory, Iowa State University, Ames, United States
2. Department of Materials Science and Engineering, Iowa State University, Ames, United States

The discovery of the giant magnetocaloric effect in Gd5Si2Ge2 and other R5T4 compounds (R = rare earth metal and T is a Group 14 element) generated a broad interest in the magnetocaloric effect and magnetic refrigeration near room temperature in particular, and in magnetostructural transitions in general. Reports on the giant magnetocaloric effect in other systems soon followed. These include MnFePxAs1-x and related compounds, La(Fe1-xSix)13 and their hydrides, Mn(AsxSb1-x), CoMnSixGe1-x and related compounds, Ni2MnGa and some closely related Heusler phases, and a few non-metallic systems, including manganites best known for their colossal magnetoresistance. A common feature observed in all materials that exhibit the giant magnetocaloric effect is the coupling of magnetic and elastic effects. In addition to the interplay between magnetic and lattice entropies, both of which are intrinsic materials' parameters that in principle can be modeled theoretically from first principles, extrinsic parameters such as microstructure and nanostructure, have been found to play a role in controlling both the magnetostructural transition(s) and magnetocaloric effect. Both the intrinsic and extrinsic parameters are, therefore, important in order to maximize magnetocaloric effect. The role of different control parameters and the potential pathways towards materials exhibiting advanced magnetocaloric effect will be discussed. This work is supported by the Materials Science and Engineering Division, Office of Basic Energy Sciences of the U.S. Department of Energy under contract No. DE-AC02-07CH11358 with Iowa State University.

FR.SP-3 - Ferromagnetic shape memory thin films: Structure and magnetic anisotropy

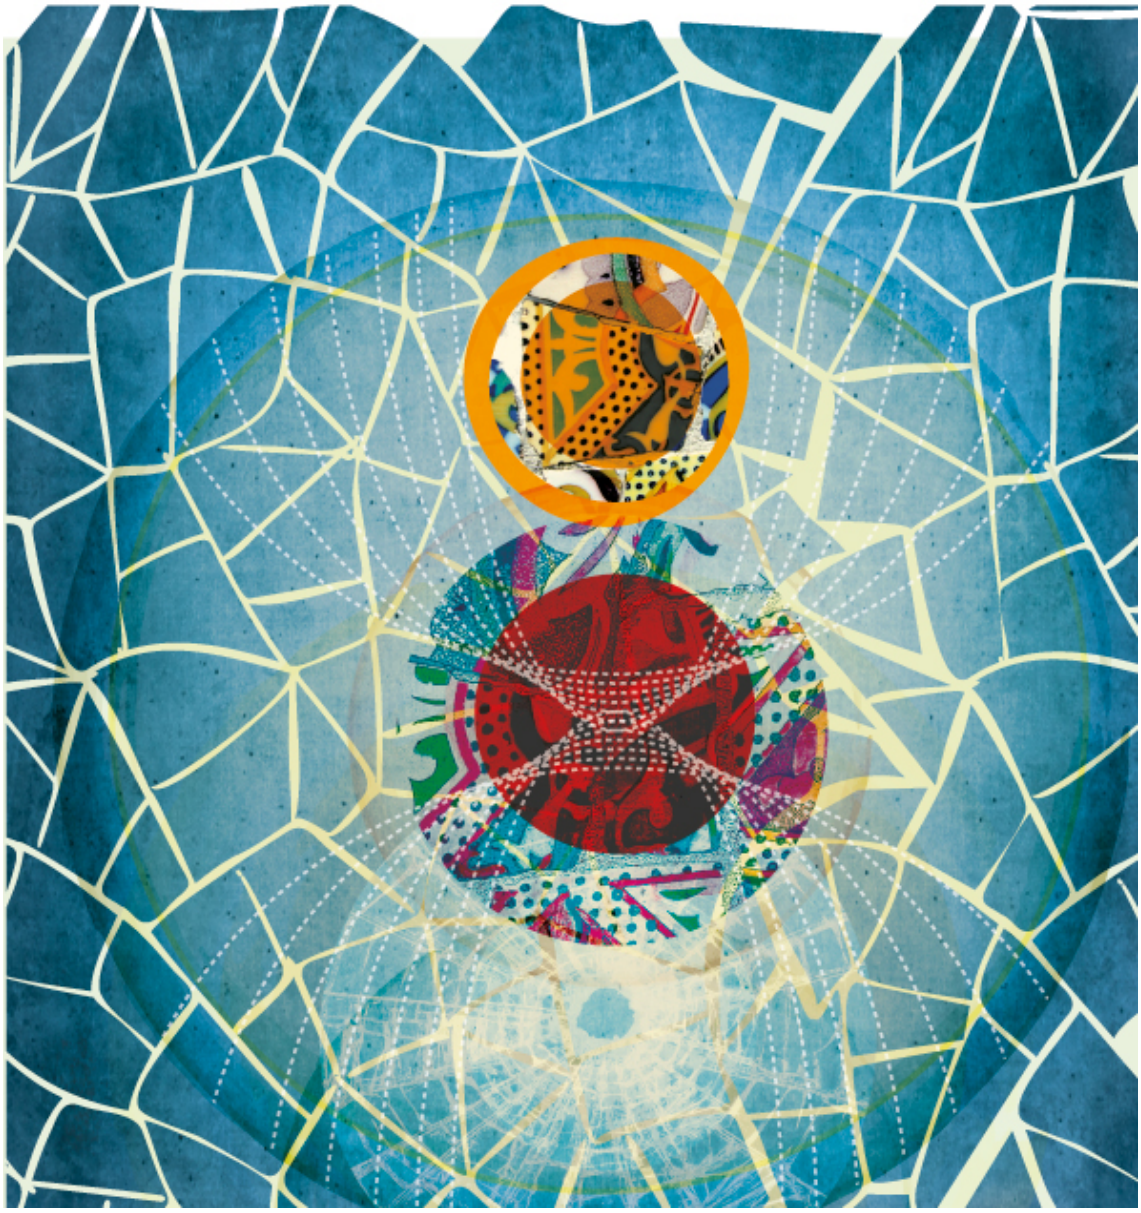
J.M. Barandiaran [1], V. Chernenko [1,2], I.R. Aseguinolaza [1]

1. BCMaterials & Univ. of the Basque Country, Leioa, Spain
2. Ikerbasque, the Basque Foundation for Science, Bilbao, Spain

Ferromagnetic shape memory alloys (FSMA) such as off-stoichiometric Ni-Mn-Ga Heusler compounds, show the "magnetic-field-induced strain" (MFIS) effect, which is due to the mobile martensitic microstructure and the strong coupling between elastic and magnetic properties. Due to their high power density, these materials have a great potential to be used in magnetic MEMS.

In the present work we overview recent advances in submicron FSMAs thin films. Particular emphasis is given to the structure of the films and to their magnetic anisotropy. Polycrystalline films deposited onto cold substrates have (220) out-of-plane fiber texture. Films grown onto hot substrates have epitaxial structures. The symmetry and strength of the magnetic anisotropy (MA) of the films have been studied by ferromagnetic resonance (FMR). They are controlled by the film crystallography, the martensitic nanostructure, the type of substrate and film thickness. The effect of the substrate in the anisotropy is demonstrated by comparing the in plane MA for a Ni-Mn-Ga film grown onto NaCl (001) and the out of plane oblique anisotropy in an identical film with the same texture deposited onto Si (001). Another important factor determining the MA is the film-substrate stress that determines the transformation volume strain. A reduction of the MA by one order of magnitude is found by FMR in single crystalline Ni-Mn-Ga films onto MgO (100). These results are explained in the framework of a magnetoelastic model of the martensite involving second- and forth-order magnetic anisotropy constants, which, thereof, can be evaluated from the experimental data. In these films the estimated value of the magnetic domain wall width is comparable with the width of the twins, indicating that the magnetic moment in neighbor twins are strongly coupled by the exchange interaction. Applications of single and double beam Si cantilevers, with deposited submicron Ni-Mn-Ga films are briefly discussed.

Special Lectures



A quick review of magnetism in Spain

A. Hernando

1. Instituto de Magnetismo Aplicado (UCM-ADIF-CSIC). Las Rozas, Madrid, Spain and Dept. Física de Materiales, Universidad Complutense de Madrid, Madrid, Spain

Magnetism has been in Spain the first scientific topic that acted as nucleus around which the spanish scientific community was born. Despite the previous existence of a few scientist, as the Nobel Price Santiago Ramón y Cajal, the experimental science was not here an ususal and respected activity until the second decade of the XX century. Blas Cabrera, after visiting Pierre Weiss at Strasbourg, started a systematic experimental study of the magnetic susceptibility of rare earth compunds. The influence of Cabrera and his school on the firm establishment of some aspects of Atomic Physics and Quantum Mechanics, was emphasised by Van Vleck. In fact, the convergence of excelent quality multidimensional cultural aspects at the Residencia de Estudiantes in Madrid, close to the Instituto de Investigaciones Físicas, allowed us to refer to the first decades of the XX century as the Silver Age of the spanish culture. Guests of the Residencia were Salvador Dalí, Federico García Lorca and Luis Buñuel and was visited by Marie Curie, Erdwing Schrodinger and Albert Einstein among other scientists.

After revisiting Cabrera´s contribution, the terrible effect of the Civil War on the spanish scientififc productivity should be also analyzed. After the war a few researchers as S. Velayos continued the spanish tradition in Magnetism. It is true that Magnetism, as other research branches, undergoes an increasing growth since 1970 that reached a maximum expansion at the end of the eighties. In Spain a lot of competitive groups develop a remarkable activity nowadays, mainly at the University and Research Institutions depending of the state. A few companies also perform technological activities related to the field of Magnetism.

I have choosen a non exhaustive but representative set of spanish labs to illustrate and summarise the more competitive activity in magnetism research carried out in our country. Most of the active groups gather together as members of the Spanish Magnetic Club.

Highlights from 30 years of Magnetism

D. Givord

1. CNRS/Université Grenoble-Alpes, Institut Néel, Grenoble, France

Some of today's most active areas of magnetism derive from a series of discoveries that occurred in the 1980's. High Tc superconductivity gave an immense impulse to the study of strongly correlated electron systems. The development of high energy product NdFeB magnets revolutionized the design of motors and generators. The most important discovery of the period, namely giant magnetoresistance, has given birth to the new scientific domain of spintronics. During the same period, X-ray magnetic dichroism and Scanning Tunneling Microcopy, followed by other near-field microscopies, were discovered. These, together with enormous progress in magneto-optical studies and numerical simulations, have profoundly transformed the nature of studies dealing with magnetism and magnetic materials.

We have learned that complex magnetic orders may be stabilized and that magnetic ordering may even disappear under the influence of frustration, that domain walls are not simple planar objects, that magnetism and superconductivity are not always antagonistic, that an external magnetic field is not always needed to reverse magnetization and that magnetization is not needed to get a magnetic signal, that spin currents may exist independent of charge currents, that spin-orbit interactions may dramatically affect the magnetic properties of matter.

A number of new magnetic materials, from magnetic semiconductors to magnetocaloric materials and half-metallic alloys have been discovered. The study of the fundamental link generally existing between magnetic properties and microstructure, benefits from tremendous developments in characterization techniques, in particular aberration corrected TEM. The search for new materials is now guided by electronic structure calculations, and the material itself may be a complex magnetic object, designed in the so-called materials engineering approach. Finally, new domains of applications have emerged for magnetism, the two most significant being in the fields of green energy and bio-medical engineering.

Highly Efficient Current Induced Domain Wall Motion in Synthetic Antiferromagnetic Racetracks

S. Parkin [1,2]

1. IBM Almaden Research Center, San Jose, California, United States
2. Max Planck Institute for Microstructure Physics, Halle, Germany

Memory-storage devices based on the current controlled motion of domain walls in magnetic racetracks promise performance and reliability beyond that of conventional magnetic disk drives and solid state storage devices (1). The materials and structures underlying racetrack memory have evolved over 4 major stages over the past decade (see Figure). Racetracks that are formed from atomically thin, perpendicularly magnetized nano-wires, interfaced with adjacent metal layers with high spin-orbit coupling, give rise to domain walls (DWs) possessing a chiral Néel structure. Domain walls that have a chiral structure, stabilized via a Dzyaloshinskii-Moriya Interaction, can be moved very efficiently with current via a chiral spin torque mechanism that relies on spin currents generated by the spin Hall effect (2). We show that DWs can be driven even more efficiently in synthetic antiferromagnetic (SAF) racetracks due to an even larger chiral exchange-coupling torque with DW velocities that can exceed 1,000 m/sec (3). The magnitude of the spin currents will also be discussed (4).

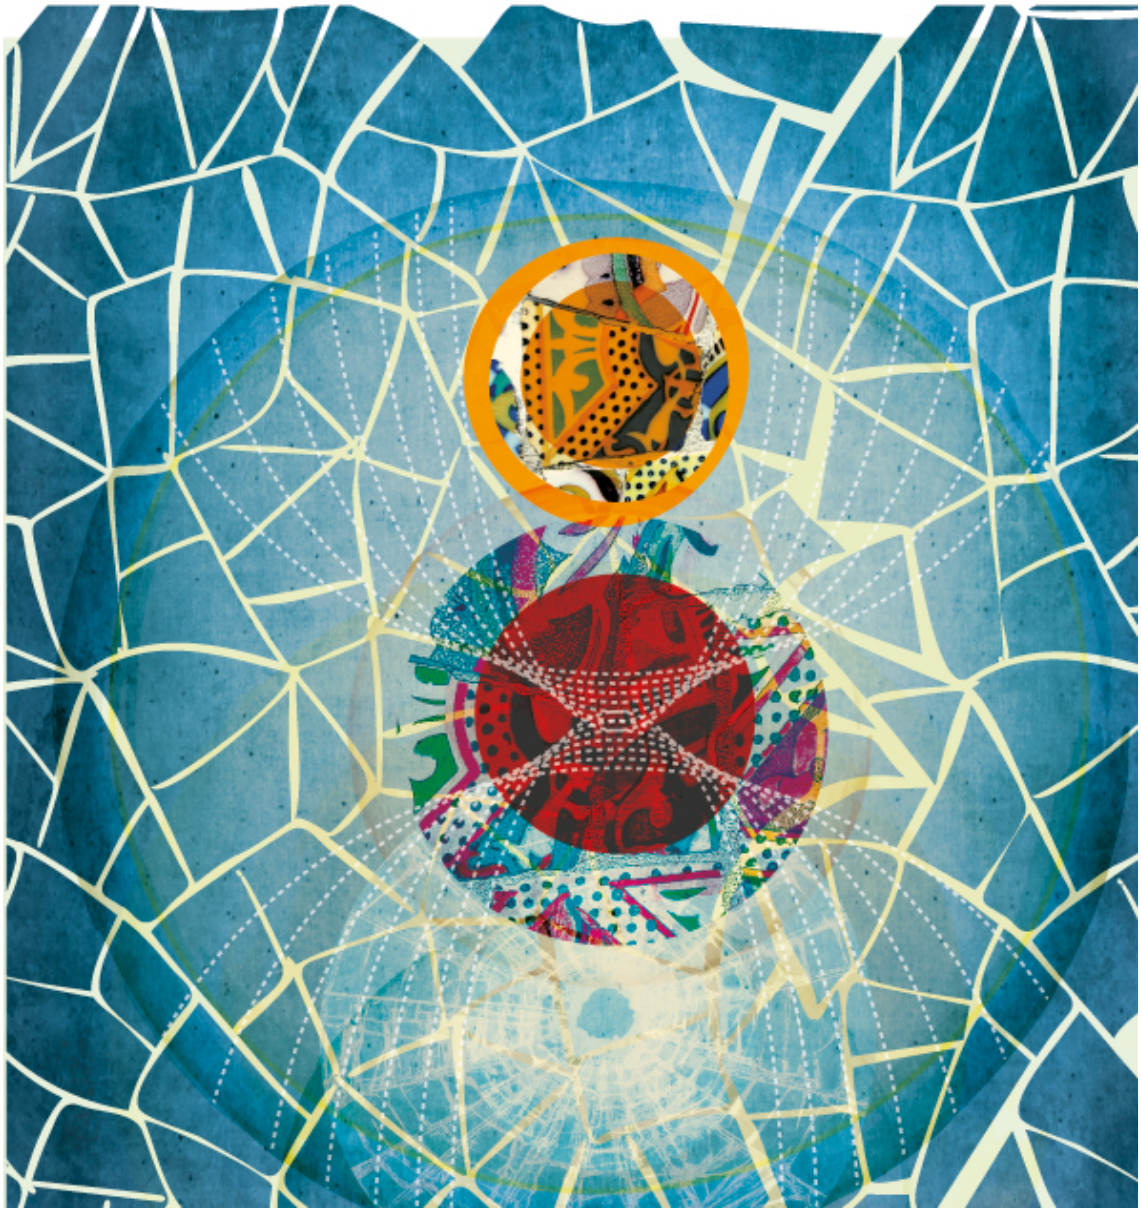
Symposium Lectures



BOOK OF ABSTRACTS

MO.SYM 1 - Topological magnetism

R. Moessner [1]

1. MPI-PKS, Dresden, Germany

Topological states of matter differ from conventional ones in that they look disordered but are in fact not at all featureless. Instead, they exhibit many remarkable phenomena related to their highly unusual low-energy degrees of freedom -- emergent gauge fields and fractionalised quasiparticles. This talk aims to provide a brief introduction to these phenomena, and will discuss recent developments in theory and experiment on quantum spin liquids and ices, in particular with view to dynamical response properties. It will also touch on the remarkably rich interplay of topology and disorder.

MO.SYM 2 - Low carrier concentration crystals of the topological insulator $Bi_{2-x}Sb_xTe_{3-y}Se_y$: a magnetotransport study

A. De Visser [1], Y. Pan [1], J. Angevaare [1], Y. Kai Huang [1], M. Golden [1], M. Snelder [2], A. Brinkman [2], S. Wiedmann [3], U. Zeitler [3]

1. University of Amsterdam, Amsterdam, The Netherlands
2. University Twente, Enschede, The Netherlands
3. Radboud University, Nijmegen, The Netherlands

Recently, it was demonstrated that the material system (Bi,Sb)2(Te,Se)3 (in short BSTS) can be prepared as genuine topological insulator (TI) with surface dominated transport (Ren et al., PRB 84, 165311, 2011). In our work to further optimize the TI properties we found that a record high resistivity and bulk-insulating behaviour, combined with a low carrier density, can be achieved for the composition Bi1.46Sb0.54Te1.7Se1.3 (Pan et al., New J. Phys. 16, 123035, 2014). The analysis within a parallel resistor model of the resistance measured for crystals with different thicknesses shows that the surface contribution to the electrical transport amounts to 97 % when the sample thickness is reduced to 1 micrometer. The magnetoconductance of exfoliated BSTS nanoflakes shows 2D weak anti-localization with the fit parameter alpha close to - 1 as expected for topological surface states. Magnetotransport experiments in high magnetic fields reveal 2D Shubnikov-de Haas (SdH) oscillations. By using the Lifshitz-Kosevich formalism, important transport parameters of the surface states, such as the carrier density, cyclotron mass and quantum mobility, were obtained. We also elaborate on the finite Berry phase, the hall mark for topological surface states, extracted from the SdH signal.

MO.SYM 3 - Transport and induced superconductivity in the topological surface and edge states of HgTe

C. Brüne [1]

1. Experimentelle Physik 3 Universität Würzburg, Würzburg, Germany

HgTe is a semimetal with an inverted bandstructure in which the Gamma_8 band is above the Gamma_6 band. Due to the semimetalic nature of the bulk material topological insulator behavior can only be observed when a band gap is opened. This can be achieved by either applying tensile strain to a bulk HgTe layer or in HgTe quantum well structures above a critical thickness. The former, strained bulk HgTe, is a 3-dimensional topological insulator while the latter is a 2 dimensional TI.

This talk will focus on the transport properties of the topological surface and edge states in HgTe. Furthermore the properties of induced superconductivity in this edge/surface states is investigated

MO.SYM 4 - Topology in Heusler compounds - from a materials perspective

C. Felser [1], B. Yan [1], C. Shekhar [1], Y. Chen [2]

1. Max Planck Institute Chemical Physics For Solids, Dresden, Germany
2. Oxford University, Oxford, United Kingdom

Topological insulators and Weyl metals are a hot topic in condensed matter physics and materials science. Heusler compounds are a remarkable class of materials with more than 1,000 members and a wide range of extraordinary multifunctionalities including half-metallic high-temperature ferri- and ferromagnets and tunable topological insulators with a high potential for spintronics and energy technologies. The tunabilty of this class of materials is exceptional and nearly every functionality can be designed. Therefore it is not surprising that we were able to design Heusler compounds with a band inversion and a non-trivial topology for multifunctional topological insulators (TI). The topological state in these zero-gap semiconductors can be created by applying strain or by designing an appropriate quantum well structure, similar to the case of HgTe. Many of these ternary zero-gap semiconductors (LnAuPb, LnPdBi, LnPtSb and LnPtBi) contain the rare-earth element Ln, which can realize additional properties ranging from superconductivity (for example LaPtBi) to magnetism (for example GdPtBi) and heavy fermion behavior (for example YbPtBi). These properties can open new research directions in realizing the quantized anomalous Hall effect and topological superconductors. C1b Heusler compounds have been grown as single crystals and as thin films. The control of the defects, the charge carriers and mobilities can be optimized. The band inversion is proven by ARPES. Heusler compounds are similar to a stuffed diamond, correspondingly, it should be possible to find the “high Z” equivalent of graphene in a graphite-like structure or in other related structure types with 18 valence electrons and with inverted bands. Dirac cones and Weyl points can occur at the critical points. Weyl points, a new class of topological phases was predicted in NbP, NbAs and TaP. We founds ultrahigh magneto resistance, mobilities and Fermi arcs in this class, proving their topological electronic state.

MO.SYM 5 - A spin-anisotropic harmonic honeycomb iridate

R. McDonald [1], K. Modic [1], T. Smidt [1], I. Kimchi [1], N. Breznay [1], A. Biffin [1], S. Choi [1], R. Johnson [1], R. Coldea [1], P. Watkins-Curry [1]

1. Los Alamos National Laboratory, New Mexico, United States

Oxygen octrahedra are prolific building blocks of correlated electron systems, for example, the numerous corner-sharing structures of the Ruddlesden-Popper series, that host phenomena ranging from high temperature superconductivity to exotic magnetism. In contrast, three dimensional structures with edge-sharing octrahedra are relatively rare. The interest in exploring such structures originates from the the threefold coordination of edge-sharing octrahedra that frustrates the nearest neighbor interactions.
Iridium-based oxides (iridates) open a further dimension to this problem by introducing strong spin-orbit interactions, such that the Mott physics has a strong orbital character. In the layered honeycomb iridates this is thought to generate highly spin-anisotropic interactions, coupling the spin orientation to a given spatial direction of exchange and leading to further frustration of magnetism. As a result quantum dynamics are expected to dominate the properties of these

materials. The potential for new physics emerging from such interactions has driven much scientific excitement; most recently in the search for a new quantum spin liquid, first discussed by Kitaev. In this talk I present a three dimensional iridate structure that has the same local connectivity as the layered honeycomb. The temperature dependence of the magnetic susceptibility exhibits a striking reordering of the magnetic anisotropy, giving evidence for highly spin-anisotropic exchange interactions.
Furthermore, the basic structural units of this material suggest the possibility of a new family of structures, the `harmonic honeycomb' iridates. This compound thus provides a unique and exciting glimpse into the physics of a new class of frustrated and strongly spin-orbit coupled Mott insulators.

TU.SYM 1 - Two dimensional spin-orbitronics (skyrmions in multilayers, 2D conversion between charge and spin currents)

F. Albert [1]

1. Unité Mixte de Physique CNRS/Thales And Université Paris Sud, Palaiseau, France

The exploitation of the Spin-Orbit Coupling (SOC) has recently opened new directions for the development of spintronics. My talk is on SOC-induced effects in 2D systems with a special focus on two topics:

1) Interface-induced magnetic skyrmions;
2) Conversion between charge and spin currents at surfaces and interfaces.

1) Interface-induced skyrmions at room temperature in multilayers: I will present i) the main features predicted by DFT calculations for the Dzyaloshinskii-Moriya Interactions (DMI) at the interfaces of magnetic layers with heavy metals, ii) what can be expected from micromagnetic simulations for the properties (nucleation, current-induced motion) of interface-induced individual skyrmions in thin films and multilayers, iii) experimental results at room temperature on skyrmions in (Pt/Co/Ir)xn multilayers. I will also assess the potential of skyrmions for technological applications.

2) Conversion between charge and spin current by SOC at surfaces and interfaces: report of the results of spin pumping experiments on the spin to charge conversion by Rashba, topological insulator or oxide interfaces; discussion of the application of SOC torques to the motion of magnetic domain walls and the switching of nanomagnets.

TU.SYM 2 - Spin-orbitronics with skyrmions in chiral magnets

C. Pfleiderer [1]

1. Technische Universität München, Munich, Germany

The emergence, stability and decay of skyrmions in chiral magnets and the associated emergent electrodynamics are reviewed. The non-zero topological winding, which corresponds to precisely one quantum of emergent magnetic flux, mediates an extremely efficient coupling between the conduction electrons and the magnetic properties. This emergent flux leads to a topological Hall signal, spin transfer torques at ultra-low current densities and emergent electric fields. Additionally skyrmions are characterised by an exceptional stability, which cannot be simply suppressed under large hydrostatic pressures or doping.

TU.SYM 3 - Spin hall effect and chiral magnetism in metallic heterostructures

M. Hayashi [1]

1. National Institute For Materials Science, Tsukuba, Japan

Strong spin orbit effects in thin film heterostructures consisting of a perpendicularly magnetized ultrathin magnetic layer sandwiched between a heavy metal (HM) layer and an oxide layer have opened new paradigms to control magnetic moments electrically. We have studied spin transport and magnetic properties of CoFeB/MgO based heterostructures with heavy metal (e.g. Hf, Ta, W, Re) underlayers. We find that the HM layer generates large enough spin current via the spin Hall effect that can significantly influence the transport properties of the system and enables manipulation of the CoFeB layer magnetic moments. The amount of spin current generated via the spin Hall effect is probed by the spin Hall magnetoresistance (SMR): a large SMR is observed in the W underlayer films. We also find that a strong chiral magnetic order emerges at the W/CoFeB interface owing to the Dzyalonshinskii-Moriya interaction (DMI). The influence of the interface on the SMR and DMI will be discussed.

5. University College London, London, United Kingdom
6. PRESTO, Japan Science and Technology Agency

Spin pumping represents a convenient way to electrically detect magnetization dynamics. In this case, however, a secondary spin-charge conversion element, such as heavy metals with large spin Hall angle, is required to convert the spin current into a charge signal. Here, we report the experimental observation of charge pumping in which a precessing ferromagnet pumps a charge current, demonstrating direct conversion of magnons into high-frequency currents via the relativistic spin-orbit interaction. The generated electric current, unlike spin currents generated by spin-pumping, can be directly detected without the need of any additional spin-charge conversion mechanism. The charge-pumping phenomenon is generic

and gives a deeper understanding of its reciprocal effect, the spin orbit torque, which is currently attracting interest for its potential in manipulating magnetic information.

TU.SYM 5 - Chiral magnetic skyrmions in ultrathin films and heterostructures: inside from materials-specific theory

S. Blügel [1]

1. Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum, Jülich, Germany

Ultrathin magnetic films and heterostructures provide a fantastic play- ground for the stabilization, manipulation and usage of magnetic skyrmions - topological magnetization solitons - magnetic entities with particle like properties that may open a new vista for spintronics. A crucial quantity for the skyrmion formation is the Dzyaloshinskii- Moriya interaction (DMI), whose presence in thin films could be estab- lished in a concerted effort of first-principles theory and spin-polarized scanning tunnelling microscopy [1]. It could be shown that the spin- orbit interaction and the structure inversion-asymmetry in these sys- tems result in a DMI that is strong enough to give rise to one- dimensional and two-dimensional lattices [2] of chiral spin-textures as well as chiral domain walls. Even single skyrmions [3] could be in- duced. In retrospect, it is surprising how little is known about the DMI in these metallic systems. In this talk I give some insight into the DMI, the relation to the transport properties of electrons such as the THE and AHE in connection to the spin texture of a skyrmion, and discuss possibilities to tailor the magnetic interactions to enlarge the materials base to stabilize single skyrmions in films and heterostructures.

4. *Departamento de Física, CINVESTAV-IPN Col. San Pedro Zacatenco, México City, México*
5. *Dept. Anatomia e Histología, Facultad de Medicina, Universidad de Zaragoza, Zaragoza, Spain*

We present experimental evidence demonstrating the suitability of Fe3O4-based magnetic nanoparticles (MNPs) to target microglial BV2 cells and to provoke cell death by magnetic hyperthermia. The MNPs, of 30-40 nm, were in situ functionalized with two different polymers, poly-acrylic-acid (PAA) and Lauric-Acid (LA) to control the final particle size for maximum heating efficiency. The measured specific power absorption (SPA) in water under alternating magnetic fields (f =560 kHz, H= 23.9 kA/m) was within the 400 - 600 W/g range, and dropped to ≈250 W/g and <150 W/g in culture medium for PAA-MNPs and LA-MNPS, respectively. The analysis of the MNPs distribution at the intracellular level showed vesicle-trapped MNPs agglomerates spread along the cytoplasm, as well as large (~0.5-0.9 mm) clusters attached to the cell membrane. In vitro magnetic and water-bath hyperthermia experiments performed in pellets of microglial MNPs-loaded BV2 cells, designed to reach a

constant temperature of 46ºC for 30 minutes, yielded a decrease of cell viability down to 25 % for both heating methods. Structural analysis of the cell structures after magnetic and water-bath hyperthermia under these conditions simulating a glial micro-tumor environment showed large amount of damage at the cellular level. It is demonstrated that those regions where the cell membrane is damaged are correlated to the MNPs clusters location. The drastic rupture of the cell and internal membranes suggest that a necrotic process triggered by the MNPs could be the main cause of cell death during hyperthermia.

WE.SYM 2 - Engineered nanoparticles for magnetic particle imaging: tailoring physics and chemistry to clinical applications

K. Krishnan [1]

1. University of Washington, Seattle, United States

The performance - sensitivity and spatial resolution - of Magnetic Particle Imaging (MPI), a new medical imaging technology for whole-body imaging of magnetic tracers, depends largely on the structural, chemical and magnetic characteristics of the tracers, in addition to instrumentation parameters. As the first biomedical imaging technique that truly depends on magnetic relaxation dynamics of nanoscale materials, MPI requires highly optimized and biocompatible magnetite nanoparticle tracers to generate good-quality images. Here, we describe the development of the most optimal tracers for MPI with magnetic properties that were designed using a sound theoretical framework, an organic synthetic route leading to highly phase-pure and monodisperse magnetite nanocrystals, subsequent phase-transfer and functionalization to ensure biocompatibility and adequate in vivo circulation. In phantom MPI imaging, with image reconstruction in either real or Fourier space, these optimized tracers showed more than 4x times signal-to-noise ratio and improved spatial resolution (50% better) than existing, commercial tracers; the latter approaching sub-mm resolution at 6T/m field gradients critical for translational applications in angiography and molecular imaging of cancer. Finally, we have established a flexible platform for functionalization of the magnetic cores with PEG (to increase water solubility, enhance circulation time up to ~160 minutes, and improve shelf life), dyes (to turn them into multimodal - MRI, MPI and NIRF - contrast agents and used to further enhance studies of their biodistribution with significant anatomical detail in rodent models) and ligands (such as Lactoferrin with specific affinity for glioma cells) tailored for targeted molecular imaging. These critical results, that pave the way for improved clinically relevant MPI performance, will be discussed with emphasis on the tracer response to both the alternating magnetic field and the biological environment.

This work was supported by NIH grants 1R01EB013689-01/NIBIB &1R41EB013520-01.

WE.SYM 3 - Can the synthesis technology and properties of magnetite nanoparticles cater the needs of biomedical applications?

J. Balachandran [1], H Mamiya [2]

1. The University of Shiga Prefecture, Hikone, Japan
2. National Institute of Materials Science, Tsukuba, Japan

Magnetite nanoparticles of different sizes are considered as the potential magnetic seeds for various biomedical applications such as magnetic hyperthermia, magnetic imaging and drug delivery from the standpoint of their magnetic property and biocompatibility. As a consequence, several techniques have been proposed to synthesize mostly spherical magnetite particles with various diameters and narrow size distribution and their application in

biomedicine is being actively pursued. This presentation will focus on the application of magnetite particles for magnetic hyperthermia from the perspective of numerical simulation, experimental verification and the practical limits posed on the magnetic properties using the synthesis techniques available at present. First, the results of the numerical simulation study undertaken to compare the magnetic loss in rotatable magnetite nanoparticles in an aqueous phase with that of non-rotatable nanoparticles anchored to localized structures in the context of magnetic heat dissipation will be discussed. Secondly, the technology available for the synthesis of magnetite nanoparticles and their magnetic properties as well as the experimental findings on the heat dissipation properties of magnetite particles with varying magnetic properties under different alternating magnetic field strengths and frequencies will be discussed. Finally, the validity of the interpretation of the experimental observation of magnetite nanoparticles using the existing theories will be discussed. It should be noted that the experimental results obtained in heat dissipation experiments are generally being explained based on models that does not consider the magnetic interaction effects into account though the magnetic interaction is inevitably present. The preparation of magnetic interaction-free magnetite particles with diameters considered suitable for magnetic hyperthermia applications and estimation of their magnetic properties will also be presented. Results obtained reveals that the potential of magnetite particles as a magnetic thermal seeds will be limited unless additional steps are taken to nurture their properties to suit the operating conditions.

WE.SYM 4 - Albumin-SPIONs: protein surface binding, nanoparticles uptake and fate in cells and C. elegans

A. Roig [1]

1. Institut de Ciència de Materials de Barcelona (ICMAB-CSIC), Bellaterra, Spain

Superparamagnetic iron oxide nanoparticles (SPIONs) are demonstrating huge potential in nanomedicine. SPIONs are investigated as MRI contrast agents, in hyperthermia treatment, for drug delivery, targeting therapies, biosensing and magnetic separation. However, the stability of SPIONs in complex biological environments remains a challenge and simple biocompatible surface coatings to stabilize nanoparticles, avoid agglomeration, enhance their therapeutic effect and prevent their dissolution, are currently being investigated. Albumin is the most abundant protein in serum with many important physiological functions in the circulatory system. Moreover, one of the first FDA-approved nanomedical products (Abraxane«) is a formulation of paclitaxel-albumin nanoparticles where the presence of albumin facilitates the transport of paclitaxel through the endothelial cells enhancing its accumulation in the tumor. I will show that bovine serum albumin (BSA) stabilizes SPIONs by controlling their aggregation and improving their colloidal stability in biological media. Moreover, BSA forms a protein corona around the nanoparticles modifying their initial surface chemistry and providing a new but distinct bio-identity to the nanoparticles when exposed to biological media, cells and organisms. Binding affinity, conformation changes of BSA upon binding to the SPIONs and the effects on cytotoxicity, cellular uptake, distribution and fate of nanoparticles in presence of albumin will be reported. Finally, nanoparticles assessment in a simple animal model, C. elegans, will also be presented. In particular, based on its transparency, short life cycle, differentiated anatomy and ease of cultivation, C. elegans is a suited model organism for in vivo NP evaluation within the synthetic laboratory (Figure 1). Interestingly, results confirm in vitro observations regarding enhanced stability of BSA-coated SPIONs in biological environment, and reduced interaction with cells. Furthermore, all findings indicate the protective effects of the protein both to the nanoparticles and to the worms especially at high concentrations.

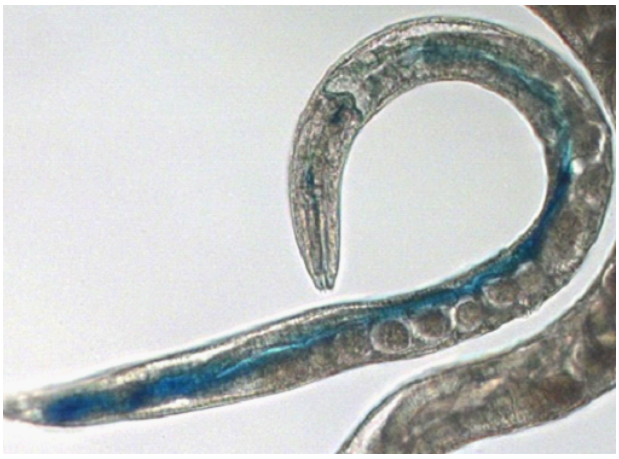

Figure1. Prussian Blue stained *C. elegans*: where SPIONs appear blue

WE.SYM 5 - Dual drug carrier for thermo-chemotherapy of cancer

D. Bahadur [1,2], L. Pradhan [1], A.K. DSwain [2]

1. Center For Research In Nanotechnology and Science, Indian Institute of Technology-Bombay, Mumbai, India
2. Department of Metallurgical Engineering and Materials Science, Indian Institute of Technology, Mumbai, India

We discuss here two different ampiphilic drug carrier systems for simultaneous thermo chemo therapy. A pH and thermo sensitive dual drug delivery system (DDDS) consisting of thin lipid layer encapsulated mesoporous magnetite nanoassemblies (MMNA) has been developed which can deliver two anticancer drugs simultaneously. Hydrophilic (Doxorubicin) and hydrophobic (Paclitaxel) drugs are used to examine the loading/releasing efficiency. This hybrid system was investigated for its ability to provide heat under AC magnetic field (ACMF). A high loading efficiency and sustained release are realized. An enhanced release of ~72 and ~68% is recorded for DOX and TXL respectively during the first hour with application of ACMF (~43 ^{o}C). Higher in vitro cytotoxic effect is observed with two drugs compared to individual ones in HeLa, MCF-7 and HepG2 cancer cells. With an aplication of ACMF for ten minutes, the cell killing efficiency is improved substantially due to simultaneous thermo-chemotherapy. Confocal microscopy confirms the internalization of drug by cells and their morphological changes during thermo-chemotherapy. We will also discuss some animal experiments. We also report here a novel nanocomposite of Fe_3O_4-graphene, stabilized with bio polymers that proves to be an effective dual drug carrier and also responsive to hyperthermia for effective cancer treatment. The nanocomposite is stabilized due to covalent functionalization of the two polymers (PVP and PVA) with Fe_3O_4-graphene (PIG). DOX and PTXL conjugated PIG exhibit a sustained release profile at acidic pH-4.3 compared to physiological pH-7.4 and controlled drug release under AC magnetic field is observed. The cellular toxicity assay suggests that the PIG has good cytocompatibilty up to 2.5 mg/ml on L929 and HeLa cell lines. But higher cytotoxicity effect is observed with DOX-PIG and PTXL-PIG at 2.5 mg/ml on HeLa cell line.

BOOK OF ABSTRACTS

MO.A.1_I1 - Superconductivity of Sr2RuO4: Current challenges

Y. Maeno [1]

1. Department of Physics, Kyoto University, Kyoto, Japan

In this talk, we will summarize the key experimental facts known so far concerning the superconducting symmetry of Sr_2RuO_4, a leading candidate of the spin-triplet, "p+ip" chiral superconductor with Tc = 1.50 K [1]. After introducing recent NMR results strengthening the evidence for spin-triplet pairing [2], we discuss how other key results [3-7], especially those evidencing the first-order superconducting transition under the accurately-aligned in-plane fields [3, 4], might resolve the outstanding issue of its superconducting symmetry. We also introduce other important approaches trying to demonstrate the phenomena specific to spin-triplet pairing. One such approach is the presence of half-quantum fluxoid (HQF) states observed in the magnetization of micro-rings of single-crystalline Sr_2RuO_4 [8]. Such states are expected to emerge in an Equal-Spin-Pairing (ESP) triplet superconductor. We describe our recent results attempting to confirm the HQF states by Little-Parks oscillations in micro-rings. Another approach is to establish long-range proximity effects of spin-triplet pairs into a ferromagnet. We have recently developed a hybrid system consisting of epitaxial thin film of ferromagnetic $SrRuO_3$ deposited on Sr_2RuO_4 [9]. It is expected that the range and the magnetic-domain-dependence of the proximity effect provide vital information about the nature of superconducting symmetry in Sr_2RuO_4.

MO.A.1_O2 - Controlling superconductivity by tunable AFM QCPs in the heavy fermion compound $CeRhIn_5$

T. Park [1], S. Seo [1], E. Park [1], E.D. Bauer [2], F. Ronning [2], J.N. Kim [3], J.H. Shim [3], J.D. Thompson[2]

1. Sungkyunkwan University, Seoul, South Korea
2. Los Alamos National Laboratory, New Mexico, United States
3. POSTECH, Gyeongsangbuk-do, South Korea

Magnetic impurities have been known to be detrimental to superconductivity because they break the Cooper pairs. In various classes of unconventional superconductors, the superconducting phase is located adjacent to a magnetic phase, suggesting that superconductivity may thrive in spite of magnetism. This viewpoint, however, has faced a challenge since the presence of a hidden quantum critical point was explicitly revealed inside the dome of superconductivity in the heavy fermion compound $CeRhIn_5$. In spite of this, the question has remained whether the superconductivity arises in spite of the QCP or because of the QCP. Even though the discovery of a hidden quantum critical point indicates that the spectrum of singular quantum fluctuations are responsible not only for the strange metallic state, but also for the Cooper pairing, a lack of further examples of a hidden QCP has raised a doubt on the role of quantum critical fluctuations in producing superconductivity. In this presentation, we show that the superconducting phase rigidly shifts commensurately with the QCP as a function of pressure and doping $CeRhIn_5$. The precise pinning of the SC phase by the tunable QCPs indicates that the singular quantum fluctuations are responsible for the unconventional superconductivity in $CeRhIn_5$. These discoveries, though specific to $CeRhIn_5$, could be broadly applicable to the SC mechanism of diverse classes of unconventional superconductors. We acknowledge support by a NRF grant funded by the Ministry of Science, ICT and Future Planning (No. 2012R1A3A2048816).

MO.A.1_O3 - Antiferromagnetic order and spatial modulation in high field superconducting phase of $CeCoIn_5$

R. Ikeda [1], Y. Hatakeyama [1]

1. Department of Physics, Kyoto University, Kyoto, Japan

For more than ten years, the issue on the high field superconducting phase (HFSP) of the heavy-fermion material CeCoIn5 remains unresolved. Originally, this phase has been identified with a FFLO vortex phase [1]. After that, HFSP has been called as a Q-phase since the discovery of a long-ranged antiferromagnetic or spin-density-wave (SDW) order in the phase. The recent observation of a discontinuous change of the SDW q-vector via in-plane rotation of the magnetic field [2] in HFSP is crucial and corroborates the presence of a spatial modulation of the superconducting order in the phase. However, it is not easy to theoretically justify the presence of the pi-triplet superconducting order proposed as the origin of such a spatial modulation in Ref.[2]. We show in the present report that the original FFLO picture [1] of HFSP, modified in the way of taking account of the SDW order induced by the strong paramagnetic pair-breaking peculiar to this material [3], can nicely explain the discontinuous change of the SDW q-vector upon the field rotation [4]. The origin of the sudden change of the q-vector in this theory is a pinning of the q-vector to the FFLO nodal plane. By combining this result and agreements with other experimental data [5] altogether, we argue that the HFSP of CeCoIn5 can be understood based only on the strong paramagnetic pair-breaking in this material.

Since the discovery of the heavy-fermion superconductivity in cerium and uranium based f-electron materials three decades ago, intensive experimental and theoretical works have been done in order to elucidate the unconventional pairing mechanisms that are widely believed to differ from conventional Debye-phonon mediated attraction. One of the most important issues is to clarify the gap structures of unconventional superconductors, which intimately reflect the pairing interactions. The oldest uranium heavy-fermion superconductor UBe_{13}, which crystallizes in a cubic structure, exhibits unconventional superconductivity at Tc~0.85 Kü[1]. In spite of numerous works, true nature of the superconductivity of UBe_{13} as well as the origin of its non-Fermi-liquid normal state has remained elusive. In order to obtain information about the superconducting gap structure, we studied the low-energy quasiparticle excitations in the superconducting state of UBe_{13} by means of heat capacity (C) measurements in a rotating field [2]. Quite unexpectedly, the magnetic-field dependence of C(H) is linear in H with no angular dependence at low magnetic fields in the SC state, implying that the gap is fully open over the Fermi surfaces [2]. Our observation contrasts starkly with previous expectations over more than 30 years [3] that the strongly correlated heavy f electrons favor a nodal superconducting gap to avoid the strong Coulomb repulsive force. We also observed a characteristic cubic anisotropy at high fields above 2 T with a maximum (minimum) for H|| [001] ([111]), both in the normal as well as in the SC states. This oscillation possibly originates from the anisotropic response of the heavy quasiparticle bands, and might be a key to understand the anomalous properties of UBe_{13}.

Strong magnetic spin fluctuations are present in many unconventional superconductors. Although the two mechanisms, magnetic order and superconductivity, are often of competing nature, in many cases the two phenomena not only coexist, but also they depend on each other for their existence. For instance, for many unconventional superconductors spin fluctuations, which mediate the magnetic order, are necessary for the formation of Cooper pairs in [1, 2]. It is, therefore, crucial to understand in detail the properties of known materials which display both magnetism and superconductivity. For this reason $Pr_2Pt_3Ge_5$ has recently gained interest in the research community. This material displays a relatively high superconducting transition temperature Tc = 7.8 K and two antiferromagnetic (AF) transitions at TN1 = 3.4 and TN2 = 4.1 K, deep in the superconducting phase. It was suggested that $Pr_2Pt_3Ge_5$ is a multiple-gap superconductor with possibly a substantial amount of anisotropy in the superconducting properties [3]. We have studied the two AF phases of this compound by means of neutron scattering and found some very unexpected results. We have identified the propagation vectors and the magnetic structures of the two AF phases existing in the superconducting phase. The HT-phase boundary separating the normal state and the two magnetically ordered phases provides insides on the question of a possible coupling of superconductivity and magnetism in $Pr_2Pt_3Ge_5$.

Recent developments have convincingly shown that charge density-wave (CDW) modulations are a universal property of cuprate superconductors and this has opened up a new era of research in the field. Understanding the origin of the CDW and its relation to the key features of cuprates, namely the superconducting state, the pseudogap phase, and the Fermi surface, are currently at the center of attention. To examine the interplay between the CDW and superconductivity, we have performed the first direct measurement of the upper critical field Hc_2 in the cuprate YBa_2Cu_3Oy [1], which provides a thermodynamic measure of the strength of superconductivity across the temperature-doping phase diagram. Our measurements reveal a strong suppression of Hc2 and of the condensation energy precisely where the CDW is strongest, and peaks in Hc2 where the CDW vanishes, showing clearly a phase competition between the two phenomena. In the field-induced normal state above Hc_2, our quantum oscillations measurements on YBa_2Cu_3Oy reveal the presence of both electron and hole pockets, whose size and mass agree with the Fermi surface expected from a reconstruction by the measured CDW [2]. In this regime, our measurements of the thermal Hall conductivity at low temperatures demonstrate that the Wiedemann-Franz law is valid above Hc_2, implying that the fundamental excitations are Landau quasiparticles carrying charge and entropy, suggestive of a Fermi-liquid state [3].

2. Department of Physics and Astronomy, University of British Columbia, Vancouver, Canada

The rich phenomenology displayed in the phase diagram of the high-Tc cuprates continues to be an active arena of investigation. Recent experimental and theoretical work appears to be converging on a picture of separate spin and charge order phase transitions , well-below and near optimal doping, respectively - along with associated Fermi surface reconstruction. As sensitive probes of the low-energy electrodynamics, microwave spectroscopy techniques are well-suited for characterizing the effects of such changes in electronic structure deep within the superconducting state. I will present the results of our survey of the complex microwave conductivity of YBCO over a wide range of oxygen contents, from 6.49 to 6.998, and discuss their implications for the evolution of electronic structure with doping. In particular, I will highlight the apparent absence of a peak in penetration depth near the proposed p ~ 0.18 quantum critical point (QCP), contrasting with its presence near the antiferromagnetic QCP of the pnictide superconductors. I will also discuss the surprising relationship we observed between quasiparticle scattering lifetimes and oxygen ordering, which carries important implications for quantum oscillation measurements.

MO.A.2_O3 - Magnetoresistance in the pseudogap phase of the high-Tc cuprate $HgBa_2CuO_{4+\delta}$

Besides high- Tc superconductivity, the identification of the pseudogap state in underdoped cuprates, which is characterized by the partial gapping of the Fermi surface below a characteristic temperature T*, remains a contentious issue within the field. Early electrical transport studies in the cuprates indicated highly anomalous behavior inconsistent with conventional Fermi-liquid descriptions in this regime. We report planar resistivity (ρ) and transverse magnetoresistance (MR) measurements for underdoped $HgBa_2CuO_{4+\delta}$ (Hg1201). Contrary to the long-standing view that Kohler's rule is strongly violated in underdoped cuprates, we find that it is in fact satisfied in the pseudogap phase of Hg1201 for temperatures above Tc [Phys. Rev. Lett. 113, 177005 (2014)]. The transverse MR shows a quadratic field dependence, $\delta\rho/\rho_0=aH^2$, with $a(T)\propto T^{-4}$. In combination with the observed $\rho\propto T^2$ dependence, this is consistent with a single Fermi-liquid quasiparticle scattering rate. A consequence of these results is that the pseudogap regime should feature a largely temperature independent Fermi surface. Furthermore, measurements of Hg1201 at low temperatures in a magnetic field sufficient to suppress superconductivity reveal Shubnikov-de Haas oscillations2 [Nat. Phys. 9, 761 (2013)] which confirms the generality of small Fermi surfaces in underdoped cuprates first observed in $YBa_2Cu_3O_{6+x}$. Recent measurements in magnetic fields up to 90 T reveal only a single oscillatory frequency in contrast to the multiple frequencies observed in YBCO. Finally, the effective electron mass diverges upon underdoping, indicating a possible quantum critical point on the underdoped side of the superconducting dome.

MO.A.2_O4 - Observation of charge order in electron-doped cuprates

The origin of high-Tc superconductivity in the strongly correlated cuprates is still a mystery, 29 years after its discovery. In the hole-doped cuprates a “pseudogap phase” is found in the underdoped part of the phase diagram and this is believed to be related to the cause of the high-Tc superconductivity. A few years ago, charge order was found in the hole-doped cuprates and this was thought to be the cause of the quantum oscillations found in the “pseudogap” region and perhaps related to the origin of the high-Tc superconductivity. Here we report the first observation of charge order (CO) in the electron-doped cuprates from resonant x-ray scattering experiments. This is an unexpected result since the electron-doped cuprates do not have a “pseudogap phase” and their physics is believed to be dominated by antiferromagnetism and its associated spin fluctuations. Moreover, the temperature onset of the CO is unusual and is not related to the onset of the spin fluctuations or to the quantum oscillations. The CO is incommensurate, short ranged (as found in hole-doped cuprates), and has an unusual doping dependence. Since the origin of the high-Tc superconductivity is the same in all the cuprates (both p- and n-types), the CO found in the n-doped cuprates suggests that neither the “pseudogap” nor the CO are related to the origin of the high-Tc superconductivity in the cuprates. Our preliminary results on the CO in n-type cuprates is published in Science 347, 282 (2015).

MO.A.2_O5 - Hybridization and formation of coherent heavy fermions: Non-Fermi liquid detection with point contact spectroscopy

Point contact spectroscopy (PCS) is a well-developed bulk spectroscopic probe used to detect bozonic excitations through classical quasiparticle scattering; and superconducting gap structure and symmetry through Andreev scattering. We have found this technique to be surprisingly sensitive to a density of states arising from non-Fermi liquid behavior in systems with strong electron correlations where we used this technique to identify electron nematic phases in the Fe pnictides and chalcogenides [1]; and developed a quantum mechanical theory to account for this.[2] We have applied this to elucidate microscopic understanding of the hybridization process in heavy electron systems. Using PCS, we have shown the hybridization gap in a heavy-fermion URu_2Si_2 opens well above the hidden order transition. [3] Recently we have shown that for the non-superconducting, non-magnetic intermediate valence compound YbAl3 exhibits a “slow crossover” yo yhr coherent state [3,4]. We show how PCS is used to provide a more rigorous identification of the onset of the hybridization process.

The discovery of superconductivity in FeSe (11)-type chalcogenides has been an important finding to progress in the understanding of Fe-based superconductors (pnictides and chalcogenides) since it has emphasized the central role played by the ubiquitous Fe-Fe planes and interacting anion (pnictogen or chalcogen) atoms. FeSe (11)-type chalcogenides have been widely regarded as a model systems to explore the physics of Fe-based superconductors [1] since lacking the spacer layers present in the most common (1111)- and (122)-type pnictides it presents the easiest crystal structure. Moreover FeSe shows a huge enhancement of the superconducting transition temperature (Tc) under high pressure [2]. This high sensitivity to pressure underlines the delicate balance between electronic and structural properties in defining its physical properties. FeSe layers have been successfully intercalated by alkaline atoms (K, Rb, Cs), with intercalated chalcogenides showing superconductivity at 32 K [3-7], unlike the (11)-type of chalcogenides (maximum Tc: 15 K). (122)-type chalcogenides are no stoichiometric systems displaying a complex phase diagram [8], coexisting phases [9-11], a remarkably large iron magnetic moment and a magnetic order that at low temperatures co-exists with bulk superconductivity [12-13]. High-energy spectroscopies are unique tools to investigate at the same time the evolution of the electronic and magnetic properties as a function of hydrostatic and chemical pressure. Here we report on the electronic and magnetic properties of Fe-based superconductors by x-ray emission (XES) and high resolution absorption spectroscopy (XAS). Comparing the effects of temperature, and hydrostatic and chemical pressure we identify clear correlations between structural, electronic, and magnetic properties, and superconductivity [1,9,14-16].

MO.A.3_O2 - Unconventional superconductivity in double quantum dots

M. Governale [1], B. Sothmann [2], S. Weiss [3], J. König [3]

1. Victoria University of Wellington, Wellington, New Zeland
2. Universitè de Genève, Geneve, Switzerland
3. Universität Duisburg-Essen, Essen, Germany

The formation of electron pairs is a prerequisite for superconductivity. The fermionic nature of electrons leads to four different classes of superconducting correlations with definite symmetries in spin, space, and time (frequency) under exchange of two electrons forming a Cooper pair. Even-frequency singlet (odd in spin and even in space) is the most common type of pairing and occurs in standard s-wave and high-temperature d-wave superconductors. Even-frequency triplet pairing (even in spin and odd in space) is less common, an example being strontium ruthenate [1]. The concept of odd-frequency triplet correlations emerges in the context of superconductor-ferromagnet heterostructures [2]. Finally, odd-frequency singlet superconductivity has not been experimental observed so far.
We show that double-quantum dots (DQDs) in proximity to a conventional s-wave superconductor are ideal systems to generate and study all four types of superconducting correlations in a single device [3]. In particular, we consider two single-level quantum dots, tunnel-coupled to a common superconducting lead in the presence of non-collinear magnetic fields.
This type of system shows an interesting interplay between superconducting correlations and Coulomb interaction [4]. We define even- and odd-frequency order parameters for the DQD and determine how they depend on gate voltages and external magnetic fields. Interestingly, we find that the odd-frequency order parameters can be expressed in terms of the even-frequency counterparts together with local and non-local expectation values of charge and spin on the DQD. Finally, we propose two detection schemes for unconventional superconductivity, based on either Josephson or Andreev spectroscopy.

MO.A.3_O3 - Electronic structure, spin excitations, and orbital ordering in a three-orbital model for iron pnictides

S. Ghosh [1], A. Singh [1]

1. Indian Institute of Technology, Kanpur, India

A three-orbital itinerant-electron model involving d_{xz}, d_{yz}, and d_{xy} Fe 3*d* orbital is proposed for iron pnictides towards understanding the (π, 0) ordered magnetism and magnetic excitations in these materials. It is shown that this model simultaneously reproduces several experimentally observed features such as circular hole and elliptical electron pockets in the electronic Fermi surface structure, quantitatively correct spin wave dispersion, as well as the ferro-orbital order between the d_{xz} and d_{yz} orbital.

MO.A.3_O4 - Superconductivity in $SrPt_3P$: An NMR study and comparison with non-centrosymmetric $LaPt_3Si$ and $CePt_3Si$

T. Shiroka [1,2], H.R. Ott [1,2], M. Pikulski [1], N.D. Zhigadlo [1], B. Batlogg [1], J. Mesot [1,2]

1. Laboratorium für Festkörperphysik, ETH Zurich, Zurich, Switzerland
2. Paul Scherrer Institut, Villigen PSI, Switzerland

The unusual properties of non-centrosymmetric superconductors, characterized by sizable antisymmetric spin-orbit couplings due to the lack of crystalline inversion symmetry, have attracted considerable interest [1]. However, the exact origin of their unconventional behaviour remains an open question. To identify the special features of this class of superconductors, we studied the properties of the centrosymmetric compound $SrPt_3P$ [2] and compare them with available results for the $LaPt_3Si$ (Tc = 0.6 K) [3] and $CePt_3Si$ (Tc = 0.75 K) [4], which adopt crystal structures that only differ in the arrangement of the Pt octahedra from that of $SrPt_3P$.
Normal and superconducting properties of $SrPt_3P$ (Tc = 8.5 K) were investigated via 31P NMR and magnetometry, indicating a weakly correlated normal state and an s-wave type superconductivity [5], respectively. A sharp drop of the (metallic) Knight shift below Tc, associated with a concomitant steep increase of the linewidth and a Hebel-Slichter type variation of the 1/(T1T) ratio, are all consistent with an s-wave pairing in $SrPt_3P$.
While $SrPt_3P$ and $LaPt_3Si$ follow a perfect Korringa law down to Tc, the 1/(T1T) ratio of $CePt_3Si$ is enhanced upon cooling due to the development of 4f-derived magnetic fluctuations. Electronically, both $SrPt_3Si$ and $LaPt_3Si$ are simple metals. The former exhibits conventional type-II superconductivity, while the nature of the superconducting state of the latter is not well established [6]. The superconductivity of $CePt_3Si$ emerges from a heavy-electron state coexisting with antiferromagnetic order. The key differences between the considered centro- and non-centrosymmetric superconductors seem to be due to both the symmetry of the crystal lattice and to the cations entering the chemical composition of the compounds.

The coupling between different magnetic layers in thin film systems is usually ferromagnetic (FM) (layers parallel to each other). However, other types of couplings such as antiferromagnetic (AFM) (i.e., antiparallel layers) have also been reported. In contrast, the magnetic properties of bi-magnetic core/shell nanoparticles remain relatively unexplored. While Monte Carlo simulations have probed the effects of different types of interface couplings from the theoretical viewpoint (e.g., FM vs. AFM coupling), experimental work so far has only reported ferromagnetic coupling between the counterparts. Here we present the existence of an interfacial AFM coupling in ferrimagnetic (FiM) hard-soft core/shell nanoparticles based on iron and manganese oxides [1]. Narrow size distributed Fe_3O_4/Mn_3O_4 and $Mn3O_4/Fe_3O_4$ core/shell, soft/hard and hard/soft, were synthesized by seeded growth. In contrast to conventional systems, the temperature dependence of the magnetization, M, and the ferromagnetic resonance field, H_R, show a downturn at the magnetic ordering temperature of the hard Mn_3O_4 phase ($TC(Mn_3O_4)$=40 K). This decrease in M and HR can be linked to an antiferromagnetic coupling between both phases, although the degree of AFM coupling is related to the quality of the interface (as determined by RIXS-MCD [2]). Moreover, element-selective X-ray magnetic circular dichroism (XMCD) spectra and hysteresis loops confirm that the magnetization of the Mn-containing phase lies opposite to the Fe-containing phase. Magnetometry hysteresis loops show that for small cooling fields the loop shifts towards negative fields similar to exchange bias in conventional FM/AFM systems. However, for large cooling fields the loops shift to the opposite direction, i.e., positive exchange bias. Finally, Monte-Carlo simulations clearly confirm that an AFM interface coupling leads to a magnetization decrease at low temperatures and a positive exchange bias for large cooling fields.

MO.B.1_O2 - Core/shell bimagnetic nanoparticles: magnetic interactions and magnetization reversal

G. Lavorato [1], E. Lima Jr [1], D. Peddis [2], D. Tobia [1], H. Troiani [1], E. Agostinelli [2], D. Fiorani [2], R. Zysler [1], E. Winkler [1]

1. Centro Atómico Bariloche CNEA-CONICET, Bariloche, Argentina
2. Istituto di Struttura della Materia, CNR, Roma, Italia

Novel bimagnetic nanoparticles (NPs) have been recently proposed for the development of new magnetic materials and comprehensive studies are required in order to understand their complex properties. In this work we compared two core/shell magnetic systems: one formed by non-magnetic ZnO NPs surrounded by ferrimagnetic (FiM) $CoFe_2O_4$ shell and the other formed by CoO antiferromagnetic (AFM) NPs surrounded by FiM $CoFe_2O_4$ shell. As both systems present analogous size and morphology (spherical NPs formed by a ~4 nm core and a ~2 nm thick shell), some general issues about core/shell systems can be discussed. The results showed that CoO/ $CoFe_2O_4$ NPs present a mean blocking temperature (TB) of ~270 K, higher than the ~110 K observed for the ZnO/ $CoFe_2O_4$ system. The field dependence of TB and the temperature variation of HC were explained through the Stoner-Wohlfarth model for ZnO/ $CoFe_2O_4$, but deviations were found for CoO/ $CoFe_2O_4$ NPs due to intra-particle interactions. A higher thermal stability of MS up to room temperature and an HC enhancement up to ~27.8 kOe at 5 K were observed for the bimagnetic sample. Magnetic remanence studies revealed that, although weak dipolar inter-particle interactions are observed, they play a minor role in determining the magnetic behavior of the materials. Relaxation experiments clarified that the magnetization reversal process of $CoFe_2O_4$ is strongly dependent on the magnetic order of the core. At 10 K, activation volumes of 46 and 96 nm3, representing ~20 and 40% of the total shell volume, were found for CoO/ $CoFe_2O_4$ and ZnO/ $CoFe_2O_4$ NPs respectively. While the main characteristic of ZnO/ $CoFe_2O_4$ NPs is the high surface-to-volume ratio, the exchange coupling at the CoO/ $CoFe_2O_4$ interface rules the magnetization reversal and the NPs' thermal stability by inducing a larger energy barrier and promoting a smaller switching volume.

MO.B.1_O3 - Surface anisotropy and tunable exchange bias in core/shell and hollow magnetic nanoparticles

H. Srikanth [1], K. Stojak Repa [1], Z. Nemati [1], H. Khurshid [1], J. Alonso [1,2], M. Phan [1]

1. University of South Florida, Tampa, United States
2. BC Materials, Derio, Spain

Core/shell Fe/γ-Fe_2O_3 and hollow γ- Fe_2O_3 nanoparticles are very promising for applications in magnetic storage due to their enhanced properties (strong exchange bias (EB) and effective anisotropy) [1-3]. Surface and interface magnetism in these nanostructures are of current interest and we have explored this in several systems. High quality Fe/γ-Fe_2O_3 core/shell, core/void/shell, and hollow nanoparticles were synthesized with two different mean sizes of 8 nm and 12 nm, and their magnetic properties including the exchange bias (EB) effect were systematically studied. We find that as the morphology changes from core/shell to core/void/shell, the magnetization of the system decays and inter-particle interactions become weaker, while the effective anisotropy and the EB effect increase. In the case of the hollow nanoparticles, the coupling between the inner and outer spin layers in the shell gives rise to an enhanced EB effect, which increases with increasing shell thickness. This indicates that the morphology of the shell plays a crucial role in these kinds of exchange-biased systems.
In addition, we have filled multiwalled carbon nanotubes (MWCNTs) with these magnetic nanoparticles using a novel magnetically-assisted capillary action method [4]. These nanostructures show tunable electromagnetic properties useful for advanced biomedical and microwave applications.

MO.B.1_O4 - Synthesis and magnetic properties of CoPt(core)-Fe/FeCo(shell) nanoparticles

J. Cuya [1], H. Miyamura [1], S. Ishio [2], J. Balachandran [1]

1. The University of Shiga Prefecture, Shiga Prefecture, Japan
2. Akita University, Akita, Japan

The development and use of exchange coupled magnets in areas such as permanent magnets, magnetic recording, etc. is being strongly considered. In the nanometric range, the use of hard magnetic FePt/CoPt cores with soft magnetic shells such as Fe, FeCo have been commonly prepared; however, the control over their particle size and composition, which are important to obtain high energy densities, (BH)max are considered difficult. Here, the CoPt core with different composition and size were synthesized at high temperatures by heating cobalt acetate, dihydrogen hexachloroplatinate in alcoholic solution containing oleylamine as surfactant. Then, these particles were introduced into a mixture of oleylamine and oleic acid, containing cobalt and iron acetylacetonates. This suspension was heated to temperatures above 250 oC to obtain the Fe_3O_4/$CoFe_2O_4$-coated CoPt particles. The formation of core-shell structured particles was confirmed by TEM-EDS mapping. Finally, these particles were heat treated at different temperatures under reducing atmosphere (3% H2/Ar) to obtain soft-hard magnetic composites. As the annealing temperature was elevated, the particles underwent transition from oxide to alloy progressively, and this was clearly visible from structural and morphological analysis using XRD and TEM measurements. Though the formation of magnetically hard core and soft shell was anticipated, our results suggested the gradual transformation of oxide to alloy exhibiting a maximum coercivity of 1.1 kOe and a saturation magnetization of ~70 emu/g of sample heat treated at 500 oC. Although, we found that the magnetic properties, Ms an Hc, were affected by the annealing temperature and composition, pure Fe or FeCo phases were not observed; consequently the magnetic properties were lower due to the remaining oxides phases or the formation of FeCoPt alloy compounds.

MO.B.1_O5 - Optimizing the magnetic properties of inverse antiferromagnetic-core / ferrimagnetic-shell nanoparticles

M. Vasilakaki [1], K. Trohidou [1], J. Nogués [2]

1. Institute of Nanoscience and Nanotechnology, NCSR "Demokritos", Aghia Paraskevi, Attiki, Greece
2. ICREA and ICN2 - Institut Catala de Nanociencia i Nanotechnologia, Campus UAB, Bellaterra, Spain

Bi-magnetic core/shell nanoparticles are gaining increasing interest due to their foreseen applications. Inverse antiferromagnetic(AFM)/ferrimagnetic(FiM) nanoparticles with soft AFM core and hard FiM shell are particularly appealing since they may overcome some of the limitations of conventional FiM/AFM systems. We study the magnetic behavior of these inverse AFM/FiM with the Metropolis Monte Carlo simulations technique. We present their magnetic properties as a function of the core and shell size. Our results show that the coercivity, HC, and the loop shift, Hex, present a non-monotonic dependence on the core diameter and the shell thickness, in very good agreement with the available experimental data [1]. Namely, for very small core sizes both coercivity and exchange bias Hex sharply increase as the core size becomes larger. At a certain size HC and Hex give a maximum and then they start to decrease. Also we observe an increase of the HC and Hex that is proportional to the FiM shell thickness for large AFM cores. Our microscopic study shows that the observed behavior arises from the competition between the AFM core spins and the hard FiM shell that expands over a wide range of core diameters leading to non-vanishing Hex even for very large cores. Based on the results, several possible ways to enhance the experimental performance of inverse core/shell nanoparticles are proposed here for diverse applications.

MO.B.3_O1 - Transport properties of 1D magnetic nanochain

J.S. Lee [1], Y.K. Kim [1]

1. Korea University, Seongbuk-gu, South Korea

An understanding of transport characteristics of 1D chain-like nanostructures assembled from nanoparticles are of scientific interest. Compared with tremendous amount of literatures reported on magnetic 3D, 2D, and homogeneous 1D nanostructures, 1D nanochain related literatures are barely found. Therefore, the preparation and measurement of this type of superstructure would allow us to investigate the electronic conduction and magnetoresistance in arrays of magnetic nanoparticles and line out the effect of disorder and dimensionality of the same. At first, magnetite (Fe_3O_4) nanoparticles with diameters of about 100 nm were synthesized by a hydrothermal polyol method. They show ferrimagnetic properties such as M_s of 75 emu/g and H_c of 40 Oe. A pair of Ti/Au electrode was deposited by e-beam evaporation utilizing a shadow mask on a Si substrate covered with SiO_2. Next, nanoparticles were aligned on the substrate by dropping under magnetic field. We have measured the electrical properties of the nanochain at various temperatures and magnetic fields by a physical property measurement system (PPMS). The current-voltage characteristic (*I-V*) of the nanochain was linear at RT with a resistance of 560 kΩ. The resistance increased monotonically with decreasing temperature, reaching ~20 GΩ at 40 K. For T below 160 K, the *I-V* characteristics became increasingly nonlinear, and, below 40 K, it became insulating. The nanochain device showed negative magnetoresistance reaching a value as high as 16 % at T = 80 K where H = 50 kOe and V_{bias} = 0. Applied field aligns the electronic spins of adjacent nanoparticles, thereby increasing the tunneling probability and conductance for electrons moving through the nanochain, leading to negative magnetoresistance.

MO.B.3_O2 - Hollow Fe_3O_4 nanospheres and their microwave applications

Z. Yang [1], Z. Li [1], Y. Wu [1], M. Chua [1], Y. Yang [2]

1. Temasek Laboratories, National University of Singapore, Singapore
2. School of Chemical and Biomedical Engineering, Nanyang Technological University, Singapore

Hollow Fe_3O_4 nanospheres with the diameter of 450 nm and the wall thickness of 80 nm were prepared using a simple Solvethermal process without using any templates. The density of prepared samples is 3.78 g/cm^3 which is much lower than their solid counterparts. The composites filled with 60 wt% of these hollow spheres show the good high-frequency and attenuation properties. μ' is 2.8 and μ' is 1.2 at 3 GHz. The broad bandwidth WP of 55 % for return loss RL<-10 dB is achieved at thickness between 0.3 and 0.4 cm. The density of the composite is only 2.71 g/cm3, which is lighter 24 and 47 %, as compared to commonly used ferrite and carbonyl iron composites with the same weight concentration. Therefore, the composites filled with hollow nanospheres are potential candidates for EM attenuation applications.

MO.B.3_O3 - Chemical order in cobalt-iron nano-objects probed by ferromagnetic nuclear resonance

Y. Shin [1,2], C. Garnero [3], K. Soulantica [3], L. Marie Lacroix [3], B. Chaudret [3], J.W. Wu [2], C. Meny [1,2]

3. Laboratoire de Physique et Chimie des Nano-objets (LPCNO), Toulouse, France

Nano-objects are involved in many research fields from spintronics to medicine. The physico chemical properties of these objects will depend on the size, shape, crystallographic structure and chemical composition of the nano-objects. In this work we investigate assemblies of nano-objects prepared by chemical roots. The assemblies of nano-objects show very narrow size distributions and well defined object shapes: spheres or cubes. The objects have been prepared will an equal ratio of Iron and Co. CoFe alloys can produce a rich variety of chemical orders [1] that are difficult to study by regular investigation techniques. Because of its sensitivity to the chemical environment of Cobalt, we have used Ferromagnetic Nuclear Resonance (FNR, i.e. Nuclear Magnetic Resonance for ferromagnets) to investigate the chemical order within these nano-objects. Indeed FNR has been extensively used for studying the chemical order in thin films and alloys [2] and more recently for studying the crystallographic structure of Co nanoparticles [3]. Our results show that although both kinds of nano-objects are prepared with similar methods, their chemical order is very different. While the spheres show a predominance of a B2 ordered CoFe alloy, the cubes FNR spectra suggest that the chemical composition in the objects is not homogeneous but present a composition gradient going from pure Fe to almost pure Co.

2. Institute of Materials Science, NCSR Demokritos, Attiki, Greece
3. Department of Physics and Astronomy, University of Nebraska, Lincoln, United States

Non-rare earth based hard magnetic materials, with both high saturation magnetization and coercivity, are of great interest for the development of future magnets to replace the current rare earth magnets because of the limited supply of rare earths. In this study, we explore the possibility of producing hexagonal cobalt nanoparticles, and hexagonal cobalt coated with iron nanoparticles to produce materials with both high saturation magnetization and moderate coercivity. The nanoparticles were synthesized using anhydrous cobalt (II) chloride and iron (II) chloride by sodium borohydride reduction in tetraglyme with and without oleylamine under a nitrogen/hydrogen flow. The reactions were done at high temperatures allowing for the formation of as-made hexagonal cobalt, which was then coated with iron nanoparticles. The size of the particles was controlled by changing the concentration of oleylamine producing a large range of different sized particles. Magnetic properties were optimized by changing the temperature of the reaction. We obtained hexagonal Co nanoparticles with saturation magnetization of (129 emu/g) and coercivity of (350 Oe). We were also able to improve the saturation magnetization of the Co particles by coating with Fe nanoparticles achieving the value of 133emu/g.

MO.C.1_I1 - Emergent interfacial phenomena in magnetic complex oxide heterostructures

S.G.E. Te Velthuis [1]

1. Materials Science Division, Argonne National Laboratory, Lemont, United States

In recent years the interested in complex oxide heterostructures has significantly increased as a myriad of intriguing phenomena have been discovered, including emergent magnetic behavior and exotic superconducting and ferroelectric phases, related to modified bonding at the interfaces. We have investigated manganite/cuprate/manganite structures that form either superconducting spin switches or magnetic tunneling junctions, depending on the type of cuprate. In both cases we have successfully correlated the influence of an induced interfacial magnetic moment in the cuprate, experimentally detected with soft x-ray magnetic dichroism, to modified electric transport behavior. In magnetic tunneling junctions, an anomalous temperature dependence of the tunneling magnetoresistance is found to be attributed to the competition between the positive spin polarization of the manganite contacts and the negative spin-filter effect from the interface-induced magnetization [1]. In the same system a reversible, voltage-driven magnetization switching without assistance from a magnetic field was demonstrated and linked a magnetoelectric coupling arising from the orbital reconstruction at the interface [2]. These contributions are important as emergent interfacial magnetization appears ubiquitous and understanding its influence on macroscopic properties can provide many opportunities to engineer oxide spintronics with tailored properties. Work at ANL supported by US-DOE, Office of Science, BES, MSE.

4. Laboratoire de Physique et d'etude des Matériaux, Paris, France

Manganites have attracted a lot of attention due to the possibility of studying many physical problems related to the strong correlation between their structural, transport and magnetic properties and their potential use in many technological applications. A renewed interested in these compounds has appeared for the developing of manganite/ferroelectric composite systems with multiferroic nature. The origin of this interest is the possibility to develop new technological devices, such as ferromagnetic/ferroelectric tunnel junctions (TJ), with new flexibility and improved performance. In order to obtain systems with increasing reading rate and low head noise, very thin tunnel barriers are required and a good knowledge of the barrier characteristics becomes critical. Recently, conductive atomic force microscopy (CAFM) has become an important tool to characterize the tunnel barrier for TJ like devices (such as spin filters, superconducting Josephson Junctions, etc.). In this work a phenomenological approach has been developed to analyze the electrical transport through an insulating barrier in ferromagnetic/ferroelectric bilayers, using CAFM. We have found that I(V) = A0 . V^alpha , where A0 and alpha depend linearly with the barrier thickness. The model allows to obtain critical information for the development of magnetic TJ. Moreover, assuming a Gaussian distribution of the barrier thickness, it is possible to fit the measured current distribution and to study the thickness homogeneity of the barrier. The influence of the substrate in the electrical properties of the FE/FM bilayers was studied in the frame of this model. CAFM images of both series of samples present an important distribution of the current, which is generally ascribed to a distribution in the barrier thickness. However, MGO substrates with higher roughness were found to increase the barrier height distribution and increase the attenuation length in the material, reducing the barrier quality for the developing of multiferroic tunnel junctions.

MO.C.1_O3 - Magneto-electric coupling in Ca_3CoMnO_6 thin films

J. Saha [1], G. Sharma [1], S. Patnaik [1]

1. Jawaharlal Nehru University, New Delhi, India

We report on the growth and magneto-electric (ME) coupling of Ca_3CoMnO_6 thin films deposited by pulsed laser deposition technique. Ca_3CoMnO_6 is interesting because of its tunable inter-chain magnetic interactions that affects its ME coupling. Thin films of thickness 200nm have been grown on single crystal sapphire substrates (0001- Al2O3). Substrate temperature was kept at 750ºC. The X-Ray diffraction pattern indicates sharp peaks corresponding to (110), (300), (330) planes. AFM measurements show a homogeneous growth of the film. An optical band gap of 1.73eV was estimated by UV visible spectroscopy. The anti-ferromagnetic transition is surprisingly increased to 39 K, much above its bulk value (15K). The increase in magnetic transition temperature is possibly due to stronger inter-chain interaction and strain caused by lattice mismatch. Due to canting, the thin films show ferrimagnetic like behavior at low temperature. For magneto-electric measurements separate films were grown. First a conducting layer of Gallium doped ZnO (100nm) was deposited on the sapphire. On top of the conducting layer 300nm film of Ca_3CoMnO_6 was deposited. Magneto-electric coupling is measured as a function of temperature. A large magneto-electric coupling was observed. The dielectric measurements show anomaly at 10 K and 40 K which are clearly visible at the first derivative of dielectric data. From direct polarization measurements we associate the 10 K transition to a magnetic structure driven ferroelectric phase. The magneto-capacitance data at 5 K and 30 K show substantial change in dielectric constant with magnetic field. The large magneto-electric coupling is also verified by polarization measurement, where 25% change in polarization is observed on the application of 5T external magnetic field.

MO.C.1_O4 - Magnetic and dielectric properties of $BaTiO_3$-Co Nano-composite films

Y. Zhang [1], N. Kobayashi [2], S. Ohnuma [1,2], M. Nose [3], H. Masumoto [1]

1. Tohoku University, Miyagi Prefecture, Japan
2. Research Institute for Electromagnetic Materials,Tokai-Mura, Japan
3. University of Toyama, Toyama Prefecture, Japan

[Introduction] Developments of electromagnetic devices require multi-functional materials, such as magnetic-dielectric films. Our early work has found that the MgF-FeCo nano-composite films show giant dielectric properties [1] and TiN-Co nano-composite films show good high-frequency magnetic properties [2]. The resistivity is important for obtain magnetic-dielectric properties. In this research, by employing high-resistivity complex oxides BaTiO3 (BTO) as matrix material, the BTO-Co nano-composite films have been deposited to realize high resistivity, magnetization (Ms) and dielectric constant.
[Experiment] The BTO-Co nano-composite films were deposited onto Si, Pt/Si and quartz substrates by differential pressure sputtering (DPS) method [3], with two separated sputtering chambers for oxide (BTO) and metal (Co). Film structures were investigated by XRD, TEM. The chemical composition of the films was analyzed by XRF. The magnetic properties were measured with VSM. The dielectric properties were tested by LCR meter.
[Result] The BTO-Co nano-composite films consist of amorphous BTO matrix and Co nano-particles. Magnetic and dielectric properties of the BTO-Co films are affected by Co content. With the Co content increasing from 13 at.% to 39 at.%, the Ms increases from 0.01 to 0.20 T. The dielectric constant was tested at 1 kHz for BTO-Co films, and increases from about 10 to 70, as the Co content increasing up to 28 at.%. BTO-Co nano-composite film shows promising prospect for multi-functional materials.

MO.C.1_O5 - Temperature dependent transport measurements of epitaxially grown copper manganese arsenide

V.A. Hills [1], P. Wadley [1], R. Campion [1], V. Novak [2], K. Edmonds [1], B. Gallagher [1], T. Foxon [1], T. Jungwirth [1,2]

1. School of Physics and Astronomy, University of Nottingham, Nottingham, United Kingdom
2. Institute of Physics ASCR, v.v.i., Prague, Czech Republic

Antiferromagnetic thin films are widely used in current magnetic sensing technologies, as they enable the pinning of magnetic domains at antiferromagnet/ferromagnet interfaces. One promising candidate is epitaxially grown CuMnAs [1]. CuMnAs grown in this way forms a simple collinear antiferromagnet that can be grown on conventional III-V semiconductors (GaAs and GaP) by MBE at (1:1:1) stoichiometry. It has been shown through neutron diffraction to have a Néel temperature of 485±5K. Using a sample held under vacuum it is possible to measure the longitudinal resistivity and see a cusp in the derivative corresponding to the Néel temperature. This method allows for a thickness study of the material to observe the dependence of Néel temperature on the layer thickness. We can also use this method to see the effect of alloying with phosphorous on CuMnAs and how this shifts the Néel temperature significantly.

4. NANO-CNR, Modena, Italy
5. INRIM, Torino, Italy

Magnetic shape memory materials show a remarkable multifunctional phenomenology (e.g. “giant” magnetomechanical, magnetocaloric, elastocaloric properties) arising from the presence of a martensitic transformation and magnetically ordered states. [1]. Low-dimensional materials, mainly thin films, have recently attracted much interest for their great potential in applications (e.g. microactuators, valves, solid-state microrefrigerators) [2]. With respect to the bulk, they offer the further possibility of tuning properties by thickness and by suitable substrates and underlayers [3]. Patterned films and 2D nanostructures are nowadays a vast and unexplored field. The present paper is addressed to the study of the effect of lateral confinement in on-substrate and free-standing nanodisks. Epitaxial thin films of NiMnGa of thickness ranging from 10 to 200 nm were grown by sputtering r.f. on MgO substrates with and without a Cr underlayer. Patterned thin films were obtained by polystyrene-nanosphere lithography, a large-scale and inexpensive nanostructuring method. Freestanding nano-disks (d=160, 650nm) were subsequently obtained by removing Cr underlayer by selective chemical etching. A multiscale structural and magnetic study was performed by means of electron transmission microscopy (HREM, STEM-HAADF, electron diffraction, Lorentz microscopy), X-ray diffraction and reflectivity, AFM/MFM, AGFM and SQUID magnetometry and susceptometry. It was found that nano-disks of both sizes preserve the salient martensitic and magnetic properties of continuous films and are then exploitable in multifunctional applications. On the other hand the twin microstructure and its temperature dependence can be influenced by lateral confinement and release from substrate. This fact, mainly exploitable in shape memory and magnetic shape memory applications, paves the way to the realization of shape-controlled nano-actuators.

MO.C.2_O2 - Tuning magnetic anisotropy by structural strain in La_2CoMnO_6 thin films

R. Galceran [1], L. Balcells [1], J. Cisneros-Fernández [1], J. Roqueta [2], L. López-Mir [1], B. Bozzo [1], C. Frontera [1], B. Martínez [1]

1. Instituto de Ciencia de Materiales de Barcelona, ICMAB – CSIC, Barcelona, Spain
2. Institut Català de Nanociència i Nanotecnologia, ICN2 (CSIC, CERCA), Barcelona, Spain

We report on the magnetic and structural properties of ferromagnetic-insulating La_2CoMnO_6 thin films grown by means of RF sputtering technique. Insulating ferromagnets are of interest because of the exchange splitting of the bands allowing obtaining tunnel barriers with different height for spin-up and spin-down carriers and spin filters. In addition, the possibility of controlling its magnetic anisotropy will also open the door to the implementation of devices based on the tunneling anisotropic magnetoresistance phenomenon. Our results indicate a close correlation between the film composition and their magnetic properties. Both Curie temperature and the features of the hysteresis loops turn out to be dependent on the oxygen stoichiometry. On the other hand, we also show that structural strain, due to film/substrate mismatch, allows controlling the magnetic anisotropy. We probe this by growing La_2CoMnO_6 film on top of different substrates and with different thermal treatments. While compressive strain induces in-plane magnetic anisotropy tensile strain promotes out-of-plane anisotropy.

MO.C.2_O3 - Stabilization of helical magnetic structures in thin multilayers

L. Dzemiantsova [1,2], G. Meier [1,3], R. Röhlsberger [1,2]

1. The Hamburg Centre of Ultrafast Imaging, Hamburg, Germany
2. Deutsches Elektronen Synchrotron, Hamburg, Germany
3. Max-Planck Institute for the Structure and Dynamics of Matter, Hamburg, Germany

Robust and energetically efficient magnetic structures that employ the spin degree of freedom to store and process information are at the heart of modern spin-based technology. It has recently been shown that the transmission and processing of information without electric currents or external fields can be subjected to internal interactions such as exchange, Ruderman-Kittel-Kasuya-Yosida (RKKY) or dipolar interaction [1]. It has been pointed out theoretically that these interactions can stabilize magnetic helices which can be used for magnetic energy storage if they are produced experimentally at the nanoscale.
Based on micromagnetic simulations [2], we report on a novel helical magnetic structure in a soft magnetic thin film that is sandwiched between and exchange-coupled to two hard magnetic layers. We show that such a structure initially twisted in an external magnetic field, stays stable even without the presence of the field. The magnetic stability is determined by the energy minimization and results in an internal effective field created by the exchange interaction in the soft magnetic layer. Changing the angle between hard magnetic layers, the helix can be stable with any twist up to 270 degrees. We show that the helix stores magnetic energy of about 8 kilojoule per cubic meter, as well as that ferromagnetic resonances (FMR) dramatically increase with the helical twist due to the presence of the internal field. In particular, the lowest resonance frequency is approximately two higher compared to that when the trilayer shows a ferromagnetic order. Thin films with a stable helical order provide, therefore, a new route to store magnetic energy and to generate high frequency signals without any presence of external fields or currents on the smallest scale.

MO.C.2_I4 - Shape-critical properties of patterned permalloy thin films

R. Shull [1], Y.P. Kabanov [2], V. Gornakov [2], A. Chen [1], V. Nikitenko [2]

1. National Institute of Standards and Technology, United States
2. Russian Academy of Science, Saint Petersburg, Russia

Steady improvement of thin film growth and patterning techniques pushes the sample physical size towards ever-smaller dimensions. In this case, the magnetization reversal in thin films with restricted lateral sizes is mostly governed by the magnetostatic fields localized in their edges [1]. A domain structure in practically isotropic Permalloy (Py) thin-film meshes demonstrates a competition between the exchange, Zeeman, and magnetostatic energies [2] and has to determine new kinetic effects in such structures. We present both experimental and simulation results of the magnetization distribution and transformation during the reversal of microstructured Py thin films. The effect of shape and edges in the magnetic elements with reduced dimensions on the magnetization reversal of cross-shaped $Ni_{81}Fe_{19}$ (30nm) films were studied. The stripes of the patterned structures had 3 - 30 μm widths and ~100 Ám lengths. Remagnetization details in these structures were visualized by the magneto-optical indicator film (MOIF) technique. The hysteresis loops were measured in a VSM. The MOIF images revealed three different types of the domain structure formation and evolution in the samples during their magnetization reversal: I) spin rotation with growth and annihilation of a cross-tie structure in the stripes perpendicular to the applied field, II) nucleation and fast motion of specific magnetization fronts, which consist of a number of coupled vortices located along both edges, in the parallel to applied field stripes, and III) new macrodomain nucleation and domain wall motion in the larger size films. It was established that, in the first two cases that magnetostatic fields, which are formed on the edges of the stripes and their intersections, play a crucial role in the formation of spin inhomogeneities and switching of the samples.

Polarized neutron reflectometry was used to study the temperature and magnetic field dependent magnetization depth profile of a Ni

x(z)Cu_{1-x(z)} film in which the local composition, and thus magnetic ordering, depends on depth into the film. It is interesting to consider the magnetic profile when the $Ni_{x(z)}Cu_{1-x(z)}$ film at intermediate temperatures, i.e., when the graded structure forms a ferromagnet/paramagnet bilayer. The effective phase boundary moves progressively deeper into the sample with decreasing T, and increasing the applied field from 5 mT to 500 mT alters the shape of the profile. Thus, this system exhibits a magnetic phase boundary that can be moved continuously along the growth axis with temperature, and modified by field. Modeling the data with a mean-field exchange strength gradient theory, we find that with increasing temperature, the magnetized thickness of the film continuously decreases, indicating a continuous distribution of local ordering temperatures. The validity of this modeling is corroborated by comparing the integrated magnetization of the profiles to the net magnetic moment from VSM; there is excellent agreement between the PNR profiles and the magnetometry results. Thus, we observe evidence of a continuous vertical distribution of the effective T_C in a compositionally graded film. The data are consistent with profiles determined from a mean-field simulation, and indicate a phase boundary between paramagnetic and ferromagnetic regions that moves continuously along the growth axis with temperature.

MO.C.3_O2 - Deposition of soft anisotropic FeCoN films on mica substrates

Y. Wu [1], Y. Yang [1], Z. Yang [1], F. Ma [1], B. Zong [1], J. Ding [1]

1. National University of Singapore, Singapore

In recent decades, ferromagnetic thin films have attracted intensive interest due to high microwave permeability. Traditionally, Si wafers or glasses are used as the substrates since the films are not able to self-support. However, for some practical applications, the rigid supporting substrates are unfavorable due to increased total volume of the material. It is imperative to find a suitable substrate which can be thinned down or removed from the deposited film. Mica exists as a promising candidate since it can be conveniently split into thin uniform layers with atomically flat surface. In this work, a series of sputtered FeCoN thin films were deposited on freshly cleaved mica sheets with different sputtering power, which was changed from 100 W to 1000 W. The effect on the static magnetic properties and microwave performance was investigated. Dramatic change in the static magnetic properties has been observed. Only the films deposited with moderate sputtering power (250 W - 350 W) exhibited pronounced in-plane anisotropy and a relative low coercivity of a few Oersted. When the deposition power was lower than 250 W or higher than 350 W, an in-plane isotropy was observed with significantly increased coercivity. Correspondingly, high microwave permeability was obtained for the films with soft in-plane anisotropy, which can be understood using Acher's Law. When the deposition power is 350 W, the imaginary permeability reaches the maximum value of 1774 and the corresponding f_r is 2.5 GHz. These soft FeCoN films on reducible mica substrates are promising for high-frequency applications in gigahertz.

MO.C.3_O3 - Study of the antiferromagnetic order in strained SrMnO3 multiferroic thin films

The interest on the $SrMnO_3$ compound has increased owing to the theoretical prediction of a multiferroic state induced by epitaxial strain[1]. In a recent paper[2], the presence of a polar state in strained $SrMnO_3$ thin films has been proven by second harmonic generation experiments. In this work we present the study of the magnetic properties of antiferromagnetic (AF) $SrMnO_3$ epitaxial thin films (10 nm in thickness) grown on different single-crystal substrates: $LaAlO_3$ (LAO), $(LaAlO_3)_{0.3}(Sr_2AlTaO_6)_{0.7}$ (LSAT) and $SrTiO_3$ (STO), which provide epitaxial strain levels of -0.4, 1.7 and 2.5 % respectively. Néel temperature (T_N) of the films has been determined by performing muon spin relaxation (μSR) experiments by means of polarized low-energy muon beam at the Paul Scherrer Institute. Using these results and the theoretical calculations,[1] a temperature-strain magnetic phase diagram is proposed.
To get a deeper insight into the magnetic properties of the AF $SrMnO_3$ thin films, $SrMnO_3/La_{0.7}Sr_{0.3}MnO_3$ bilayers were grown on LAO, LSAT and STO substrates with a thickness of around 8 nm each, and their exchange bias (EB) effect was studied. In all samples the EB field shows an exponential dependence on temperature and vanishes well below T_N. Moreover, the EB field increases with increasing the epitaxial strain value in the $SrMnO_3$ film. The EB field thermal dependence has been explained assuming the existence of a spin-glass (SG) state as a result of competing magnetic orders and spin frustration at the $SrMnO_3/La_{0.7}Sr_{0.3}MnO_3$ interface[3]. The dependence on strain is originated by the changes induced in the SG interfacial state by the variation of the magnetic interactions on the epitaxial strain.

MO.C.3_O4 - Exploiting magneto-optics as a gateway to the magnetism of Ce-YIG films grown on strongly paramagnetic garnet substrates

B. Casals [1], M. Espinola [1], G. Herranz [1], J. Fontcuberta [1]

1. Icmab-Csic, Bellaterra, Spain

The insulating ferrimagnet yttrium iron garnet (YIG) has come under limelight over the years because of its remarkable properties that make it appealing for a wide range of applications. Traditionally, because of their outstanding high magneto-optic activity, YIGs have been considered the staple materials for nonreciprocal devices in optical communications. Additionally, the remarkably small damping parameters for spin waves have gathered a high interest for magnonics, spintronics and spin caloritronics. For these applications, the deposition of YIG thin films on gadolinium gallium garnet (GGG) crystals is usually a desirable requirement. Yet, in spite of the outstanding structural compatibility between YIG and GGG, the strong paramagnetic susceptibility of the latter is a serious shortcoming when it comes to the magnetic characterization, as strong magnetic signals from GGG substrates obscure severely the much weaker response of YIG thin films. Here we show that magneto-optics is a way around to circumvent this difficulty. The magneto-optic activity results from the interaction of polarized light with magnetic materials and the spectral response is extremely sensitive to the electronic structure. With this in mind, we have measured the Kerr rotation and ellipticity of both Ce-doped YIG thin films grown on GGG and bare GGG substrates. We used cerium as a dopant as it is known to enhance further the magneto-optic activity of YIG. Our extensive spectroscopic study in the visible helped to identify the particular wavelengths for which the rotation and ellipticity of GGG vanished, while the magneto-optic activity of Ce-YIG remained large. That allowed us to access the individual magnetic properties of the Ce-YIG films that were otherwise unreachable using conventional magnetometry. This methodology was instrumental to achieve thin films with optimized magnetic properties.

MO.D.1_I1 - Magnetic shape memory alloys for energy applications

L. Mañosa [1], A. Planes [1]

1. Universitat de Barcelona, Barcelona, Spain

Magnetic shape memory alloys feature interesting functional properties associated with the martensitic transition they undergo. Prominent among these properties are the giant caloric effects that arise when the transition is driven by an external field such as magnetic field, uniaxial stress and hydrostatic pressure. The large isothermal entropy and adiabatic temperature changes associated with these caloric effects make these alloys excellent candidates for environmental friendly solid-state refrigerating devices with low energy consumption. In my talk I will survey recent results on the several caloric effects in magnetic shape memory alloys.

MO.D.1_O2 - Tuning magnetic properties of isotropic ferrite powders as a feasible alternative for permanent magnet applications

F.J. Pedrosa [1,2], K. Golasinski [1], J. Rial [1], A. Quesada [3], F. Rubio-Marcos [3], M.N. Guzik [4], S. Deledda [4], J.F. Fernández [3], J. Camarero [1,5], A. Bollero [1]

Rare earth-based permanent magnets (RE-PMs) are used in a large number of nowadays technological applications. The rapidly increasing market of green technologies demands increased amounts of this type of magnets. This demand in combination with the strategically geographical distribution of REs (especially critical for heavy REs) make necessary the search of alternatives to these PMs in as many applications as possible. NANOPYME is a European project that addresses the design and development of high quality PMs based on ferrites [1]. In this work authors will show:
(a) Achievement of high-coercive cobalt ferrite ($CoFe_2O_4$) powders by using milling times as short as 1.5-6 minutes and in contrast with previous studies [2];
(b) Tuning of microstructure and magnetic properties by proper choice of heat treatment parameters for as-milled material, resulting in isotropic powders with enhanced (BH)max. $CoFe_2O_4$ powders were prepared by sol-gel and co-precipitation followed by heating in air. X-ray diffraction showed the presence of exclusively spinel $CoFe_2O_4$ phase.
Milling of the starting powders for only 90 seconds has led to powders with a high coercivity Hc=4.1 kOe (four times larger than that obtained for the starting powders) [3]. This coercivity in combination with values Ms=63.5 emu/g and Mr=40 emu/g result in a (BH)max=12.6 kJ/m3. The large coercivity is due to a combination of a fine microstructure and the stress anisotropy induced on the particles during milling. Heat treatment of the as-milled material results in isotropic powders with (BH)max>18 kJ/m3. The excellent combination of magnetic properties achieved by using extremely short milling times makes of these powders good candidates for PM applications.

MO.D.1_O3 - phase formation and magnetic properties of the L10 phase in Mn-Ga alloys

T. Mix [1,2], K. Müller [1], T.G. Woodcock [1], L. Schultz [1,2]

1. IFW Dresden, Institute for Metallic Materials, Dresden, Germany
2. Department of Physics, TU Dresden, Dresden, Germany

The Mn-Ga binary system contains an L10 phase (cP4; P4/mmm) with high magnetocrystalline anisotropy, which may be a suitable candidates for rare earth free permanent magnets. The aim of this work is to understand the formation and stability of the L10 phase and to optimise both the intrinsic and extrinsic magnetic properties of the alloys. Mn-Ga binary alloys with compositions in the range 50-70 at.% Mn were produced by arc melting and annealing. Phase formation was studied using thermal analysis, x-ray diffraction and magnetometry. Measurements of the magnetocrystalline anisotropy constant and anisotropy field were performed in applied magnetic fields of 14 T. The single-phase L10 structure was obtained in the range 55-65 at.% Mn by annealing the high temperature phases, which were retained at room temperature after casting. A saturation magnetisation of μ0Ms = 0.807 T together with an anisotropy field of μ0Ha = 4.4 T could be reached for the Mn55Ga45 alloy. With increasing Mn content the saturation magnetisation decreases, whereas the anisotropy field increased. Mechanically milled Mn55Ga45 powder had coercivity of μ0Hc = 0.393 T, which was a twentyfold increase compared to the bulk material but the magnetisation was reduced (cf. powder: μ0M5T = 0.576 T, bulk: μ0M5T = 0.780 T). Annealing the powder at 400 ºC led to recovery of the magnetisation but reduced the coercivity, which was still ten times as high as the bulk value. A degree of texture of 0.45 was achieved by magnetic alignment of the powder particles, leading to a remanence of 0.526 T. Furthermore, isotropic hot compacts of powders were produced with packing density from 83 to 99%, in which the improved coercivity of the powders was partially retained.

MO.D.1_O4 - Atomic-scale characterisation of phase boundaries in hot deformed Nd-Fe-Co-B-Ga magnets infiltrated with a Nd-Cu eutectic

T.G. Woodcock [1], Q.M. Ramasse [2], T. Shoji [3], M. Yano [3], A. Kato [3], O. Gutfleisch [4]

1. IFW Dresden, Dresden, Germany
2. SuperSTEM Laboratory, Warrington, United Kingdom
3. Toyota Motor Corporation, Prefecture Aichi, Japan
4. TU Darmstadt, Darmastadt, Germany

In order to develop Nd-Fe-B magnets with high coercivity (H_c) at elevated temperature without using Dy-substitution, precise engineering of the microstructure is needed. Hot deformed Nd-Fe-Co-B-Ga magnets have therefore been infiltrated with a Nd-Cu eutectic liquid, resulting in a 71% increase in coercivity to $\mu_0 H_c$ = 2.4 T without the use of Dy. Aberration-corrected scanning transmission electron microscopy and electron energy loss spectroscopy (EELS) have been used to reveal the structure and chemical composition of phase boundaries in the magnets on the atomic scale [1]. EELS elemental profiles resolved the composition of individual lattice planes and were correlated with corresponding High Angle Annular Dark Field (HAADF) images, which revealed the crystal structure at atomic resolution. The results showed that the Nd-Cu eutectic liquid penetrated the ≈ 1 nm thick intergranular regions. The H_c increase following infiltration was therefore attributed to improved volume fraction and distribution of the intergranular phases. Co enrichment in the outermost 1-2 unit cells at several surfaces of the $Nd_2(Fe,Co)_{14}B$ crystals was shown for the infiltrated sample. The as-deformed sample did not appear to show this Co enrichment. Interfacial segregation of Cu between the $Nd_2(Fe,Co)_{14}B$ and the Nd-rich intergranular phase was observed in the infiltrated sample. All the secondary phases measured here contained significantly less Fe and more Nd than $Nd_2(Fe,Co)_{14}B$.

MO.D.1_O5 - Bi doped Mn_2Sb: a novel rare-earth free permanent magnet material

K. Aanand [1], N. Singh [1], N. Chirstopher [1], A. Gupta [1], A. Dhar [1]

1. National Physical Laboratory, Middlesex, United Kingdom

The demand for high-performance permanent magnets is rapidly growing worldwide due to their extensive usage in a wide range of energy generation and conservation applications. However, due to the recent global shortage and rising costs of rare-earth (RE) elements, it becomes imperative to develop permanent-magnets, which are free of RE elements. In the present work, we report the synthesis of Bi doped Mn_2Sb, as a potential RE-free permanent magnetic material. Mn_2Sb, crystallizes in a Cu_2Sb-type tetragonal structure, having two non-equivalent atomic sites for Mn, which is anti-parallel to each other, resulting in ferrimagnetic state of this compound. However, suitable doping of Mn_2Sb, transforms it into a ferromagnet and hence it could be a potential material for a RE-free permanent magnet. In the present work, we investigate the effect of Bi alloying in Mn_2Sb, on the magnetic properties of the resulting compound. A series of Mn_2Sb:Bix (x= 0.8 to 1.2) alloys was prepared by repeated arc-melting of the constituent elements under a high-purity argon gas atmosphere. This arc-melted master alloy was subsequently melt-spun, at optimized process parameters, to obtain continuous nanocrystalline ribbons. Phase purity and lattice parameters were determined employing X-ray diffraction and its Rietveld refinement. FESEM and HRTEM studies were conducted on the synthesized nanocrystalline ribbons and these results were correlated with their resulting magnetic properties. The magnetic properties of melt-spun Mn_2SbBi ribbon sample exhibited a considerable improvement over their arc-melted counterparts. The coercivity of the melt-spun Bi doped Mn_2Sb, nanocrystalline ribbons, after optimized annealing treatment, was found to be ~ 6 kOe with a (BH)max ~ 4 MGOe. Further efforts are being made to optimize the material processing and annealing parameters to further enhance the magnetic properties.

MO.D.2_I1 - Advances in magnetocaloric characterization

M. Solzi [1], G. Porcari [1], F. Cugini [1]

1. Dipartimento di Fisica e Scienze della Terra - Università di Parma, Parma, Italy

Magnetocaloric devices are a new generation of refrigerators aiming at a more efficient production of cooling power. The recent discovery of materials [1] showing high and reversible changes of temperature and entropy in magnetic field ranges (DeltaB = 1 T) that are reasonable for real machines is now pushing the envelope [2].
Together with materials preparation, magnetocaloric characterization techniques are evolving: 1) to give reliable estimations of materials 'reversible and irreversible thermomagnetic properties and 2) to explore the materials' response on wider frequency ranges [3]. In-field calorimetry and conventional direct temperature change probes belong to the first group [4,5]. Non-contact temperature change setups are on the other hand useful solutions to overcome, or reduce at least, the thermal capacity of the temperature sensor. These techniques belong to the second group identified above since their characteristic time constant can be even 3 orders of magnitude lower than the fastest thermocouples (20 ms) available. Non-contact temperature change techniques may give useful insight into materials dynamic magnetocaloric response and direct temperature change of low dimensionality systems [6].

MO.D.2_O2 - Quasi-zero volume change 1st order phase transition on (Mn,Fe)2(P,A) A = Ge, Si magnetocaloric compounds

L. Caron [1,2], G. Porcari [2,3], X.F. Miao [2], N.T. Trung [2], N.H. Dung [4], M. Solzi [3], E. Brück [2]

1. Max Planck Institute for Chemical Physics of Solids, Dresden, Germany
2. Delft University of Technology, Delf, The Netherlands
3. Parma University, Parma, Italy
4. Institute Neel, Grenoble, France

(Mn,Fe)2(P,A) A = Ge, Si compounds are, to date, the most promising materials for use as active regenerators in magnetic refrigeration based on the magnetocaloric effect. These compounds show extremely sharp first order isosymmetric phase transitions between ferro and paramagnetic states. As a result very large entropy and adiabatic temperature changes are observed which can be tuned varying the Mn:Fe and P:A ratios. Through the phase transition, the hexagonal unit cell lattice parameters show large discontinuous changes in opposite directions. In materials showing low thermal hysteresis it has been observed that the changes in lattice parameters, although large, compensate each other, giving rise to near zero volume changes. From this scenario two questions arise. The first fundamental question is: if there is no volume change, why is there hysteresis? The second, practical question concerns applications: does the near zero volume change mean better structural stability over a refrigeration cycle? In this work we show how Mixed Magnetism, as the underlying mechanism for the large magnetocaloric effect in these materials, conciliates near zero volume change and hysteresis. Near zero volume changes were observed directly and indirectly using temperature dependent XRD and high pressure magnetometry. Finally, thermo-magnetic cycling was used to test physical stability and showed that these compounds remained stable through ~1000 thermo-magnetic cycles simulating operating conditions.

MO.D.2_O3 - Gd-Zn biphasic magnetic composites synthesized in a single preparation step: increasing refrigerant capacity without decreasing magnetic entropy change

J.Y. Law [1], L.M. Moreno-Ramírez [1], J.S. Blázquez [1], V. Franco [1], A. Conde [1]

1. Sevilla University, Seville, Spain

Magnetocaloric composites have been shown to exhibit enhanced refrigerant capacity in comparison to pure phases. Nevertheless, to be realistically applicable in devices, it is essential that each of the existing phases in the composite present a large magnetocaloric response. To date, the typical approach to combine different phases involves the preparation of multilayers, mixing powders etc. However, these methods entail drawbacks, such as poor thermal conductivity between surfaces, additional preparation steps during the synthesis etc. Hence, in this work, we aim to use an alternative approach to develop, in a single fabrication step, a material with mixed constituent phases within the composite (Gd and GdZn) with large magnetocaloric response. Gd-Zn alloy series, with a global composition of Gd(50+x)Zn(50-x) (with x=0, 5, 15 and 25 at.%), were successfully obtained by induction melting. X-ray microdiffraction results reveal the homogeneity of all the prepared samples and indicate a combination of GdZn and Gd phases with different proportions. The minor content of oxides detected in all cases, indicates it as superficial oxidation. A ~50 % enhancement of the refrigerant capacity for an applied field of 1.5 T is obtained when x increases from x=0 to x=25 while maintaining the same values of peak magnetic entropy change in the vicinity of room temperature. Field dependent heat capacity curves also exhibit a broadened multipeak behavior which remains upon the application of magnetic field. This work was supported by Spanish MINECO and EU-FEDER (project MAT2013-45165-P) and the PAI of the Regional Government of Andalucía.

MO.D.2_O4 - Thermal Conductivity study of (Mn-Fe)$P_{1-x}Si_x$ magnetocaloric materials with first and second order phase transitions

A. Davarpanah [1], X.F. Miao [2], L. Caron [2], E. Bruck [2], J.S. Amaral [1], V.S. Amaral [1]

1. Department of Physics / CICECO - Aveiro Institute of Materials, University of Aveiro, Aveiro, Portugal
2. Department of Radiation Science & Technology, Delft University of Technology, Delft, The Netherlands

Magnetic refrigeration attracts much attention as an environmentally friendly and efficient cooling procedure. One of the most promising materials for applications are the $MnFeP_{1-x}Si_x$ compounds. These rare-earth free alloys are composed of abundant raw materials, showing large magnetocaloric entropy and adiabatic temperature changes, small thermal hysteresis and enhanced mechanical stability. These compounds crystallize in the Fe_2P-type hexagonal structure and undergo w transition between the paramagnetic and ferromagnetic states at the Curie temperature Tc which can be tuned changing P/Si and Fe/Mn ratios.
Besides the magnetocaloric properties, thermal conductivity plays a critical role for practical applications. However, studies on thermal conductivity of magnetocaloric materials are seldom reported.
In this study, the Hot Disk Transient method was used to measure the temperature dependence of the thermal conductivity in $Mn_{1.3}Fe_{0.65}P_{0.4}Si_{0.6}$ (T_C=297K, 2nd-order) and $Mn_{1.25}Fe_{0.7}P_{0.45}Si_{0.55}$ (T_C= 303K, 1st-order). At 273K (in the ferromagnetic phase), we obtain thermal conductivity values of 2.06 and 1.62 W/mK for $Mn_{1.3}Fe_{0.65}P_{0.4}Si_{0.6}$ and $Mn_{1.25}Fe_{0.7}P_{0.45}Si_{0.55}$, respectively. Notice that, the thermal conductivity of the 2nd order sample is consistently higher over the whole temperature range. The thermal conductivity of both samples rises with temperature (almost 100% going from 253K to 393K) with an abrupt change near T_c, which is stronger for the 1st-order sample. Both samples display the same behavior: above T_c the slope is steep, while below T_c the thermal conductivity is much less temperature dependent.
These features point to the role of the magnetic ordering influence on the electronic and structural properties on thermal transport. The role of the electronic contribution is expected to be of major importance, since the electrical resistivity of similar samples presents sharp anomalies and large changes near T_C, with correlation of electrical and thermal conductivities expected from Wiedemann-Franz Law.

MO.D.2_O5 - Conventional and rotating magnetocaloric effects in RAl_2 (R=Ho and Nd)

N. Antunes De Oliveira [1], J. Caro Patiño [1], P. von Ranke [1]

1. Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil

In this work we theoretically discuss the conventional and the rotating magnetocaloric effects in RAl_2, which crystallize in cubic symmetry and exhibit large magnetocrystalline anisotropy due to the crystal electric field. For this purpose, we use a model of interacting magnetic moments including a term to account for the anisotropy [1]. First, we apply the model to calculate the entropy changes and the magnetocaloric quantities in $HoAl_2$. Our calculations show that the entropy changes exhibit the usual behavior when the magnetic field is applied along the easy magnetization direction <110>. However, when the magnetic field variation is applied along the hard direction <100> anomalies appear on the magnetocaloric quantities ΔS_{iso} and ΔT_{ad}. These findings are in reasonable agreement with the available experimental data [2].
We also calculate the caloric quantities in $HoAl_2$ by fixing the magnitude of the magnetic field and rotating its direction. Our calculations show that the magnetocaloric quantities exhibit sizeable values when the magnetic field rotates from <111> to <110> direction. On the other hand, our calculations predict changes of sign in the caloric quantities when the constant magnetic field rotates from <100> to <110> direction.This very interesting fact, which is basically due to the magnetocrystalline anisotropy, needs experimental data to be confirmed. Our calculations show that both the conventional and rotating magnetocaloric quantities in $NdAl_2$ exhibit similar behavior.

MO.D.2_O6 - Magnetic entropy change in materials with first- order magnetic transitions under cycling

B. Kaeswurm [1], V. Franco [2], K.P. Skokov [1], M. Fries [1], T. Gottschall [1], O. Gutfleisch [1]

1. Institut für Geo- und Materialwissenschaften, Technische Universität Darmstadt, Darmstadt, Germany
2. Departamento Fisica de la Materia Condensada, Universidad de Sevilla, Sevilla, Spain

Materials exhibiting a first-order magnetic phase transition are of interest for application in magnetic refrigeration due to the large magnetocaloric effect (MCE) associated with the transition. This effect may be expressed in terms of an entropy change ΔS or in terms of an adiabatic temperature change ΔT_{ad}. ΔS is related to the heat that can be transferred by magnetic means, while ΔT_{ad} characterises the efficiency of heat transfer in an active magnetic regenerator cycle. In a non-regenerative cycle such as Carnot or Bryton, measurement of ΔT_{ad} provides information on the maximum achievable thermal span. Magnetic refrigeration occurs in cycles, which is usually not replicated in laboratory tests. Measurements of both magnetocaloric quantities can be obtained by direct or indirect means. Direct measurements of the MCE require dedicated devices which are not broadly available. ΔS is indirectly obtained from measurements of either magnetisation isotherms $M(H)_T$ or thermomagnetisation curves $M(T)_H$ and subsequent application of the Maxwell relation. For materials undergoing a first order phase transition, the measurement protocol should include the preparation of the sample by erasing its thermal and magnetic history and the material starts from a homogeneous state before any transition takes place. Consequently, the measurement of any subsequent cycle would produce unphysical results. Here we present a procedure on how the cyclic behaviour of the magnetocaloric effect can be determined from indirect measurements of entropy change. We select three model materials with a first order phase transition: (La,Pr)$(Fe,Si)_{13}$, Fe_2P-type ($Mn_{1.25}Fe_{0.7}P_{0.5}Si_{0.5}$) and a compound with Heusler structure ($Ni_{45}Mn_{38}In_{12}Co_5$). Our method provides a basis for the comparison of the suitability of different hysteretic magnetocaloric materials for their application in a refrigerator device, taking into account the material's response to periodic variations of field and temperature. The method allows extracting the cyclic magnetic entropy change from quasi-static measurements, without the need for dedicated devices.

MO.D.3_O1 - Neutron scattering study of J1-J2 zig-zag chains in $SrDy2O_4$ frustrated magnet

N. Gauthier [1], A. Fennell [2], A. Désilets-Benoît [3], B. Prévost [3], A.D. Bianchi [3], C. Niedermayer [2], M. Frontzek [2], C. Baines [4], J. Ollivier [5], L.P. Regnault [5], G. Nilsen [5], M. Kenzelmann [1]

5. Institut Laue-Langevin, Grenoble, France

Competing interactions in geometrically frustrated magnets can lead to ground states with large degeneracies and open the way to novel states of matter. Compounds of $SrR2O_4$ family (R=Gd, Tb, Dy, Ho, Er, Tm and Yb) have first been pointed out to be candidates for frustrated magnetism in 2005. Since then, various interesting properties have been observed in these systems: spin-liquid-like ground-states, coexistence of two different magnetic orderings, low-dimensional correlations, magnetization plateaus and magnetic field induced order. Zig-zag chains in the structure are thought to be an important source of frustration in these compounds. The physics in the zig-zag chains is equivalent to a 1D chain with nearest neighbour J1 and next-nearest neighbour J2 interactions, usually called Ising J1-J2 chain model. The presence of two inequivalent rare earth sites in the structure probably leads to the coexistence of two different orders in compounds such as $SrHo_2O_4$ and $SrEr_2O_4$. The $SrDy_2O_4$ compound is especially interesting because it does not feature long range order down to 50 mK, thus showing a high degree a frustration. Different neutron scattering techniques have been used to characterize the low temperature properties of $SrDy_2O_4$ and to understand the absence of long range order. Diffuse scattering indicates short range correlations mainly along the c-axis originating from only one of the two inequivalent sites. Inelastic neutron scattering reveals the presence of a dispersive crystal field level and a gap opening at 60 mK, whose origin is not understood at present. Under applied field, a 1/3 magnetization plateau has previously been observed. This field-induced phase features a propagation vector consistent with the up-up-down state expected from theory.

MO.D.3_O2 - Micromagnetic characterisation of gyroid nanostructures

D. Love [1], J. Llandro [1], A. Kovacs [2], A. Kakay [2], M. Scherer [1], C. Cimorra [1], U. Steiner [1], R. Dunin-Borkowski [2], C. Barnes [1]

Gyroids are 3D self-assembled artificial materials that consist of a periodic network of struts, similar to the tetrahedral arrangement of pyrochlores [1]. Through a precise excursion in temperature, block copolymers can be self-assembled into a gyroid network. Selective dissolution of the minority phase then leaves an organic template that can be filled electrochemically to form metallic gyroid nanostructures [2]. Gyroid films have found applications in photovoltaics [3], photonics [4], catalysis [5], electrochromics [6] and supercapacitors [7] due to their porosity and high surface area to volume ratio.
While basic bulk magnetometry of gyroid films has previously been presented [8], the random nucleation process of orientational domains during self-assembly prevents true micromagnetic understanding of the system. However, the gyroid geometry forms a fundamentally interesting network and a potentially frustrated artificial magnetic material in 3D whose micromagnetic states have so far been left uncharacterised.
Here we present the fabrication of suitable gyroid crystallites with single orientational domains, 42nm unit cells and features sizes down to 10nm, suspended on TEM grids for nanometre-resolution electron holography and tomography characterisation. The holography results reveal magnetic flux patterns that indicate magnetically frustrated behaviour as well as onion states within the gyroid network. We use bespoke micromagnetic modelling to further aid in the characterisation of this unique self-assembled 3D artificial magnetic material.

3. Forschungsneutronenquelle Heinz Maier-Leibnitz, Garching, Germany
4. Oak Ridge National Laboratory, Oak Ridge, United States

In the multiferroic Cu_2OSeO_3 system, the interplay of interatomic exchange and the Dzyaloshinskii-Moriya (DM) interactions leads to the twisting and canting of magnetic moments and, consequently, to the formation of a spinspiral ground state. An exotic skyrmion-lattice arrangement can be further stabilized by the application of magnetic field. Here we employed a combination of time-of-flight and triple-axis neutron spectroscopy to investigate the complete spectrum of spin excitations in Cu_2OSeO_3 over energies ranging from sub-meV to 50-60 meV. Several magnon bands are observed, in qualitative agreement with theoretical predictions, although a significant quantitative adjustment of exchange interaction parameters is required to match the neutron-scattering data. The experimentally measured dynamical structure factor of the magnons will be also discussed in relationship to the real-space crystal structure of the material.

MO.D3_O4 - Scaling Laws in speckle dynamics on artificial spin ices

3. Universidad de Tarapaca, Arica, Chile

Speckle is an interference pattern produced by scattering from an illuminated surface, and is able to provide unique information about correlations in the scatterers [1]. We discuss how speckle can provide information about relaxation processes occurring over widely different times scales for magnetisation dynamics in patterned magnetic structures known as artificial spin ice [2]. These arrays are strongly correlated two-dimensional arrays of sub-micron sized magnets designed to produce competition between interactions that can result in degeneracies and frustration. We show that for two-dimensional lattices one can define a characteristic length scale for the domain growth, which in the coarsening approximation can be described by a multiple time scales model. The amplitude scattering has a direct relation to characteristic lengths of the system [3]. The theoretical model describes well the experimental data on a square array.

Frustrated magnets are a hot topic of the up-to-date magnetism in which many fundamental problems remain unresolved. In this talk we present results of experimental and theoretical studies of one- and two-magnon excitations in an orthorhombic borate $Ni_3B_2O_6$ (Pnmn group #58, Z=2) in which magnetic Ni^{2+} ions (S=1) in the unit cell occupy 2a and 4f distinct positions. Interactions between magnetic ions leads to an antiferromagnetic ordering below T_N=46 K with the magnetic structure formed by two inter-penetrating ribbons …a-2f-a-2f… running along the x axis with the spins along the y axis. Far-infrared and Raman spectroscopic studies revealed new bright features arising below T_N in the range below the lowest phonon frequencies. First of all, infrared studies showed two absorption bands at 17.2 and 26.5 cm^{-1} in $H(\omega)||z$ polarization whereas only one band at 17.5 cm^{-1} was observed in $H(\omega)||x$ polarization. All these infrared features showed sharp decrease of their frequency and intensity and completely disappeared at T_N. Such behavior together with the polarization properties of the bands allowed us to assign them to one-magnon intra-ribbon spin excitations formed by different single ion anisotropies of Ni^{2+} ions at 2a positions (26.5 cm^{-1}) and 4f positions (17.2 and 17.5 cm^{-1}). Raman studies allowed observation of new spectrally complicated bands in a broad range of 50-200 cm^{-1} with a pronounced sharp peak at 92-94 cm^{-1} with behavior typical for two-magnon excitations. They showed appreciable temperature dependence when approaching T_N from below but they survived even above T_N as broad tails distinguishable up to 180 K. We relate such behavior of one-magnon and two-magnon excitations with the quasi-one-dimensional magnetic structure of $Ni_3B_2O_6$ caused by highly frustrated interactions between the magnetic ribbons composed of Ni^{2+} ions at 2a and 4f positions.

MO.E.1_I1 - Soft X-ray photoemission spectro-microscopy at the ALBA Synchrotron: applications in magnetism

L. Aballe [1], M. Foerster [1], E. Pellegrin [1], J. Nicolas [1], S. Ferrer [1]

1. ALBA Synchrotron Light Facility, Cerdanyola, Spain

The PhotoEmission Electron Microscopy (PEEM) experimental station of the CIRCE soft X-ray beamline at the ALBA synchrotron is presented, together with representative results from magnetism. The station is based on an Elmitec LEEM III low energy electron microscope with energy analyser. Using electrons emitted from the sample upon excitation by the variable polarization X-ray photons, surface imaging with high chemical, structural, and magnetic sensitivity is performed down to a lateral resolution better than 20 nm [1]. PEEM with X-Ray Magnetic Circular Dichroism (XMCD) contrast is a versatile, non/invasive, and powerful tool for the study of magnetic materials and micro/nanomagnetic systems. It provides element specific magnetic contrast with high spatial resolution and sensitivity (low moment). Thanks to the azimuthal sample rotation and the near grazing X-ray incidence, full 3D magnetization information can be obtained. Using X-Ray Magnetic Linear Dichroism contrast, even antiferromagnetic domains can be imaged (XMLD-PEEM). In the energy domain, X-ray absorption (XAS) and Photoemission (XPS) spectra can be measured down to the spatial resolution of the microscope (spectro-microscopy) with sufficient quality to determine surface magnetic moments through sum rule analysis [2]. The experimental station comprises standard in-situ surface preparation techniques, complementary characterization techniques such as microspot electron diffraction, and allows the application of electric and (weak) magnetic fields in the variable temperature sample stage during measurements.

Nuclear Magnetic Resonance (NMR) is a technique that is very popular in medicine, chemistry or biology, but it is much less used for studying ferromagnetic materials. However when used for ferromagnetic materials, NMR (also called in this case Ferromagnetic Nuclear Resonance, FNR) has the ability to provide, simultaneously and at the same scale, information about the local structure (crystallographic structure, chemical environment) as well as about the local magnetic properties of the probed atoms. For this purpose we have developed 3D NMR spectra in ferromagnets that allow visualising simultaneously the structural and magnetic inhomogeneities into the studied samples [1]. The magnetic information is recorded in the form of a local magnetic stiffness (inverse of the transverse susceptibility). To further improve the field of application of FNR we have recently developed a new investigation methodology based on temperature depend measurements that is specifically devoted to the study of assemblies of nano-objects.
After presenting the particularities of NMR in ferromagnets, the use of FNR is exemplified through the study of systems for applications in spintronics, optics and catalysis. We will successively investigate the hybridization of cobalt atoms at the interface with graphene, the interface morphology of Co-based multilayers [2] and the crystallographic structure and chemical composition within the size distribution of Co-based nanoparticles [3].

MO.E.1_O3 - AGFM for magnetic characterization of samples in A.C. magnetic field

M. Pérez [1], R. Ranchal [2], I. De Mendizabal [1], P. Cobos [1], J.L. Mesa [3], M. Díaz [3], C. Aroca [1]

1. Universidad Politecnica de Madrid (ISOM), Madrid, Spain
2. Universidad Complutense de Madrid, Madrid, Spain
3. Instituto Nacional de Técnicas Aeroespacial (INTA), Madrid, Spain

Vibrating Sample Magnetometers (VSM) [1] and Alternating Gradient Force Magnetometers (AGFM) [2] are commonly used techniques to characterize magnetic materials. They have a similar sensitivity, 10-5-10-6 emu for the VSM and 10-6-10-7 emu for the AGFM and both systems allow the application of relatively large magnetic fields. Nevertheless, they cannot be used to characterize samples in AC because in these two systems, the samples are magnetized under continuous magnetic fields. Inductive methods are required when a sample has to be characterized as a function of frequency [3]. The main limitations of these inductive methods are the maximum field that can be applied to magnetize the sample (around 0.015 T) and the temperature increase in the primary coil. We have designed and fabricated a magnetometer that can work both as an AGFM and as a susceptometer without any modification in the experimental set-up because of the electronics we have developed. Another innovation of our prototype is the possibility of being used to characterize samples in a wide range of frequencies, from 0 to 30 kHz. We have demonstrated the capability of measuring different odd harmonics in a wide range of frequencies for small quantities of ferro-, para- and diamagnetic materials. Our system has also proved to be more adequate than a commercial VSM to characterize small quantities of dia- and paramagnets. Spurious effects such as hysteresis are not observed when measuring few micrograms of this type samples in our system.

MO.E.1_O4 - Towards quantitative magnetic measurements with atomic spatial resolution

J. Rusz [1], J.C. Idrobo [2], J. Spiegelberg [1], A. Edström [1]

1. Department of Physics And Astronomy, Uppsala University, Uppsala, Sweden
2. Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, Oak Ridge, United States

We present recent advances in electron magnetic circular dichroism (EMCD) - a measurement technique performed using transmission electron microscope (TEM). EMCD is an electron-microscopy analogue of the well-established x-ray magnetic circular dichroism (XMCD). State-of-the-art aberration corrected scanning TEM (STEM) routinely allow to reach atomic spatial resolution, which brings a promise of measuring MCD of individual atomic columns. Electron vortex beams and other electron probes, with phase profiles tuned to the symmetry of local neighborhood of the studied atomic column, were predicted to enable detection of EMCD signal at atomic resolution. Early experimental tests together with advanced statistical processing of large datasets provide indications of EMCD signal on Mn-edge of an antiferromagnetic compound LaMnAsO, extending the reach MCD studies also to the domain of antiferromagnetic compounds.

MO.E.1_O5 - Bidirectional and co-resonant quantitative magnetic force microscopy sensors

T. Muehl [1], C.F. Reiche [1], J. Koerner [1], S. Vock [1], V. Neu [1], L. Schultz [1,2], B. Buechner [1,3]

Dynamic operation modes of scanning force microscopy are very successful methods to study force-related properties of surfaces with high spatial resolution. Here, we report on a concept of bidirectional force gradient microscopy sensors that enables a direct, fast, and quantitative real space mapping of force component derivatives in both the perpendicular and a lateral direction. This novel technique relies solely on multiple-mode flexural cantilever oscillations related to vertical probe excitation and vertical deflection sensing [1]. In particular, our approach includes the capability of in-situ switching between the two measurement directions. Exploring this concept we present a bidirectional magnetic force microscopy (MFM) sensor setup, corresponding quantitative measurements, and data analysis with emphasis on the calculation of mode-dependent spring constants that are the basis of quantitative force gradient studies.
Furthermore, we introduce a co-resonant MFM sensor design which combines a conventional cantilever oscillator and a low-stiffness magnetic nanowire oscillator. According to a coupled harmonic oscillator model, this nanowire oscillator strongly influences the cantilever oscillation if nanowire and cantilever have similar resonance frequencies even though the spring constants and the effective masses of the two partial systems differ by orders of magnitude. Thus, the magnetic interaction of the oscillating magnetic nanowire with the sample stray field leads to a large frequency shift of the coupled MFM sensor system which can be measured at the cantilever using conventional methods.
Finally, we apply this high sensitivity co-resonant oscillator approach to the lateral mode of our bidirectional MFM sensors.

We report on recent advances in the realization of high-performance nano-scale superconducting quantum interference devices (nanoSQUIDs), which can be used for continuous measurements of magnetization loops of single magnetic nanoparticles in strong magnetic fields (applied in the plane of the SQUID loop) up to the Tesla range at cryogenic temperatures. We fabricated $YBa_2Cu_3O_7$ SQUIDs based on submicron grain boundary junctions patterned by focused ion beam milling [1] and Nb SQUIDs based on Nb/HfTi/Nb junctions patterned by e-beam lithography [2]. The nanoSQUIDs show very low flux noise down to ~100 nPhi_0/sqrt(Hz) (Phi_0 is the magnetic flux quantum) in the thermal white noise limit at temperature T=4 K, yielding spin sensitivities of down to a few μ_B/sqrt(Hz) (μ_B is the Bohr magneton). This opens new possibilities in the study of non-equilibrium dynamics of small spin systems at low T. We will discuss issues related to further improvement of the spin sensitivity, challenges related to operation in strong magnetic fields and approaches to position magnetic nanoparticles in close vicinity to the nanoSQUIDs. As some proofs-of-principle, we demonstrate measurements on a Co nanoparticle, a Fe nanowire (embedded in a carbon nanotube) and a Ni nanotube. In the latter case, a novel multifunctional system has been used, combining flux detection by a nanoSQUID and torque magnetometry with a ferromagnetic nanotube, mounted on a soft cantilever, as a scanning tip [3]. This system can be used for the detection of magnetic states of a single nanotube [4].

MO.E.2_O2 - Three-axis low energy neutron spectroscopy at the institut laue-langevin

M. Boehm [1], S. Roux [1], J. Kulda [1], V. Sechovsky [2], P. Svoboda [2], J. Saroun [3], P. Steffens [1]

1. Institut Laue-Langevin, Grenoble, France
2. Faculty of Mathematics and Physics, Charles University, Prague, Czech Republic
3. Nuclear Physics Institute AS CR, Rez, Czech Republic

Neutron inelastic scattering studies using three-axis spectrometers (TAS) are indispensable for measuring elementary excitations of magnetic correlated systems. Although other experimental techniques (NMR, muon spin rotation) can provide valuable information on the same systems, neutron inelastic scattering remains the method yielding the most complete information on the role of space and time correlations and their interplay in the behavior of condensed matter systems. Moreover, neutrons couple with comparable strength to both the structural and magnetic degrees of freedom and the two scattering components can be quite cleanly separated using polarized neutron techniques.
The new cold neutron spectrometer *ThALES* at the Institut Laue-Langevin has been optimized for exploring correlated magnetic systems beyond the experimental possibilities of its predecessor IN14 spectrometer [1-3] in terms of data collection rate, kinematical range and neutron polarization analysis. *ThALES* will cover momentum transfers up to 2 $Å^{-1}$ and energy transfers up to 18 meV with enhanced energy resolution (~0.05 meV at incident wavenumber k_i = 1.5 $Å^{-1}$). The modified spectrometer shielding can host high field measurements up to 15 T in the complete dynamical range, while the new Heusler monochromator will provide a polarized neutron flux comparable to the old IN14 in its unpolarized mode. The challenge of measuring magnetic excitations in mm^3-sized samples has been addressed by combining the virtual source concept with a focusing guide and a Si 111 focusing monochromator.
The commissioning phase of ThALES will finish in spring 2015 and the instrument will be available to the user community from summer 2015. Results of the commissioning phase will be presented.
The ThALES project is a collaboration between ILL and Charles University, financed by the Czech Ministry of Science and Education (Project no. LM2010001).

MO.E.2_O3 - Nanoscale magnetic imaging using single nitrogen vacancy centers in diamond

M. Ganzhorn [1], P. Appel [1], L. Thiel [1], B. Shields [1], E. Neu [2], P. Maletinsky [1]

1. University of Basel, Basel, Switzerland
2. University of Saarland, Saarbrücken, Germany

Recent developments in magnetic imaging have led to important advances in material science, mesoscopic physics or life science [1]. In particular, scanning probe based approaches such as magnetic resonance force microscopy [2] or SQUID based detection schemes [3] have proven to play a pioneering role as they enable nanoscale spatial resolution, combined with a high sensitivity for small magnetic fields. However, the performance of these magnetometers is still limited by factors such as detector size and operation at cryogenic temperature only [1]. In this context, magnetic imaging with the isolated electronic spin of a nitrogen vacancy (NV) center in diamond offers a promising alternative. The NV center's atomic size and exceptionally long spin coherence time, even at room temperature, enables magnetic imaging with spatial resolution of tens of nanometers and a magnetic field sensitivity in the nanotesla range over a broad range of temperatures [4]. Here we report on our approach to such a high performance NV center based magnetometer. We will give an overview of the quantitatively imaging of magnetic stray fields in various nanoscale magnetic systems, for instance in ferromagnetic nanorods. Quantitative probing the stray fields of nanomagnetic structures will in the future allow us to study and image the dynamics of domain walls [5], spin waves [6] or high frequency magnetic fields.

MO.E.2_O4 - Ultra high-resolution magnetic imaging of perpendicular magnetic recording media by near-surface alternating magnetic force microscopy

S.R. Kapa [1], S. Okayasu [1], H. Qi [2], F. Zheng [2], G. Egawa [1], Y. Kinoshita [2], S. Yoshimura [1], H. Saito [1]

1. Graduate School of Engineering and Resource Science, Akita University, Akita, Japan
2. Venture Business Laboratory, Akita University, Akita, Japan

Magnetic force microscopy (MFM) is a powerful tool to observe fine magnetic domain structure with high spatial resolution down to about 10nm. To improve the resolution, magnetic imaging at near surface is quite effective, while conventional MFM has a difficulty to detect magnetic force near sample surface where short range forces are dominant. Therefore we developed alternating magnetic force microscopy (A-MFM) which enables near- surface imaging of DC & AC magnetic fields with high spatial resolution [1-2]. A-MFM utilizes the frequency modulation (FM) of a cantilever oscillation generated by an off-resonance alternating magnetic force between a magnetic sample and a magnetic tip. For DC magnetic field imaging, A-MFM uses a soft magnetic tip of which magnetic moment is driven by an AC magnetic field to generate the alternating magnetic force. A-MFM can distinguish the zero level and the polarity of magnetic force. By using these merits, we can detect the amplitude and direction of perpendicular DC magnetic fields from the sample simultaneously. The spatial resolution of less than 10nm was obtained by soft magnetic crystalline FeCo tips. Here the resolution was determined by the half of the minimum wave length where MFM magnetic signal reaches white noise level for the A-MFM image. To obtain higher spatial resolution, development of a sharpened soft magnetic tip with high sensitivity is important. In the present study, we have developed high-magnetization amorphous FeCoB soft magnetic tips and optimized the measuring conditions of A-MFM by using the evaluation result of AC magnetic field response of the tips.Ultra high-spatial resolution less than 5nm was obtained for the images of CoCrPt-SiO_2 perpendicular magnetic recording media.

MO.E.2_O6 - Quantitative magnetic force microscopy: A method to determine physical properties of superconducting materials

U. Wolff [1], F. Rhein [1], S. Vock [1], H. Stopfel [2], N. Joshi [3], S. Ízer [3], H.J. Hug [3], V. Neu [1], L. Schultz [1]

3. Department of Physics, University of Basel, Basel, Switzerland

Since the discovery of superconducting materials research is focused on the applicability of these materials which has already succeeded in some areas of medicine and instrumentation. Nevertheless, the potential for energy storage and supply still can be exploited and therefore the understanding of the unconventional superconductivity needs to be improved.
The visualization and analysis of the flux line arrangement and the determination of the temperature dependent magnetic penetration depth λ(T) of a $BaFe_2(As_{0.24}P_{0.76})_2$ single crystal is performed using low temperature magnetic force microscopy. The results of the statistical evaluation methods of the flux line distribution are indications of a disordered hexagonal flux line arrangement. By three different evaluation methods the temperature dependent magnetic penetration depth λ(T) was determined. The first approach analyses the force gradient by means of a monopole-monopole-model (MMM) with unknown tip properties whereas in the second method the tip properties are well known. The last possibility is a deconvolution by means of the previous determined tip transfer function (TTF). The calculated magnetic penetration depth λ_{output} can be compared to the known $\lambda_{input.}$ The three different approaches show clearly that the deconvolution method of the MFM data provides the best results and is ubiquitous applicable.
From the measured magnetic force microscopy images the material specific magnetic penetration depth $\lambda(0)$ can be determined by extrapolation of its temperature dependency. The quantitative analysis of the magnetic penetration depth λ(T) results in a specific magnetic penetration depth λ(0) = (239 ± 40) nm for the investigated $BaFe_2(As_{0.24}P_{0.76})_2$ single crystal.
Quantitative magnetic force microscopy has been proven to be a powerful tool for the determination of physical properties of superconducting materials. Moreover, the deconvolution approach established in this work allows to investigate all kind of samples and is not dependent on the scan height and therefore ubiquitous applicable.

MO.E.3_I1 - Manipulation of hybrid magnetic nanostructures through exchange bias and interfacial strain

Nanoscale manipulation of thin film magnetic properties can be achieved through proximity effects in hybrid heterostructures. For example, the unidirectional anisotropy induced in FM films by the proximity with an antiferromagnetic (AF) layer upon cooling through the AF NÚel temperature (TN) (exchange bias effect) is crucial in numerous applications. Recently, ferromagnetic/antiferromagnetic (FM/AF) nanostructures exhibiting both negative and positive exchange bias have been proposed as model systems for multistate switching memory units. Furthermore, the proximity of a FM film with a vanadium oxide results in a large and reversible modification of the magnetic properties due to the magnetoelastic anisotropy caused by the interfacial stress. In particular, large changes in coercivity in Ni/V_2O_3 bilayers across the structural phase transition (SPT) of V_2O_3 have been recently reported. In this work, we use synchrotron X-ray photoemission electron microscopy to analyze the spin configurations of model exchange biased Ni/FeF_2 nanostructures and Ni/V_2O_3 nanostructures. For the Ni/FeF_2 case, we show that a progressive spatial confinement of the bilayers, either through FM thickness variation or via antidot patterning the whole FM/AF heterostructure, actively controls the domain configuration of uncompensated spins in the AF. The final spin structure is determined by the balance between the competing FM and AF magnetic energies. The underlying mechanism of the AF domain formation in Ni/FeF_2 may be generic to other magnetic systems with complex non-collinear FM/AF spin structures. For the Ni/V_2O_3 bilayers, we find that the SPT in V_2O_3 induces nucleation of reversed Ni domains, and their fraction grows monotonically with the predominance of one of the coexisting structural phases. The changes in domain structure are fully reversible over the narrow temperature window of the SPT. A local distribution of transition temperatures is found across the sample. The lateral domain correlation length allows us to discern the SPT character.

MO.E.3_O2 - Nonlinear magneto-plasmonics in hybrid metal-ferromagnet multilayer structures

I. Razdolski [1], A. Kirilyuk [1], T. Rasing [1], D. Makarov [2], O. Schmidt [2], V. Temnov [3]

1. Institute of Molecules and Materials, Radboud University Nijmegen, Nijmegen, The Netherlands

3. Institut des Molécules et Matériaux du Mans, UMR CNRS 6283, Université du Maine, Le Mans, France

Linear magneto-plasmonics represents a new way to probe the electromagnetic field in metal-ferromagnet nano-structures and better understand nano-optical interactions [1,2]. Nonlinear magneto-plasmonics [3] aims to utilize plasmonic excitations to control the mechanisms and taylor the efficiencies of nonlinear light frequency conversion at the nanoscale. We investigate the mechanisms of magnetic second harmonic generation in a hybrid gold-cobalt-silver multilayer structure supporting propagating surface plasmon polaritons at both fundamental and second harmonic frequencies. Using Kretschmann experimental configuration we observe a huge magneto-optical intensity modulation (magnetic contrast of up to 33%) which is dominated by the excitation of surface plasmon polaritons at the second harmonic frequency, as shown by tuning the optical wavelength over the spectral region of strong plasmonic dispersion. Our proof-of-principle experiment, as well as a simple phenomenological theoretical description open up the pathway to novel magneto-plasmonic devices and contribute to the general understanding of nonlinear optics with electromagnetic surface waves.

MO.E.3_O3 - Stability of single skyrmionic bits

J. Hagemeister [1], N. Romming [1], K. von Bergmann [1], E. Vedmedenko [1], R. Wiesendanger [1]

1. University of Hamburg, Hamburg, Germany

The switching between topologically distinct skyrmionic and ferromagnetic states has been proposed as a bit-operation for information storage. Generally, long lifetimes of the bits in combination with short switching times are required for data storage devices. The lifetimes of skyrmions however, have not been addressed so far. To study the feasibility of the realization of skyrmionic bits, we have investigated their energy landscape in a broad range of magnetic fields and temperatures theoretically by means of classical Monte-Carlo (MC) simulations. A critical field Bc at which the mean lifetimes of the skyrmionic (Sk) and ferromagnetic (FM) states are identical has been identified. Notably, the field dependent mean lifetimes of the two states show a high asymmetry with respect to Bc in contrast to conventional uniaxial magnetic bits. The main reason for the asymmetry has been found to be a different field dependence of the skyrmionic and ferromagnetic activation energies. We were also able to correlate the stability of skyrmions in systems on discrete lattices with their attempt frequency rather than with their activation energy. We use this knowledge to propose a procedure permitting the determination of effective material parameters and the quantification of the MC time scale from the comparison of theoretical and experimental data.

MO.F.1_I1 - Antiferromagnetic spintronics

T. Jungwirth [1]

1. Institute of Physics ASCR and University of Nottingham, Nottingham, United Kingdom

Louis Néel pointed out in his Nobel lecture that while abundant and interesting from theoretical viewpoint, antiferromagnets did not seem to have any applications. Indeed, the alternating directions of magnetic moments on individual atoms and the resulting zero net magnetization make antiferromagnets hard to control by tools common in ferromagnets. Strong coupling would be achieved if the externally generated field had a sign alternating on the scale of a lattice constant at which moments alternate in AFMs. However, generating such a field has been regarded unfeasible, hindering the research and applications of these abundant magnetic materials.
We have recently predicted [1] that relativistic quantum mechanics may offer staggered current induced fields with the sign alternating within the magnetic unit cell which can facilitate a reversible switching of a biaxial antiferromagnet by applying in-plane electrical currents along two orthogonal directions. The effect occurs in antiferromagnets with specific crystal and magnetic structures for which the spin sublattices form space-inversion partners. Among these materials is a high Néel temperature antiferromagnet, tetragonal-phase CuMnAs, which we have recently synthesized in the form of single-crystal epilayers structurally compatible with common semiconductors, such as Si or GaP [2]. Relativistic current-induced fields strongly coupled to the Néel order, combined with antiferromagnetic CuMnAs epilayers and micro-device anisotropic magnetoresistance, are the key elements that led to our demonstration of the electrical writing and read-out in an antiferromagnetic memory device [3].

MO.F.1_O2 - High temperature spin dynamics studied by solid state nuclear resonance and electron paramagnetic resonance in 29Si:B crystals

R. Morgunov [1], O. Koplak [1], A. Talantcev [1]

1. Institute of Problems of Chemical Physics RAS, Moscow, Russia

The Si:B micro crystals enriched with 29Si isotope were studied by high resolution nuclear magnetic resonance (NMR-MAS) and electron paramagnetic resonance (EPR) in the 300 - 800 K high temperatures range. Recovery of nuclear magnetization saturated by radiofrequency impulses obeys pure power-law kinetics at 300 K, while admixing exponential contribution takes place at 500 K. The power-law relaxation corresponds to direct electron-nuclear relaxation due to inhomogeneous distribution of paramagnetic centers, while exponential kinetics corresponds to nuclear spin diffusion mechanism. Effect of plastic deformation on boron centers EPR lines was found and its interrelation with NMR data is discussed. Inhomogeneous distribution of deformation defects is a most probable reason of the power-law kinetics of nuclear spin relaxation.

MO.F.1_O3 - Amplification of spin polarization using electro-nuclear spin-spin transistor

K. Olejník [1], R. Campion [2], Z. Soban; [1], V. Novák [1], T. Jungwirth [1,2]

We experimentally demonstrate operation of an all electrical hybrid ferromagnetic metal/semiconductor (Fe/n-GaAs) device which utilizes dynamically polarized nuclear spins to control electrically injected electron spins in a GaAs channel. The operation principle of the device consists of two steps. In the first step a weak out-of-plane electron spin polarization is generated by the Spin Hall effect on sides of a cross-channel structure which is used for the dynamic polarization of GaAs nuclei (time necessary for nuclear spin polarization is on the order of minutes). In the second step the non-local spin Hanle experiment is performed: electrons are injected from an Fe injector with in-plane spin polarization and the non-local spin signal is detected on an adjacent Fe detector as function of external out-of-plane field. The precession of in-plane spins is manipulated by the nuclear spin polarization via hyperfine interaction. Under defined conditions the change of the width of the Hanle curve is a measure of the degree of the nuclear spin polarization and hence provides effective direct tool for determination of nuclear polarization. In our device, the subtle out-of-plane nuclear spin polarization (0.01-0.1%) controls precession of the strong in-plane spin polarization (1-10%) of injected electrons. From this perspective the device performs amplification of the original spin signal generated by SHE used for the polarization of nuclei. The amplification allows for convenient electrical detection of very weak spin polarization.

MO.F.1_O4 - Novel bulk form diluted magnetic semiconductors with decoupled charge and spin doping: Synthesis and NMR investigation

F. Ning [1]

1. Zhejiang University, Zhejiang, China

The research of DMS has been mostly confined to the MBE-grown thin films. Recently, many bulk form DMSs that are derivatives of Fe-based superconductors have been reported, i.e., “111” DMS system I-II-V Li(Zn,Mn)As with TC ~ 50 K [1], “122” DMS system (Ba,K)(Zn,Mn)2As2 with TC ~ 230 K [2,3], “1111” DMS system ($La_{1-x}Bax$) ($Zn_{1-x}Mnx$)AsO with TC ~ 40 K [4]. These ferromagnets are all p-type, and have the advantage of decoupled spin and charge doping. In this talk, I will give an introduction of these novel DMSs, and talk about the NMR results of Li(1+y)Zn(1-x)MnxP [5], which has an identical cubic structure to that of III-V (Ga,Mn)As and II-VI (Zn,Mn)Se. We will show that the new 7Li NMR peak induced by Mn doping enabled us to probe local static and dynamic properties of Mn spins with NMR for the first time [6]. We present unequivocal experimental evidences that the ferromagnetic ordering is indeed caused by randomly substituted Mn in Zn sites, instead of Mn cluster or other magnetic impurities. This result is also confirmed by muon spin relaxation (muSR) measurement [7], which shows a nearly full ferromagnetic ordered volume. Our experimental results establish that Mn-Mn ferromagnetic interaction are not limited to the near-neighbor sites, but extend over many unit cells.

The Rashba effect is a manifestation of spin-orbit interaction (SOI) in solids, where the spin degeneracy associated with the spatial inversion symmetry is raised due to a symmetry-breaking electric field perpendicular to the heterointerface [1] and giving rise to field modulation effect at oxide LAO/STO interfaces like demonstrated very recently [2]. On the other hand, Eldelstein was the first to realize that in a Rashba two-dimensional electron system, the flow of a charge current is accompanied by a non-zero spin accumulation coming from uncompensated spin-textured Fermi surfaces [3]. Recently, the converse effect, corresponding to a spin-to-charge conversion through SOI (inverse Edelstein effect or IEE), was demonstrated at Ag/Bi(111) interfaces [3]. We performed spin injection by ferromagnetic-resonance-(FMR)-spin-pumping on $NiFe/LaAlO_3/SrTiO_3$ heterostructures. Our results suggest an efficient spin-to-charge current conversion at the STO/LAO interface taking advantage of the IEE on the 2 dimension electron gas at low temperatures (around 10 K). Moreover, by applying a gate voltage at the SrTiO3 substrate and perpendicular to the LAO/STO interface we are able to tune the spin-to-charge current conversion, with the charge current production depending on both the amplitude and the direction of the gate voltage. We interpret these results in terms of the large SOI in $LaAlO_3/SrTiO_3$ and will discuss the corresponding electrostatic modulation of the IEE by the back-gate voltage.

MO.F.2_I1 - Templated self assembly of magnetic nanostructures

C.A. Ross [1], S. Ohja [1], N. Aimon [1], W. Bai [1], K. Tu [1]

1. Massachusetts Institute of Technology, Cambridge, United States

Self assembly techniques provide a route to the rapid synthesis of nanostructures whose long range order and registration can be controlled by pre-patterning the substrate lithographically. An example is the codeposition of immiscible spinel and perovskite oxide phases producing epitaxial thin film nanocomposites in which ferrimagnetic cobalt ferrite (CFO) pillars are embedded in a ferroelectric bismuth orthoferrite (BFO) matrix. The pillars form a regular array when templated by pits of pitch 60 nm and above made in the substrate, and have a strong magnetoelastic anisotropy due to lattice strain from the BFO matrix. The arrays show magnetoelectric switching, in which an electric field leads to strain in the BFO which is transferred to the CFO, lowering its total anisotropy and enabling switching to occur driven by the stray field of the neighboring pillars. In (Co,Ni)Fe_2O_4/BFO arrays with 100 nm period the interactions were sufficiently strong to produce a checkerboard pattern of up/down magnetic moments after ac demagnetization. The behavior is verified by a model of coupled dipoles with an anisotropy distribution. The second process is the use of templated block copolymer films for patterning of metallic magnetic films and multilayers into arrays of lines or dots with feature sizes of 10 nm and above. Liftoff, damascene and ion beam etching processes were used to produce Co dot arrays and MTJs with 50 nm diameter and their properties were compared, with ion beam etching producing a narrower switching field distribution. Co nanowires and junctions with 30 nm width were fabricated and magnetic force microscopy showed the presence of transverse domain walls, allowing their structure and interactions to be probed.

MO.F.2_O2 - $Ni_{80}Fe_{20}$ nanodisks by nanosphere lithography for biomedical applications

P. Tiberto [1], G. Barrera [1,2], F. Celegato [1], M. Coisson [1], G. Conta [1,2], F. Vinai [1], K. Martina [3], M. Caporaso [3], L. Serpe [3], R. Canaparo [3]

3. Dipartimento di Scienza e Tecnologia del Farmaco, Università di Torino, Torino, Italy

Magnetic nanoparticles have been intensively studied for applications as contrast enhancement agents in magnetic resonance imaging, drug delivery and hyperthermia. The magnetic moment is exploited for target-directed delivery, detection, separation, and manipulation. Recent publications describe the preparation of composite materials suitable for biorecognition, targeting, multimodal imaging, and therapy. However, it is intrinsically difficult to control nanoparticles size and magnetic properties. Bottom-up nanolithography allows the production of nanodisks with controlled diameters and magnetic properties. In this work, the fabrication and magnetic behavior of $Ni_{80}Fe_{20}$ nanodisks suspended in ethanol are presented. Arrays of nanodisks were obtained by sputtering continuous $Ni_{80}Fe_{20}$ films on an optical resist, then by self-assembling commercially available polystyrene nanospheres (starting diameter 800 nm). After depositing a monoloyer of nanospheres on the film surface, spheres diameter is reduced by plasma in Ar. Subsequently, magnetic material among the nanospheres is removed by sputter-etching. The removal of the remaining spheres is performed by sonication. Finally, the resist layer is dissolved in aceton resulting in freely nanodisks that are dispersed in ethanol. Room-temperature magnetic hysteresis curves have been recorded at several stages of the process indicating that the continuous film displays a typical soft magnetic behaviour. Patterning leads to a hysteresis loop having the typical shape of magnetisation vortex nucleation with a higher coercive field, as confirmed by AFM/MFM images. The free-standing nanodisks are characterised by a similar behavior, maintining a vortex magnetisation process. SQUID magnetometry in the 5-300 K range has been exploited to study possible magnetostatic interactions among the disks. To assess the suitability of the nanodisks in targeted drug delivery, chemical bioderivativation has been taken into account. Bioderivatization was aimed to the production of a nanoscaled functional material that combine multiple functionalities for enhanced therapeutic efficacy. The in vitro toxicity assessment of the nanodisks will be discussed.

MO.F.2_O3 - Investigation of different magnetocrystalline anisotropies with FORC analysis in electrodeposited Co-Pt nanowires

Ferromagnetic nanowires (NWs) have potential application in magnetic sensors, biomedical applications and racetrack memory devices. In the present work, we have fabricated Co-Pt NWs via potentiostatic electrodeposition into two different membranes, polycarbonate (PC) and alumina (AAO) membrane with the same pore diameter. The deposition conditions were kept the same in both cases. XRD results showed that NWs fabricated in both membranes have *hcp* crystal structure. However, analysis on XRD showed that only NWs in AAO membranes have strong texturing perpendicular to the NWs long axis. The global hysteresis loop showed that NWs fabricated in both membranes have strong perpendicular anisotropy due to hcp phase. In order to obtain information about magnetostatic interactions in the NWs we performed Henkel plots which showed strong interaction between the NWs in both cases. The quantitative information about this interaction were possible with first order reversal curves (FORC) measurements. FORC measurement showed that local interactions (within the NWs) is stronger than mean field interaction effect between the NWs in both membranes. Interestingly, in AAO membrane in perpendicular field direction two distinct interaction peaks were obtained which is related to two different switching field distributions. It can be possible if two different kind of NWs are present in our system. For that reason Magnetic force microscope (MFM) imaging was applied to observe magnetic domain patterns on the basis of the magnetization profile in NWs lying horizontally on specially prepared Si substrates, used to locate the NWs under the MFM. We performed statistical analysis and found two different type of domain structures present in NWs in AAO membrane, probably the reason for two FORC peaks. Moreover, micromagnetic simulations (NMAG) on NWs confirmed that such two different domain structures (due to different anisotropies) can present different switching field distribution.

MO.F.2_O4 - Magnetic domain walls in interconnected nanowire structures

D. Burn [1], M. Chadha [1], L. Cohen [1], W. Branford [1]

1. Imperial College London, London, United Kingdom

Magnetic meta-materials exhibit interesting and complex magnetisation behaviour which originates from nanoscale patterning in addition to the intrinsic properties of the magnetic material. Artificial spin ice is one such example where interconnected magnetic nanowires are arranged in a kagome network. Here, the collective behaviour originates from multiple magnetic domain walls (DWs) which propagate along nanowires and interact at vertices.[1,2] In this work, spatially resolved magnetisation reversal behaviour in a kagome artificial spin ice structure is investigated through focussed MOKE magnetometry. With the application of a magnetic field, magnetisation reversal due to the nucleation and propagation of magnetic DWs is observed. Varying the applied field direction relative to symmetry axes in the patterning allows us to bias particular sub-lattice directions giving physical insight into the DW propagation and vertex interactions taking place.
Localised pulsed-field injection techniques[3] allow the DW propagation behaviour to be probed at fields below the intrinsic nucleation field of the system. This means that the relative influence of the DW nucleation and propagation processes upon the magnetisation reversal can be differentiated. Furthermore, the localisation of the DW injection shows behaviour associated with the bulk of the sample in comparison to that resulting from boundary effects at the edges of the structure.
This research builds on our understanding of complex interconnected magnetic systems and opens pathways to further explore the manipulation of magnetic charges[4] and potential technological applications.

MO.F.2_O5 - Segmented nanowires for multi-level high-density magnetic data storage: Modeling and experimental proof-of-concept

N. Del-Valle [1], S. Agramunt-Puig [1], E. Pellicer [1], J. Zhang [1], J. Nogués [2,3], C. Navau [1], A. Sanchez [1], J. Sort [1,2]

3. ICN2 - Institut Catala de Nanociencia i Nanotecnologia, Bellaterra, Spain

The use of arrays of high-aspect ratio magnetic nanowires (NWs) has been proposed in recent years as a promising strategy to increase the areal density of information in magnetic memories with out-to-plane magnetic anisotropy, while avoiding superparamagnetic effects. The recording density of such systems can be further enhanced by taking advantage of a multi-level magnetic storage approach. In such systems, each NW consists of N segments of different ferromagnetic materials (i.e., with dissimilar anisotropies and coercivities) separated by non-magnetic spacers, thus rendering N bits per wire. The success of such designs strongly depends on achieving a delicate balance between two opposing technological demands: the need for an ultra-high density of NWs per unit area (high density of NWs in close proximity) and the minimization of inter-wire and inter-segment dipolar interactions. Here we introduce a powerful model to evaluate the magnetic response of large arrays of NWs composed of two magnetic segments. The model, which is first validated by comparison with micromagnetic calculations, captures the essential aspects of the underlying physics in these systems while it is, at the same time, computationally tractable even for relatively large arrays of NWs. The minimum lateral and vertical distances rendering densely packed weakly-interacting NWs and segments are calculated in order to optimize the performance of this type of recording media. As a proof-of-concept of such designs, multisegmented NWs consisting of hard ferromagnetic (CoPt)/ non-magnetic (Cu) / soft ferromagnetic (Ni) segments have been prepared by electrodeposition. Clear step-like hysteresis loops with four possible remanent magnetization states are obtained. The magnetic orientation of the two ferromagnetic segments at remanence can be tailored to be either parallel or antiparallel, depending on the applied external magnetic field.

MO.F.3_O1 - Demonstration of spin-MOSFET using n-type Si at room temperature

M. Kameno [1,2], T. Sasaki [3], Y. Ando [2], T. Shinjo [2], H. Koike [3], T. Oikawa [3], T. Suzuki [4], M. Shiraishi [2]

4. AIT, Akita, Japan

Spin-metal-oxide-semiconductor-field-effect-transistors (spin-MOSFETs) hold the possibility of reconfigurable computing units on information-processing devices [1]. Spin-MOSFETs have been anticipated as the one of the powerful candidates for Beyond-CMOS devices based on spintronics. For developing spin-MOSFETs, silicon (Si) channel is well known as one of the promising materials since it is prevalent in electronics devices and has small spin orbit interaction, resulting in good spin coherence in Si. Spin transport in n-type Si channel up to RT has been achieved in our study [2], and spin transport properties, i.e., spin diffusion and spin drift have been revealed quantitatively in a degenerate state [3,4]. This time, we report the experimental demonstration of spin transport in a nondegenerate Si with a spin-MOSFET structure.
We fabricated spin valve devices on a Si-on-Insulator substrate, which consisted of a phosphorus-doped (~2 times 10^18 cm-3) n-type channel. Beneath ferromagnetic electrodes (FMs), MgO tunneling barrier layers and highly-doped layer are prepared in order to decrease the thickness of Shottkey barrier. When the device was measured with the gap length of FMs as 21 um, we successfully observed the Hanle-type spin precession signals by applying perpendicular magnetic field at RT [5]. We found that the effect of spin drift made the reasonable contribution to quite long-range spin transport in the nondegenerate Si channel. In addition, the successful gate-voltage-induced modulation of the spin signals was obtained with the Elliott-Yafet-type spin relaxation mechanism.

The field of spintronics is based on the manipulation of the spin degree of freedom. It uses the carrier spin angular momentum as a basic functional unit in addition to the charge. By combining charge and spin, a single electronic device could then integrate both logic and memory functions limiting power consumption and speeding up data processing. The first requirement of a semiconductor-based spintronic technology is the efficient generation of spin-polarized carriers into the device heterostructure made of Si or Ge (the materials of mainstream microelectronics) at room temperature. In this presentation, we focus on the generation of a sizeable spin population into Ge by spin pumping. Spin pumping corresponds to the generation of a pure spin current in the Ge film by exciting the ferromagnetic resonance of an adjacent ferromagnetic electrode with microwaves. The pure spin current is then detected using spin-orbit based effects. Our aim is to understand the basic mechanisms of spin pumping into Ge as well as the spin-to-charge conversion by inverse spin Hall effect (ISHE, bulk effect) and Rashba effect (interface effect). In particular, the influence of the doping type (n and p) and interface resistance on spin pumping-ISHE measurements in Ge will be shown. The influence of interface states is clearly demonstrated. Moreover, using the spin-split Rashba sub-surface states of the Ge(111) surface, we succeeded in demonstrating the giant conversion of a spin current generated by spin pumping into a charge current by the Rashba Edelstein effect. Our experimental findings are supported by ab-initio calculations.

MO.F.3_O3 - Impurity-assisted tunneling magnetoresistance: the physics behind electrical three-terminal hanle experiments

Injection of spins into semiconductors is essential for the integration of the spin functionality into conventional electronics. Insulating layers are often inserted between ferromagnetic metals and semiconductors for avoiding the conductivity mismatch and obtaining an efficient spin injection. This is the case when employing the so-called three-terminal (3T) setup, in which spin accumulation is induced and probed by a single magnetic tunnel contact, through the Hanle effect [1]. Since this geometry does not require submicron-sized fabrication processes, 3T-measurements have become very popular. However, it has been increasingly realized that the magnetoresistance (MR) reported depends much on the tunneling process and too little on the semiconductor [2,3].
In this work, we perform measurements with a 3T geometry on devices with aluminum-oxide sandwiched between different metallic electrodes [2,3]. First, we use two strategies for the tunnel barrier fabrication: single plasma-exposure oxidation, or multistep deposition and subsequent natural oxidation of aluminum thin films. The MR effect is observed in impurity-rich multistep tunnel barriers and suppressed in plasma-oxidized barriers where direct tunneling is dominant, meaning that the effect is entirely impurity-driven [3]. Second, we detect similar MR effects in ferromagnetic-insulator-nonmagnetic (FIN) and nonmagnetic-insulator-nonmagnetic (NIN) devices, demonstrating that spin accumulation is not being measured in our setup [3]. Last, we explain the observed MR effect with a theory that considers the magnetic-field-induced on/off switching of the tunneling current through impurities embedded in the tunnel barrier [3,4]. The reported effect is universal for any impurity-assisted tunneling process and provides an alternative interpretation to a widely used technique that employs the same ferromagnetic electrode to inject and detect spin accumulation.

While the method of semiconductor spin noise spectroscopy has attracted significant attention, it is not directly suitable to detect the spin Hall Effect in typical semiconductors. Recently, we have suggested a method of hybrid spin noise spectroscopy, which is based on a simultaneous analysis of spin and transverse voltage fluctuations [1]. One can show that in the spin Hall Effect regime, the spin fluctuations are dressed by charge dipoles that lead to the transverse voltage fluctuations. Therefore, the transverse voltage fluctuations (that could be measured electronically) correlate with the spin fluctuations (that could be measured optically). Moreover, the strength of the transverse voltage fluctuations is proportional to the spin Hall coefficient. These observations form the basis for the hybrid spin noise spectroscopy [1] that will be discussed in this talk from the theoretical point of view. We anticipate the potential of the spin noise spectroscopy to study the spin-charge coupling in semiconductors and other materials.

MO.G.1_I1 - A study of antiferromagnetic/ferromagnetic systems using X-ray magnetic dichroism

Z.Q. Qiu [1]

1. University of California at Berkeley, Berkeley, United States

Epitaxial CoO/Fe/Ag(001) and NiO/Fe/Ag(001) systems allow an element-specific measurement of the ferromagnetic (FM) and antiferromagnetic (AFM) elements using X-ray Magnetic Circular Dichroism (XMCD) and X-ray Magnetic Linear Dichroism (XMLD), respectively. The response of the AFM spins to the FM spin rotation shows that the CoO spins consist of rotatable and frozen spins and that only the Fe uniaxial magnetic anisotropy follows the CoO frozen spins. For the softer NiO AFM materials, we show that the NiO spins can form a Mauri domain wall in Fe/NiO/Fe as the two Fe layer magnetizations twists. However, the Mauri domain wall forms only up to ~90 degree twisting angle, at which the NiO domain switches its chirality and unwinds as the twisting angle increases from 90 to 180 degrees. This result explains why the AFM order could induce a strong uniaxial anisotropy but a weak exchange bias in the FM layer.

MO.G.1_O2 - Topologically protected magnetic helix for energy storage

E. Vedmedenko [1]

1. University of Hamburg, Hamburg, Germany

The novel generation of computers is supposed to be based on logical elements made of chains of magnetic atoms or nanomagnets. Any logical elements require energy supply, but use the energy not all the time. A key issue for technology's competitiveness is to figure out how to store energy when it isn't used. Here, we discover that it can be stored in magnetic helices with integer number of revolutions corresponding to the stationary states of a chain of magnetic elements coupled via the antiferromagnetic exchange, the dipolar or the RKKY interaction [1]. Based on simulations and a benchmarked prototype, this finding permitted to propose a magnetic energy storing element. To store energy one has to rotate one of the end-nanomagnets in a chain until the helix will click into one of the stationary states. At the later time the end-element may be released to deliver the energy on demand. The longer is a chain, the larger number of rotations can be stored. The stable magnetic helices can be also used to transfer information. To do so, one has to read out when a knot, created at one end of the chain will arrive at the other chain's end. The main advantage of the proposed concept is it's scalability from the macro- to the atomic scale and applicability to the great diversity of systems with different interactions like e.g. magnetic multilayers, magnetic or molecular nanoarrays and colloids.

MO.G.1_O3 - Atomistic spin dynamics and effective models of AFM/FM multilayer systems

I. Stockem [1], C. Schröder [1], G. Reiss [2]

1. Department of Engineering Sciences and Mathematics, University of Applied Sciences Bielefeld, Bielefeld, Germany
2. Department of Physics, Center for Spinelectronic Materials and Devices, Bielefeld University, Bielefeld, Germany

Antiferromagnets (AFM) are of growing interest for spintronic applications. Traditionally they are used as passive elements to statically fix the magnetization of the ferromagnetic (FM) layer in spin valves and magnetic tunnel junctions by exchange bias [1]. We have investigated two stacks, where the AFM plays a key role as an active element. The first system is a Co/Cr2O3 stack with a perpendicular anisotropy (PEB) and a switchable exchange bias [2]. Here the AFM is used to pin the magnetization of the FM and a strong field pulse can reverse the exchange bias direction.
The second system is a NiFe/IrMn/MgO/Pt stack showing spin-valve-like magnetoresistance [3]. The huge magnetoresistance is based on the tunneling anisotropic magnetoresistance effect of the IrMn/MgO interface (AFM-TAMR) in combination with the rotation of the antiferromagnetic moments that are pinned to the magnetic moments of the FM layer. Depending on the geometry and the interactions within and between layers, the AFM pins the FM magnetization or the FM rotates the AFM magnetization. We have studied the magnetization dynamics of these FM-AFM stacks subject to an external field for the two systems described above. We will discuss first a simplified effective model that can identify the basic mechanisms of the magnetization dynamics. Next, we will compare these results with atomistic spin dynamics simulations of the full scale systems [4]. To include finite temperature effects, we couple the system to a heat bath. The results show, that the orientation of the magnetic moments can be quite complex depending on the next neighbor interactions.

MO.G.1_O4 - Enhancement of Blocking Temperature of Cr2O3/Co Perpendicular Exchange Coupling System with Thin Cr2O3 Layer

T. Nozaki [1], N. Shimomura [2], S.P. Pati [3], M. Sahashi [4]

1. Tohoku University, Miyagi Prefecture, Japan

Magnetization reversal using Magneto-electric (ME) effect and perpendicular exchange bias (PEB) in antiferromagnetic (AF) Cr_2O_3 thin film has been established [1]. For the applications, thin Cr_2O_3 is required. But with decreasing thickness, blocking temperature (TB) of PEB in thin Cr_2O_3/Co exchange coupling system decreases due to the product of AF anisotropy and thickness (KAF*tAF) become smaller than exchange coupling energy JK [2]. To obtain sufficient TB using thin Cr2O3 layer, increase of AF anisotropy KAF is essential. In this study, we tried to enhance the TB in thin Cr_2O_3 layer by inducing lattice strain.
Sample design is c-Al2O3 sub. /Pt 25 or Fe_2O_3 20/ Cr_2O_3 20/metal spacer/Co 1/Pt 5 (nm). Samples are fabricated by using a RF-DC magnetron sputtering. Magnetic properties were measured by SQUID magnetometer. Structural characterizations were performed by XRD and TEM measurement. Metal spacer is inserted at Cr_2O_3/Co interface to control the exchange coupling energy JK. A higher TB was obtained in Fe_2O_3-buffered Cr_2O_3 sample compared with Pt- buffered sample, while the exchange coupling energies of both samples are almost identical. . In case of Pt-buffer, TB was limited to 150 K. On the other hand, much higher TB (~260 K) was obtained for Fe_2O_3-buffered sample. ~260 K was almost identical to the Neel temperature TN of this sample. Since the change in TB correlate with change in the lattice parameters, we believe this is due to the enhancement of KAF by lattice strain. That is, we succeed to obtain TB ~ TN using only 20nm thick Cr_2O_3 layer. This work was partly funded by ALCA Program of JST and ImPACT Program of Council for Science, Technology and Innovation (Cabinet Office, Japan Government).

Exchange-bias describes the peculiar magnetic properties characterizing exchange-coupled antiferromagnetic-ferromagnetic (AFM-FM) systems: shifted hysteresis cycle and additional ferromagnetic coercivity. It is attributed to the existence of some un-compensated magnetic moments in the antiferromagnetic material at the interface with the ferromagnetic one. The establishment of exchange-bias requires that a uniaxial direction be defined e.g. cooling under an applied magnetic field. Beyond this qualitative understanding, exchange-bias resists a quantitative description.
In the present study, we demonstrate that reversal of the ferromagnetic layer moment is fundamentally different whether it occurs from the “positive” initial orientation (defined by the field applied during cooling) or from the “negative” reversed orientation. This is due to moment reconfiguration under the effect of the interfacial AFM-FM coupling, which occurs for the negative orientation of the ferromagnetic layer, and transforms the reversed state, usually assumed to be a state of maximum coupling energy, into a metastable magnetic state. A simple expression is derived relating the bias-field, Heb, and the coercive field, Hc.
At finite temperature, another phenomenon is involved in the magnetization processes of exchange-bias systems, namely thermal activation, which is acting on essentially exchange-decoupled AFM grains, as discussed in particular by O’Grady et al. [1]. Taking both above phenomena into account, a quasi-quantitative description of the temperature dependence of both Heb and Hc is demonstrated for two different exchange-bias samples, involving antiferromagnetic Mn_2Au. The generality of the model will be further discussed.

MO.G.2_I1 - Accelerated discovery of high-performance magnets

S. Sanvito [1]

1. School of Physics, AMBER and CRANN Institute, Trinity College, Dublin, United Kingdom

Magnetic materials underpin a vast and diverse range of modern technologies, going from data storage to energy production and use. However, the choice of magnets for mainstream applications is limited to a few dozens and the development of a new high-performance magnetic compound is a long and often unpredictable process. Here we describe a systematic pathway to the discovery of novel magnetic materials for multiple applications, which demonstrates an unprecedented throughput and speed up in the discovery process. We have constructed a massive electronic structures library for Heusler alloys containing 236,856 materials. We have then extracted those magnetic compounds with specific electronic properties, such as half-metallicity and large magnetization density, and finally established whether these can be fabricated at thermodynamical equilibrium. A full analysis for stability has been carried out on a sub-set of 36,000 intermetallic Heuslers. This has identified 249 stable, including 21 new magnets. Our work paves the way for large scale design of novel magnetic materials at unprecedented speed.

MO.G.2_O2 - Cluster monte carlo algorithms for fept hamiltonian

A. Lyberatos [1], G. Parker [2]

1. University of Crete, Crete, Greece
2. HGST,a Western Digital Company, San José, United States

The temperature dependence of the magnetization, susceptibility and specific heat of FePt in the critical region close to T_c is required for calculation of critical exponents and for multiscale modeling. The accuracy of single flip (Metropolis) Monte Carlo algorithms is limited by a) the critical fluctuations of the magnetization and energy and b) the divergence of the correlation time $\tau \sim \xi^z$, where ξ is the bulk spin correlation length and z is the dynamic exponent (critical slowing down). Critical fluctuations are an innate physical feature of any model, however, cluster flipping algorithms were proposed to solve the problem of critical slowing down for Ising and Heisenberg Hamiltonians with nearest neighbor interactions [1] and Ising models with long range interactions [2].
The case of a Heisenberg Hamiltonian with long range interactions has not been treated to our knowledge before. The classical spin Hamiltonian of FePt [3] also includes magnetic anisotropy and antiferromagnetic exchange coupling for some Fe-Fe pairs. We developed hybrid Metropolis/Swendsen-Wang and Metropolis/Wolff algorithms for FePt. Cluster moves must preserve the anisotropy energy and Metropolis steps are included to satisfy the requirement of ergodicity. The temperature dependence of the magnetization (Fig.1) and susceptibility are found to be in good agreement with the Metropolis algorithm, so the algorithms also satisfy the detailed balance condition. The Wolff algorithm has the advantage of reduced memory requirements. An estimate of the dynamic exponent $z = 2.13 \pm 0.05$ was obtained by plotting the correlation time as a function of grain size (Fig.2) at the Curie temperature for bulk FePt estimated as T_c=677 K [4]. It is shown that in the critical region the results are affected by the presence of a percolation cluster involving most of the spins in the grain, and we discuss efforts to control the cluster size using Niedermayer's algorithm.

MO.G.2_O3 - Bimodal distribution of blocking temperature for exchange-bias ferromagnetic/antiferromagnetic bilayers: a granular Monte Carlo study with less stable magnetic regions spread over the interface

D. Ledue [1], G. Lhoutellier [1], R. Patte [1], F. Barbe [1], B. Dieny [2], V. Baltz [2]

1. GPM UMR 6634 CNRS-Université & INSA De Rouen, Saint-Étienne-du-Rouvray, France
2. SPINTEC, Univ. Grenoble-Alpes/CNRS/INAC-CEA, Saint-Martin-d'Hères, France

In exchange bias based devices, ferromagnetic/antiferromagnetic (F/AF) disordered interfacial spins which exhibit low freezing temperatures contribute to the alteration of the exchange bias properties. In particular, the blocking temperature distributions (DTB) earlier observed experimentally show two contributions: the common high-temperature peak due to the antiferromagnetic grain volume distribution and a less usual low-temperature contribution presumably attributed to disordered interfacial spins [1,2]. Here, our goal is to propose a granular level model which can reproduce bimodal DTB. To that purpose, the model includes small magnetic grains with weaker anisotropy and smaller interfacial coupling at the F/AF interface to account for the disordered interfacial spins. Then, the experimental 'Soeya et al' protocol [3] with a sufficiently low reference-temperature Tm = 4K [1] is reproduced by Monte Carlo simulations to calculate the DTB. As a result, the bimodal character of blocking temperature distributions is reproduced and varying the amount of these smaller magnetic grains tunes the low-temperature contribution of the distribution. These simulations therefore validate the assumption that less stable magnetic regions spread over the F/AF interface may originate the bimodal character of DTB, as earlier brought forward by experimentalists to explain their results. In addition, because of the heterogeneities of the interface in presence of less stable small grains, our simulations show that such bilayers cannot be described using a simple model of uniform rotation of the ferromagnetic layer interacting with an average interfacial coupling [4].

MO.G.2_I4 - Vortex nonlinear dynamics

C. Serpico [1], M. d'Aquino [2], S. Perna [1], A. Quercia [1]

1. DIETI, University of Naples Ferderico II, Naples, Italy
2. Department of Engineering, University of Naples Parthenope, Naples, Italy

This work is devoted to the analysis of spin-torque nano-oscillators (STNOs) based on spin-valve structure with the free layer in a vortex state. This type of STNO promises to have an important role in forthcoming microwave communication technologies [1],[2]. In vortex-based STNOs, the magnetization oscillation typically occurs through a gyrotropic motion of the vortex and can be reasonably well described by a reduced set of variables such as the position of the vortex core. In order to design STNOs with sufficient emitted power, it is crucial to gain an understanding of the dynamics of such oscillators in regimes where the vortex is driven far from equilibrium, in nonlinear regimes. In this paper, we present a theoretical treatment of injection locking and nonlinear resonance of vortex oscillations, driven by AC injected currents and applied fields, based on a Thiele-like model of vortex core dynamics. By exploiting separation of time scales and using appropriate averaging technique[3], we derive equations which are applicable to the study of phase-locking for arbitrary large vortex core motion. The bifurcation diagram of nonlinear vortex core dynamics is obtained which enables one to have a comprehensive understanding of phase-locking and nonlinear resonance phenomena.

MO.G.3_O1 - Magnetic field dependence of phonons in the terbium gallium garnet

M. Mori [1], A. Spencer-Smith [2], O. Sushkov [2], S. Maekawa [1]

1. Japan Atomic Energy Agency, Ibaraki, Japan
2. University of New South Wales, Sydney, Australia

When a magnetic field is applied perpendicular to a heat current in a terbium gallium garnet (TGG), $Tb_3Ga_5O_{12}$, a transverse temperature gradient is induced in the third perpendicular direction [1,2]. This is the ügphonon Hall effect (PHE)üh. Since the effect takes place at low temperature (~ 5 K) in the insulator, there are no mobile charges such as electrons nor holes to assist the thermal transport. Phonons are not charged and hence cannot be induced by the Lorentz force such as the Hall effect. Spin-orbit interaction for phonons is not obvious unlike the spin Hall effect for electrons. Furthermore, the TGG is a paramagnet around 5 K, at which the PHE is observed. Hence, one cannot expect a considerable contribution from magnons unlike the magnon Hall effect [3]. Therefore, an origin of the PHE is non-trivial and a fundamental question in condensed matter physics.
In this talk, we show that the PHE originates from the resonant skew scattering of phonons by quasi-doublet states at superstoichiometric Tb3+ ions [3]. Phonons interact with the crystal field due to the electrostatic interaction of lattice with electric multipole moments of the ion. Thus, the scattering of phonons can be attributed to the coupling of lattice strain and the quadrupole moments of Tb3+ ions. The phonon Hall angle (S), given by the ratio of off-diagonal and diagonal thermal conductivities divided by the magnitude of the magnetic field, is calculated using Boltzmann transport theory. Obtained magnitude of the effect is in agreement with experiments. It is also shown that S significantly grows with temperature, and a magnetic field can modulate the dispersion relation of phonons due to the coupling of lattice strain and the quadrupole moments of Tb3+ ions.

MO.G.3_O2 - Magnetic susceptibility anisotropy in noncentrosymmetric $CePt_3Si$ due to rashba-type spin-orbit coupling

B. Fak [1,2], V. Mineev [2]

1. Institut Laue-Langevin, Grenoble, France
2. CEA and University, Grenoble Alpes, France

Noncentrosymmetric metals with tetragonal structure are characterized by an antisymmetric Rashba-type spin-orbit interaction, which has been predicted to give rise to an anomalous spin susceptibility. We have studied the normal phase of the heavy-fermion unconventional superconductor $CePt_3Si$ using polarized inelastic neutron scattering. Our measurements show a clear anisotropy in the spin susceptibility, in qualitative agreement with theoretical calculations based on the Hubbard model. The observed effect is larger than predicted, which may be due to the strong spin-orbit coupling of rare-earth heavy fermions.

MO.G.3_O3 - Distribution of relaxation times in the skyrmion compound Cu_2OSeO_3

I. Zivkovic [1,2], I. Levatic [1], V. Surija [1], H. Berger [2]

1. Institute of Physics, Zagreb, Croatia
2. Institute of Condensed Matter Physics, Lausanne, Switzerland

he investigation of skyrmions presents many challenging aspects to science. Some of the fundamental questions about the formation and the stability of the skyrmion lattice are still open, while at the same time there are several possible routes for the application of skyrmions, especially in spintronics. Skyrmions are whirls of spins, resembling the magnetic vortex in type-II superconductors. Skyrmions can form a long range ordered state called the skyrmion lattice, which can be found in several chiral magnets. The best known examples are conductive MnSi and insulating Cu_2OSeO_3.
We present here the results of our investigation [1] of Cu_2OSeO_3 and the phase transitions that surround the skyrmion pocket. Although it has been suggested that the skyrmion lattice disintegrates through the first-order phase transition both into the paramagnetic (disordered) state as well as into the conical state, we have found a significant difference between the two. The conical-skyrmion lattice phase boundary is characterized by a wide dissipation region, as reveal by our high-sensitivity ac susceptibility measurements. Within the skyrmion phase one can follow a dissipation profile which demonstrates the presence of a distribution of relaxation times, usually found in spin-glass and superparamagnetic systems. Here, we present evidence that the distribution is intrinsic to the skyrmion lattice and not due to impurities.

MO.G.3_O4 - Guiding of a zigzag spin spiral by local uniaxial strain relief

P. Hsu [1], A. Finco [1], L. Schmidt [1], A. Kubetzka [1], K. von Bergmann [1], R. Wiesendanger [1]

1. Department of Physics, University of Hamburg, Hamburg, Germany

Spin spirals typically result from competing magnetic interactions. In the presence of a sizable Dzyaloshinskii-Moriya interaction (DMI), the spin spirals exhibit a unique rotational sense and their periodicity is governed by the ratio of the exchange and DM-interaction strength. Here, we study the double-layer (DL) Fe grown on Ir(111) by means of spin-polarized scanning tunneling microscopy (SP-STM). We observe periodic reconstruction lines with a spacing of about 3.3-3.7 nm as a consequence of uniaxial strain relief induced by lattice mismatch. Using vectorial field-dependent spin mapping, a cycloidal spin spiral of a typical period of about 1.1 nm with unique rotational sense has been resolved. Interestingly, the spiral wavefronts are guided by the reconstruction lines, leading to three rotational domains. This is in contrast to the spin spirals found in the pseudomorphic area, which are propagating isotropically. Not only the wavevector of spin spirals is linked to the reconstruction lines, but also the wavefront is tied to the local symmetry of the atom arrangement which results in a zigzag shape. Furthermore, an atomic scale canting of spins with respect to reconstructions lines has been observed, which is proposed to originate either from DMI or alternatively from magneto-crystalline anisotropy. The zigzag spin spiral state is stable without magnetic phase transition under external out-of-plane field up to 9 Tesla.

MO.H.1_I1 - Spin-torque nanodevices for bio-inspired computing

J. Grollier [1]

1. CNRS Thales, Palaiseau, France

Biological systems have impressive computing abilities. We, humans, are able to recognize people we barely know in just a fraction of second, even in a crowd. And we do this incredibly complex task with 10^4 times less power than any supercomputer! It therefore makes sense to take inspiration from biology to build data processing systems to perform low power 'cognitive' tasks on-chip and complement our traditional microprocessors. As biological systems, bio-inspired hardware should be composed of a huge number of computing nodes and connections in order to be efficient (there are 10^11 neurons and 10^15 synapses in the brain). While CMOS technology might appear as the most mature technique to build such systems, it suffers from the high number of transistors required to imitate synapses and neurons, and the related power dissipation issues. Fabricating devices that can emulate synapses and neurons at the nanoscale therefore appears as the key for the development of dense, efficient bio-inspired chips. In this talk, I will highlight that spin torque nanodevices, as multi-functional and tunable nonlinear dynamical nano-components, are interesting building blocks for the hardware implementation of bio-inspired models. In particular, they appear to be well suited for adapting on the nanoscale computing models inspired from the brain non-linear dynamics. I will describe the first steps that we achieved towards this long-term goal, including the realization of spin torques synapses, and noise-enhanced synchronization of stochastic oscillators.

MO.H.1_O2 - Current-induced spin orbit torques and magnetization switching in antiferromagnet/ferromagnet/oxide structures

B. Park [1]

1. Kaist, Daejeon, republic of Korea

The utilization of antiferromagnetic (AFM) materials in spintronics as an active element has recently been reported in magnetic tunnel junctions and AFM memories. Moreover, an observation of a large inverse spin Hall effect (ISHE) demonstrates its sizable spin-orbit coupling (SOC). Those results imply that the AFM can replace heavy-metal (HM) as underlayer in the HM/ferromagnet(FM)/oxide based devices, which are intensively investigated because of the potentials in a low-power magnetization switching and a high speed domain wall motion. The spin Hall effect in HM layer and/or interfacial Rashba effect can generate so-called spin-orbit torque (SOT), of which magnitude and sign mostly relies on the SOC of the HM or HM/FM interface. Therefore, the non-negligible magnitude of the SOT from the AFM can be expected due to its large SOC.
In this work, we investigated the SOTs in a perpendicularly magnetized AFM IrMn/CoFeB/MgO heterostructures using harmonic lock-in measurements. It was observed that the sign of the SOT of the AFM IrMn underlayer is opposite to that of the Ta measured in Ta/CFB/MgO structure, implying a positive spin Hall angle of IrMn, while the magnitude of the SOT is comparable to that of Ta. We also performed switching experiments where an in-plane pulsed-current of 50us was applied while sweeping the longitudinal magnetic field. The magnetization of the samples can be switched by applying an in-plane current pulse and an in-plane magnetic field. The preferred magnetization direction for a certain current polarity and in-plane field direction is reversed as the IrMn layer is replaced with the Ta layer. Furthermore, we controlled the magnetization direction of the AFM layer and explored the effect on the SOTs and current-induced switching properties.

MO.H.1_O3 - Spin-orbit torque switching in a ferromagnet/antiferromagnet bilayer system

Spin-orbit torque (SOT)-induced magnetization switching[1-3] has attracted great attention due to its potential to be used in three-terminal spintronics devices that can achieve high-speed and high-reliability operation[4]. Up to now, the study on SOT switching has been focused on ferromagnet/non-magnet (FM/NM) bilayer structure. Here we show that ferromagnet/antiferromagnet (FM/AFM) bilayer system also exhibit the SOT large enough to induce magnetization switching. Furthermore, we elucidate the following two characteristics unique to the FM/AFM system: (I) ability to switch the perpendicular magnetization with no external field; (II) memristor-like behavior where the portion of reversed magnetization can be controlled in an analog manner.

We here study current-induced magnetization switching in Hall devices made of antiferromagnetic PtMn and ferromagnetic Co/Ni multilayer at room temperature. Magnetization curves of blanket films show that the Co/Ni multilayer has perpendicular easy axis with an in-plane unidirectional anisotropy originating from the exchange bias of PtMn layer. The magnetization switching at zero field is observed with the current density of about 6×10^{10} A/m^2, which is comparable to the one obtained in a Ta/CoFeB/MgO system with the same device geometry[3]. The direction of switching reverses when the direction of exchange bias is reversed or a large external field opposite to the bias is applied, indicating that Slonczewski-like SOT is the origin of the switching whose direction is determined by the exchange bias. Sign of the SOT is opposite to the Ta/CoFeB/MgO, which is consistent with a previous report on inverse spin Hall effect in PtMn[5]. We also find that the Hall resistance varies continuously with the magnitude of the applied current, indicating that the device works as a memristor, which is useful for bio-inspired computing.

Spin-orbit interaction (SOI) in heavy nonmagnetic metal/ferromagnetic metal bilayers attracted considerable interest due to the possibility to generate transverse pure spin currents via the spin Hall effect using in-plane charge currents. The spin current generated in the nonmagnetic layer diffuses in the ferromagnetic layer and exerts a torque on its magnetization. This provides important perspectives for novel spintronic devices with a spin torque control of magnetization switching.
Our study was performed in bilayers based on permalloy (Py) and a nonmagnetic adjacent layer constituted by a Cu conductive matrix doped with heavy metals impurities (Ir, Bi). As expected [1], this provides a large and tunable spin Hall angle via the extrinsic skew scattering contribution to the spin Hall effect. Prior to magneto-electric characterization, the samples have been lithographically patterned in stripes with Hall transverse contacts. Then, on these microstructures, a quasi-static technique has been used to evaluate the spin orbital field generated in Cu(Ir,Bi)/permalloy bilayers with different heavy metal impurity concentrations. This technique involves the generation of the spin orbital field by applying a direct current and the compensation of the spin orbital field using and external applied magnetic field [2]. Then, the statically measured spin-torque induced field in the Cu(Ir,Bi)/permalloy bilayer samples has been compared with the one measured in conventional [Pt (or Ta in the high resistive phase)]/permalloy bilayers [3,4]. We demonstrate similar orbital fields in less conventional Cu(Ir)/Py (60 A/m) as compared to the more conventional Pt/Py bilayers (80 A/m), at a charge current density of around 1010 A/m2.
Eventually, the quasi-static magneto-electric characterization results in patterned stripes have been confronted with dynamic ferromagnetic resonance experiments. This correlated analysis demonstrate the direct correspondence between the spin pumping by spin-orbitronic effects and the Gilbert damping enhancement in permalloy layer adjacent to nonmagnetic metallic layers with enhanced SOI.

Recently, magnetization switching via spin-orbit torque (SOT) attracts increasing attention as a new switching method for magnetic tunnel junction devices[1-3], and much effort has been made on Ta/CoFeB/MgO system. Among them, a large discrepancy in the magnitude of switching current density J_{th} has been found[1-4], which may be related to the different device sizes and/or different measurement conditions. To address the origin of this discrepancy, we here systematically investigate SOT switching in Ta/CoFeB/MgO structures with various sizes (down to 30 nm) in various conditions.

We fabricate Hall devices from a film with a stack structure of substrate/Ta(5)/CoFeB(1.2)/MgO(1.5)/Ta(1) (nm), in which a CoFeB dot with various diameters D is prepared on a Ta channel. Switching probability P_{sw} is measured using pulsed currents with various durations τ under various in-plane magnetic fields H_x along the current direction. In the range D = 30~80 nm, J_{th} ~ 3×10^{12} A/m^2 is almost independent of D at τ = 10 ns and $\mu_0 H_x$ = 20 mT. The obtained J_{th} is more than one order of magnitude larger than that of micrometer-sized devices where the switching is more likely to be initiated with nucleation reversal followed by domain wall motion. We analyze the τ dependence of P_{sw} for the device with a 40 nm dot by using a theoretical model[5] with the effective spin Hall angle θ_{SH}, effective anisotropy field $\mu_0 H_K^{eff}$, and thermal stability factor E/k_BT as adjustable parameters. As τ decreases from 100 μs to 5 ns, θ_{SH} and $\mu_0 H_K^{eff}$ are almost constant (0.2 and 0.5 T), whereas E/k_BT increases from 64±11 to 98±11, reflecting the decrease of the Joule heating due to the high current density.

MO.H.2_I1 - Spin pumping through a topological insulator probed by x-ray detected ferromagnetic resonance

A.I. Figueroa [1], A.A. Baker [1,2], L.J. Collins-McIntyre [2], G. van der Laan [1], T. Hesjedal [1]

In the field of spintronics, the generation of a pure spin current (without macroscopic charge flow) through spin pumping of a ferromagnetic (FM) layer is crucial for the new generation of dissipation-less devices. Microwave driven ferromagnetic resonance (FMR) can generate a pure spin current that enters adjacent layers, allowing for both magnetization reversal (through the spin transfer torque) and to probe of the spin coherence properties of non-magnetic (NM) materials. However, standard FMR is unable to study multilayer dynamics directly, since the measurement averages over the contributions of the whole system. The synchrotron radiation-based technique of x-ray detected FMR (XFMR), offers an elegant solution to this drawback, giving access to element-, site-, and layer-specific dynamical measurements in heterostructures [M. Marcham et al., Phys. Rev. B 87, 180403 (2013); G.B.S. Stenning et al., New J. Phys. 17, 013019 (2015)]. In this work, we present selected examples of how XFMR has provided unique information to understand spin pumping and spin transfer torque effects on magnetic heterostructures. We describe our most recent results of spin pumping through a topological insulator (TI) layer in a pseudo-spin valve heterostructure, where we demonstrate that TIs function as efficient spin sinks, while also allowing a limited dynamic coupling between ferromagnetic layers [A. A. Baker et al., Sci. Rep. 5, 7907 (2015)]. These results shed new light on the spin dynamics of this novel materials class, and suggest future directions for the development of room temperature TI-based spintronics.

MO.H.2_O2 - Control of the spin-wave relaxation in a magnetic insulator of macroscopic dimensions via spin-transfer torque

It was shown recently, that in the magnetic insulator yttrium iron garnet (YIG) the spin-wave damping can be controlled by means of spin-orbit torque (STT) [1]. For this purpose, a dc current was applied to an adjacent Pt layer generating a spin current via the spin Hall effect (SHE), that consequently transferred angular momentum into the YIG layer. In those studies, a micro-structured YIG/Pt disk of 5 µm diameter was used to demonstrate the damping control. However, one of the main advantages of the SHE-STT-based damping compensation is its predicted applicability to a system of macroscopic dimensions. Here, we present experimental studies of the SHE-STT-based spin-wave relaxation control in a YIG(100 nm)/Pt(10 nm) sample with dimensions 4 x 2 mm^2. The change of the relaxation frequency with the applied dc current was determined from the investigations of the threshold of the parallel parametric instability [2]. The parametrically excited spin waves were detected by Brillouin light scattering (BLS) spectroscopy that allowed for the determination of the threshold values of the pumping magnetic field. The dc current, as well as the pumping magnetic field were pulsed (pulse duration to repetition time as 1:100), in order to avoid effects associated with parasitic heating. In contrast to [1], with the parallel pumping geometry we investigated the SHE-STT-based relaxation variation for spin waves with large wavenumbers of k = 1E4 rad/cm. We found that the relaxation frequency changes linearly with the dc current and can be tuned by ±7.5% for a current density of 5E10 A/m^2, which was the largest current density used in the experiment. The tuning direction depends on the current direction with respect to the magnetizing field polarity.

The recent demonstration of so called Spin hall Nano-Oscillators (SHNOs)1,2 driven by pure spin currents has greatly increased the versatility of spin transfer torque (STT) driven devices. In comparison with the much more studied Spin Torque Nano-Oscillators (STNOs) where a spin-polarized current is injected in a current perpendicular to plane (CPP) geometry, the auto-oscillations in SHNOs are driven by a laterally injected spin currents in between two low-resistance needles, which allow for direct optical access to the magnetically active region. As a consequence, SHNOs allow for simultaneous measurement and characterization of their magnetization dynamics via wide range of different techniques ranging from electrical measurement to optical techniques such as micro-focused scanning Brillouin Light Scattering (u-BLS). What is not yet clear is the impact of the tilted field on the dynamics of such devices, and the nature and interplay mechanism of the multimode operation at room temperature. In order to study in depth the effect of field tilting and room temperature operation a sample SHNO device is prepared of thin bilayer with Py(5nm)/Pt(6nm), The spin injection is concentrated to a nanometric region via focusing the charge current flow in small region of the Pt. Here we, for the first time, demonstrate SHNO operation in tilted magnetic fields. We demonstrate improved spectral characteristics of the electrical signals with linewidths below 2 MHz at room temperature. The electrically detected modes are spatially resolved via u-BLS that permits the observation and the understanding of the excited modes. We show the existence of two different oscillation modes, a self-localised solitonic bullet mode and a field-localized linear mode. Micromagnetic simulations, using Mumax33, shed additional light on both modes and their mutual interplay, including significant mode-hopping between the two.

MO.H.2_O5 - Effect of spin-transfer-torque induced dynamics of a synthetic antiferromagnetic reference layer on a spin-torque diode spectrum

R. Matsumoto [1], H. Kubota [1], T. Yamaji [1], H. Arai [1], S. Yuasa [1], H. Imamura [1]

1. National Institute of Advanced Industrial Science and Technology (AIST), Tokyo, Japan

Quantitative understanding of the spin-transfer-torque (STT) acting on a synthetic antiferromagnetic reference layer is important for the development of future spin-valve (SV) devices such as STT-MRAMs. The size of the SV devices tend to become smaller and smaller, and a large current pulse needs to be applied for a very fast magnetization switching. In such tough situations the STT induced magnetization dynamics in the reference layer cannot be neglected. Until now, the STT acting only on the free layer has been quantitatively understood by the spin torque diode (STD) effect [1]. Here, an RF current is rectified by the SV device which synchronizes the RF current and magnetoresistance oscillation caused by the STT [2]. In this study, the STD effect of the SV with the reference layer is theoretically analyzed [3]. Based on the macrospin model the analytical expression of the STD spectrum is derived. The obtained result enables us to analyze the STT acting on the reference layer. The peak of the STD spectrum at the resonance frequencies of the reference layer changes its sign depending on the magnitude of the STT which is generated by the RF current injected from the pinned layer.

Novel spin textures such as magnetic vortex structures have recently been attracted much interests due to their interesting and unique non-trivial topological properties, but also for potential applications in information technologies due to increased storage densities with lower power consumption and robust high frequency oscillations with easy tuning methods. An important milestone to utilize such systems in applications is a fully reliable control of vortex structures, which requires a complete understanding and controlling of the dynamic behavior in their formation process. It has been known that a chirality of vortex can be controlled by forming vortex structures in asymmetric circular nanodisks; the chirality is determined by the saturation direction before a forming of vortex structures from the saturation states under in-plane magnetic field, whereas the polarity occurs randomly during the formation of vortex structure. From our micromagnetic simulations, it is found that the typical behavior of chaos, known as the butterfly effect, in vortex polarity formations on asymmetric disks. Very small fluctuation of initial spin configuration can affect the whole dynamic process of vortex formation and thus, the polarity occurs randomly. However, we found that the resultant polarity direction can be manipulated by applying very small external in-plane magnetic fields with a few Oe along the perpendicular direction to the saturation direction; the direction of the external in-plane magnetic field determines the polarity of the vortex structure. Interestingly, such small external fields do not vary the formation dynamics but choose the way of formation dynamics to one polarity. They turn the polarity formation process in asymmetric nanodisks into deterministic one. Our results offer fundamental understandings on chaos in spin structure formations as well as novel methods to manipulate by means of controlling the chaos.

MO.H.3_O2 - Skyrmions at room temperature: From magnetic thin films to magnetic multilayers

C. Moreau-Luchaire [1], C. Moutafis [2], N. Reyren [1], J. Sampaio [1], N. Van Horne [1], C. Vaz [2], K. Bouzehouane [1], K. García [1], C. Deranlot [1], P. Warnicke [1], P. Wohlhüter [2], J.M. George [1], M. Weigand [3], J. Raabe [2], V. Cros [1], A. Fert [1]

Facing the ever-growing demand for data storage will most probably require a new paradigm. Magnetic skyrmions are anticipated to solve this issue as they are arguably the smallest spin textures in magnetic thin films in nature. Numerical simulations have shown that the interfacial Dzyaloshinskii-Moriya interaction (DMI) can stabilize such skyrmions in nanoscale disks or tracks for a large range of DMI amplitudes. We designed cobalt-based multilayered thin films where the cobalt layer is sandwiched between two heavy metals providing additive interfacial DMI. We acquired maps of the magnetization by using scanning transmission X-ray microscopy combined with the XMCD effect at different perpendicular magnetic fields, evidencing magnetic bubble-like domains in these multilayers. From two different analysis of the magnetic domain configurations, we evaluate a DMI amplitude as large as 2 mJ/m2 in Pt|Co|Ir. The good agreement of the size dependence and the stability of the bubble domains are strong evidences that these domains are skyrmions. The value of D is further confirmed by studying the typical width of the worm domains observed at zero magnetic field, indicating consistency in the analysis. This discovery of stable skyrmions at room temperature in a technologically relevant material opens the way for device applications in a near future.

MO.H.3_O3 - Broadband microwave spectroscopy on the skyrmion lattice phase of different chiral magnets

D. Grundler [1], I. Stasinpoulos [2], J. Waizner [3], M. Garst [3], A. Bauer [4], S. Weichselbaumer [2], H. Berger [5], T. Schwarze [2], C. Pfleiderer [4]

5. Institut de Physique de la Matiére Complexe, École Polytechnique Fédérale de Lausanne, Lausanne, Switzerland

Recently topological spin solitons, so-called skyrmions, have been discovered in chiral magnets. Strikingly, the skyrmions have been evidenced in all three materials classes needed for modern information technology, i.e., metallic, semiconducting and insulating materials. It has already been argued that such nanoscale spin structures might allow for advanced storage or high-frequency device concepts that exploit the exceptional emergent electrodynamics of these compounds. For this, an accurate and unified quantitative account of the dynamics and resonant responses induced by microwave fields is key.
We report broadband spectroscopy of the collective spin excitations in the metallic, semiconducting and insulating chiral magnets MnSi, Fe_1-xCoxSi and Cu_2OSeO_3, respectively. Using differently designed coplanar waveguides (CPWs) and a cryogenic magnetcryostat we explore the resonant eigenmodes across the entire magnetic phase diagrams depending on temperature and magnetic field strength. We observe that the spectral weights of different modes expected for the skyrmion lattice phase depend decisively on the design of the CPW and the orientation of the bulk chiral magnets. Our observations are in agreement with a theoretical approach taking into account dipolar interactions [1]. Using two material-specific parameters that quantify the chiral and the critical field energy we achieve a precise quantitative modelling. The detailed understanding of both eigenfrequencies and the spectral weight of modes is relevant for purpose-designed applications based on the resonant response of the different chiral magnets with tailored electric conductivity.

Magnetic whirls, so-called skyrmions, emerge in various chiral magnets and attract tremendous attention due to their exotic properties. For example, skyrmions can be moved at ultra-low current densities and give rise to the topological Hall Effect. Despite the intense research on skyrmion materials little is known about their actual magnetic ground state. This includes fundamental aspects such as the thermal stability, local magnetization dynamics, spin-defect interactions and related consequences for their technological utilization. The fragmented knowledge is partially due to the challenging experimental access and the general difficulty to image antiferromagnetic order at the nanoscale.
Here, we present spatially resolved investigations of the helimagnetic ground state in the skyrmion system FeGe using magnetic force microscopy (MFM) and diamond nitrogen-vacancy (NV) center magnetometry. Our MFM measurements reveal local temperature-driven changes in the magnetic domain structure as well as jump-like collective movements of the helical spin texture. By using single NV centers as non-invasive nano-probe, we demonstrate that these magnetization dynamics are intrinsic to the spin system. We attribute the detected variations in the magnetic microstructure to thermally activated Barkhausen jumps that occur due to spin-defect interactions. Such Barkhausen jumps are usually neglected regarding the performance of magnetic bulk materials, but may play a vital role for the use of skyrmions and helimagnetism in future nanotechnologies.

MO.I.1_I1 - Room-temperature edge magnetism in graphene nanoribbons

Atomic vacancies of the graphene lattice are known to host unpaired spins. However, it is not clear under which conditions such magnetic moments can couple together to form long-range magnetic order. Here we propose that in contrast to random defect distributions, atomic scale engineering of graphene edges with precisely zigzag crystallographic orientation - comprising edge atoms only from one sub-lattice of the bipartite graphene lattice - can give rise to a robust magnetic order along the edges. We employ a nanofabrication technique [1] based on Scanning Tunneling Microscopy to define graphene nanoribbons with such edge orientation. Tunneling spectroscopy investigations revealed a sharp semiconductor-metal transition for zigzag graphene nanoribbons as a function of their width. This has been identified as a signature of magnetic order emerging along the ribbon edges. The transition was attributed to the switching of the magnetic coupling between opposite ribbon edges from antiferromagnetic to ferromagnetic configuration [2].

The nature of magnetism which emerges in strongly correlated metals and semiconductors presents one of the most challenging and fundamental problems in physics of these systems. It is also widely believed to be of profound practical importance, rendering much of their fascinating behaviors, such as the unconventional high-temperature superconductivity, and others. Here we report a neutron scattering studies of the $Fe(1-x)Cr(x)Sb_2$ materials, where an unusual one-dimensional magnetic dynamics emerges as material evolves from a parent material, a partially metallic narrow-gap semiconductor $FeSb_2$, to a wide-gap semiconductor $CrSb_2$, which is a quasi-one-dimensional (1D) S=1 spin-chain system. The magnetic response emerges at x ~ 0.5, where the material has an effectively half-filled band, and one could naively expect S=1/2 spin system. We, however, observe an unusual dynamical magnetic response of quasi-1D nature, where magnetic susceptibility likely originates from local spins, whose interactions nevertheless are determined by the Fermi surface nesting properties. Our observations are perhaps the first case where the emergent magnetic dynamics in a doped metal/semiconductor can be uniquely identified with an interplay of strong correlation and Fermi surface nesting, eventually rendering an unusual quasi-1D spin system.

MO.I.1_O3 - Longitudinal and transverse zeeman ladders in the ising-like chain antiferromagnet $BaCo_2V_2O_8$

5. CNRS, Laboratoire National des Champs Magnétiques Intenses, Grenoble, France

The nature of the excitations in spin half antiferromagnets is a topic of considerable current interest in the field of quantum magnetism. The one-dimensional case is especially interesting as quantum fluctuations melt the classical long-range Néel order. The ground state remains disordered, with a spin excitation spectrum consisting of a continuum composed of pairs of spinons. Physical realizations of 1D systems, however, eventually order at very low temperature, owing to a small coupling between chains. The metamorphosis of the continuum of spinons that accompany this dimensional crossover towards a 3D state is an appealing issue. In this context, we explore the spin dynamics emerging from the Néel phase of the chain compound antiferromagnet $BaCo_2V_2O_8$ [1,2]. Our inelastic neutron scattering study reveals unconventional discrete spin excitations, so called Zeeman ladders, understood in terms of spinon confinement, due to the interchain attractive linear potential. These excitations consist of two interlaced series of modes, respectively, with transverse and longitudinal polarization. The latter, which correspond to a longitudinal fluctuation of the ordered moment, have no classical counterpart and are related to the zero-point fluctuations that weaken the ordered moment in weakly coupled quantum chains. Our analysis reveals that $BaCo_2V_2O_8$, with moderate Ising anisotropy and sizable interchain interactions, remarkably fulfills the conditions necessary for the observation of discrete long-lived longitudinal excitations [2].

MO.I.1_O4 - Pressure-induced quantum phase transitions in low-dimensional organic quantum magnets

J. Möller [1], G. Perren [1], A. Mannig [1], A. Zheludev [1]

1. ETH Zürich, Zürich, Switzerland

We discuss several spectacular examples of pressure-induced quantum phase transitions in low-dimensional organic quantum magnets. Organic systems offer `soft' molecular frameworks and more accessible energy scales compared to inorganic oxides and thus enable a strong coupling between lattice and magnetism, providing a fruitful playground for exploring quantum critical physics. We will focus on the pressure-induced quantum phase transition in the frustrated quantum spin liquid piperazinium hexachlorodicuprate (PHCC). Recent MuSR experiments on PHCC have shown the existence of a quantum critical point (QCP) around 4.3 kbar separating the low-pressure quantum spin liquid from high-pressure magnetically ordered phases [1]. This work was in apparent contradiction with previous inelastic neutron scattering (INS) experiments [2] which observed no closing of the gap in this pressure range. In very recent INS experiments, we have observed Goldstone modes in the dynamic structure factor at 10 kbar [3]. This demonstrates long-range (magnetic) order at this pressure, in good agreement with the MuSR findings and the presence of a pressure-induced quantum critical point at moderate pressure [1]. We suggest an explanation for the apparent contradiction with the previous INS study [2]. Our discussion on PHCC will be complemented with other recent examples from our group concerning the study of QPTs in a number of organic quantum magnets using a range of techniques.

MO.I.1_O5 - Phonon-modulated magnetic interactions and spin tomonaga-luttinger liquid in the p-orbital antiferromagnet CsO_2

M. Klanjsek [1,2], D. Arcon [1,3]

1. Jozef Stefan Institute, Ljubljana, Slovenia
2. EN-FIST Centre of Excellence, Ljubljana, Slovenia
3. Faculty of Mathematics and Physics, University of Ljubljana, Ljubljana, Slovenia

Quantum magnetism is a term encompassing phenomena like Tomonaga-Luttinger liquid, Bose-Einstein condensation of magnons or spin-liquid behavior, which occur in d-orbital electron systems where spins are decoupled from orbital and lattice degrees of freedom. In p-orbital electron systems, such a decoupling is not possible due to a stronger interplay of various degrees of freedom, a prototypical example being molecular solids based on magnetic O_2- magnetic anions: alkali superoxides, AO_2 [1], and alkali sesquioxides, A_4O_6 [2] where A is the alkali metal. A recent important X-ray and Raman scattering study of CsO_2 demonstrated the ordering of O_2- p orbitals below the structural phase transition at 70 K, which leads to the formation of one-dimensional antiferromagnetic spin-1/2 chains in an otherwise two-dimensional magnetic lattice [1]. Using nuclear magnetic resonance, we show that the low-temperature phase of CsO_2 exhibits a Tomonaga-Luttinger-liquid behavior, while the librations of O_2- 'dumbbells' in the high-temperature phase lead to a strongly temperature-dependent magnetic exchange interactions [3]. These are, respectively, the first example of quantum magnetism in a p-orbital system and the first demonstration of the phononic modulation of magnetic interactions, a phenomenon proposed in the 1970s that may be relevant for a range of other molecular solids.

MO.I.2_I1 - Strong magneto-chiral dichroism detected by hard X-rays in a molecular helix

R. Sessoli [1], A. Rogalev [2], F. Wilhelm [2], M.E. Boulon [1], M. Mannini [1], L. Poggini [1], A. Caneschi [1] N

1. University of Florence, Florence, Italy

Chiral magnetic structures have been recently the focus of intense research because they offer the possibility to store information in topological protected structures like skyrmions. Chirality and magnetism are also directly connected in the interaction between matter and electromagnetic radiation through the magneto-chiral dichroism and birefringence[1]. Magneto-chiral dischroism, a non-reciprocal effect with different absorption of unpolarized light by systems with opposite chirality in the presence of a magnetic field, is a fascinating phenomenon that has been suggested to be at the origin of homochirality of life on the earth and observed only recently.[2] It is in general very weak, being assumed in first approximation to be related to the product of natural and magnetic circular dichroism, and only few examples are available in literature with limited information on the factors that originate the phenomenon. We report here a detailed synchrotron investigation [3] of the magneto-chiral effect detected at the 3d-metal K edge in two isostructural molecular helices comprising either isotropic Manganese(II) or anisotropic Cobalt(II) bridged by stable organic radicals. The experiments have revealed a strong magneto-chiral dichroism associated with the non-collinear spin structure of the Cobalt(II) derivative, which is also the archetype of Single-Chain Magnets, i.e. one-dimensional structures showing magnetic bistability due to short-range magnetic correlation. The magneto-chiral dichroism has an unusual symmetry, it is odd with respect to both parity and time-reversal symmetry but is invariant with respect to their product. It is closely related to the anapole moment, which in this particular case is originated from the toroidal orbital currents of the cobalt atoms. Orbital toroidal currents are of relevance for many phenomena, ranging from multiferroicity to superconductivity.

MO.I.2_O2 - B-T phase diagram of solid oxygen in the megagauss region

T. Nomura [1], Y.H. Matsuda [1], S. Takeyama [1], A. Matsuo [1], K. Kindo [1], T. C. Kobayashi [2]

1. ISSP Univ. of Tokyo, Tokyo, Japan

Solid oxygen is known as the only antiferromagnetic insulator consisting of single chemical species. In addition to the van deer Waals force, the exchange interaction between O_2 molecules contributes to the condensation energy of the solid oxygen, leading to a strong interplay between the magnetic and structural systems. Nowadays, a novel phase of solid oxygen is discovered by applying the magnetic field as high as 130 T [1]. This is the 8th phase of solid oxygen, and we call theta phase. Up to now, it is suggested that the theta phase is characterized by the large magnetic susceptibility and isotropic crystal structure [1]. In this study, we conducted two kinds of measurements, magnetization and magneto-transmission, to determine the B-T phase diagram. The field induced phase transition to the theta phase is observed at below 42 K, and the results in the two measurements are in good agreement. The transition field (Hc) from the lower field phases to the theta phase is almost temperature-independent, and the phase boundary is as steep as dHc/dB~-10 K/T. By the analysis using the magnetic Clausius-Clapeyron equation, it is suggested that the entropy change in this phase transition is rather small. This result means that the theta phase is explicitly distinguished from the gamma phase, which is the plastic phase characterized by molecular rotation and large entropy. Therefore, it is concluded that the molecular axis is ordered in the theta phase as same with the alpha and beta phases.

MO.I.2_O3 - Light-Induced spin-state switching of an Fe(II) complex adsorbed on HOPG

M. Bernien [1], H. Naggert [2], L.M. Arruda [1], L. Kipgen [1], F. Nickel [1], J. Miguel [1], C.F. Hermanns [1], A. Krüger [1], D. Krüger [1], E. Schierle [3], E. Weschke [3], F. Tuczek [2], W. Kuch [1]

3. Helmholtz-Zentrum Berlin für Materialien und Energie, Berlin, Germany

Using magnetic molecules as building blocks for spintronic devices is a promising approach for miniaturization of functional units since it provides structural control and reproducibility on the atomic level by the chemical design of the molecules. We have studied submonolayers of the Fe(II) spin-crossover complex [Fe(bpz)2(phen)] (bpz=dihydrobis(pyrazolyl)borate, phen=1,10-phenanthroline) by x-ray absorption spectroscopy and x-ray magnetic circular dichroism. Such molecules are appealing because they possess a metastable spin state that can be switched by external stimuli, such as temperature or light. They can thus function as tiny molecular magnetic switches that can be controlled optically. However, if these complexes are immobilized on a solid surface, the spin transition is often quenched due to the interaction with the substrate. Using highly oriented pyrolytic graphite (HOPG) as a weakly interacting substrate we show that even molecules that are in direct contact with a solid surface can undergo a spin-crossover transition as a function of temperature. The transition temperature of T1/2 = 161 K is the same as for the bulk material, but the transition is much more gradual due to the isolated character of the complexes in the molecular layer. X-ray magnetic circular dichroism shows that the spin of [Fe(bpz)2(phen)] can be switched from S=0 (low spin) to S=2 (high spin) using green light of 520 nm wavelength at T = 4.8 K. The light-induced switching process is highly efficient with a time constant of 18.9 s, leading to a complete spin conversion from low spin to high spin. Increasing the temperature to 65 K resets the molecules back to their low-spin state. We can thus switch the magnetic moment of [Fe(bpz)2(phen)] in direct contact with an HOPG surface reversibly, where it is switched on by illumination with green light and off by increasing the temperature.

4. Institute of Chemistry, Academy of Sciences of Moldova, Chisinau, Republic of Moldova
5. European Synchrotron Radiation Facility, Grenoble, France

The intramolecular exchange interactions within the single-molecule magnet (SMM) "butterfly" molecule [$Fe_3Ln(\mu_3\text{-}O)_2(CCl_3COO)_8(H_2O)(THF)_3$], where Ln(III) represents a lanthanide cation, have been determined by a combination of x-ray magnetic circular dichroism (XMCD) and vibrating sample magnetometry (VSM) along with an interaction model [1]. The three Fe atoms can be considered as a self-unit with total spin S_{Fe3}=5/2 [2]. We have studied compounds with Ln=Tb and Ho, both with non-Kramers lanthanides and high uniaxial anisotropy, and with Ln=Lu, and Y(III) as pseudolanthanide that supply a nonmagnetic Ln reference case. Using the element selective of the XMCD magnetometry, measured at the Ln $L_{2,3}$ edges, together with the VSM measurements, the local magnetization of the Ln ion and the Fe_3 subcluster, as a function of the field and low temperature (T≈2.5 K), has been determined separately. These results are described quantitatively in the framework of a theoretical model based on the effective spin Hamiltonian, which considers the competing effects of intracluster interactions and the external applied magnetic field [1]. The Ln-Fe_3 exchange interaction within the {Fe_3LnO_2} cluster has been determined to be antiferromagnetic, in both Tb and Ho compounds, with $J_{Tb\text{-}Fe3}$ = −0.13 K and $J_{Ho\text{-}Fe3}$ = −0.18 K, respectively. In both cases, a field-induced reorientation of the Fe_3 and Ln spins from antiparallel to parallel orientation takes place at a threshold field $\mu_0 H$ = 1.1 and 2 T, for the {Fe_3TbO_2} and {Fe_3HoO_2} compounds, respectively. By comparison with other compounds of the series, it is concluded that the Fe_3 subcluster magnetization polarizability decreases in the trend {Fe_3YO_2}→{Fe_3TbO_2}→{Fe_3HoO_2}→ {Fe_3DyO_2}, because of the increasing opposition of the exchange antiferromagnetic field caused by the Ln ion. It is the Ln ion which dominates the anisotropy of the molecule.

MO.I.2_O5 - Landing functional molecular spin clusters on surfaces

M. Affronte [1]

1. Università Di Modena E Reggio Emilia, Modena, Italy

Molecular nanomagnets have shown fascinating behaviour when observed as collection in 3D assemblies. Yet, one may wonder to what extent properties and functionalities of such systems survive when individual molecular units are extracted from crystalline environment and deposited on surfaces. First challenge is to learn to deposit and characterize molecular units in clean and safe way. Second challenge is the organization of molecules on surface by exploiting both self assembling or functional grafting. Then, we wish to control and understand interactions with different surfaces. Final goal is to exploit this control to fabricate hybrid devices where functionalities of individual molecular spin are combined with other active nanosystems, such as carbon-based circuits. I propose here to glimpse some of these aspects through the keyhole of our recent results and to discuss issues and achievements by presenting examples from our experiences.

MO.I.3_O1 - Probing hidden orders with resonant inelastic X-ray scattering

L. Savary [1], T. Senthil [1]

1. Massachusetts Institute of Technology, Cambridge, United States

We propose a general scheme for the derivation of the signals resonant inelastic x-ray scattering (RIXS) gives access to. In particular, we find that RIXS allows to directly detect many hidden orders, such as spin nematic, bond nematic, vector and scalar spin chiralities. In the derivation, we choose to take the point of view of effective operators, leaving microscopic details unspecified, but still keeping explicit experimentally controllable parameters, like the incoming and outgoing polarizations. (In other words, here we ask not what microscopic processes can lead to a specific outcome, but, rather, what couplings are in principle possible.) This approach allows to systematically enumerate all possible origins of contributions to a general RIXS signal, a highly desirable feature, especially in light of some recent controversies. We emphasize that, although symmetry-based approaches have been put forth in scattering techniques in the past, the generality of the derivation and that of the results as well as the conclusions drawn from the latter are new. Although we mainly focus on magnetic insulators, for which we give a number of examples, our analysis carries over to systems with charge degrees of freedom, which we briefly address. We hope this work will help guide theorists and experimentalists alike in the design and interpretation of RIXS experiments.

MO.I.3_O2 - Femtosecond dynamics of magnetic excitations from resonant inelastic x-ray scattering

S. Kourtis [1]

1. TCM Group, Cavendish Laboratory, University of Cambridge, Cambridge, United Kingdom

Taking spinon excitations in the quantum antiferromagnet $CaCu_2O_3$ as an example, we demonstrate that femtosecond dynamics of magnetic electronic excitations can be probed by direct resonant inelastic x-ray scattering (RIXS). To this end, we isolate the contributions of single and double spin-flip excitations in experimental RIXS spectra, identify the physical mechanisms that cause them, and determine their respective time scales. By comparing theory and experiment, we find that double spin flips need a finite amount of time to be generated, rendering them sensitive to the core-hole lifetime, whereas single spin flips are, to a very good approximation, independent of it. This shows that RIXS can grant access to time-domain dynamics of excitations and illustrates how RIXS experiments can distinguish between excitations in correlated electron systems based on their different time dependence.

MO.I.3_O3 - Spin and charge interplay of interacting and frustrated electrons on the 1/3-filled Kagome lattice

A. Ralko [1], K. Ferhat

1. Neel Institute, Grenoble, France

Geometrical frustration is at the center of intense theoretical and experimental research activity of nowadays condensed matter, thanks to the extremely rich and exotic quantum magnetic phases unravelled these last years. Together with the correlations, the frustration also affects the charge degrees of freedom, and by competing with the spins, makes room for unconventional physics. This is particularly true on the Kagome lattice, the most frustrated two-dimensional lattice.
At 1/3 filling and under correlations, electrons on such a geometry obey local 'ice-rule' constraints that make the classical ground state to be massively degenerate. We show that the interplay between the charges and the spins, together with the frustration allow for unconventional physics. In particular, we establish the presence of two peculiar states of matter driven by the strong quantum fluctuations. The first one consists of polarized droplets of metal standing on the hexagons of the lattice, and an enlarged kagome pinned charge order, inversely polarized, on the remaining sites. The second, obeying a local ice-rule type constraint on the triangles of the kagome site, is driven by an antiferromagnetically coupling of spins and is constituted of disconnected 6-spin rings.Those phases perfectly illustrate the importance of the frustration on charge ordered systems, as well as the strong resulting interplay with the spins.

K.Ferhat and A. Ralko, Phys. Rev. B 89, 155141 (2014)

MO.I.3_O4 - Magnetic field dependence of 6 k anomaly in spin liquid state of k-(BEDT-TTF)$_2$Cu$_2$(CN)$_3$ investigated by 13C NMR

K. Miyagawa [1], K. Umeda [1], K. Kanoda [1]

1. University of Tokyo, Tokyo, Japan

The family of quasi-two dimensional organic conductors, k-(BEDT-TTF)$_2$X, is a prototype for investigating the Mott physics. The salt with X=Cu[N(CN)$_2$]Cl is a Mott insulator with an anisotropic triangular lattice, which shows an antiferromagnetic ordering with a moment of 0.45muB. On the other hand, another Mott insulator with X=Cu$_2$(CN)$_3$ shows no magnetic ordering due to the quasi-triangular lattice, while J is estimated at 250 K from spin susceptibility. We previously reported NMR experiments that show anomalous behavior around 6 K; an enhancement of 13C NMR line broadening and an marked decreases in the Knight shift and the nuclear spin-lattice relaxation rate, 1/T1, below 6 K. Yet, the measurements of heat capacity, thermal conductivity and lattice constant found peculiarities that occur at approximately the same temperature. Thus, it is believed that the 6 K anomaly is a key phenomenon for clarifying the nature of the spin liquid of this material. To look further into the 6-K anomaly in of k-(BEDT-TTF)$_2$Cu$_2$(CN)$_3$, we have investigated the external-field strength and direction dependences of 13C NMR spectra and 1/T1 up to 15 T. The external filed is applied to parallel and perpendicular to conducting plane, and rotated between the two geometries. We have found the line broadening and shift decrease persistent up to 15 T, regardless of the field geometry. The accelerated fall-off of 1/T1 below 10K and levelling-off below 6 K remains essentially unchanged in both field directions up to 15 T. This indicates that the orbital degrees of freedom is not responsible for 6 K anomaly and that a simple spin singlet transition does not explain that, either.
We also mention the NMR studies of k-(BEDT-TTF)$_4$Hg$_3$-dX$_8$ (X=Br,d=2.89 and Cl,d=2.78) that have an isotropic triangular lattice and a band filling 11% and 22% away from a half, namely a candidate of a doped spin liquid.

MO.J.2_I1 - Spin transport in molecular films: beyond conventional spin valves

L.E. Hueso [1,2], X. Sun [1], A. Bedoya-Pinto [1], M. Gobbi [1], H. Prima-García [3], S. Gómez-Miralles [3], E. Coronado [3], F. Casanova [1,2]

1. CIC NanoGUNE, San Sebastian, Spain
2. IKERBASQUE, Basque Foundation for Science, Bilbao, Spain
3. ICMOL, Universidad de Valencia, Valencia, Spain

Spin injection and transport into molecular semiconductors has attracted great interest recently, especially due to the small sources of spin decoherence in these materials [1]. However, there are still many open questions in this nascent field which range from the actual spin transport mechanisms across the molecular layers to the integration of molecular functionalities into spintronic devices. In this talk I will review several recent experimental highlights from our group. As a common link, they all share the use of novel molecules for spin transport with the development of meticulous fabrication techniques for vertical molecular-based spin valves.
By using bathocuproine (BCP) and fluorinated copper phthalocyanine (FCuPc) we have unambiguous proved that spin transport occurs via molecular levels, finally disregarding any eventual role of metallic filaments or defects in the electronic transport [2,3]. Our experiments point out to the critical role of the interfacial barriers for carrier injection into the molecular levels. Moreover, in the FCuPc case we have shown concomitant spin transport and photoresponse. Thanks to the emergence of two molecular-based properties, four distinguishable resistance states adjustable by light and/or magnetic field can be configured in a simple 2-bit memory cell [3]. On a more fundamental side, I will present spin valves based on rare-earth quinolines. In spite of the very different magnetic behaviour of the molecules (either paramagnetic or diamagnetic) involved, the magnetoresistance of the devices is largely unaffected thus pointing out to the major role of molecular orbitals in the spin transport [4].

MO.J.2_O2 - Voltage-controlled inversion of tunnel magnetoresistance in epitaxial spin valve based on graphene

F. Godel [1], V. Kamalakar [2], B. Doudin [1], Y. Henry [1], D. Halley [1], J.F. Dayen [1]

1. Ipcms-Cnrs, Strasbourg, France
2. Chalmers University of Technology, Göteborg, Sweden

The large spin filtering effect predicted at the graphene/Nickel(111) interface [1] has recently driven major effort to build and characterize current perpendicular to plane (CPP) spin valve based on graphene [2,3]. Here, we report the fabrication and characterization of CPP epitaxial Magnetic Tunnel Junctions (MTJs) made by Molecular Beam Epitaxy: a 3 nm thick MgO barrier followed by a 50 nm Cobalt top electrode are deposited on CVD graphene directly grown on top of a Nickel thin film. We perform X-Ray Diffraction measurements to confirm the good quality and the (111) orientation of the MgO and ferromagnetic layers. The X-ray Photoelectron Spectrocopy also reveals the absence of oxidation of the bottom Nickel electrode, confirming its passivation by the graphene layers and leading to the use of the unique properties of Graphene Protected Ferromagnetic Electrode (GPFE) for spintronics applications [3,4]. In our junctions, we observe tunneling magnetoresistance (TMR) signals for different active area, from 1 µm² to 1000 µm², with a resistance-area product in the range of 10-100 MΩ.µm^2, indicating the good quality of the tunnel barrier. Varying the applied bias voltage across the junction, a reproducible and scalable bias dependence of TMR is observed: it can be explained using a model of phonon-assisted transport mechanisms that relies on the peculiarity of the band structure and spin density of states at the hybrid graphene/Ni interface [1,4].

The electronic structure at the interface between graphene and metal contacts determines the charge and spin injection efficiency into graphene and is therefore a fundamental issue for the performance of nanodevices. The graphene-Ni interface represents an interesting case where the strong interaction with the ferromagnetic substrate opens hybridization gaps and induces magnetic moments [1,2]. Consequently, graphene is predicted to behave as a perfect spin filter in contact with a magnetic Ni electrode.
Previous studies focused on electron injection perpendicular to this interface. We investigate electron scattering in the most common current-in-plane geometry. For that purpose we grow graphene nanoislands on Ni(111) with varying geometry and atomically controlled edges. The shape can be selected by controlling the reaction temperature during the CVD growth [3], whereas the stacking with the substrate stabilizes different edge configurations depending on their relative orientation [4]. The electronic and scattering properties of the nanoislands are studied by combining local tunnelling spectroscopy and ab initio calculations [5]. We find that the hybridization between graphene and Ni states results in strongly reflecting graphene edges. Quantum interference patterns formed around the islands reveal a spin-dependent scattering of the Shockley bands of Ni, which we attribute to their distinct coupling to bulk states. Moreover, we find a strong dependence of the scattering amplitude on the atomic structure of the edges, depending on the orbital character and energy of the surface states.

Switching the electronic or magnetic states of molecules or assemblies of molecules is one of the foremost paradigms in molecular electronics. Up to now numerous switchable molecular compounds have been synthesized, involving different physical phenomena, but the common challenge remains the construction of active devices. In particular, devices based on charge transport properties attract a great deal of attention, due to the substantial technological developments accomplished to probe charge transport down to the single molecule level. Here we focus on the charge transport properties of the $[Fe(Htrz)_2(trz)](BF_4)$ (Htrz = 1H-1,2,4-triazole) coordination network, which displays molecular spin-state switching. We used electric-field assisted directed assembly to organize high aspect-ratio spin crossover nanorods between interdigitated electrodes with a high degree of alignment. The temperature-dependent current-voltage characteristics of each device revealed a bistability of the current intensity associated with the spin-state switching. We also studied the effect of light irradiation on the electrical conductance of the samples. By illuminating the sample with different wavelengths (between 295 and 655 nm) either in air or under a nitrogen atmosphere we observed both a reversible and an irreversible change of the current flowing in the device. The reversible process consists of an abrupt decrease of the current intensity (ca. 10-50%) upon light irradiation, while the irreversible process is characterized by a slow, but continuous increase in time of the current, which persists also in the dark. These photo-induced processes were only detected in the high conductance low-spin state of the complex. On switching the rods to the high spin state the conductance decreases by two orders of magnitude and - as a consequence - the photo-effect vanishes. These results appeal perspectives for nano-scale switching and memory devices.

MO.J.2_O5 - XMCD investigation of the magnetic anisotropy of Co and Fe adatoms and clusters adsorbed on Gr/Pt(111)

P. Gargiani [1], H. Babu Vasili [1], J. Herrero [1], E. Pellegrin [1], A. Barla [2], M. Valvidares [1]

1. ALBA Synchrotron Light Source, Cerdanyola del Vallés, Spain
2. Istituto di Struttura della Materia, ISM CNR, Area Science Park Basovizza, Trieste, Italy

Graphene, due to its peculiar electronic and transport properties is considered one of the most promising candidates for the development of novel electronic devices.[1] Being formed by a light element such as carbon, graphene is appealing as a material for spintronic application showing large spin diffusion lengths in spin-transport devices. Manipulating its magnetic properties via chemical modification [2], exchange coupling [3] or with magnetic adatom impurities [4-6] may facilitate the possibility to actually use it for such applications. Transition metal adatoms and cluster supported on graphene can be used as a model system to investigate the role of the interaction between the adatom 3d orbitals and the graphene substrate, leading to different magnetic properties of the impurities and clusters. In this study, we have investigated the magnetic configuration and in particular the magnetic anisotropy of Co and Fe adatoms and small clusters deposited on a graphene layer (grown via the CVD method on a Pt(111) substrate) by means of X-ray Absorption Spectroscopy (XAS) and X-ray Magnetic Circular Dichroism (XMCD) experiments. The results show that both Co and Fe adatoms on graphene are characterized by a planar magnetic anisotropy in contrast to Fe and Co adsorbed on Pt(111). The magnetic anisotropy energy (MAE) has been determined by angle- and field-dependent XMCD measurements showing that Co atoms are characterized by a higher anisotropy than Fe. The differences may be interpreted as being related to the orbital character of the two atomic species.

The ability to generate, control and detect spin excitations is one of the main challenges in the recently emerged areas of magnonics [1] and spintronics [2], which might revolutionize the information processing technology [3]. Opto-magnetism provides an effective tool to control spins with light [4]. Recently, it has been demonstrated that the generation and control of spin waves in the centre of the Brillouin zone [4] and in the vicinity of it [5] can be effectively achieved on the femtosecond time scale. It is also known that light can access high wave vector spin waves [6]. However, the femtosecond magnetic dynamics following the ultrafast laser excitation of spin waves at the edges of the Brillouin zone has not been disclosed yet. Here we show that such coherent magnons are excited in the Heisenberg antiferromagnet KNiF3, by sub-20 femtosecond laser pulses. The fastest possible dynamics of the order parameter, which follows the generation of the high wave vector magnons, appears to be significantly different from what can be anticipated on the basis of previous experiments in the frequency domain [7]. In particular, we demonstrate that the off-resonant optical excitation of the 22 THz magnetic mode allows the femtosecond coherent control of the antiferromagnetic order parameter. Our experiment discloses the pathways of the energy transfer between light and spins, resulting in an unprecedented ultrafast magnetic dynamics in an antiferromagnet.

MO.J.3_O2 - Parametric Amplification of Spin Waves Using Bulk Acoustic Waves

P. Chowdhury [1], P. Dhagat [1], A. Jander [1]

1. Oregon State University, Corvallis, United States

Spin waves are a promising prospect for the development of spin-based information processing devices, where they can be used as information carriers in logic devices and for transmitting information along spin wave buses between devices. However, the large intrinsic spin wave damping in most known magnetic materials limits the utilization of spin waves for interconnects. Viable amplification mechanisms for spin waves are therefore crucial to make further progress in the field. In this work, we investigate a novel technique of parametric amplification of spin waves using bulk acoustic waves. The device used for our experiment consists of a thin film acoustic transducer fabricated on one side of a gadolinium gallium garnet (GGG) substrate with an epitaxial Yttrium Iron Garnet (YIG) film on the opposite side. Longitudinal bulk acoustic waves generated by the transducer resonate in the GGG, a low acoustic loss substrate and couple into the YIG film. This induces strain in the YIG film which by inverse magnetostrictive effect, modulates the anisotropy of the YIG film at the same frequency as the acoustic waves. Parametric amplification may be achieved by driving this anisotropy variation at twice the frequency of the spin wave. The acoustic resonator was impedance matched to be driven at an acoustic resonance at 2.4632 GHz, exactly twice the frequency of the backward volume spin wave excited at 1.2316 GHz with a bias field of 10.1 mT in the YIG film. The intensity of the transmitted spin wave is seen to increase as a function of the acoustic power indicating modulation of the spin wave by acoustic energy. A threshold acoustic power of 160 mW is observed for parametric pumping. No such spin wave amplification was observed by driving the acoustic transducer off-resonance, thus confirming that the modulation is indeed related to the presence of acoustic waves.

MO.J.3_O3 - Spin-Orbit torques driven ferromagnetic resonance in ultrathin YIG disks

Spin Transfer induced high frequency dynamics has been up to now mainly studied in magnetic materials that are metallic as the spin current acting on the magnetization flows together with a charge current. Recently, this constrain has been released in using the Spin Orbit Interaction as a source of spin current through Spin Hall Effect (SHE) or Rashba effect. In this case, the spin current flows perpendicular to the charge current and thus opens the field of spin torque induced auto-oscillators to the wide family of insulating magnetic materials.
We have fabricated magnetic micro-disks (1 to 4 Ám) based on $Y_3Fe_5O_{12}$ (YIG) (20nm\Pt(7nm) bilayer. In a previous study, we demonstrate that our ultrathin YIG films grown by Pulsed Laser Ablation have excellent dynamical properties with a Gilbert damping that can be as low as 2.3.10-4. DC electrical contacts as well as radio-frequency inductively coupled antennas have been lithographically defined on the top of each disk.
In this study, we demonstrate that spin wave modes can be excited by simply injecting a dc current in the top Pt layer of the YIG/Pt disks. The threshold density current necessary to overcome the damping is ~ a few 10^11 A.m-2, in excellent agreement with theoretical predictions. This result proves that the Spin Orbit torque due to SHE is efficient enough to drive the YIG magnetization dynamics at a frequency that we can actually relate to the ferromagnetic resonance mode. These auto-oscillations can be detected either by Inverse SHE on the Pt electrode or inductively using a spectrum analyzer connected to the antennas. Note that these YIG auto-oscillations are limited to a narrow range of current and field and that their amplitudes remain small. We believe that the demonstration of the electrical control of YIG dynamics in artificial microstructures paves the path to active magnonic devices.

Mo.J.3_O4 - Theory of Current-induced Spin Torque Resonance of Magnetic Insulators

The magnetic insulator yttrium iron garnet (YIG) has attracted much attention as a new spintronic material for magnetic information technology because of its very low magnetization damping. Near-dissipationless propagation of spin waves makes YIG application to low power data transmission and logic devices. A crucial breakthrough is the discovery that the magnetization in YIG can be excited electrically by Pt contacts, thereby creating an interface between electronic-spintronic and magnonic circuits. However, the current-induced spin wave excitation is a strongly non-linear process and the critical threshold currents found by the experiment have not yet been explained. Here we suggest a simpler method to get to grips with the current-magnetization interaction in the YIG/Pt system without a problematic threshold, viz. by employing the recently discovered spin Hall magnetoresistance (SMR)ü@to detect current-induced spin torque ferromagnetic resonance (ST-FMR). We study the alternating current-induced magnetization dynamics of a magnetic insulator, such as YIG, through the spin transfer effect by heavy normal metal, such as Pt, contacts. Based on the drift-diffusion spin model with quantum mechanical boundary conditions and the Landau-Lifshitz-Gilbert equation with a current-induced oscillating spin transfer torque, we find that a dc voltage is generated in the normal metal as an SMR-induced rectification effect. We also model the ST-FMR for all magnetization directions and in the presence of field-like spin-orbit torques. The dc voltage as a function of an external magnetic field or current frequency has recently been measured the current-induced magnetization dynamics of magnetic insulators, which also shows that ac spin pumping is reversible to the ST-FMR. Our results may expose crucial information on the spin-orbit coupling between currents and magnetization.

TU.A.1_I1 - Magnetic properties evolution vs. microstructure in Fe-Mn-Si-B-P-Cu submicron wires

N. Lupu [1,2], A. Makino [2,3], S. Corodeanu [1], P. Sharma [3], A. Takeuchi [3], H. Chiriac [1]

The soft magnetic nanocrystalline materials are playing an increasing role in specific applications, namely energy efficient magnetic devices, power electronics, electrically powered vehicles and nuclear reactors [1]. Here we report on the preparation of $Fe_{85-x}MnxSi_2B_8P_4Cu_1$ (x = 0; 1; 3 at.%) glass-coated submicron wires with metallic nucleus diameters (Φ_m) between 600 nm and 1.2 Ám and the glass coating thickness (tg) of 4÷5 μm, with the aim to study the dependence of their magnetic properties on the diameter of the metallic core and structural changes induced by one-step and/or two-step annealing at different temperatures (Ta) ranging between 250 and 5500C. All samples are magnetically bistable, irrespective of dimensions and structure. The larger the Mn content the smaller the coercive and switching fields are. The bistability is preserved even for the annealed samples, this being a characteristic of the uniaxially magnetized materials indicating the formation of a central magnetic domain in the amorphous state. However, the submicron wires annealed below 4250C are much softer (the coercive field decreases), whilst after annealing above 4250C the coercivity increases significantly as the results of the increase of the grains size over the critical limit. Additionally, for the same total diameter, the smaller the diameter of the metallic core the larger the coercive field is. The measurement of the domain wall velocity (velocities of over 1500 m/s are obtained for optimum nanocrystalline structures) offers a more accurate image over the microstructure developed in glass-coated submicron wires than the conventional magnetic measurements (permeability and switching field). Despite the fact that the nanograins have similar sizes after annealing, the increase in their number after annealing at higher temperatures results in a slightly different mechanism for the magnetization processes, with the nucleation of the larger number of small irregular domains competing with the displacement of the domain walls.

This work was jointly supported by the Cooperative Research and Development Center for Advanced Materials, IMR, Tohoku University and the Romanian NUCLEU Programme (Project PN 09-43 01 02).

TU.A.1_O2 - Circular magnetization process in a Co-rich microwire with negative magnetostriction

N. Usov [1], S. Gudoshnikov [2]

1. Pushkov Institute of Terrestrial Magnetism, Ionosphere and Radio Wave Propagation RAS, Moscow, Russian Federation
2. National University of Science and Technology MIS&S, Moscow, Russian Federation

The small angle magnetization rotation method is widely used [1] to determine magnetostriction constants of amorphous ferromagnetic microwires. Here, the wire is nearly uniformly magnetized in magnetic field $H > H_a$, where H_a is the anisotropy field, and its longitudinal magnetization component undergoes small oscillations at the frequency $2f$ under the influence of a circular magnetic field of alternating current, $I(t) = I_0\sin(2\pi f)$. These ocsillations give rise to electro-motive force (EMF) arising in the receiving pick-up coil wound around the microwire. In this report it is experimentally shown that for amorphous Co-rich microwire with negative magnetostriction in the range of low magnetic fields, $|H| < H_a$, there are two different oscillation modes of the longitudinal magnetization component depending on the alternating current amplitude. When I_0 is less than the critical value, $I_0 < I_{0c}(H)$, the first harmonic gives the main contribution to the EMF signal. However, at $I_0 > I_{0c}(H)$ a significant contribution of the second EMF harmonic appears. As numerical simulation of the circular magnetization process shows, in the latter case the reversal of the circular magnetization component occurs twice during the period. When compared with the numerical simulation data, the measurement of the relation $I_{0c}(H)$ at different applied tensile stresses allows to determine the microwire saturation magnetization and the magnetostriction constant.

3. IKERBASQUE, Bilbao, Spain

The influence of changing temperature on stable operation of magnetic sensors that use microwires as active elements, is the subject of the present work. The investigations have been performed using magneto-optical Kerr effect (MOKE) technique in Co- and Fe- rich magnetic glass covered microwires within 300-550 K temperature range. The images of surface magnetic domains have been obtained by means of MOKE microscope with a thermo-controlled system. It was found different types of domain structure depending on the temperature and the microwire composition. These types are characterised by the different domain period and the angle of the inclination of domain walls. The MOKE hysteresis loops reflect the transformation of surface domain structure. It was established the direct correlation between the domain structures and hysteresis loops. In particular, the coexistence of domain walls with different value of mobility has been found. Also it was observed original mechanism of the domain structure transformation: sharp change in the domain structure without movement of the domain walls. During increasing of the external magnetic field only the switching of the magnetization occurs in surface magnetic domains. The existence of the complex domain structures is considered in the frame of the complex stresses distribution. The value and the sign of internal stresses experience considerable change near the interface between the metallic nucleus and glass-coating.

TU.A.1_O4 - Visualizing decoupling in nanocrystalline alloys: FORC-temperature analysis

M. Rivas [1], J.C. Martínez-García [1], P. Gorría [1]

1. Departamento de Física & IUTA, Universidad de Oviedo, Gijón, Spain

Nanocrystalline microstructures obtained by partial devitrification of ferromagnetic glassy metals present a variety of magnetic behaviors ranging from ultra-soft to semi-hard or hard depending on the strength of the ferromagnetic coupling among nanograins. This is in turn conditioned, not only by the morphology and volume fraction of the crystalline phase, but very importantly by the magnetic characteristics of the amorphous spacer. In this work, the temperature-dependent coupling/decoupling of a Fe-based two-phase nanocrystalline system is analyzed. The main novelty of the study resides on the chosen technique: First-Order Reversal Curves (FORC) analysis proves its competency to discriminate different magnetic phases and explore their internal and mutual magnetic interactions. The 2D-representation of the FORC diagram provides a portrait of the different phases, visualized as separate colored spots whose position is directly related to the corresponding critical fields; the spatial distribution of the colors is associated to the magnetic interactions between the two phases or among the constituents within a particular phase. The FORC diagrams of samples obtained after different thermal treatments, from annealing temperatures in the onset of the first crystallization point to well above it, reveal two strongly coupled phases (amorphous and nanocrystalline) at room temperature. Except for the samples annealed at higher temperatures, the patterns show a gradual weakening of the coupling when heating up. Well above the amorphous phase Curie temperature a complex pattern is revealed corresponding exclusively to the crystalline phase.

TU.A.1_O5 - Enhanced magneto-optical properties of Ce:YIG thin films grown on GGG substrates

L. Beran [1], M.C. Onbasli [2], M. Zahradnik [1], J. Dusek [1], M. Kucera [1], J. Mistrik [3], M. Veis [1], C.A. Ross [2]

3. University of Pardubice, Faculty of Chemical Technology, Pardubice, Czech Republic

Recent development in intergrated photonics calls for the on-chip integration of non-reciprocal optical elements based on magneto-optical effects. However, this relies on the preparation of high quality magneto-optical materials in form of thin films with well defined optical and magneto-optical properties. Cerium-doped Ytrium Iron Garnet (Ce:YIG) is one of the materials used for magento-optical applications. Althought strong Faraday rotation (3300 deg/cm at 1.55 um) [1] and high transparency in visible and infrared region were observed on bulk samples, thin films of this matrial still lack these properties and exhibit lower than bulk magneto-optical figure of merit (defined as Faraday rotation over optical loss). Here we present a systematic optical and magneto-optical study of 80 nm and 14 nm thick single crystal Ce:YIG films grown on (100), (110) and (111) GGG substrates by pulse laser deposition. X-ray and VSM measurements confirmed bulk-like structural and magnetic properties. Spectroscopic ellipsometry together with magneto-optical spectroscopy in Kerr and Faraday configurations were employed to derive the complete dielectric permittivity tensor of this material in the photon energy range from 1.2 to 5.6 eV. Obtained experimental data clearly demonstrated the influence of the substrate orientation on optical and magneto-optical properties as well as on magnetic coercivity and squareness (magnetic remanence over saturation moment) of investigated samples. A strong enhancement of magneto-optical properties was observed in films on (111) GGG substrates. The Faraday rotation reached 30000 deg/cm at a wavelength of 780 nm and 6000 deg/cm at 1550 nm, exceeding the bulk values.

4. Materials Science Division, Lawrence Berkeley National Laboratory, Berkeley, United States

The coupling of electronic, magnetic, and structural properties from one material into another when in close physical proximity can induce novel functionalities in hybrid materials. Hybrid materials allow the engineering of new material properties by creative uses of proximity effects, for example when different length or time scales are competing in each material. Interesting possibilities arise when ferromagnets are in proximity to oxides that undergo a structural phase transition (SPT). In a series of recent studies we have shown the possibility of inducing large changes of magnetization and coercivity of ferromagnetic films brought in contact with two members of the vanadium oxide family, VO_2 and V_2O_3 (1, 2). Some of these hybrid structures show a 500 % coercivity enhancement across the phase transition. Our results show that the strain produced by the thermally induced SPT and the nanoscale phase coexistence across the first-order phase transition of the oxides are responsible for the observations in these hybrid materials. The results suggest the existence of similar effects in other hybrid materials with first-order structural phase transitions and give rise to interesting and perhaps useful properties.

5. Leibniz Institute for Solid State and Materials Research, Dresden, Germany

The excellent magnetic softness of Fe based melt-spun nanocrystalline alloys is primarily due to averaging of the local magnetocrystalline anisotropy energy of grains over the exchange correlation length (L_{ex}). Hence, this characteristic length has been discussed extensively in many literatures. However, experimental observation of L_{ex} has been rather limited and the current understanding of the excellent magnetic softness relies on theoretical arguments based on the random anisotropy model (RAM). Our aim is to investigate L_{ex} of nanocrystalline soft magnetic materials experimentally by means of the Kerr microscopy and thereby verifying RAM. Two nanocrystalline $Fe_{84}Nb_6B_{10}$ samples were prepared by annealing a melt-spun amorphous precursor alloy under a static field (TFA) or under a rotating field (RFA) at 898 K for 1.8 ks. The applied field ($\mu_0 H$) was 0.8 T. Due to the static field, an induced uniaxial magnetic anisotropy (K_u) of 100 J/m^3 was confirmed for TFA. The remanence ration of RFA was above 0.5, indicating that K_u is negligible and the random magnetocrystalline anisotropy ($\langle K_1 \rangle$) governs the magnetization process in RFA. Well-defined regular 180° domain walls were seen on the Kerr images obtained from TFA and the average surface wall width is 0.33 ± 0.05 mm. 180° domain walls were also seen on RFA. However, the wall width tends to fluctuate considerably and the average width is 1.64 ± 0.5 µm. These wall widths suggest that the exchange length in RFA is approximately 5 times larger than that in TFA. Since L_{ex} is inversely proportional to the square root of anisotropy energy, the observed wall width indicates that $\langle K_1 \rangle$ in RFA is as small as 4 J/m^3. This value agrees exceptionally well with $\langle K_1 \rangle$ estimated from RAM (5 J/m^3) for the nanocrystalline $Fe_{84}Nb_6B_{10}$ sample (grain size of 10 nm and crystalline fraction of 0.7).

TU.A.2_O3 - Drastic reduction of Ni-Zn ferrites during consolidation by spark plasma sintering (SPS)

Y. Flores-Arias [1], T. Gaudisson [2], S. Ammar [2], R. Valenzuela [1]

1. Instituto de Investigaciones en Materiales, Universidad Nacional Autónoma de México, México D.F., México
2. ITODYS, Université Paris-Diderot, PRES Sorbonne Paris Cité, Paris, France

The consolidation of ferrite nanoparticles (NPs) can provide nanostructured materials with novel and interesting magnetic properties, especially for electronics applications. Spark plasma sintering (SPS) has shown many advantages to perform this sintering; it is an extremely fast method [1] which can be operated at very low temperatures as compared with the classic solid state sintering. To achieve high densities it is typically needed a sintering process at 1200°C for 8 hours. By using the SPS method, 500°C for 10 minutes is enough to reach such densities [2]. However, for some cases, particularly for NiZn ferrites with high Zn content, significant differences between the expected and the obtained magnetic properties have been observed. In this work, we report on the consolidation of $Zn_{0.7}Ni_{0.3}Fe_2O_4$ ferrite nanoparticles by SPS, their structural characterization, and their magnetic properties. The initial ferrite NPs were synthesized by the polyol method, leading to NPs about 8 nm, with a blocking temperature ~ 70 K. These NPs were consolidated by SPS at 600 °C for 10 min, resulting in a polycrystalline solid with grains ~ 160 nm. Magnetization saturation and Curie temperature, however, exhibited values significantly higher than those reported for the bulk ferrite of this composition. X-ray diffraction patterns revealed a small content of metallic Ni for the SPS samples. The experimental results are interpreted in terms of a partial reduction of Ni to a metallic second phase, and the occupation of the spinel sites left by Ni_2+ by Fe_2+ reduced from Fe_3+. A good agreement with the magnetic properties of $Zn_{0.7}Ni_{0.3}$-yFe_2+y$Fe_{3+2}O_4$ [3], where y is the reduced cation concentration (Ni and Fe), is obtained.

TU.A.2_O4 - Development of a very low loss MnZn ferrite for power applications

V. Tsakaloudi [1], V. Zaspalis [1,2]

1. Centre for Research and Technology Hellas-CERTH, Thessaloniki, Greece
2. Aristotle University of Thessaloniki-AUTh, Thessaloniki, Greece

Current market trends of the switching power supplies industry indicate the demand of even lower energy losses in power conversion systems that maintain satisfactory initial permeability levels. Thus, the need for medium frequency power conversion ferrite materials in the magnetic components that exhibit optimal performance at operation conditions of 100 kHz, 200 mT is continuous. In this work the development of a polycrystalline MnZn ferrite material that satisfies this demand, exhibiting initial permeability above 2500 units and very low power losses at medium frequencies is presented. The MnZn ferrite samples were prepared following the ceramic process of solid state reaction and sintering was performed under controlled atmosphere conditions. The combinatorial role of TiO_2 and CoO together with Zn content, as well as the effects of the process parameters on the magnetic performance of the MnZn ferrite were evaluated. It is shown that the development of the adequate polycrystalline microstructure that is characterized by a) high sintered density, b) homogenous grain size that is free of morphological or chemical pinning effects and c) high resistivity grain boundary structure can be achieved by means of appropriate compositional and dopant adjustment, anisotropy control and specific resistivity optimization. The newly developed MnZn ferrite is characterized by high sintered density of 4.91 g/cm3, initial magnetic permeability of 2512 (at 10 kHz, 0.1 mT, 25^o C), high saturation magnetic flux density of 560 mT (at 10 kHz, 1200 A/m, 25 ^{o}C) and very low power losses of 224 mW/cm3 (at 100 kHz, 200 mT, 100^o C) combined with very low power losses of 470 mW/cm3 even at room temperature, establishing it as ideal for power applications.

TU.A.2_O5 - Study of the induced anisotropy in field annealed Hitperm alloys by M÷ssbauer spectroscopy and Kerr microscopy

J. S. Blázquez [1], J. Marcin [2], F. Andrejka [2], V. Franco [1], A. Conde [1], I. Skorvanek [2]

1. Departamento de Física de la Materia Condensada, ICM-SE CSIC, Universidad de Sevilla, Sevilla, Spain
2. Institute of Experimental Physics, Slovak Academy of Sciences, Kosice, Slovakia

Samples of $Fe_{39}Co_{39}Nb_6B_{15}Cu_1$ alloy were nanocrystallized under zero field annealing (ZF) and transverse field annealing (TF) (640 kA/m, parallel to the ribbon plane and transverse to its axis). For TF sample, induced anisotropy K=860 J/m3 and anisotropy field HK=1390 A/m were obtained. A reduction in coercivity with respect to ZF sample (16 and 45 A/m, respectively) is also observed as wiping out the domain structure during TF prevents the unwanted effect of domain walls stabilization that occurs for ZF sample. Kerr microscopy show a well defined parallel domain structure, transversally oriented to the ribbon axis for TF unlike for ZF sample, for which a disordered pattern is observed with large and small domains at the surface of the ribbon. Although M÷ssbauer spectra are clearly different for the two studied samples, they confirm that there is no significant difference between the hyperfine field (HF) distributions of TF and ZF samples. The site contributions (inner core of nanocrystals) are also very similar for both samples, without differences in the average values of HF and the isomer shift. In fact, the only significant difference is the angle between the gamma radiation and the magnetic moments, Theta. Whereas for TF samples Theta=pi/2 rad, in agreement with the well defined domain structure observed by Kerr microscopy, ZF samples show Theta=0.91 rad, close to a random orientation and much smaller than that of as-cast amorphous samples, indicating that moments change their orientation to out of the ribbon plane during ZF unlike during TF annealing.

Theory [1] and early results from Nernst and torque experiments [2] suggest that in underdoped cuprates a large vortex liquid phase persists even at zero temperature. The issue of the existence of such a phase at high magnetic field is especially pressing as quantum oscillations (QO) have been observed just above the vortex melting field in underdoped YBCO [3] and there is still intense debate about whether Cooper pairs persist in the region of the H-T plane where quantum oscillations are seen. Two recent experiments on underdoped YBCO (p=0.11) have given conflicting answers to this question: Grissonnanche et al. showed through thermal conductivity measurements that there is a sharp feature at 22T which corresponds to the extrapolation of the irreversibility field at T = 0K and they interpret this signature as Hc2[4]; Fan Yu et al. found through high field torque magnetometry that the diamagnetism persists above 22T and conclude that the vortex-liquid phase exists well above 22T [5]. We performed our own torque measurements on underdoped YBCO (p=0.12) at fields up to 33T and temperature down to 4.5K. Our results are qualitatively similar to Fan Yu et al. [5], however there are important quantitative differences both below Tc and in the normal state. Detailed analysis suggests that the most likely scenario involves weak superconductivity above 22T that is heavily suppressed by competition with the charge density wave instability seen by X-ray scattering [7].

TU.A.3_O2 - Ferro-type order of magneto-electric quadrupoles in the pseudo-gap phase of $YBa_2Cu_3O_6 + x$

S.W. Lovesey [1,2], D.D. Khalyavin [2], U. Staub [3]

1. ISIS Facility, STFC Oxfordshire, United Kingdom
2. Diamond Light Source Ltd, Oxfordshire, United Kingdom
3. Swiss Light Source, Paul Scherrer Institut, Villigen, Switzerland

Magnetoelectric effects are important for materials, in which magnetism couples to electronic degrees of freedom due to the absence of inversion symmetry. These effects can be related to basic multipole moments beyond those of the charge, the magnetic dipole and the electric quadrupole (orbitals). These atomic multipoles are magnetic and break inversion symmetry (magnetoelectric) and they have been previously found in multiferroics such as $GaFeO_3$ [1, 2] and CuO [3]. However, their importance as order parameter for the electronic phase remains unclear. Here we apply these concepts to $YBa_2Cu_3O_6 + x$ in its pseudo gap phase. Our theory [4] allows us to fully describe previously observed neutron Bragg intensities indicative of magnetic order in the pseudo-gap phase of to $YBa_2Cu_3O_6 + x$. Magnetic diffraction intensities, collected using polarization analysis, are explained by magnetoelectric quadrupoles at in-plane Cu sites arranged in a simple ferro-type motif. An absence of conventional spin and orbital angular momentum dipoles in our theory is compatible with the occurrence of superconductivity at low temperature. This strongly suggests that these multipoles are the primary order-parameter in the pseudo-gap phase.

TU.A.3_O3 - The SU(2) symmetry in cuprate superconductors

C. Pépin [1]

1. IPhT, CEA – Saclay, France

In this talk we review the recent theoretical approach to the theory of high temperature superconductors, which considers the SU(2) rotation between d-wave pairing and the charge sector as a main player in the physics of these compounds [1-4]. We first discuss the role of this symmetry in the physics of the pG phase, its relation with AFM fluctuations and the recently observed charge orders in the under doped regime. We show recent numerical findings suggesting that the splitting of the SU(2) symmetry is minimal for a wide range of parameters, and gets smaller and smaller as the coupling is increased [4]. We argue that the collective mode associated with this symmetry corresponds to the A1g resonance observed in Raman scattering at 41 meV around optimal doping.

TU.A.3_O4 - The spin glass phase in cuprates and iron-based high temperature superconductors

J. Mydosh [1]

1. Kamerlingh Onnes Laboratory, Leiden, The Netherlands

For over 40 years the spin glass (SG) problem has intrigued the magnetic community and generated an enormous spin-off into many diverse non-magnetic areas. Lately there has been fresh stimulation of SG behavior from the newly discovered randomly doped materials, e.g., the high T_c superconductors. Here the phase diagram of temperature versus the various doping included an antiferromagnetic phase which becomes weakened and disappears into the superconducting dome. Generally there is a small coexisting wedge between the antiferromagnetism and the superconductor that displays SG behavior. The extent of the SDW is defined by the doping that creates magnetic disorder. Many years ago a proposed SG model was the incommensurate SDW but not of the long-range phase transition type. Instead a short-range (SR), randomly propagating, finite correlation length SDW was detected by neutron scattering in some canonical SG. Now we wish to use this SR-SDW model to describe the SG-like behavior claimed in the cuprates and pnictides. We present experimental evidence for the this overlapping SG-superconducting state [1].

TU.A.3_O5 - High-pressure phase diagram and electronic structure of FeSe

T. Terashima [1]

1. *National Institute For Materials Science, Tsukuba, Japan*

FeSe is an intriguing member of the iron-based superconductors. It undergoes a structural transition at T_s ~ 90 K but no antiferromagnetic transition at ambient pressure. Although the superconducting transition temperature T_c at ambient pressure is low, ~ 8 K, it can be enhanced remarkably by pressure or in single-layer films.

We have performed resistance and ac magnetic susceptibility measurements on FeSe single crystals under high pressure up to 27 kbar. Our resistance data clearly show anomalies most likely associated with the pressure-induced antiferromagnetic transition, which was previously suggested by muSR measurements [M. Bendele et al., PRL 104, 087003 (2010)]. The superconducting and antiferromagnetic transitions exhibit an intriguing interplay: Both transition temperatures increase with pressure as if the two orders cooperate, but the superconducting transition broadens when the antiferromagnetism coexist as if the two orders compete. The structural transition temperature is quickly suppressed by pressure and the transition line almost meets the antiferromagnetic one at ~18 kbar, the highest pressure where the transition was observed. The antiferromagnetic transition line however shows no clear kink indicating the point where the two transition lines meet. This might indicate that the two orders are nearly independent.

We have also performed Shubnikov-de Haas measurements [T. Terashima et al., PRB 90, 144517 (2014)]. We have found that the Fermi surface at ambient pressure is surprisingly different from that predicted by band structure calculations. It most likely consists of one hole and one electron cylinder at the zone center and corner, respectively. The carrier number is one order-of-magnitude smaller than predicted. Simple band-energy shifts and renormalization cannot explain these observations. Clearly, elaborated theories incorporating correlations and orbital ordering together are necessary. We will further report how the Fermi surface evolves with pressure.

TU.B.2_I1 - Exchange bias effect in CoO@Fe3O4 core-shell octahedron-shaped nanoparticles

V. Salgueiriño [1], N. Fontaíña-Troitiño [1], B. Rodríguez-González [1], B. Rivas-Murias [2]

1. Universidade de Vigo, Vigo, Spain
2. CIQUS-Universidade de Santiago de Compostela, Santiago de Compostela, Spain

Increased coercive and tunable exchange bias field values were registered in hybrid CoO@Fe3O4 core-shell octahedron-shaped nanoparticles of different average edge length. The metal cation chemical potential at the interface between the antiferromagnetic and ferrimagnetic oxides, captured as the dynamic variable, causes the effective magnetic anisotropy to increase and the type of interface to change after growing the magnetite shell epitaxially onto the cobalt oxide {111} surface facets, and consequently, to tune the exchange bias effect.

Although electron energy loss (EEL) spectrum volume tomography enables access to 3D chemical information at the nanoscale, it has never been used to elucidate the 3D-distribution of oxidation states. Here we present the first EELS-tomography 3D-reconstruction of oxidation states in a nanoheterostructured system with high spatial resolution. The success of the data analysis relies on the optimized use of multivariate analysis (which is very effective in handling large number of spectra) and the novel use of compressed sensing (which allows reliable 3D-reconstructions even with a limited number of datasets) in tomography algorithms. The feasibility to perform complex spectra treatment in spectrum volume tomography opens the door to a wide range of applications in solving complex nanostructures. In the presented case (45-nm wide FeO/Fe_3O_4 core/shell cubic nanoparticles), due to the similarities in the composition and effective atomic number of the compounds, high angle annular dark field (HAADF) imaging could not be used to resolve the structure, justifying the need of a more sofisticated approach. As an alternative, EELS fine structure is used to obtain information on the iron oxidation state, thus making it possible to distinguish between Fe2+ and Fe3+. However, there is the limitation that EELS projects the information of the 3D nanoparticle into a 2D map. To overcome this issue, EELS spectrum image data-sets are considered for 3D tomographic reconstruction after data processing. The reconstruction not only contains information on the chemical composition of the sample but also on the oxidation state of iron at each voxel.

TU.B.2_O3 - Effect of the oxygen content in the reaction environment on size and shape of $CoFe_2O_4$ nanoparticles: morphological analysis by aspect maps.

G. Muscas [3,4,5], G. Singh [1], W.R. Glomm [2], R. Mathieu [5], P. Anil Kumar [5], G. Concas [4], E. Agostinelli[3], D. Peddis [3]

5. Department of Engineering Sciences, Uppsala University, Uppsala, Sweden

Advanced synthesis approaches are necessary to achieve a strict control of the structural, morphological and chemical properties of nanomaterials, being at the basis of the reproducible manipulation of their physical behavior. In fact, any advanced application of nanoparticles (NPs) system will also rely on the achievement of such control, especially for magnetic nanoparticles that are complex physical objects, whose properties greatly differ from their parent massive material, being particularly sensitive to the particle size [1].
Within this context, the synthesis of spinel ferrite nanoparticles ($MeFe_2O_4$, Me = Fe^{2+}, Co^{2+}, Ni^{2+}, Zn^{2+}, …) with controlled morpho-structural features represents an important issue due to the strong interest from both a fundamental and a technological point of view (e.g., MRI, hyperthermia, drug delivery, catalysis).
Crystalline cobalt ferrite nanoparticles were prepared by a modified high temperature thermal decomposition (HTD) synthesis of acetylacetonate precursors [1,2]. This approach was improved introducing a strict control on the residual oxygen in the reaction environment. A detailed analysis of the effect of the oxygen content on the growth mechanism was carried out analyzing TEM images through a statistical approach and using aspect maps [3].
The aspect maps allowed to follow the growth process of nanoparticles and to select the optimal value of residual pressure to produce particles size of ~ 19 nm and a narrow size distribution (polydispersity 0.4 nm-1). The magnetic measurements showed an improvement of the switching field distribution (SFD) which is a key parameter for technological applications. Furthermore, our results suggest that particles with larger sizes can be also stabilized.

Spinel ferrites magnetic nanoparticles have promising potential in different fields of application as magnetic recording, spintronics, sensoristics and biomedicine. Unlike their bulk counterparts, where the composition can be considered mainly as homogeneous, in nanosized magnetic ferrites the increased surface/volume ratio can give rise to a faster oxidation process, leading to a not pure chemical structure. Traditional magnetic measurements do not allow for discriminating between the different magnetic phases, in particular between the magnetite and the maghemite. Their magnetic properties have been analyzed by several studies but the possible oxidation of Fe^{2+} ions of the metastable magnetite phase to Fe^{3+} of maghemite can be relevant for the physical properties of the nanosystem.
Magnetic circular dichroism (MCD) spectroscopy, being sensitive to specific electronic transitions[1], represents a simple and valid alternative to other expensive investigation techniques for the detection of different cationic species. In this study spherical iron oxide nanoparticles with increasing size between 5 to 10 nnm are investigated by MCD in the nUV-vis-nIR range [2].
Moreover the time evolution of different nanoparticles is monitored to investigate the progressive oxidation. The measurements show the presence of two definite spectral structures, whose intensity evolved in time, likely originated by different magnetic contributions. The analysis of the MO hysteresis loops allows the deconvolution of the two phases. The results support the hypothesis of two distinct magnetic phases, related to the presence magnetite and maghemite, which transformation is size dependent.

TU.B.2_O5 - Synthesis, structural and magnetic properties of $CdFe_2O_4$ ferrite

J.Z. Msomi [1]

1. School of Physics, University of KwaZulu-Natal, Durban, South Africa

Nanoparticles of $CdFe_2O_4$ with particle size of about 10 nm have been synthesized by high energy ball milling and co-precipitation processes. The synthesis route appears to have some effects on the properties. The compounds have been characterized by X-ray diffraction, Fourier Transform Infrared (FTIR), transmission electron microscopy (TEM), Mössbauer and magnetization measurements. The XRD pattern of $CdFe_2O_4$ provides information about single-phase formation of spinel structure with cubic symmetry. The FTIR measurements between 400 and 4000 cm-1 indicate intrinsic cation vibration of the spinel structure. The Mössbauer spectra were recorded at 4 K and 300 K. The hyperfine fields appear to be highly sensitive on particle size. The evolution of the properties as a function of particle size is also presented.

TU.B.3_O1 - Anisotropic Interaction of Ferromagnetic Nanoparticles Intercalated Inside Carbon Nanotubes

4. University of Barcelona, Barcelona, Spain

We investigate magnetic properties of iron based nanoparticles (NPs) intercalated into carbon nanotube (CNT) aligned arrays for magnetic fields oriented both along and perpendicular to the CNT axes. Samples have been synthesized by floating catalyst chemical vapor deposition. We show that for the parallel field the interplay between the exchange coupling and magnetic anisotropy depends both on the NP content Nc and temperature T. For low Nc and T the magnetic anisotropy dominates [1]. Temperature increase leads to strengthening of the exchange interaction. Moreover, analyzing the law of the approach to saturation we have obtained evidence of long range coherent magnetic anisotropy at low T which takes place between NPs belonging to a single nanotube [2]. This magnetic order is strengthened by the CNT alignment and is due to the peculiar influence of the inner magnetic properties of CNTs. Increase in concentration of NPs destroys the coherent anisotropy. For the perpendicular field the exchange interaction dominates in the whole studied temperature range (2-300K) independently on the Nc value. This is because NPs belonging to different CNTs have to be considered in this case. Consequently, coherent anisotropy is destroyed due to loss of orientation of CNTs, and the exchange interaction is maintained by the indirect exchange via the conduction electrons of different CNTs, arbitrarily contacting each other.

Magnetic multi-core nanoparticles consist of several magnetic single-domain nanocrystals positioned in different types of geometrical configurations (particle morphology). Depending on the nanocrystal size, particle morphology and the multi-core particle size, different types of magnetic behavior can be obtained. The result depends strongly on the interrelation between the nanocrystal size distribution, multi-core particle morphology and size. Thus, the magnetization process of the multi-core particle ensemble depends on both the individual magnetic moments of the nanocrystals as well as on the total effective magnetic moment of the particle (that depends on both the magnetic moment values and moment orientations of the individual nanocrystals). In this work, we use different analysis techniques, such as static magnetization, AC susceptometry (ACS), TEM, DLS, field rotation, and magnetorelaxometry (MRX), as well as modeling using Monte-Carlo techniques and Langevin dynamics in order to study the properties of different multi-core particles and also how the properties are different compared to single-core particles. Iron oxide based multi-core nanoparticle systems with mean particle diameters from 60 nm to 150 nm and nanocrystal mean sizes in the range of 15 nm - 30 nm are studied. From the ACS, MRX and field rotation analysis we can see that Brownian relaxation is the dominant process with some minor fast relaxation due to the Néel process. The size analysis result from the ACS and MRX method is in good agreement with the TEM and DLS data. The intrinsic saturation magnetization at 300 K obtained from DC magnetization is in the range of 340 kA/m and 390 kA/m, typical for iron oxide nanocrystals. DC magnetization and ACS results show that the low field magnetization process is different for the studied multi-core systems and is explained by differences in nanocrystal size and particle morphology.
Work is supported by EC FP7 NMP NanoMag project (grant no. 604448).

TU.B.3_O3 - Quantifying dipolar interaction effects in Fe oxide nanoparticles coated with oleic acid or silica by comparison with simulations

C. Moya [1], O. Iglesias [1], X. Batlle [1], A. Labarta [1]

1. Dpt. Física Fonamental and IN2UB, Universitat de Barcelona, Barcelona, Spain

Distinguishing surface from interaction effects on the magnetic properties of nanoparticle assemblies is a complicated task due to their concomitance. In order to separate both effects, uniform variation of the interparticle distance in an assembly, avoiding also aggregation, is desirable but this cannot be simply achieved by changing the concentration. In this work, we present a detailed magnetic study of 5 nm non-aggregated Fe oxide nanoparticles, with narrow size distribution, synthesized by the organic decomposition method. By using oleic acid (S1) or silica (S2) to coat particles from the same batch, we could study the magnetic properties of a unique assembly with (S1) or without (S2) interactions among the particles, guaranteeing that the only difference between them is the mean interparticle distance. This was clearly corroborated by the excellent H/T scaling of isothermal magnetization curves for S2 which was not observed for S1, and the correspondent features in ZFC/FC processes. The effects of interactions on the dynamics were characterized by measuring the time dependence of the thermoremanence after application of different fields during the FC process. The effective energy barrier distributions extracted from a scaling analysis of relaxation curves have maxima at higher values and extend to higher energies for S1 than for S2. Moreover, the maximum and shape of the distribution for the interacting sample S1, progressively reduces as the field applied during the FC prior to relaxation increases. The results of dipolar field and energy barrier histograms obtained by Monte Carlo simulations of macrospin assemblies with different concentrations allow to demonstrate that the observed phenomenology is due to interactions. Comparison of numerical with experimental results allows quantification of the dipolar interaction effects on the energy barriers.

TU.B.3_O4 - MnBi magnetic nanoparticles: New synthesis to realize rare-earth replacement nanomaterials

M. Rowe [1], E. Skoropata [2], Y. Wroczynskyj [2], J. van Lierop [2]

1. Toyota Research Institute of North America, United States
2. University of Manitoba, Winnipeg, Canada

There are few candidate magnetic materials that show promise of competing in energy product with rare-earth permanent magnets. MnBi, when formed correctly in an exchange coupled magnetic nanocomposite with a soft magnetic phase, is one of these few candidates. For over 50 years now, the production of MnBi has been challenging. The peritectic nature of molten Mn and Bi restricts formation of the intermetallic. The obvious solutions of melt spinning suffers from the drawbacks of MnBi forming in either a matrix of Mn or Bi, ill suiting it for formation of a nanocomposite with soft magnetic material. Ferromagnetic MnBi nanoparticles have been synthesized from a new reagent material known as Mn Ligated Anionic Element Reagent Complex (Mn LAERC), which is a construction of Mn and lithium borohydride, ligated by undecyl cyanide, as shown by FT IR analysis peaks versus literature values and authentic samples of the component materials. The Mn LAERC is used to produce MnBi nanoparticles simply and in large scale (gram quantities) through a solution based reduction of bismuth carboxylates. SEM EDX analysis of the as-synthesized MnBi nanoparticles agree with the powder XRD that nanoparticles are indeed being formed. M(H) hysteresis loop data of these crude, magnetically aligned, nanoparticles show a magnetic coercivity (Hc) value of 660 Oe, with a magnetization saturation (Ms) of 0.28 emu/g at 300 K. Because the MnBi nanoparticle synthesis is kinetically fast (almost instantaneous), a large amount of crystalline disorder is expected to occur in the material. This notion is supported by the improvement that can be realized in the crude nanoparticles. A simple 2 hour long annealing process is effected to increase these magnetic performance values to Hc = 1800 Oe and Ms = 25 emu/g at 300 k, which increase to Hc = 7960 Oe and Ms = 19 emu/g at 400 K with an energy product of 2.8 MGOe.

TU.C.1_I1 - 3D Curved Magnetic Surfaces

D. Makarov [1], R. Streubel [1], M. Melzer [1], D. Karnaushenko [1], G. Lin [1], P. Fischer [2], F. Kronast [3], U. K. Röβler [4], O. G. Schmidt [1]

Conventionally magnetic films and structures are fabricated on flat surfaces. The topology of curved surfaces has only recently started to be explored and leads to new fundamental physics and applied device ideas. Advancing in this field calls for the understanding of the magnetic responses of thin films on curved surfaces. Here, two basic geometries, i.e. hemi-spherical [1,2] and tubular [3,4], will be addressed. To enable the microscopic characterization of 3D architectures, we put forth the concept of magnetic soft x-ray tomography. This concept will be introduced and the angle- and layer-resolved imaging of rolled-up tubes [4,5] will be presented Based on this knowledge, we fabricated flexible [6,7], printable [8] and stretchable [9] magnetic sensorics. The unique mechanical properties open up new application potential of magnetic field sensors for printable electronics and smart skins, allowing to sense and manipulate objects of the surrounding us physical as well as digital world [10].
This work is supported in part via ERC project SMaRT number 306277 and FET programme under FET-Open grant number 618083.

TU.C.1_O2 - A New Path to Spin Engineering in Ultrathin Magnetic Layer Systems

K. Schlage [1], D. Erb [1], H. Wille [1], L. Bocklage [1,2], D. Schumacher [1,] J. Comfort [1], R. Röhlsberger [1,2]

Spintronics with its multifaceted applications requires control over the magnetic properties of thin films. However, in conventional ferromagnetic thin film preparation, the magnetic anisotropy and coercivity cannot be chosen unrestrictedly, limiting the flexibility of spintronic multilayer device design. We demonstrate that the field-dependent magnetization behavior can be adjusted completely freely and set separately for the individual magnetic layers in a multilayer system by using oblique incidence deposition (OID). While the polar angle of deposition can be used to adjust the coercive field of practically every sputter deposited magnetic thin film in a range of 1 mT to 50 mT, the azimuthal orientation of deposition can be used to precisely define the orientation of its in-plane easy axis.

We demonstrate the capabilities of the new method by preparation of model systems with tailor-made magnetic properties: First, by stacking thin films with non-parallel in-plane easy axes of magnetization, multilayer hybrids are fabricated which are switchable between different ground states (ferromagnetic, ferrimagnetic, antiferromagnetic). Second, multilayers composed of thin films with different switching fields demonstrate the possible adaptability of magnetic field sensors to particular applications. In order to pinpoint the microscopic mechanism that leads to these features we have employed high-resolution magnetic x-ray scattering, magneto-optical Kerr effect measurements and cross-sectional TEM studies. Applicable to a wide range of material combination the proposed approach can provide access to diverse new routes in fundamental research and multilayer device design [1].

TU.C.1_O3 - Helimagnetic thin films: surface reconstruction, surface spin-waves and magnetization

H.T. Diep [1], S. El Hog [1]

1. LPTM, University of Cergy-Pontoise, CNRS, Cergy-Pontoise, France

We study surface spin configuration, surface spin-waves and temperature-dependent surface magnetization in quantum Heisenberg helimagnetic thin films using the Green's function technique. We show that the helical angle is strongly modified at the surface and a few beneath layers. The ground-state spin configuration across the film is shown as a function of the interaction J2 between next-nearest neighbors along the c-axis perpendicular to the film surface. The spin-wave spectrum is calculated for the non-collinear spin configuration. The surface localized spin-wave modes are identified. Using the spectrum, we calculate the layer magnetizations across the film as functions of temperature T, J2 and surface anisotropy. Effects of quantum fluctuations at low T are shown and discussed. In particular, we show effects of surface exchange interaction on the zero-point spin contraction and the existence of a crossover between layer magnetizations at very low T. We also show and discuss the case of a helimagnetic nanotube.

TU.C.1_O4 - Direct imaging of the magnetic dead layer in strained manganite thin films

The substrate-induced strain effect in epitaxial manganite thin films is one of the main factors that produces dramatic changes in their magnetic and transport properties. In the past, different indirect methods have been employed to elucidate the reasons of these phenomena detecting, for instance, the appearance of a non-ferromagnetic/insulating layer, also called dead layer [1-3]. In this work, we show the first experimental image obtained by electron holography at low temperature of the formation of this dead layer. In the case of epitaxial strained $La_{2/3}Ca_{1/3}MnO_3$ thin films, we directly visualized that such dead layer is produced in the topmost surface of the film. Macroscopic magnetization measurements, as well as theoretical calculation have demonstrated that this layer has an antiferromagnetic (AF) behavior, and is produced by the epitaxial strain induced by the substrate [4]. In addition, we showed that by a suitable tuning of the out-of-plane lattice parameter of the film (i.e. reducing the c/a ratio of the film), such a dead layer can be avoided. In summary, we can control the appearance of an AF layer at the surface of the manganite being of interest for possible exchange bias applications.

The occurrence of ferro-antiferromagnetic (F-AF) interfaces in Fe/NiO bilayers brings about the possibility of significantly varying the Fe layer hysteretic properties through the uniaxial anisotropy induced by the presence of unbalanced antiferromagnetic phase moments at that interface. In this work, we report on the Fe-thickness (5 - 20 nm) and temperature dependencies of the hysteretic parameters measured in Fe/NiO (200 nm)/ Al_2O_3 (nanoporous membranes). The Fe layers were deposited using pulsed laser ablation whereas the NiO ones were fabricated by means of magnetron sputtering on top of the Al_2O_3 membranes. Sample morphology was examined by both scanning electron and atomic force microscopies, which evidenced that the Fe/NiO bilayer maintained the Al_2O_3 membrane nanopores and grew in a six-fold columnar way around each original nanopore. The in-plane hysteresis loops measured (vibrating sample magnetometer) by field cooling the samples down to different temperatures below RT evidenced the occurrence of coercive forces larger than that associated to the Fe anisotropy field and also significant loop displacements, both of them clearly associable to the occurrence of exchange bias at the Fe/NiO interface. Also, and interestingly from the standpoint of the hysteresis control, the Fe thickness dependence of the coercivity evidence that the interphase coupling fundamentally influences the nucleation at the interface of a reversed domain whose propagation rules the Fe columns switching.

TU.C.2_I1 - Random Fields in Magnets and Superconductors: The Role of Topology

E. Chudnovsky [1], T. Proctor [1], D. Garanin [1]

1. Lehman College and Graduate School of the City University of New York, Bronx, United States

Random fields in magnets and superconductors have been discussed for decades but their effect on the long-range order was not fully understood. Recently it has been argued that the answer depends on the topology of the order parameter. The n-component fixed-length continuous-symmetry order parameter in d dimensions, interacting with the random field, exhibits glassy behavior at $n < d + 1$ due to the pinning of singularities. Presence of nonsingular topological objects at $n = d + 1$ leads to a weak metastability. At $n > d + 1$ topological defects are absent and the behavior of the system is fully reversible, characterized by the exponential decay of correlations. Theoretical arguments have been confirmed numerically on lattices of up to one billion sites. Along the same lines the effects of magnetic impurities on the ferromagnetic order and random anisotropy effects in amorphous and sintered magnets have been studied. Our findings shed new light on properties of pinned charge density waves and properties of pinned flux lattices in superconductors.

5. The Open University of Japan, Chiba, Japan

Recently, numerous experimental and theoretical studies have focused on chiral helimagnets in which antisymmetric Dzyaloshinskii-Moriya interactions induce long-range modulation of the magnetic order. Because they provide an opportunity to observe stable magnetic topological structure such as whirls of magnetization called skyrmions and, a spiral helimagnetic order that can be deformed by an external field such as the chiral soliton lattice (CSL) that is observed when a magnetic field is applied perpendicular to the helical axis in $Cr_{1/3}NbS_2$. Most of inorganic chiral magnetic materials form racemic-twinned crystals, having the left and right-handed crystalline domains in a specimen so that it is difficult to study the relation between crystallographic and magnetic structures. However, MnSi is known as one of unique examples to form only left-handed crystal structure, and the helimagnetic chirality follows the crystalline chirality. Moreover, our group succeeded in controlling the crystallographic chirality and obtained mm-sized single crystals of chiral helimagnet $CsCuCl_3$. X-ray diffraction measurements show that each crystal adopts either a right or left-handed crystallographic chirality only. In order to elucidate the existence of CSL in MnSi and to clarify the relation between crystallographic and magnetic structures in $CsCuCl_3$, we performed polarized small angle neutron scattering (SANS) and muon spin rotation measurements. The polarized SASN experiments detected the higher harmonics indexed as (2δ,2δ,-2δ) under the applied field non-parallel to the helical axis. By evaluating the difference in intensities between the up and down-spin incident neutrons, it had the left-handed incommensurate magnetic structures. These results are well interpreted by formation of the left-handed CSL. Muon spin precession signals were observed in both the crystals under a zero field below T_N. Temperature dependence of the precession frequencies behaves the same way, suggesting that the right and Ieft-handed samples are a pair of complete isomers in terms of both crystallographic and magnetic structures.

TU.C.2_O3 - Two step pressure induced collapse of magnetic order and fluctuating chiral phase in MnGe Chiral magnet

Cubic helimagnets such as MnSi or FeGe are model cases of pressure-induced collapse of band ferromagnetism in metals, accompanied with exotic partial order and chiral spin textures [1]. Their long wavelength helical structures arise from the spin orbit coupling, the Dzyaloshinskii-Moryia anisotropy perturbing the ferromagnetic exchange.
MnGe stands out owing to its much shorter helix pitch and high magnetic moment [2], yielding a giant Topological Hall Effect [3]. Using high pressure neutron diffraction, we show that helical order in MnGe transforms around 6 GPa from a high spin to a low spin state, recalling the weak ferromagnetism of MnSi at ambient pressure. Above 6 GPa an intermediate magnetoelastic state with strong spin fluctuations likely accommodates the volume mismatch between high spin and low spin regions. Helical order collapses only above 10 GPa, suggesting a second transition from a low spin to a non-magnetic state, in agreement with ab initio calculations [4].
At ambient pressure, we studied the spin fluctuations versus temperature by combining neutrons with Mössbauer spectroscopy on a 57Fe-doped sample [5], and recently with Muon Spin Resonance (MuSr). A inhomogeneous chiral phase is stabilized in a very large temperature range (TN+-70K) around the Néel temperature (TN=170K), where fluctuating moments with short range ferromagnetic correlations coexist with frozen moments involved in the helical order. This coexistence is clearly detected on the MuSR spectra, and the temperature dependence of the fluctuating fraction well agrees with that deduced from Mössbauer spectroscopy. This unusual broad transition to paramagnetism, also studied by small angle neutron scattering [6] suggests a dynamical phase separation triggered by temperature. Our results show that in MnGe, as in MnSi and FeGe [7], spin fluctuations play an important role in the pressure induced spin transitions.

8. Institute for Advanced Materials Research, Hiroshima University, Japan

Recently, large attention has been paid to the chiral helimagnetic compounds, allowing an asymmetric Dzyaloshinskii-Moriya (DM) interaction. Under an applied magnetic field, it forms unique magnetic structures such as Skyrmion and chiral magnetic soliton lattice.

However, there have been few experimental results due to the difficulty to synthesize the suitable materials to realize such research. In chiral helical magnetic structures, the pitch angle, mainly determined by the ratio of exchange interaction and DM interaction, is usually very small. As a result, the helimagnetic period can be hundreds of angstroms. Therefore sometimes the angle resolution of thermal neutron diffraction experiments is not high enough to separate fundamental Bragg peaks and magnetic satellite peaks. As consequence, some compounds with chiral helimagnetic ordering may be easily misinterpreted as ferromagnetic ordering.

In order to observe the long periodic helimagnetic structure, we performed neutron diffraction experiments at BL08 (SuperHRPD) in the Materials and Life Science Experimental Facility (MLF) of J-PARC in Japan. By means of super high-resolution powder neutron diffraction in SuperHRPD, we observed very long periodical magnetic satellite peaks in CrM_3S_6 (M = Nb and Ta) compounds. Magnetic structure analysis indicates these compounds forms helimagnetic structure.

TU.C.2_O5 - Microscopic theory of dzyaloshinskii-moriya coupling and related exchange-relativistic effects

A. Moskvin [1]

1. Ural Federal University, Sverdlovsk Oblast, Russia

I present an overview of the microscopic theory of Dzyaloshinskii-Moriya coupling and other related exchange-relativistic effects such as exchange anisotropy, antisymmetric magnetoelectric coupling, antisymmetric magnetogyrotropic effects, and electron-nuclear antisymmetric supertransferred hyperfine interactions in strongly correlated 3d-based compounds. Theoretical results are applied to different classes of 3d compounds from conventional weak ferromagnets (FeF_3, Fe_2O_3, RFeO_3,RCrO_3,..) to unconventional systems such as weak ferrimagnets (e.g., RFe_(1-x)Cr_xO_3), helimagnets (e.g., CsCuCl_3, MnSi), cuprates (La_2CuO_4,...), and different multiferroics. Particular emphasis will be placed on the role of crystal field effects, the sense and direction of the Dzyaloshinskii vector, its dependence on the superexchange bonding geometry, and other subtle features of exchange-relativistic effects. A critical analysis will be given of different approaches to exchange-relativistic coupling based on the cluster and band calculations.

The work was supported by the Government of the Russian Federation Program 02.A03.21.0006 and by the Ministry of Education and Science of the Russian Federation, projects Nos. 1437 and 2725.

TU.C.3_O1 - New results for triangular-lattice quantum antiferromagnets in a magnetic field

G. Marmorini [1], D. Yamamoto [2], I. Danshita [1]

1. YITP Kyoto, Kyoto, Japan
2. Waseda Institute for Advanced Studies, Tokyo, Japan

Frustrated antiferromagnets are a very rich class of physical systems, in which various new phases of matter are expected to be realized. From a theoretical point of view, however, they present challenging difficulties and typically defy a full quantum treatment. Restricting to a specific region of the parameter space, namely the one of high applied magnetic field, the problem can be solved within the dilute Bose gas of magnons. This also provides benchmarks for a numerical approach based on cluster mean-field theory, with which we determine the ground-state phase diagram of the prototypical spin-1/2 XXZ model on the triangular lattice and explain the magnetization process of $Ba_3CoSb_2O_9$. In a more complicated model with competing exchange interactions we find a new phase characterized by striped chiral order. We will also touch upon the relation between three-magnon scattering and a first-order phase transition between coplanar states, which is currently an open problem.

TU.C.3_O2 - Study of magnetic phase transitions and magnetostriction by means of reversible villari effect

S. Kustov [1], A. el Hichou [1], M.L. Corró [1]

1. Departament de Física, Universitat de Les Illes Balears, Palma de Mallorca, Spain

A new technique referred to as mechanomagnetic spectroscopy (MMS) has been used to study the peculiarities of magnetic phase transitions and of magnetoelastic coupling in different magnetically ordered phases of several materials: single and polycrystalline Ni-Fe-Ga-(Co) shape memory alloys, rare earth polycrystalline Dy and such classical ferromagnetic transition elements as Fe and Ni. The method is based on registration of the reversible Villari effect (RVE) as the main experimental parameter [1].
Experimental results obtained for the shape memory alloys belonging to the Ni-Fe-Ga family [2,3], both in the martensitic and cubic phase, point to the existence of a certain domain in the H-T plane, which corresponds to the variation of the sign of magnetoelastic coupling (Villari critical points). The upper temperature limit of this domain is usually very close to the Curie temperature. In single crystalline cubic Ni-Fe-Ga samples such anomaly is found only for the λ_{100} mode of lattice strain.
The highly sensitive method used allows us to study the RVE in ferro- , antiferro- and paramagnetic phases of polycrystalline Dy. We found strong differences in the magnetic hysteresis between cooling to and heating from the ferromagnetic phase as well as time dependence of magnetoelastic coupling in the antiferromagnetic phase. The last effect has been attributed to the relaxation of internal stresses induced during thermal cycling and antiferro-ferromagnetic transition of the first order. A magnetic transition on heating from ferromagnetic phase was observed and related with the helix-fan transition, which was previously considered to occur only on cooling.

3. Faculty of Physics, M.V.Lomonosov Moscow State University, Moscow, Russia
4. Materials Science, Technische Universität Darmstadt, Darmstadt, Germany

Structural and magnetic properties across the martensite-austenite phase transitions in the shape memory alloy $Ni_{45}Mn_{37}In_{13}Co_5$ are studied using complementary experimental techniques: ferromagnetic resonance, macroscopic magnetization measurements and x-ray magnetic circular dichroism in the temperature range from 5 K to 450 K [1].
Magnetization measurements exhibit a zero-field-cooled-curve and the field-cooled-curve (and field-warmed) splitting for T < 30 K, which indicates the presence of a field and history dependent magnetic state of the sample. This reveals spin glass like behaviour. While in the martensite state the sample shows a low but finite magnetization, in the austenite state the magnetization is increased and the sample is ferromagnetic.
In the ferromagnetic resonance experiments different resonance lines are observed which show coexisting antiferromagnetic and ferromagnetic correlations for the martensite phase and ferromagnetic and paramagnetic correlations in the austenite phase.
Ni and Co K-edge x-ray magnetic circular dichroism measurements confirm an assignment of ferromagnetic resonance lines purely to Ni and Co for a wide temperature range from 125 K to 225 K. Hence, combined ferromagnetic resonance and x-ray magnetic circular dichroism analysis allows to interpret the ferromagnetic resonance measurements in an element selective manner in the alloy.

2. Department of Physics, Chemistry and Biology, Linköping University, Linköping, Sweden
3. Institute of Molecular Physics, Polish Academy of Sciences, Poznan, Poland

Ni-Mn-Z (Z = Ga, In, Sn, Sb) Heusler alloys belong to a class of magnetic shape memory alloys, in which a martensitic transformation takes place in a ferromagnetic state. This magnetostructural transformation leads to field-induced strains, magnetocaloric effect, modification of exchange coupling, large magnetoresistance, etc. The aforementioned effects depend strongly on the magnetic structure of the alloy, which often changes with the composition. We present the phase diagram of $Ni_{50}Mn_{50-x}Snx$ (0 = x = 25) obtained by means of ab initio calculations and Mean Field Approximation. The phase diagram includes temperatures of martensitic transformation (TM) estimated from a difference of calculated total energies of austenite and martensite phase. It also includes the estimated values of Curie temperature of austenite phase (TCA) and Curie and Néel temperatures of martensite phase (TCM, TNM). The calculated values are in good agreement with the experimental ones.

TU.C.3_O5 - Spin-stripe phase in a frustrated spin chain

6. Faculty of Mathematics and Physics, University of Ljubljana, Ljubljana, Slovenia

Periodic modulations of various shapes and sizes are encountered in a variety of natural systems, where at least two rival states are present [1]. In strongly correlated electron field such behavior has typically been associated with competition between short- and long-range interactions, e.g., between exchange and dipole-dipole interactions in the case of ferromagnetic thin films. Here we show that spin-stripe textures may develop also in antiferromagnets, where long-range dipole-dipole magnetic interactions are absent. Employing magnetic susceptibility, high-field magnetization, specific heat, and neutron diffraction measurements, we find beta-TeVO4 [2] to be a nearly perfect realization of a frustrated ferromagnetic spin-1/2 chain [3], namely, a zigzag chain with competing ferromagnetic nearest-neighbor (NN) interaction J1 and the antiferromagnetic next-nearest neighbor (NNN) interaction J2. The ground state of this system has vector-chiral (VC) correlations, while at higher magnetic fields collinear spin-density-wave (SDW) states evolve. Surprisingly though, in a narrow field/temperature range between these two parent states, we discover a remarkable spin strip phase with temperature-dependent nanometer-scale modulation. We associate its existence with weak frustrated short-range interchain exchange interactions, which hereby release the degeneracy of the VC and SDW states present in that particular field range. Effect of interchain interactions may be further assisted by the symmetry allowed electric polarization. The proposed concept provides an alternative route for the stripe formation in strongly correlated electron systems and may help understanding other widespread, yet still elusive, stripe-related phenomena.

TU.D.1_I1 - Thermalization and exotic frustration in artificial spin ice

P. Schiffer [1], I. Gilbert [1], S. Zhang [2], C. Nisoli [3], G. Chern [3]

1. University of Illinois at Urbana-Champaign, Champaign, United States
2. Argonne National Laboratory, Lemont, United States
3. Los Alamos National Laboratory, New Mexico, United States

Artificial spin ice consists of arrays of lithographically fabricated single-domain ferromagnetic elements, arranged in different geometries such that the magnetostatic interactions between the moments are frustrated. We have probed a number of different lattice geometries and find both local ordering and disordered states that match classic models for frustrated spin systems.
Our recent work has focused on thermalization of these arrays as well as investigation of lattice geometries that are unavailable in natural systems and are specifically designed to exhibit unusual behavior associated with frustration, e.g., the shakti lattice. Thermalization reveals ordering both of the moments and of the effective magnetic charges that characterize correlated many-body dynamics in these systems.

TU.D.1_O2 - Spin correlations in the randomness-induced quantum spin-liquid state of the spin-1/2 kagome Heisenberg antiferromagnet -- application to herbertsmithite --

T. Shimokawa [1], K. Watanabe [1], H. Kawamura [1]

1. Osaka University, Osaka Prefecture, Japan

Herbertsmithite, the spin-1/2 Heisenberg antiferromagnet on the kagome lattice, has attracted considerable interest of researchers as a promising candidate of the possible quantum spin-liquid state [1]. Recent theoretical study has suggested that the effect of the quenched randomness might be important in understanding the nature of the quantum spin-liquid of this material [2]. Namely, the spin-1/2 antiferromagnetic Heisenberg model on the kagome lattice with the bond-random exchange interaction was observed to exhibit a gapless spin-liquid-like ground state, i.e., the random singlet (or the valence-bond glass) state [2,3]. In this study, we investigate the spin correlations of the random-bond spin-1/2 antiferromagnetic Heisenberg model on the kagome lattice by means of an exact diagonalization method to get further insight into the spin-liquid-like ground state of the model. We pay special attention to the dynamical structure factor of the model, with systematically varying the extent of the quenched randomness. The result is compared with the recent inelastic neutron-scattering data on a single-crystal herbersmithite [4]. Good qualitative agreement is then obtained including a broad peak-like behavior without any gap signature at lower energies and a flat plateau-like behavior at higher energies, supporting the view that the experimentally observed quantum spin liquid state of herbertsmithite might indeed be the random singlet state.

TU.D.1_O3 - Magnetic excitations and phase diagram of the hyperkagome garnets Gd3Ga5O12 and Gd3Al5O12

O. Florea [1], E. Lhotel [1], P. Deen [2], H. Jacobsen [3], A. Wildes [4], C. Knee [5], P. Henry [2]

4. Institut Laue-Langevin, Grenoble, France
5. Chalmers University of Technology, Göteborg, Sweden

Antiferromagnets on the hyperkagome lattice generate a great interest in frustrated magnetism. Indeed, on this highly frustrated 3D lattice, the ground state is highly degenerate, resulting in unconventional spin liquid behavior and emergent excitations. $Gd_3Ga_5O_{12}$ (GGG) is one of the few realizations of this model system, the magnetic Gd ions being on two interpenetrating corner sharing triangular sublattices. Many studies have been devoted to this compound, without giving a clear understanding of its (H,T) phase diagram. No long range order was found down to 25mK, despite a Curie-Weiss temperature of -2K, but a spin freezing was reported below 140mK [1].
We present a new approach to understand the puzzling physics of GGG by combining neutrons scattering and magnetization measurements, and comparing these measurements with the homologous compound Gd3Al5O12 (GAG). We recently showed that the rich phase diagram of GGG can be understood in terms of competing interactions with loops of spins, trimers and decagons in addition to antiferromagnetic, ferromagnetic and incommensurate order. The phase diagram centers around a multiphase convergence to a single point at 0.9T and 350mK [2]. In GAG, the lattice parameter is slightly smaller than in GGG and a transition was reported in specific heat around Tc=170mK [3]. Our magnetization measurements evidence a spin freezing below 270mK, and an anomaly around Tc. However neutron scattering only observed short range correlations down to the lowest temperature (60mK), revealing a complex ground state in the manner of GGG. The phase diagram for GAG is also reminiscent of that for GGG. We expect that these results will clarify the mechanisms that stabilize fragile ground states and unusual excitations in these 3D frustrated systems.

TU.D.1_O4 - Spin liquid ground state in a vanadium based S=1/2 trimerized kagome compound

J.C. Orain [1], F. Bert [1], P. Mendels [1], L. Clark [2], F.H. Aidoudi [2], P. Lightfoot [2], R.E. Morris [2]

1. Laboratoire de Physique des Solides, Université Paris-Sud, Orsay, France
2. School of Chemistry and EaSTChem, University of St. Andrews, St. Andrews, United Kingdom

The search for quantum spin liquid states such as the resonant valence bond state (RVB) formed by the macroscopic resonance between the various spin singlet coverings of the lattice, is a major challenge in both experimental and theoretical condensed matter research [1]. The prime candidate to host this state of matter is the S=1/2 Kagome antiferromagnet (KAFM) in two dimensions. Among the rare experimental realizations of the KAFM model the recently synthesized compound, $[NH_4]2[C_7H_{14}N][V_7O_6F_{18}]$ (DQVOF) [2], is the first one to host magnetically active V4+ (d1) ions rather than more usual Cu2+ (d9) thus allowing to investigate the effects of different perturbations to the ideal Heisenberg Hamiltonian. Further, this compound seems to be the first experimental realization of the trimerized Kagome model, formed by two different equilaterals triangles, initially theoretically studied by M. Mambrini and F. Mila [3]. Our low temperature magnetization and specific heat results suggest that DQVOF is a good candidate for the S=1/2 KAFM physics despite a complex structure [4]. Besides, the low temperature specific heat and ÁSR studies evidence a gapless spin liquid behaviour down to 40mK. Recent NMR studies unveil the intrinsic susceptibility of the Kagome layers which is hidden in the macroscopic measurements by the Curie like interlayer V3+ contribution. Under strong magnetics fields, those studies revealed a spin gap of about 15 K (J/4). As a consequence, this material exhibits an exotic excitation spectrum, with a continuum of non magnetic excitations, quite reminiscent of the short range RVB physics which could be remarkably favoured by the trimerization of the Kagome model.

TU.D.1_O5 - Thermal, transport, and spectral properties of generic quantum spin ice beyond the mean-field theory

S. Onoda [1]

1. Riken, Wako, Japan

Quantum spin fluctuations in spin-ice related materials have attracted current great interest in a quest of bosonic U(1) quantum spin liquids hosting unconventional excitations, including deconfined spin-ice monopoles and emergent artificial photons. Reliably describing the nature of these novel excitations beyond naive mean-field approaches is indispensable for properly understanding experiments in relevant materials, such as $Pr_2Zr_2O_7$, $Yb_2Ti_2O_7$, and $Tb_2Ti_2O_7$. Here, taking into account fluctuations of both gauge fields and spinons (spin-ice mopoles) beyond the mean field theory, we revisit the zero- and finite-temperature phase diagram of the generic nearest-neighbor quantum spin ice model and uncover the spectral properties. Weakly first-order transitions due to the spinon condensation via the Higgs mechanism have been reproduced as in the mean-field theory. Furthermore, a finite-temperature confinement-deconfinement crossover has been obtained as a classical to quantum spin ice crossover obtained by quantum Monte-Carlo simulations. This sharply contrasts to a mean-field theory predicting a finete-temperature confinement-deconfinement phase transition. A simple confined phase showing any simple 2-in, 2out magnetic structure is not stable because it does not gain the kinetic energy of spinons. Effects of the applied magnetic field are also examined. In particular, the <111> magnetic field can induce a quantum criticality of spinons as 2-in, 2-out states become locally degenerate with 3-in, 1-out states. Then, transport properties of spinons are discussed.

TU.D.2_I1 - Fluctuations and all-in / all-out state in the Ising antiferromagnet Nd2Zr2O7

E. Lhotel [1], S. Petit [2], M.C. Hatnean [3], S. Guitteny [2], C. Colin [1], J. Robert [1], I. Mirebeau [2], M.R. Lees [3], G. Balakrishnan [3]

1. Institut Néel CNRS, Grenoble, France
2. Laboratoire Léon Brillouin CEA Saclay, Saclay, France
3. University of Warwick, Coventry, United Kingdom

Pyrochlore compounds (R2M2O7, R=rare-earth, M=metal) are a rich playground for exploring magnetic frustration in a corner-sharing tetrahedron lattice. Depending on the rare-earth element, different spin anisotropy (Ising, easy-plane, Heisenberg) and interactions (antiferromagnetic, ferromagnetic, long-range, anisotropic) come into play, so that exotic phases such as spin-ices or spin liquids can be stabilized [1].

We have investigated single crystals of $Nd_2Zr_2O_7$, in which the Nd_{3+} magnetic moments exhibit a strong local <111> Ising anisotropy with an effective value of about 2.4μB [2]. Magnetization measurements performed along the [100], [110] and [111] axes of a crystal down to 70 mK, together with powder neutron diffraction experiments, reveal that $Nd_2Zr_2O_7$ undergoes an antiferromagnetic transition at 285 mK towards an all-in / all-out state. In addition, measurements as a function of field allow us to establish the full (H,T) phase diagram in the three directions of the applied field. This compound exhibits a metamagnetic transition towards an ordered spin ice state around 1000 Oe, associated with strong time dependent effects. $Nd_2Zr_2O_7$ thus appears as a model system of antiferromagnetic Ising spins on the pyrochlore lattice.

These findings are important since conventional ideas usually associate the all-in / all-out structure with the simple canonical un-frustrated case. However, surprisingly, our experiments demonstrate that the magnetic moment is only partially ordered (0.6μB), while the full moment of 2.4μB is recovered in the field induced phases. These findings point to the predominance of quantum fluctuations, and show that this case is a lot more complicated than it first appears.

TU.D.2_O2 - What is the nature of the ground state in the stoichiometric pyrochlore $Yb_2Ti_2O_7$?

6. Canadian Institute for Advanced Research, Toronto, Canada

Rare-earth pyrochlores magnets are known to be prime examples of the rich physics generated by magnetic frustration. Among them, $Yb_2Ti_2O_7$ has attracted a lot of attention recently due to the exciting possibility that it could host a Quantum Spin Liquid (QSL) state below a first-order transition observed in specific heat at Tc = 265mK. However, the nature of the ground-state in $Yb_2Ti_2O_7$ is greatly debated, and several studies find some evidences for long range ferromagnetic order below Tc. Moreover, these experimental observations seem to vary from sample to sample, perhaps due to a slightly off-stoichiometry affecting real materials. We will present low temperature neutron scattering measurements carried out on a well characterized polycrystalline sample of stoichiometric $Yb_2Ti_2O_7$.

Our measurements reveal that there is change of intensity at nuclear Bragg positions upon warming which does not occur sharply at Tc, and which is consistent with an ordered moment size of ~1.1 muB (58% of the saturation moment). The inelastic excitations at low temperature suggest the presence of dispersive modes coexisting with incoherent low energy fluctuations. The data is very reminiscent to what was recently found on the related pyrochlore compound $Yb_2Ti_2O_7$.

Our results suggest that the ground state in nominally pure $Yb_2Ti_2O_7$ is not a conventional ordered ferromagnet, but instead involves only partial polarization of the magnetic moments coexisting with a disordered component, a situation reminiscent of the partially polarized QSL called the Coulomb Ferromagnetic phase.

TU.D.2_O3 - Anisotropy tuned magnetic order in pyrochlore iridates

E. Lefrançois [1,2], V. Simonet [2], R. Ballou [2], E. Lhotel [2], P. Lejay [2], P. Manuel [3], D. Khalyavin [3], L.C. Chapon [1]

1. Institut Laue-Langevin, Grenoble, France
2. Institut Néel, CNRS & Université, Grenoble, Framce
3. ISIS Facility, STFC, Rutherford Appleton Laboratory, Swindon, United Kingdom

Attention of the condensed matter community was recently attracted by the pyrochlore iridates $R_2Ir_2O_7$ (R = rare-earth ion) where magnetic frustration, strong spin-orbit coupling associated to the Ir4+ ions and magnetocrystalline anisotropy associated to the rare earth ions coexist and may lead to exotic magnetic phases and unprecedented electronic transport properties. These compounds exhibit a metal-insulator transition at the temperature corresponding to the onset of the Ir4+ magnetic ordering. The transition temperature and the high-temperature electronic state both depend on the rare-earth ion [Matsuhira et al., JPSJ 80 (2011) 094701]. We studied $Er_2Ir_2O_7$ and $Tb_2Ir_2O_7$ by means of magnetization measurement and neutron diffraction on polycrystalline samples. A bifurcation between the zero-field-cooled and field-cooled magnetic susceptibility was observed at respectively 140 K and 130 K, which is attributed to the Ir4+ magnetic moment ordering. The neutron diffraction patterns revealed magnetic Bragg peaks below 40 K in $Tb_2Ir_2O_7$. We show that these result from a freezing of the Tb3+ magnetic moments, induced by the Ir-Tb exchange, along their local 3-fold axis to form the so-called all-in/all-out magnetic configuration. On the other hand, no evidence of magnetic ordering was found in $Er_2Ir_2O_7$ down to 2K by neutron diffraction, though measurements on a magnetometer equipped with a dilution refrigerator show an extra thermomagnetic hysteresis suggesting a possible freezing below 0.6 K The contrasting behaviors between $Er_2Ir_2O_7$ and $Tb_2Ir_2O_7$ are explained as being inherent to the change of magnetocrystalline anisotropy between Er (easy-plane) and Tb (easy-axis), which respectively competes against or is consistent with the molecular field associated with the Iridium magnetism [arXiv: 1502.00787]. This in turn strongly supports an all-in/all-out magnetic order on the Ir pyrochlore sublattice, which was awaited as a signature of the topological nature of the low temperature insulating state [Wan et al., PRB 83 (2011) 205101].

TU.D.2_I4 - Quantum order-by-disorder and excitations of anisotropic Kagome antiferromagnets

S. Chernyshev [1], M. Zhitomirsky [2]

1. University of California, Irvine, United States
2. CEA, Grenoble, France

In our work we advance theoretical understanding of the quantum effects in kagome-lattice antiferromagnets and provide deep insight into the quantum order-by-disorder mechanism, important for the broad class of realistic frustrated spin systems. We challenge general expectation that quantum fluctuations simply follow thermal ones in selecting the ground state and present a rare example of the situation when quantum order-by-disorder effect defies this trend and yields the ground state that is different from one favored by thermal fluctuations. We also demonstrate that the order selection is generated by topologically non-trivial tunneling processes, making loops around elementary hexagons. We proposed phase diagram of the model and suggest further theoretical studies [1]. Further progress is made in understanding the spectral properties of realistic kagome-lattice antiferromagnets such as Fe-jarosite, for which we demonstrate a remarkable wipe-out effect for a significant portion of their spectrum. This phenomenon is related to the existence of the so-called 'flat mode',---a ubiquitous feature of the kagome-lattice and other highly-frustrated antiferromagnets,---and is due to decay process involving two of such modes.

TU.D.3_O1 - In-situ neutron investigation of hydrogen absorption kinetics in $La(Fe_xSi_{1-x})^{13}$ magnetocaloric alloys for room-temperature refrigeration application

X. Hai [1,2], C. Mayer [2], C.V. Colin [1], S. Miraglia [1]

1. Univ. Grenoble Alpes, Institut Néel, Grenoble, France
2. Erasteel SAS, Tour Maine Montparnasse, Paris, France

The $La(Fe_xSi_{1-x})^{13}$ system has attracted wide interest due to its large magnetocaloric effect and tunable transition temperature and nature. Hydrogen interstitials can adjust the temperature range near room-temperature. However, fully hydrogenated alloys are unstable upon heating. In order to get a precise knowledge of the hydrogen location and sequential filling of the interstitial sites, an in-situ high-flux neutron diffraction experiment is performed at Institut Laue Langevin. Moreover, carbon is added as a secondary interstitial element to investigate the site accommodation.

Two interstitial sites (48f and 24d) are considered for hydrogen or carbon accommodation. Refinements confirm that carbon and hydrogen are accommodated in the 24d octahedral site. Knowing that the volume of the interstitial site plays a major role in the stability, we have analyzed the variation of selected Fe-Fe distances of the Fe/Si icosahedral cluster in the course of interstitial insertion. This variation is related to that of the lattice parameter and reveals the one-to-one correspondence between lattice parameter and the Fe-Fe bond.
This time-resolved experiment makes it possible to analyze the absorption and desorption kinetics in the framework of the Avrami model. Results show slower hydrogen kinetics in carbon-containing compounds. It is proposed that there are distinctive diffusion paths for the interstitial atoms in the lattice. The pre-occupied interstitial carbon atoms distort the interstitial hole and this may lead to the blocking of the diffusion paths, depressing rate of the hydrogen absorption/release.

Within the desorption schemes, an asymptotic residual hydrogen concentration is observed for both cases regardless of the presence of carbon. Additional thermal activation is therefore necessary to achieve complete hydrogen desorption. Further investigation with substituted samples (by Ce and/or Mn) is planned to illustrate a substituting effect in the interstitial site space.

TU.D.3_O2 - Prototype energy harvesting device using high permeability amorphous ribbon

J. Samaniego [1], A. Mitra [2], C. Gómez-Polo [1]

1. Universidad Pública de Navarra, Pamplona, Spain
2. CSIR - National Metallurgical Laboratory, Jamshedpur, India

Energy harvesting on a miniature scale based on the utilisation of various properties of materials like piezoelectric, electromagnetic, electrostatic, thermoelectric etc. have generated considerable research interest over the years. In such devices the spent energies have been reused to develop miniature sized power generating system to replace the extensive use of the storage batteries.
Among the available energy harvesting systems, vibration based miniaturized generators have recently attracted a great deal of interest within both the academic community and industry, as a potential inexhaustible source for low-power devices [1,2] due to their better mechanical reliability and higher output signal . The present work is related to the development of a prototype vibration based energy harvesting device using high permeability Co-based amorphous ribbon and NdFeB permanent magnet. Two sets of coils having 1000 turns each were placed in mutually perpendicular direction for measuring the pick-up voltages generated due to the relative vibration of the permanent magnet. The dimension and resistance of each coil were 20mm x 7mm x 5mm and 70 Ohm respectively. Two sets of multiple poles NdFeB magnets separated by a distance were placed on a spring. The maximum flux density of the NdFeB magnet was 0.4T. Rapidly solidified high permeability $Co_{66}Si_{16}B_{12}Fe_4Mo_2$ ribbon was used to couple the flux from the permanent magnet to the coil. Four layers of the ribbon (30mmx5 mmx25µm) were used to couple the flux of the permanent magnet to the pick-up coils. The entire system was made to vibrate using linear vibrator. Maximum pick-up voltages were obtained at a vibrating frequency of 14.5 Hz with a full width at half maximum as 9 Hz.

TU.D.3_O3 - An in-situ computed tomography study of the magnetovolume transition in $LaFe_{11.8}Si_{1.2}$

A. Waske [1], A. Funk [1,2], A. Rack [3], J. Eckert [1,2]

1. Institute for Complex Materials, Dresden, Germany
2. Institute for Materials Science, Dresden, Germany
3. ID - 19, ESRF, Grenoble, France

First-order transitions in magnetocaloric materials are the source of strong changes in their magnetization and entropy, giving rise to large magnetocaloric effects. These kind of transitions show interesting phenomena, like phase coexistence and thermal arrest. The way each phase nucleates from the other phase is largely unknown at a microscopic level, besides this being important not only from a fundamental point of view, but also for technical aspects like choosing the geometry of the sample or identifying an upper limit for the cycling frequency.

In $La(Fe,Si)^{13}$, an isostructural first-order transition occurs at the critical temperature TC, which retains the structural symmetry of the crystal but leads to an abrupt increase in the lattice parameter. We apply low-temperature in-situ computed tomography on magnetocaloric $La(Fe,Si)^{13}$ to study the magnetovolume transition as a function of temperature. The in-situ experiments have been carried out at the beamline ID 19 at the ESRF in Grenoble (France). A stream of cold nitrogen gas was used to drive the magnetocaloric material through the phase transition upon cooling. Using this method, we show how the transition proceeds through a small sample of $LaFe_{11.8}Si_{1.2}$ upon cooling by tracking the subvolumes that turn at each temperature step around the critical temperature TC. We observe that the regions which perform the magnetovolume transition first are determined by the surface morphology, and that there are big differences in the evolution of the phase transition for flat and rough sample regions. These findings connect microstructural aspects of the first-order transition to important properties like hysteresis and kinetics of the phase transition and can therefore help to tailor magnetocaloric materials towards application.

TU.D.3_O4 - Element resolved thermodynamics of magnetocaloric LaFe_13−x Si_x

Ferroic materials allow for a significant adiabatic temperature change induced by realistic electrical and magnetic fields, under pressure and external stress [1]. This approves their use in solid state refrigeration concepts, which offer an energy efficient alternative to the classical gas-compressor scheme. A good cooling material is characterized by a large isothermal entropy change $|\Delta S_{iso}|$, which determines the latent heat to be taken up during a first-order transformation in conjunction with a high adiabatic temperature change $|\Delta T_{ad}|$, which controls the operating range. Apart from the prototype Gd-based systems, a large number of suitable materials have evolved, which undergo a magnetic first-order transition and perform well with respect to both quantities, and $LaFe_{13-x}Si_x$-based compounds are found among the best [2, 3]. They consist of largely abundant components and are significantly less expensive than Gd- or Rh-based alloys. By combination of two independent approaches, nuclear resonant inelastic x-ray scattering (NRIXS) and first principles calculations in the framework of density functional theory, we demonstrate significant changes in the element-resolved vibrational density of states across the first-order transition from the ferromagnetic low temperature to the paramagnetic high temperature phase of $LaFe_{13-x}Si_x$ [4]. These changes originate from the itinerant electron metamagnetism associated with Fe and lead to a pronounced magneto-elastic softening despite the large volume decrease at the transition. The increase in lattice entropy associated with the Fe subsystem is significant and contributes cooperatively with the magnetic and electronic entropy changes to the excellent magneto- and barocaloric properties.

We recently reported giant tunability of ferroelectric polarization (ΔP=5000 $\mu C/m^2$) in the multiferroic $GdMn_2O_5$ with external magnetic fields[1]. The zero field magnetic model determined from x-ray magnetic scattering indicates that the Gd-Mn symmetric exchange striction plays a major role in the tunable ferroelectricity of $GdMn_2O_5$, differently from other members of the same family. The Gd spins plays a key role in the giant magnetoelectric coupling in $GdMn_2O_5$. Magnetic field polarization measurements evidenced a very strong polarization dependence showing a sign reversal upon switching or increasing (H>6T) magnetic field. Here we present the magnetic phase diagram as determined from recently performed neutron diffraction experiments on an isotopically pure sample. This investigation is crucial to our understanding of the giant polarization reversal observed in this sample [2].

TU.E.1_O2 - Magnetic structure of LuFe2O4 studied by soft x-ray magnetic circular dichroism

S. Lafuerza [1], J. García [2], G. Subías [2], J. Blasco [2], J. Herrero-Martín [3]

1. European Synchrotron Radiation Facility (ESRF), Grenoble, France
2. Instituto de Ciencia de Materiales de Aragón (ICMA), Zaragoza, Spain
3. ALBA Synchrotron, Barcelona, Spain

The mixed-valence oxide $LuFe_2O_4$ is among the most studied multiferroic candidates since a new type of ferroelectricity based on charge ordering (CO) of Fe^{+2} and Fe^{+3} was postulated below $T_{CO} \approx 320$ K [1]. $LuFe_2O_4$ shows ferrimagnetic ordering with $T_N \approx 240$ K and therefore both the electric and magnetic orderings would interestingly occur at high transition temperatures. Regrettably, the ferroelectric character of $LuFe_2O_4$ has been discarded in the light of new electric properties measurements [2]. This finding has been further supported by results of x-ray absorption spectroscopy [3], resonant x-ray scattering and high resolution powder diffraction [4] that agree with the presence of multimodal Fe valence distributions $Fe^{+2.5\pm\delta}$ below T_{CO} and T_N in which the maximum charge disproportionation is such that $\delta \approx 0.25$ electrons, far from the pure ionic CO model.
In the view of these results, the generally accepted ferrimagnetic ordering for $LuFe_2O_4$ in terms of Fe^{+2}/Fe^{+3} ionic species needs to be revisited. We have performed x-ray magnetic circular dichroism (XMCD) measurements at the Fe $L_{2,3}$-edges in polycrystalline and single crystal samples of $LuFe_2O_4$. These measurements were carried out at BL29-BOREAS beamline of ALBA synchrotron (Spain) by using both total electron yield and fluorescence yield for the x-ray absorption spectra detection. The XMCD signal magnitude reproduces the strong anisotropy found in the macroscopic magnetization between the *c*-axis and the *ab*-plane of the hexagonal structure. Regarding the spectral features, two contributions with opposite sign are obtained in agreement with an antiferromagnetic coupling between two sublattices. Our experimental results along with multiplet theory calculations lead us to propose an alternative ferrimagnetic model for $LuFe_2O_4$. In our spin-ordering model the moments of $Fe^{+2.2}$ and $Fe^{+2.5}$ are aligned parallel (↑) to the applied magnetic field while the $Fe^{+2.8}$ moments are antiparallel (↓) as opposed to the initially established model Fe^{2+} (↑) + 1/3Fe^{3+} (↑) + 2/3Fe^{3+} (↓).

TU.E.1_O3 - Multiferroic perovskite $RMnO_3$ crystalline films studied by resonant soft and hard X-ray diffraction

W. Windsor [1], L. Rettig [1], A. Alberca [1], M. Ramakrishnan [1], K. Shimamoto [2], S. Huang [1], Y. Hu [2], V. Scagnoli [1], T. Lippert [2], C. Schneider [2], U. Staub [1]

$RMnO_3$ perovskites with heavier R ions (R = Ho, Tm, Yb, Lu) are type-II multiferroics known to acquire significantly large electric polarizations when magnetic order sets in (~10 times larger than in $TbMnO_3$ [1]). These prototypical multiferroics are of great theoretical interest due to the ambiguity surrounding the mechanisms driving the multiferroic behavior [2,3]. Unfortunately the absence of high quality crystals of the heavy-R species has limited experimental work. Here we present a synchrotron X-ray diffraction study of high-quality single-crystalline o-$RMnO_3$ films with R=Ho, Tm, Yb and Lu. We will show that the magnetic order and the ferroelectric structural distortion appear concomitantly, and are directly controlled by epitaxial strain [4].

For this we directly probed the Mn magnetic structure with resonant magnetic diffraction at the Mn L-edges, and we probed the ferroelectric behavior through the appearance of symmetry-forbidden charge reflections. These are directly sensitive to the lowering of crystal symmetry at the multiferroic transition due to the ferroelectric structural distortion, and allow estimating how much the atoms actually move within the unit cell. We will also show that epitaxial films differ from bulk, as their magnetic structure is incommensurate, and not a “pure” E-type. A model for the magnetic order induced by the Mn on the R ion will also be discussed.

5. University of Illinois, Illinois, United States
6. Boise State University, Idaho, United States

In this talk, we discuss our recent measurements on the hexagonal $LuFeO_3$ multiferroic in thin film and bulk forms.
While the ferroelectric order sets in at ~1000 K, magnetic order occurs at a far lower temperature.
We present results for MBE grown films on YSZ and Al_2O_3 substrates of thicknesses ranging from 22-250 nm in thickness.
In all cases the antiferromagnetic transition temperature is < 160 K. We also present our data on doping stabilized bulk $LuFeO_3$ in which we determine how the crystallographic structure influences the magnetic structure.
We also present the results of inelastic measurements in which we determine the basic exchange parameters for this compound.

TU.E.1_O5 - A high-pressure misfit-related polymorph of $LuFe_2O_4$ with room temperature antiferromagnetic order

F. Damay [1], M. Poienar [2], M. Hervieu [3], A. Guesdon [3], J. Bourgeois [1,3], T. Hansen [4], E. Elkaïm [5], J. Haines [2], P. Hermet [2], L. Konczewicz [2], T. Hammouda [6], J. Rouquette [2], C. Martín [3]

6. Laboratoire Magmas & Volcans, Clermont-Ferrand, France

Branded for its potential electronic ferroelectricity [1], [2], charge-ordered $LuFe_2O_4$ [3] has a layered Fe triangular framework, whose topology is source of degeneracy, both at the charge and spin levels. A high-pressure form of this material, $LuFe_2O_4$-*hp*, metastable at ambient pressure and temperature, was recently identified [4], but a comprehensive structural investigation of this compound was impaired by complex twinning mechanisms and modulation phenomena, the latter possibly related to charge ordering.
In this work, new samples of the high-pressure form of $LuFe_2O_4$ have been synthesised and thoroughly characterized by synchrotron X-ray, electron and neutron diffraction, combined with density functional theory (DFT) calculations and transport measurements. Although the pseudo-triangular lattice of the Lu layer is preserved in $LuFe_2O_4$-*hp*, the structure of the more deformable Fe bilayer changes to rectangular. $LuFe_2O_4$-*hp* is thus characterized by an original *misfit*-like monoclinic structure, accommodating a buckled triangular $[Lu]_\infty$ layer and two shifted adjacent rectangular $[Fe]_\infty$ planes belonging to a distorted rock salt-type layer. The release of the geometric frustration of the Fe magnetic lattice in the *hp* form leads to collinear antiferromagnetic ordering at T_N = 380 K, the room-temperature magnetic ground state of $LuFe_2O_4$-*hp* bearing close resemblance to that of NaCl-type monoxide FeO [5]. A stable stripe-like CO configuration is derived from DFT calculations of $LuFe_2O_4$-*hp*, though transport measurements are not conclusive as to whether, and in which temperature range, $LuFe_2O_4$-*hp* could be charge-ordered. The room-temperature coexistence of charge and magnetic orders in this material remains therefore an open issue.

4. Lawrence Berkely National Laboratory, Berkeley, United States

We present a study on the ultrafast spin dynamics in multiferroic $TbMnO_3$, the model spin-cycloid multiferroic where the ferroelectric polarization arises directly from the frustrated magnetic order. We discuss the magnetic and structural response of multiferroic $TbMnO_3$ to short cycle Thz pulses and to excitations with 800 nm electromagnetic radiation. In the first case, we show that this excitation resonantly drives an electromagnon, which is studied by ultrafast resonant x-ray diffraction. [1] We can quantitatively determine its spin motion in real time and estimate the E-field strength required for switching the polarization. In the second case we excite mainly d-d intersite transitions of Mn, which leads to a suppression of magnetic order within 5-20 ps after excitation. This is unexpectedly slow compared to other multiferroics such as CuO. [2] This slow decay is attributed to a non-thermal melting of magnetic order, indicating that the excited electronic system transfers energy slowly to heat the spin system. Whether this energy is mediated by the lattice due to the creation of a small polaron or simple lattice heating could be addressed in the future by probing other diffraction peaks sensitive to lattice and charge order. The lack of any significant change in the scattering wavevector indicates that despite ultrafast pump, the extremely low magnon group velocity prohibits fast changes in the spin-spiral length.

TU.E.2_O1 - Giant Magnetoelectric effect in FeCo and FeCo/Ag films on (011) oriented PIN-PMN-PT

M. Staruch [1], P. Finkel [1]

1. Naval Research Laboratory, Washigton, United States

To engineer large magnetoelectric coupling in composites, it is necessary to optimize the properties of both the magnetic and ferroelectric components. There has recently been much interest in single crystals of relaxor ferroelectric Pb(In1/2Nb1/2)O3-Pb(Mg1/3Nb2/3)O3-PbTiO3 (PIN-PMN-PT) due to high piezoelectric coefficient with larger linear range and temperature stability than binary relaxors, which could provide for large tunability of the magnetization. In this work, thin films of FeCo and FeCo/Ag multilayers were deposited on (011) PIN-PMN-PT crystals. The coercive field was significantly decreased in the multilayer film, which also showed a larger piezomagnetic coefficient at a lower magnetic field as compared to FeCo. Angular dependence measurements of the magnetization show an in-plane easy axis that is rotated with an electric field applied to the PIN-PMN-PT crystal. Giant converse magnetoelectric coupling up to 2 x 10-6 s m-1 were observed in heterostructural composites with both FeCo and FeCo/Ag.

This work was funded by the Office of Naval Research (ONR) through the Naval Research Laboratory Basic Research Program.

TU.E.2_O2 - $Mn_{1-x}Co_xWO_4$: x = 0.135 and x = 0.15: a study of the multiferroic state under high pressure

M. Gooch [1], N. Poudel [1], B. Lorenz [1], K.C. Liang [1], Y.Q. Wang [1], Y.Y. Sun [1], J. Wang [2], J. Fernández-Baca [2], F. Ye [2], C.W. Chu [1,3]

1. Texas Center for Superconductivity at The University of Houston, Houston, United States

3. Lawrence Berkeley National Lab, Berkeley, United States

It is well understood that multiferroic materials are sensitive to small perturbations induced through chemical substation, magnetic and electric fields, or external pressure. One such system is $Mn_{1-x}Co_xWO_4$, which has an interesting and complex phase diagrams where two multiferroic phase coexist at x = 0.15. At this boundary on the phase diagram the conical spin extends to lower temperature, in addition to the a-c spiral spin structure forming below 7 K. On either side of the boundary we have a spiral spic structure for $x < 0.15$ and a conical spin for $x > 0.15$. To gain further insight into this system, high pressure measurements were conducted up to 18 kbars. Beginning with x = 0.135, only an a-axis polarization is observed at ambient pressure, which is consistent with the a-c spiral by symmetry. However, with increasing pressure a b-axis component of the polarization is observed and the a-axis component is decreasing. At the highest pressure measured, no a-axis polarization is observed and the polarization of the b-axis is comparable to the ambient data for x = 0.17. High pressure polarization measurements for the x = 0.15 are consistent with the previously mentioned measurements, where with pressure an increase in the polarization is observed. The effect of external pressure on the $Mn_{1-x}Co_xWO_4$ system can be described as similar to Co doping. Suggesting we have a polarization flop, where the a-c spiral is stabilized into the conical spin leading to the increased polarization that is observed.

TU.E.2_O3 - Magon-phonon interactions in hexagonal multiferroic $YMnO_3$

A. Kreisel [1], S. Mukherjee [1], B.M. Andersen [1], T. Schäffer [1], S. Holm [1], K. Lefmann [1], N.C.R. Momsen [1], J. Larsen [2], A. Fennell [3], U. Stuhr [3], Z. Yamani [4]

2. Institute of Physics, Technical University of Denmark, Lyngby, Denmark
3. Laboratory of Neutron Scattering, Paul Scherrer Institute, Villigen, Switzerland
4. Chalk River National Laboratory, Ontario, Canada

The multiferroic material $YMnO_3$ is known to show a large spin lattice coupling such that the spin and lattice degrees of freedom influence various properties, as for example the thermal conductivity that is found to have an anomalous contribution. The magnetoelastic modes have been measured recently in neutron diffraction experiments and linked to certain spectral features in Raman signals. Starting from a Heisenberg model on a triangular lattice with single ion anisotropies, we investigate the spin-phonon coupling via the magnetostriction mechanism and derive a coupled magnon-phonon model valid in the entire Brillouin zone. Within a spin-wave approach, where the coupling yields a hybrid magnon-phonon mode, we calculate the dynamic structure factor and compare to recent experimental neutron results.

TU.E.2_O4 - Field-induced phase transitions and magnetoferroelectricity in the perfect triangular lattice antiferromagnet $RbFe(MoO_4)_2$ in a vertical magnetic field

H. Mitamura [1], R. Watanuki [2], N. Onozaki [2], Y. Amou [2], Y. Kono [1], S. Kittaka [1], Y. Shimura [1], I. Yamamoto [2], K. Suzuki [2], T. Sakakibara [1]

2. Faculty of Engineering, Yokohama National University, Yokohama, United States

The perfect triangular-lattice antiferromagnet $RbFe(MoO_4)_2$ (RFMO), in which Fe3+ carries spin 5/2, orders at TN=3.9 K in a planar spin structure characterized by the ordering vector q=(1/3,1/3,0.458), an in-plane 120-degree rotation with helicity along the c axis [1]. Interestingly, RFMO exhibits ferroelectricity below TN [1], and its origin has recently been identified to be due solely to the in-plane triangular-spin chirality [2]. Indeed, the obtained phase diagram for the electric polarization (P // c) with B // c plane [2] agrees well with the one theoretically predicted for the spin chirality of a Heisenberg spin triangular lattice antiferromagnet [3]. However, not much has been known for the field evolution of chirality with B // c axis [4].

We performed P(B), dielectric constant and magnetization (M) measurements on RFMO in high magnetic fields applied along the c axis. Whereas M(B) at T=1.5 K monotonically increases with B up to the saturation at B=21 T, P(B) disappears about 14 T, far below the saturation point. In a field range 13≤B≤14 T, the temperature variation of the dielectric constant shows double peaks below 2.8 K, indicating two successive transitions. These results strongly suggest the presence of a new high-field phase; the magnetic structure changes from a low-field conical state having chirality to a high-field coplanar non-collinear structure without chirality. The obtained phase diagram is in agreement with a theoretical prediction on hexagonal XY-like Heisenberg antiferromagnets [5].

Modern society has a critical demand for materials with multifunctional physical properties. They have become an integrating part of many applications, especially those that display a strong coupling between magnetic and polar degrees of freedom, the so-called magnetoelectrics. These materials, promise a paradigm-shift on technologies for magnetic data storage, high-frequency magnetic devices, spintronics, and micro-electromechanical systems. The clear determination of the complex interplay between electronic, magnetic, and lattice degrees of freedom usually is the solution to explain the mechanisms behind the exhibited physical properties. Among the numerous materials with an intimate coupling between all the degrees of freedom are the group of ACr2X4 spinels(A=Zn,Cd,Hg;X=O,S,Se). The tight alliance between structural, vibrational, magnetic, and charge degrees of freedom, makes the variation of lattice by external pressure an appealing route for studying the physical properties of these materials. Measuring the pressure dependence of the magnetic transition temperature may assist in getting new insights about the ordering mechanism and its relationship to the electronic structure (e.g. disordered local moments coupled with frustration mechanisms). In fact, external pressures are known to control bond lengths and bond angles as well as the degree of overlap between electron orbitals in solids. A shift and/or split of the energy levels and changes in exchange interactions strength in response to pressure variations can also occur. External press. when compared to the chemical press., is a cleaner tool to avoid substitutional induced disorder and spurious effects due to different chemical compositions. Several studies reported structural and electronic transitions under pressure for various Cr-based spinels. Nevertheless, studies on the relaxor-like temperature zone are not yet reported. Our results of dc magnetisation measurements under hydrostatic pressure for the $CdCr_2S_4$ spinel compound will be presented. The measurements have been performed on a polycrystalline sample under different applied hydrostatic pressures (up to 14 kbar) in the 30-220K temperature range (with 3Oe applied magnetic field). The anomalous behaviour of the magnetic susceptibility indicates that the local-cluster- phase that exists at low applied magnetic fields persists with applied pressures up to 14kbar and has a dependency on the applied pressure.

TU.E.2_O6 - Dual ferroic properties of hexagonal ferrite ceramics $BaFe_{12}O_{19}$ and $SrFe_{12}O_{19}$

L. Panina [1], V. Kostishyn [1], L. Kozhitov [1], A. Timofeev [1], A. Zyuzin [2]

1. National University of Science And Technology MISIS, Moscow, Russia
2. Science and Technology Institute of Interbranch Information, Moscow, Russia

Coexistence of ferromagnetism and large ferroelectricity has been observed in hexaferrites $BaFe_{12}O_{19}$ and $SrFe_{12}O_{19}$ prepared by a standard ceramic technique from high-purity raw materials. The addition of boron oxide at the stage of wet milling makes it possible not only to restrict the grain size (with the average value of 300-400 nm) but also to increase the bulk resistivity. The latter is of primary importance to realise ferroelectric properties. The prepared polycrystalline samples had a single hexagonal phase, which was confirmed by X-ray diffraction patterns. The magnetic hysteresis is consistent with hard magnetic behaviour having the remanence induction of 3700 G and coercivity of 2 kOe. Large spontaneous polarisation in the range of 25-30 ƒÝC/cm2 and coercivity of 100-200 kV/m were observed by measuring the electric hysteresis loops. A strong coupling between magnetic and electric ordering was confirmed by measuring the magnetoelectric parameter, magnetodielectric ratio and magnetic hysteresis in the presence of electric field. The obtained results are compared with the available data on multiferroic properties of widely studied $BiFeO_3$ films [1]. The magnetic properties of hexaferites are much greater and the magnetoelectric coupling is stronger. On the other hand, the observed multiferoic properties are similar to those reported for corresponding hexaferrites sintered by polymer precursor technique [2]. This suggest great application potential of M-type hexaferrites in devices utilising magnetoelectric coupling.

The field of magnonics addresses the transfer and processing of information by spin waves and their quanta, magnons. Magnons are bosons and, thus, they can condense into a macroscopic quantum state. Condensates of magnons relate to Bose-Einstein condensates (BEC), and they spontaneously form a spatially extended, coherent ground state, which can be established independently of the magnon excitation mechanism even at room temperature. It is expected that magnon condensates can move in a form of a supercurrent, which represents a novel type of macroscopic quantum transport phenomenon analogous to the low-temperature effects of superconductivity and superfluidity. Magnon supercurrents constitute the transport of angular momentum, which is driven by a phase gradient in the magnon-condensate wave function. In this presentation, first experimental evidence of a magnonic supercurrent will be presented and its further implications will be discussed. The magnon supercurrent is created in a magnon BEC subject to a thermal gradient which imposes the phase gradient.

TU.E.3_O2 - Controlling the magnetic properties of spinel ferrite nanoparticles by chemical tuning

C. Sangregorio [1], M. Albino [2], V. Bonanni [2], G. Campo [2], P. Ghigna [3], J.M. Greneche [4], D. Peddis[5], F. Pineider [2], N. Yaacob [4], C. de Julián Fernández [6]

6. CNR-IMEM & INSTM, Parma, Italy

Magnetic nanoparticles, MNP, are expected to have a tremendous impact on several technological fields, ranging from electronics, to spintronics and clinical applications, one of the most prominent reasons being the possibility of fine tuning their physical properties to match the required optimal values. The feasibility of such a control requires the exact knowledge of the effect of size, morphology, structure and chemical composition on the magnetic properties of the final product. However, much information is still missing, mostly because of the difficulty in controlling independently each of the above parameters. However, the recent development of improved wet-chemistry syntheses, allowing for a tighter control on the MNP's features, has boosted a renewed interest in the field. In this contribution we present an in-depth investigation of the magnetic properties of a family of doped ferrite MNPs of formula $Co_xNi_{1-x}Fe_2O_4$ whose magnetic anisotropy was systematically varied by controlling the relative amount of divalent ions ($0 \leq x \leq 1$). TEM and XRD analysis showed that all samples comprise highly crystalline, monodisperse, spherical particles with average size of 6 nm. Temperature- and field-dependent magnetic measurements displayed a strong dependence of the magnetic properties on the chemical composition; indeed, upon rising, x a high increase of both magnetic anisotropy and magnetization saturation is observed. Magneto-optical spectra, XMCD at Fe, Co and Ni L-edges and high-field temperature variable Mossbauer spectra allowed to explain the observed behavior, not only in terms of the intrinsic magneto-crystalline anisotropy of the cationic species involved, but also concerning their distribution between Td and Oh cavities in the spinel structure. In addition, a spin canted structure which becomes less prominent with increasing the Ni content was evidenced. Altogether these results underline the large tunability of the physical properties of this appealing class of nanomaterials. Research funded by project MAGNANO (INSTM-Regione Lombardia).

TU.E.3_O3 - Ledge-type Co/$L1_0$-FePt exchange-coupled composites

T. Speliotis [1], G. Giannopoulos [1], D. Niarchos [1], W. Li [2], G. Hadjipanayis [2], G. Barucca [3], E. Agostinelli [4], D. Fiorani [4], S. Laureti [4], D. Peddis [4], A.M. Testa [4], G. Varvaro [4]

3. SIMAU, Università Politecnica delle Marche, Ancona, Italy
4. Istituto Di Struttura Della Materia - CNR, Monterotondo Scalo, Roma, Italy

FePt-based exchange-coupled composite (ECC) systems, consisting of a magnetically hard $L1_0$-FePt phase exchange coupled to a softer ferromagnetic material (such as Fe, Co, FeCo, [Co/Pd(Pt)]n) are one of the most promising candidates for future ultra-high density (> 1 Tbit/in2) perpendicular magnetic recording media. Tuning both intrinsic and extrinsic properties of the two components allows simultaneously achieving high thermal stability and low switching fields [1,2]. The phase boundary between the two materials can be sharp or graded, and the cross-sectional shape of the magnetic phases is identical in conventional ECC, while in the ledge-type ECCs the soft section is more extended covering adjacent and discrete hard elements [3]. In this communication, the effect of the thickness of a soft Co layer, 3 < th(Co) < 20 nm, on the magnetic behavior of ledge-type $Co\text{-}fcc(100)/L1_0\text{-}FePt(001)$ nanocomposites deposited on an MgO (100) substrate is systematically studied by combining morpho-structural analyses (XRD, SAED, HRTEM) and angular magnetic measurements (vector VSM). Starting from a FePt film consisting of isolated $L1_0$-FePt(001) islands, the ledge-type structure was obtained by depositing a Co layer that either covered the FePt islands or filled up the inter-island region, gradually forming a continuous layer with the increase of th(Co). Magnetic measurements revealed a significant reduction of the switching field, which is well below the writing field of currently available write heads for th(Co) > 5 nm, the system still maintaining a perpendicular anisotropy up to th(Co) < 9.5 nm. Recoil loops measurements confirmed the exchange-coupled behavior, corroborating the potential interest for future magnetic recording media.

Electronic correlations give rise to a plethora of interesting phenomena and phases. For example, hybridization between 4f and conduction electrons in heavy fermion metals may result in the generation of low-energy scales that can induce quantum criticality and unconventional superconductivity. One of the most important techniques that helped shaping our understanding of nonlocal correlations, both magnetic and superconducting, has been scanning tunneling spectroscopy (STS) with its unique ability to give local, microscopic information that directly relates to the one-particle Green's function. We combine STS with bulk measurements (specifically magnetotransport, thermopower and x-ray diffraction) to obtain complementary information on different length scales. We studied the temperature evolution of hybridization effects and Kondo lattice coherence as observed by STS, focusing on the model heavy fermion metal $YbRh_2Si_2$ and the intermediate-valence insulator SmB_6. Our STM and STS studies on high-quality single crystals of $Yb(Rh_{1-x}Mx)2Si_2$ (M = Co, Ir) focus on the evolution of the signatures of the development of Kondo lattice coherence upon lowering the temperature. We also show how Kondo coherence connects with quantum criticality. These results by STS are compared to magnetotransport and thermodynamic measurements, as well as to findings on other heavy fermion materials. Low-temperature in-situ cleaving of SmB6 single crystals mostly resulted in reconstructed surfaces, while non-reconstructed patches were found less frequently. The different surface terminations give rise to marked differences in the STS results. Moreover, small non-reconstructed areas exhibit a diminished conductance at zero bias whereas larger ones can be described by a Fano resonance, confirming the hybridization picture typically considered for this material. All types of surfaces, reconstructed and non-reconstructed, displayed a finite zero-bias conductance of considerable magnitude confirming the robustness of the metallic surface states. Results obtained by STS on other strongly correlated materials are also discussed.

TU.F.1_O2 - Fermi surface instabilities in $CeRh_2Si_2$ at high magnetic field and pressure

A. Pourret [1,2], A. Palacio-Morales [1,2], G. Knebel [1,2], D. Braithwaite [1,2], G. Seyfarth [3], M. Suzuki [4], D. Aoki [1,2,5], J. Flouquet [1,2]

The interplay between spin fluctuations, valence fluctuations and charge ordering with Fermi surface (FS) instabilities is a key point in the understanding of quantum criticality in itinerant electronic systems. Heavy fermion materials are important examples as their low renormalized characteristic temperature give the opportunity to switch for example from long range antiferromagnetic (AF) to paramagnetic (PM) ground states under moderated pressure of few GPa and to recover, by applying magnetic field, a polarized paramagnetic state (PPM) above the AF-PM transition at Hc. We present thermoelectric power (TEP) studies under pressure and high magnetic fields in the antiferromagnetic heavy fermion compound CeRh2Si2 at low temperature. Under magnetic field, the observation of large quantum oscillations in the TEP, S(H), in the AF phase and the sudden disappearance of these oscillations when entering in the polarized paramagnetic state at Hc state points out an important reconstruction of the FS. Under pressure, the strong increase of S/T at low temperature near the critical pressure Pc, corresponding to the collapse of the AF order, implies the interplay of FS change and low energy excitations driven by spin and valence fluctuations. The difference between TEP signal in the PPM state above Hc and in the paramagnetic state above Pc can be explained by different FS. New band structure calculations at P = 0 stress that in the AF phase the 4f contribution at the Fermi level (EF) is weak while it is the main component in the PM domain. By analogy to previous work on $CeRu_2Si_2$, in the PPM phase of $CeRh_2Si_2$ the 4f contribution at EF will drop.

TU.F.1_O3 - ARPES study of $CeRh_2Si_2$: Paradigmatic 4f spectral response in an enigmatic Kondo lattice

D. Vyalikh [1], C. Geibel [2]

1. Institute of Solid State Physics, Dresden University of Technology, Dresden, Germany
2. Max Planck Institute for Chemical Physics of Solids, Saarbrücken, Germany

CeRh2Si2 is an intensively studied antiferromagnetic Kondo lattice system, which presents a striking duality in the properties of the 4f electrons: The large 4f entropy of Rln2 just above TN = 35 K and the large value of the ordered moment mAF = 1.4 muB points to a fully localized 4f electron, while other properties, e.g. the width of the quasielastic line in inelastic neutron scattering, indicate a Kondo scale of about 33 K implying a strong 4f hybridization. The way how to reconcile these conflicting observations is yet not clear. Here we present an angle resolved photoemission study of this compound. Thanks to the nice cleavability of our single crystals and our knowledge on the surface state in homologues $RERh_2Si_2$ compounds (RE = Yb, Eu, Gd), we were able to discriminate between different surface terminations and to obtain distinct and highly resolved ARPES spectra for both the Si-terminated and the Ce-terminated surfaces. The former ones are representative for strongly correlated 4f states as present in bulk $CeRh_2Si_2$, the latter ones are representative for weakly hybridized Ce as expected at the surface. The differences in these spectra reflect the differing in the f- hybridization strengths: The pronounced 4f0 peak in the 4f spectral function of the Ce terminated surface gets suppressed in the signal of the Si-terminated surface due to stronger f-d hybridization. In contrast, for the latter we observe a fine structure near the Fermi edge which reflects the crystal electric field splitting of the ''magnetic'' 4f1 configuration, a signature which is absent for the weakly hybridized surface Ce. Analyzing this ‘bulk’ 4f1 signal along with recent specific heat data provides direct evidence why the simple picture for Kondo lattices cannot account for the exceptional dual nature of the 4f electrons in $CeRh_2Si_2$.

TU.F.1_O4 - Large fermi-surface antiferromagnetism in the Kondo lattice model

R. Peters [1], N. Kawakami [2]

1. Riken, Wako, Japan
2. Kyoto University, Kyoto, Japan

Using large-scale inhomogeneous dynamical mean field theory, we theoretically study the antiferromagnetic phase of the Kondo lattice model on a square lattice away from half filling. In previous works, authors have focused on the Neel state, which is the energetically stable state exactly at half filling. However, doping the system, the perfect Neel state is not commensurate with the Fermi momentum. In this situation, the system can gain energy by forming a long-range spin density wave (SDW), where the amplitude of the local polarization spatially oscillates. In this talk, we will analyze the properties of these SDWs. We will study static as well as dynamical correlations. We find that the transition between the SDW phase and the paramagnetic phase changes its character depending on the coupling strength. While for strong coupling, we observe the expected continuous transition between the SDW state and the paramagnetic state, the transition seems to be of first order for weak coupling strengths. Analyzing dynamical correlation functions, we observe a Lifshitz transition within the antiferromagnetic phase. However, looking at the Fermi surface and spin-spin-correlation functions, we conclude that the volume of the Fermi surface behaves smoothly within the SDW phase as well as across the phase boundary between the SDW phase and the paramagnetic phase. The SDW phase in the Kondo lattice model away from half filling is metallic with the local moments participating in the Fermi surface.

TU.F.1_O5 - Experimental Investigation on Magnetism and Pressure induced Superconductivity in $CeCu_2Si_2$, $CeCu_2Ge_2$, and $CeAu_2Si_2$

G. Werner Scheerer [1], G. Giriat [1], Z. Ren [1], G. Lapertot [2], D. Jaccard [1]

1. DPMC - University of Geneva, Geneva, Switzerland
2. SPSMS, CEA-INAC/UJF, Grenoble, France

We present studies on Ce-based heavy-fermion single crystals, via resistivity, ac-susceptibility, ac-specific heat, and thermopower techniques in pressurized environment (up to 20 GPa) and under magnetic field (up to 8.5 T, 15 T at zero pressure).
In $CeCu_2Si_2$, the superconducting-transition temperature T_{SC} rises strongly, between the low-pressure region (~ 2 GPa) where T_{SC} is almost constant and the pressure p_V ~ 4.5 GPa where T_{SC} is maximum [1]. In this intermediate pressure range, the width of the SC-transition is found to be strongly sample-dependent, which is presumably due to surface quality (cleaved/polished). Here, a high T_{SC}^{onset} is due to partial or surface superconductivity, as shown by resistivity measured with nonlinear contacts.
Recently, we discovered pressure-induced SC deep inside the AF-phase of $CeAu_2Si_2$ (p_c ~ 22.5 GPa), where SC sets in at 11.8 GPa, which corresponds to p_c - 11 GPa [2]. Likewise, it is known that in $CeCu_2Ge_2$ superconductivity sets in at p_c ~ 10 GPa [3]. One can imagine that under specific conditions SC will be established at zero pressure in $CeCu_2Ge_2$. Therefore, we did zero-pressure measurements on $CeCu_2Ge_2$ in magnetic fields. T_N is found to be field-resistant at least up to 15 T. In the range 8 - 12 T, several crossover-like anomalies were observed, indicating successive field-induced modifications of the AF-structure.
High-pressure measurements on $CeAu_2Si_2$ were carried out to refine its phase diagram. We observe an interplay between a pressure-induced, progressive change of the magnetic structure and the establishment of partial superconductivity deep inside the AF-phase. Furthermore, an unusual behavior of the magnetism is revealed: while T_N decreases with increasing pressure, the magnetic phase becomes much more stable in magnetic field. For p = 0, AF is suppressed by $\mu_0 H$ = 5T, but for pressures above 7 GPa, AF survives beyond 8 T.

TU.F.3_O1 - Chirality density wave of the "hidden order" phase in URu_2Si_2

G. Blumberg [1], K. Haule [1], H. Kung [1], John Mydosh [2], R. Baumbach [3], E. Bauer [3]

1. Rutgers University, Piscataway, United States
2. Kamerlingh Onnes Laboratory, Leiden University, Leiden, The Netherlands
3. Los Alamos National Laboratory, Los Alamos, New Mexico, Untied States

A second-order phase transition in a physical system is associated with the emergence of an -order parameter and a spontaneous symmetry breaking. The heavy fermion superconductor URu_2Si_2 has a "hidden order" (HO) phase below the temperature of 17.5 K; the symmetry of the associated order parameter has remained ambiguous. Here we use polarization resolved Raman spectroscopy to specify the symmetry of the low energy excitations above and below the HO transition. We determine that the HO parameter breaks local vertical and diagonal reflection symmetries at the uranium sites, resulting in crystal field states with distinct chiral properties, which order to a commensurate chirality density wave ground state. TU.F.3_O2 - Cubic hastatic order

R. Flint [1]

1. Iowa State University, Ames, United States

Typical Kondo systems are built from ions with an odd number of f-electrons, which allow the hybridization between the local moments and conduction electrons to be treated as a scalar and leads to the development of a non-symmetry breaking heavy Fermi liquid ground state via a crossover. However, if the local moment ground state is instead a non-Kramers doublet (requiring an even number of f-electrons), the hybridization mixing the Kramers conduction electrons and non-Kramers local moment must be spinorial in nature, and the resulting heavy Fermi liquid must also break some symmetry and therefore develop at a phase transition. This kind of hastatic order was proposed to describe the hidden order state in the tetragonal URu_2Si_2 [1], however the non-Kramers nature of the U ground state is controversial. Motivated by Pr based cubic compounds with clear non-Kramers doublet ground states like $PrInAg_2$ [2] and PrMg3 [3], we study the emergence of time-reversal symmetry breaking hastatic order in a two-channel Anderson model based on the quadrupolar Gamma_3 doublet [4] using a slave boson approach.

TU.F.3_O3 - Heavy fermion superconductivity and double multipolar transition in PrV_2Al_{20}

Y. Matsumoto [1], M. Tsujimoto [1], A. Sakai [1], T. Tomita [1], S. Nakatsuji [1]

1. ISSP, Univ. of Tokyo, Tokyo, Japan

Novel quantum phases may arise from *f* electrons' orbital degrees of freedom through hybridization with conduction electrons. In particular, quadrupole Kondo effect, originally suggested as a single ion effect in the nonmagnetic cubic G_3 crystal electric field doublet [1], has attracted a lot of attention because of its non-Fermi liquid ground state. It is an interesting open question what happens in the lattice systems. To study this, the material should be clean enough and the hybridization should be large. However, there has been no prototypical system that satisfies both requirements.

On the other hand, recent studies have revealed that PrT_2Al_{20}(T = Ti, V) are ideal systems to study the quadrupole Kondo effect and quantum criticality arising from orbital degrees of freedom [2-4]. The both systems have the nonmagnetic cubic Γ_3 crystal electric field doublet. In addition, the hybridization is strong as is evident in many physical properties.
We found that both exhibit heavy fermion superconductivity inside the mutipole ordering phases [3-5]. Especially, in the case of PrV_2Al_{20}, the effective mass is highly enhanced (m^*/m_0 ~ 140) even at ambient pressure, revealing even stronger hybridization in PrV_2Al_{20} [5]. This observation indicates the first realization of the novel superconductivity arising from the orbital fluctuation of the *f* electrons at ambient pressure.

While $PrTi_2Al_{20}$ exhibits a ferro-quadrupole ordering at 2.0 K, our recent success in growing the pure crystals has allowed us to reveal that PrV_2Al_{20} exhibits double multipolar orderings at T = 0.65 and 0.75 K [5]. The specific heat exhibits the T^4 power law behavior below 0.5 K indicating the formation of the gapless mode due to strong orbital fluctuation. Although the origin of the double transition is not clear so far, the response to the magnetic field is anisotropic reflecting the anisotropic nature of the order parameter.

TU.F.3_O4 - Observation of a magnetic-resonance excitation mode in the Kondo insulator $CeFe_2Al_{10}$

J.M. Mignot [1]

1. Laboratoire Leon Brillouin, CEA-CNRS, Gif sur Yvette, France

Kondo insulators (KI) form an important class of strongly correlated electron systems. Their ground state is typically a nonmagnetic singlet, with a spin-gap in their magnetic excitation spectrum. The possible competition between the KI state and a long-range antiferromagnetic order is an interesting, yet unsettled, problem.
The family of orthorhombic compounds CeT_2Al_{10} (*T*: Fe, Ru, Os) offers a unique opportunity to study this phenomenon, since changing the transition metal element T drives the system from a KI behavior ($CeFe_2Al_{10}$) to a more complex situation ($CeRu_2Al_{10}$, $CeOs_2Al_{10}$), in which the development of the KI state is disrupted by the onset of AFM order. In the latter two compounds, previous elastic and inelastic neutron scattering (INS) studies have characterized the ordered magnetic structure and revealed the existence of a spin gap and magnonlike excitations in the magnetic response, whose dispersion implies unusually large anisotropy in the exchange interactions. It has been suggested that these systems are located close to a localized-itinerant transition.
Here we report [1] new single-crystal INS experiments on $CeFe_2Al_{10}$. The data indicate that a spin gap develops in the magnetic dynamic response below about 50 K, with a magnetic excitation branch dispersing from E = 10.2 ± 0.5 meV at $\boldsymbol{q}$ = (0,1,0) (*Y* zone-boundary point) to approximately12 meV at the top of the branch. The excitation shows a pronounced polarization of the magnetic fluctuations along a, the easy anisotropy axis. This spectral component, observed in the absence of long-range magnetic order, is contrasted with that previously found in CeRu2Al10, where the modes had transverse character and existed only in the antiferromagnetic state. It is ascribed to a “magnetic exciton” mechanism similar to that reported previously for other KI compounds such as SmB_6 or YbB_{12}.

TU.G.1_I1 - Origin of ferromagnetism and critical behaviour in insulating (Ga,Mn)N

M. Sawicki [1]

1. Institute of Physics, Warsaw, Poland

After a decade of contradicting reports, the last years have witnessed a breakthrough progress in the understanding of magnetism of (Ga,Mn)N. Due to the strong p-d hybridization the Mn2+/3+ acceptor level occupies the mid band gap position in GaN precluding the existence of carrier-mediated spin-spin coupling. Nevertheless, in uncompensated films, where Mn3+ ions prevail, the superexchange interaction becomes ferromagnetic for all Mn-Mn distances resulting in a ferromagnetic order persisting up to the Curie temperature TC=13 K for x=0.10, yet retaining their insulating character. The experimentally established TC(x) ~ x^2.2 supports the superexchange scenario as the same exponent describes the dependence of spin-glass freezing temperatures on x in Mn- and Co-doped DMSs, in which the antiferromagnetic superexchange is the established spin coupling mechanism. Moreover, the experimental TC values are in a remarkable agreement with those obtained from the tight-binding and Monte Carlo simulations of ferromagnetic superexchange between Mn3+ ions in zinc-blende GaN. This finding indicates that (Ga,Mn)N emerges as a model system making it possible to explore properties specific to dilute ferromagnetic insulators. Having in hand a system with short-range ferromagnetic interactions between randomly distributed localized spins, we address experimentally the fundamental and long-standing question on how disorder influences the critical behaviour of continuous phase transitions. Our results confirm experimentally that in contrast to the magnetically clean case (x=1) the Curie transition in the dilute alloys studied here is characterised by an effective gamma which exhibits a strong maximum above TC, a behaviour anticipated by a renormalization-group theory. Surprisingly, however, our results point to a certain smearing of the transition which is likely to result from macroscopic inhomogeneities in Mn distribution inherent to virtually all real magnetic alloys.

This work was supported in part by the (Polish) National Science Centre through projects: PRELUDIUM (UMO-2012/07/N/ST3/03146) and OPUS (UMO-2013/09/B/ST3/04175.

Tu.G.1_O2 - Electronic structure of (Ga,Mn)As revisited: an alternative view on the -Battle of the bands-

K. Karlsson [1], J. Kanski [2], L. Ilver [2], I. Ulfat [3], M. Leandersson [4], J. Sadowski [4], I. Di Marco [5]

3. Department of Physics, University of Karachi, Karachi, Pakistan
4. MAX IV Laboratory, Lund University, Lund, Sweden
5. Department of Physics and Astronomy, Uppsala University, Uppsala, Sweden

The detailed nature of electronic states mediating ferromagnetic coupling in dilute magnetic semiconductors, specifically (Ga,Mn)As, has been an issue of long debate. Two confronting models have been discussed emphasizing host band vs. impurity band carriers. Using angle resolved photoemission we are for the first time able to identify a highly dispersive Mn-induced energy band. Our results show that the electronic structure of the (Ga,Mn)As system is significantly modified from that of GaAs. Most importantly, the bands in the region of valence band maximum are distorted and extend into the band gap region of GaAs. For Mn concentrations above 1% Mn the band reaches the Fermi level, and can thus host the delocalized holes needed for ferromagnetic coupling.

TU.G.1_O3 - Laser-induced ultrafast modification of electron-spin dynamics in GaAs with adjacent ferromagnetic epilayer

D. Butkovièová [1], P. Nýmec [1], K. Olejník [2], V. Novák [2], T. Janda [1], F.k Trojának [1], T. Jungwirth [2]

Absorption of circularly-polarized light leads in semiconductors to photo-injection of carriers that have spin polarized along the light propagation direction. If an external magnetic field is applied perpendicularly to this direction the photo-injected electron-spins presses around this field. The time-evolution of the electron spin orientation can be determined by measuring the time-resolved magneto-optical signal due to polar Kerr effect. We investigated electron-spin dynamics in GaAs covered by a thin (~ 20 nm) epitaxial layer of ferromagnetic semiconductor (Ga,Mn)As with various Mn doping [1] at temperature of 15 K and using the light tuned above the GaAs band gap. Since the light penetration depth (~ 1 μm) is much larger than the thickness of (Ga,Mn)As, optical spin-injection takes place in both the ferromagnetic film and the GaAs substrate. We observed that the direction of electron-spins photo-injected in GaAs is ultrafast reoriented due to the presence of (Ga,Mn)As which is reflected in a substantial (up to 180 degrees) initial phase shift of the measured oscillations with respect to the signal measured in bare GaAs. This phase shift is developed within very short time (< 50 ps) after the laser pulse impact on the surface of the sample. The value of the phase shift depends on the Mn concentration in (Ga,Ma)As and on temperature. If an insulating barrier is embed between the ferromagnet and GaAs the phase shift disappears which suggests that the electron-spin reorientation is related to an electron transfer between ferromagnet and the adjacent paramagnetic GaAs.

The study of Zn1-xCoxO has excited much interest due to its possible use in spintronic devices. There are some samples where the Co is present only as Co2+ on Zn sites that are magnetic at room temperature with small coercive fields, typically less than 100 Oe at room temperature and less than 200Oe at helium temperatures. There are other samples where the magnetisation is obviously due to metallic nanoparticles. We use x-ray near edge absorption, magnetometry and MCD to investigate if these two types of magnetism can coexist and if so if they are coupled together. We compared samples with, and without, small concentrations of Al. The fraction of Co ions present as metallic cobalt was determined by x-ray near edge absorption and EXAFS. The fraction of the saturation magnetism at low temperatures that might be assigned to the fraction of the sample that was present as metallic clusters was found to be ~0.2 assuming that the magnetic moment of Co atom in a metallic cluster was 1.78 Bohr magnetons, thus indicating that both components were present in our samples. Optical MCD is a very powerful technique to determine the relative importance of both types of magnetism because the MCD signals from metallic Co and from the matrix of ZnCoO containing Co2+ have different energy spectra. The MCD spectrum, taken at remanence to avoid any paramagnetic contamination, allows for an estimate of the strength of the signal from both components and MCD loops determines the coercive field for each component. It was found that samples of Zn1-xCoxO could be described in terms of two independent contributions to the magnetisation whereas the coercive field for the sample that contained Al was the same for both components at all temperatures and hence magnetism of both components are coupled.

In the search for dilute magnetic semiconductors and oxides, typical (and critical) issues concern the potential presence of extrinsic contamination and/or unwanted precipitates of 3*d*-atoms being the source of ferromagnetism, when investigated by volume-integrating techniques. In the recent years, contradictory results have been reported in very similar systems, under apparently comparable preparation conditions. In this contribution, the magnetic properties at the atomic level of Fe atoms incorporated in ZnO, in a concentration range of more than five orders of magnitude from $1x10^{-5}$ to 2.2 at.% are probed using emission ^{57}Fe Mössbauer spectroscopy on implanted ^{57}Mn and ^{57}Co produced at ISOLDE/CERN. In the ultra-dilute regime (10^{-5} at. %), the system shows isolated paramagnetic Fe^{3+} ions with a spin-lattice type of relaxation. At higher concentrations (between 0.02 and 0.2 at. %) a transition to spin-spin type of relaxation between neighboring Fe^{3+} is observed, without any signature of magnetic ordering up to 2.2 at.% [1]. Our results suggest that the absence of room temperature magnetic ordering in wide band gap and truly diluted semiconductors could be a general conclusion, attributable to the absence of efficient mechanisms to mediate long-range interactions.

The exchange coupling between antiferromagnetic (AFM) and ferromagnetic (FM) materials yields a shift of the hysteresis loop along the magnetic field axis. The magnitude of this shift is known as exchange bias field, Heb. It was experimentally and theoretically demonstrated that Heb decreases with the FM thickness, following an inverse proportionality law, which is assumed to be valid for any FM thickness thinner than the ferromagnetic correlation length [1]. We demonstrate that AFM/FM bilayers with spring-like domain walls can break the inverse proportionality law even for FM thicknesses smaller than the ferromagnetic correlation length. FeF_2/NiFe bilayers with NiFe thicknesses between 10 and 140 nm were deposited by electron beam evaporation. This magnetic system shows spring-like domain walls, parallel to the AFM/FM interface, at low temperature. The thickness dependence of Heb significantly deviates from the inverse proportionality law as the NiFe thickness increases. The exchange bias magnitude of spring-like domain walls is always lower than the predicted by the inverse proportionality law. A model of magnetization planes parallel to the interface accounts for the experimental results. Both the shape of the hysteresis loops and the magnitude of Heb were reproduced in excellent agreement with the experiment [2]. Moreover, the thermal evolution of the FM spin structure leads to an anomalous temperature dependence of Heb. These findings reveal the importance of the FM domain structure on exchange bias.

The role of interfacial and bulk antiferromagnetic spins in the exchange bias (EB) phenomenon is a topic of ongoing discussion. While it is generally established that the antiferromagnetic bulk must affect the EB, the interface, near interface and regions far away from the interface are most often not clearly distinguished.
We used an EB geometry in which the antiferromagnetic FeF_2 layer is grown atop of the ferromagnetic Ni layer, and employed light ion irradiation to selectively create defects at and far away from the ferromagnetic/antiferromagnetic interface. Several sets of Ni/FeF_2 thin films capped with an inert Au layer were irradiated with He-ions of constant energy and dose. The penetration depth of the He-ions was controlled by the thickness of the nonmagnetic Au capping layers. This leads to a varying depth profile of vacancies induced in the thin film structure, which was confirmed by numerical simulations. A quantitative comparison of structural and magnetic characterizations before and after the bombardment of each sample revealed changes in the EB. The experiment allows to simultaneously detect and separate contributions from all layers and depths involved in the EB phenomenon. A substantial reduction in EB magnitude is observed even for vacancy profiles leaving the interface unaltered. These studies show that defect creation in the antiferromagnetic bulk far away from the interface has an effect and therefore the AF bulk must play a crucial role in the determination of EB.

TU.G.2_O3 - Isothermal switching of in-plane exchange bias in orthogonal coupled DyCo/NiFe bilayer

D. Lott [1], K. Chen [2]

1. Helmholtz Zentrum Geesthacht, Geesthacht, Germany
2. Synchrotron SOLEIL, Gif-sur-Yvette, France

Alloys of rare-earth elements and 3d transition metals became recently again in the focus of attention due there rich variety of magnetic effects owed to the different anisotropies of both material classes [1,2,3]. In this paper, dual in-plane exchange bias effects were found in the orthogonal coupled $Dy_{20}Co_{80}$/NiFe bilayer at room temperature. Particularly interesting, the direction of the exchange bias effect can be switched by changing solely the direction of the perpendicular magnetic fields in relative moderate fields of about 200mT. The in-plane exchange bias keeps stable even at extern in-plane magnetic fields of more than 6T. The underlying mechanism behind the extraordinary effect was investigated with magnetic optical Kerr effect (MOKE), X-ray magnetic circular dichroism (XMCD) and polarized neutron reflectometry measurements (PNR). The exchange bias in NiFe is caused by the interface exchange coupling to the DyCo layer, while the exchange bias in DyCo layer is due to the formation of chirality in its spin structure formed during the deposition on NiFe. Latter indicates a Dyzaloshinskii-Moriya like term in the interacting energy originating from the broken inversion symmetry at the interface between both magnetic layers.

The present work focuses in a completely new exchange bias (EB)-like phenomenon observed in orthogonally coupled ferromagnetic (F) bilayers by comparison with previous studies done on [Pt/Co]-NiFe [1-3]. As an important conclusion of those studies, the strength of the out-of-plane anisotropy of the underlayer F has been shown to be decisive to guarantee appearance of EB effects, through creation of a metastable magnetic state in the bilayer. $SmCo_5$ possesses the largest known uniaxial magnetocrystalline anisotropy of Ku=14 MJ/m3 at room temperature as a bulk phase.
Following these observations we have designed a new system consisting of a hard magnet epitaxial SmCo5 film with perpendicular anisotropy [4] in interaction with a soft magnetic layer (CoFeB and NiFe) with in-plane anisotropy through a Cr/Pt spacer of varying thickness. By contrast with conventional EB films, this system shows -independently of the nature of the soft layer (CoFeB or NiFe)- extraordinary features induced without changing the magnetic history of the system and measured by vectorial-MOKE (v-MOKE):
- In-plane loop shift with no need of any post-depositional treatment by comparison with conventional F-AF bilayers.
- Unprecedented effect consisting of pinning of exclusively the ascending hysteresis loop branch in a 90º rotation. This allows for tuning, not only the magnitude, but also the sign of the bias field.
The influence of varying the thickness of the spacer existing between both F layers on the EB-like effects has been studied in detail, proofing that the observed phenomena are a result of competing anisotropies of the orthogonally coupled ferromagnets.

Exchange-biased [1] antiferromagnetic/ferromagnetic bilayers are of a great technological value for advanced electronics production [2]. In this work, we studied crystal structure and exchange bias (EB) effect in UO_2 (bulk Néel temperature TN 30.8 K) combined with Fe_3O_4. The use of particular substrates for the UO_2 films production can play a crucial role in the properties of deposited material [3]. We used reactive sputter deposition from metallic targets to prepare sets of samples with different thicknesses of magnetic layers using commercially available $LaAlO_3$ (100), CaF_2 (100) and (111) subsrates. The stoichiometry of each deposited layer was controlled by X-ray Photoelectron Spectroscopy. Epitaxial growth of the UO_2 films was revealed by X-ray diffraction for all substrates while the layer of magnetite was found to be twinned [4]. $LaAlO_3$-based films were further characterized by means of Transmission Electron Microscopy. Rutherford Backscattering Spectroscopy (RBS) used for the CaF_2-based films showed no intermixing at the interface. The magnetic study of the $UO2/Fe_3O_4$ bilayers showed EB exceeding 2000 Oe at 5 K. Interestingly, exchange bias did not vanish at TN of UO_2. Non-zero values of EB were observed up to 125 K, where a Verwey transition in magnetite takes place.

The work has been supported by the Czech Science Foundation, grant No. 13-25866P. The samples were prepared in the framework of the EARL project of the European Commission Joint Research Centre, ITU Karlsruhe. RBS measurements were carried out at the CANAM infrastructure of the NPI ASCR Rez supported through MŠMT project No. LM2011019.

We present a comprehensive study of the exchange bias phenomenon (EB) in an antiferromagnetic (AF)/ferromagnetic (FM) continuous film and in arrays of square dots with different size (D), aimed at elucidating thermal and spatial confinement effects on the AF/FM exchange coupling and their correlation with the AF structural and magnetic properties. For this purpose, an AF/FM $Ir_{25}Mn_{75}$[10 nm]/$Ni_{80}Fe_{20}$[5 nm] continuous film and arrays of square dots (D = 1000 nm, 500 nm and 300 nm) were prepared by electron beam lithography and lift-off using dc-sputtering. Structural investigations by electron microscopy techniques indicated that the AF layer consists of nanograins (mean size ~ 10 nm), but also clearly revealed the existence of a structurally disordered IrMn region (2-3 nm thick) at the interface with the NiFe phase. The magnetic properties, in particular the temperature dependence of the exchange field Hex and coercivity HC, were studied by SQUID and MOKE measurements. At room temperature, Hex decreases with reducing the size of the dots and it is absent in the smallest ones, whereas the opposite trend is visible at T = 10 K (Hex ~ 1140 Oe for D = 300 nm). The EB mechanism and its thermal evolution have been explained through a phenomenological model [1] that combines spatial confinement effects with other crucial items concerning the AF phase: the magnetothermal stability of the IrMn nanograins, the glassy magnetic nature of the structurally disordered IrMn region, the stabilization of a low-temperature (T < 100 K) frozen collective regime of the IrMn interfacial spins, implying the appearance of a length of magnetic correlation among them. The model predictions have been supported by micromagnetic calculations, satisfactorily reproducing the experimental findings.

This research work has been sponsored by MIUR under project FIRB2010-NANOREST.

Spintronics devices and in particular thermally assisted magnetic random access memories (TA-MRAM) use ferromagnetic/antiferromagnetic (F/AF) exchange biased bilayers: one for reference and one for storage. A TA-MRAM consists in a matrix of memory-cells where each cells carries a bit of information. For improved performances, lowering the cell to cell variability of the storage layer exchange bias is necessary. In this study, we prove that disordered magnetic phases, which exhibit low freezing temperatures and are located over the F/AF thin film, are the main cause of such variability once the layers are nanofabricated into a device. In particular, we show that the less the amount of disordered magnetic phases, the lower the cell to cell variability of exchange bias. More precisely, the amount of disordered magnetic phases was varied by sputtering different TA-MRAM stacks with various AFs in the storage layer: IrMn, FeMn and their alloys [1]. Blocking temperature distributions were measured to quantify the amount of disordered magnetic phases at the wafer level [2]. The wafers were then patterned to obtain two series of TA-MRAM chips on CMOS with circular magnetic cells of diameter 140 and 200 nm. The cells were then tested electrically. Finally, the resulting loop shift cumulative distribution functions accounting for the cell to cell variability of exchange bias were correlated to the initial amount of disordered magnetic phases. In addition to bridging the gap between fundamental disordered magnetic phases and a technological application, we also demonstrate here that blocking temperature distributions are a versatile method to qualify TA-MRAM production batches before processing [3].

TU.G.3_O3 - Phase diagram in exchange biased CoTb/[Co/Pt] multilayer based magnetic tunnel junctions

M. Bersweiler [1], D. Lacour [1], K. Dumesnil [1], F. Montaigne [1], M. Hehn [1]

1. Institut Jean Lamour, Nancy, France

The magnetic properties of [Pt/Co]4/MgO/[Co/Pt]3/Co/CoTb full stack have been studied. Since the strength of the coupling between the Co layers through the Pt decreases rapidly when the Pt thickness increases, two reversal modes of the hard electrode have been highlighted at room temperature. For thin Pt thicknesses, the simultaneous reversal of the [Co/Pt]3/Co multilayer and of the CoTb layers is observed whereas for large Pt thicknesses, the reversal occurs in two steps (first reversal of the [Co/Pt]3 multilayer followed by the Co/CoTb reversal for larger applied fields). At low temperatures, the drastic increase of the anisotropy and the decrease of the magnetization in CoTb prevents its reversal, leading either to a spring magnet behavior for thin Pt thicknesses or to an exchange bias behavior for large Pt thicknesses. Finally, it is possible to stabilize a remanent intermediate magnetization state with the persistence of domains in the hard electrode. The different magnetic behaviors observed by magnetometry have been reproduced by micromagnetic calculations and summarized in original phase diagrams.

The magneto-transport properties of patterned MTJs have been explored to investigate how the various magnetic behaviors affect the transport properties. Beyond the usual cases where the applied field can reverse both electrodes, the resistance versus magnetic field characteristics have highlighted two interesting behaviors for magnetic fields in the range of the hard electrode magnetization reversal: (i) if the magnetic field is large enough to reverse the [Co/Pt] multilayer without CoTb reversal, the R(H) loops exhibit some common characteristics with M(H) : an exchange biased loop or a reversible spring magnet behavior. This last property is very attractive and could be used in the development of magneto-resistive sensor at room temperature and high fields; (ii) if the magnetic field is large enough to reverse the [Co/Pt] multilayer in the hard electrode and a part of the CoTb layer, the development of magnetic domains in the hard electrode gives rise to a domains duplication phenomenon from the hard to the soft electrode. This is nicely observed via the occurrence of a low resistance intermediate state.

TU.G.3_O4 - Search for exchange bias effect in antiferromagnetic Heusler alloy - ferromagnet bilayers

E. Simon [1], S. Khmelevskyi [1], R. Yanes-Diaz [2], L. Szunyogh [1], U. Nowak [2]

1. Department of Theoretical Physics, Budapest University of Technology and Economics, Budapest, Hungary
2. Department of Physics, University of Konstanz, Konstanz, Germany

The growing technological demand for spintronics applications raised increased interest for searching novel antiferromagnets (AFM). Promising candidates are the full Heusler compounds like Ni_2MnAl in the B2 phase or Ru_2MnZ (Z= Si, Ge) having Néel temperature above the room temperature. In this contribution we present a theoretical attempt to explore the possibility for exchange bias (EB) effect in bilayers formed by these AFM Heusler alloys and ferromagnetic (FM) metals like Fe and Co. Our approach is based on a combination of ab initio calculations and spin-dynamics simulations. We use the relativistic Screened Korringa-Kohn-Rostoker method to determine the electronic structure of the bilayer self-consistently and the relativistic torque method to derive exchange interactions in the system. In particular, by using the latter method we go beyond the usual Heisenberg model as it allows for calculating tensorial interactions that, beyond the isotropic interactions, account for two-site anisotropies and Dzyaloshinsky-Moriya interactions (DMI). In case of Ni_2MnAl/Fe bilayer we find AFM interface Fe-Mn coupling and sizable DMI in the interface Fe layer. In the interface Fe and Mn layers we calculated in-plane magnetic anisotropy. In case of Ni_2MnAl/Co bilayer the interface Mn-Co coupling is FM, the DMI's s in the interface Mn and Co layers have similar magnitudes, and the interface Co layer exhibits a large out-of-plane magnetic anisotropy. By using the tensorial exchange interactions we performed simulations to determine the hysteresis loops of ordered Ni_2MnAl/Fe bilayers for different thicknesses of the AFM and FM layers. Our preliminary findings, however, indicate that for perfect Ni_2MnAl/Fe bilayers there is no (in-plane) EB effect. A possible way to generate EB is to consider defects in the AFM layer.

TU.G.3_O5 - IrMn/MgO-based tunneling junctions for room temperature antiferromagnet spintronics: effect of Mgo and IrMn thickness

M. Cantoni [1], C. Rinaldi [1], L. Baldrati [1], S. Bertoli [1], M. Asa [1], D. Petti [1], E. Albisetti [1], R. Bertacco[1]

1. Politecnico Di Milan, Milano, Italy

Memory elements based on pure antiferromagnetic templates (AF) have recently deserved large interest, because of their high packaging density (absence of stray fields) and robustness versus external perturbations. In a previous work [1], we demonstrated that in Ta/MgO/IrMn(2.5 nm) tunnelling junctions distinct metastable resistance states can be set by field cooling (FC) the heterostructures from above the NÚel temperature (~170 K), with the external magnetic field along different orientations. Tunneling Anisotropic Magnetoresistance (TAMR) [2] up to 10% upon field cooling along the in-plane or out-of-plane direction provided the first demonstration of an electrically readable magnetic memory device, in which the information is stored within the AF active layer.
As a first step in order to extend the operation of the device to room temperature (RT), we studied the temperature dependence of the exchange bias versus the IrMn thickness in Si/SiO_2//CoFeB/IrMn(t)/Ru and Si/SiO_2//CoFeB/IrMn(t)/MgO/Ru structures. We demonstrated that, in structures without MgO, t=3.5 nm already presents a Blocking temperature larger than RT. Anyway, for t< 6 nm the presence of MgO suppresses the exchange bias (present if the MgO layer is removed), whereas t= 6 nm guarantees operating temperature above 180 ° C.
Being IrMn/MgO an essential building block of AF spintronics, we investigated by photoemission spectroscopy this enabling/disabling influence of MgO on IrMn. We found that MgO plays a fundamental role in preserving the IrMn interface stoichiometry (Ir0.22Mn0.78), while in its absence a strong Mn depletion takes place (Ir0.47Mn0.53). The correlation between this chemical effect and the magnetic properties is currently under investigation.
IrMn/MgO/Ru tunneling junctions have finally been realized, with t ranging from 2.5 nm to 8 nm, in order to test the feasibility of TAMR at room temperature.

Spin-torque nano-oscillators (STNOs) are novel devices which may be exploited for wirelesscommunication applications [1-3]. In particular, it has recently been demonstrated that STNOs utilizing an in-plane magnetized polarizer (also acting as read-out layer) and out-of-plane magnetized free layer allow for the full parallel-to-antiparallel resistance variation to be exploited in the limit of 90° precession angle, thereby maximizing the output power [1]. However, for this specific geometry, steady-state precession can only be sustained if the spin-transfer torque exhibits an asymmetric dependence on the angle between the free and the polarizing layer, such as in the case of fully metallic devices [1]. Nevertheless, it has recently been reported that dynamics have been experimentally observed in similarly designed MgO-based magnetic tunnel junctions (MTJs) under constant applied electrical current, in spite of the fact that such devices do not exhibit any asymmetry in the spin-torque angular dependence [4,5]. These results have so far been interpreted based on the formalism for metallic devices.

Here, we explore potential mechanisms for sustaining steady-state precession in MgO-based STNOs with this specific geometry. To this end, we analytically and numerically solve the Landau-Lifshitz-Gilbert-Slonczewski equation under a constant perpendicular applied current and field. We take into account both the angular and the bias dependence of the resistance of the nanopillar in order to convert the current into voltage, which is the relevant parameter in an MgO-MTJ. The field-like torque is neglected. We demonstrate that the angular dependence of the resistance introduces sufficient asymmetry of the in-plane spin-torque term to sustain precession in this system, but the bias dependence of the resistance gradually quenches this asymmetry as the current is increased and consequently suppresses precession above a given threshold. We furthermore prove that in an STNO with circular cross-section an external field is required to observe steady-state dynamics, but this constraint is lifted when introducing an in-plane easy axis, which opens new avenues to be explored for designing devices for mobile communication.

We studied vortex oscillators based on ultra-low resistance magnetic tunnel junctions in which vortex is driven into a periodic motion by spin transfer torque (STT). The vortex oscillations are observed when the junction is subjected to a large dc bias current. The dc current produces both a large Oersted field which contributes to the vortex nucleation and a STT that starts the vortex oscillation [1].
Frequency modulation experiments were performed on this vortex oscillator for a wide range of modulation frequency, up to 10% of the oscillator frequency (about 500 MHz). A thorough analysis of the intermodulation products shows that the key parameter that describes these experiments is frequency-current dependence.
So we have developed an analysis based on modulation theory to treat the whole set of data at once. It appears that the description previously used to describe modulation experiments where the modulation frequency was much less than the natural frequency, does not apply when the modulation frequency is a significant fraction of the natural frequency. More precisely, the vortex response time appears to play a significant role, so that the concept of deviation sensitivity has to be introduced to explain the observations. Until now, deviation sensitivity was overlooked in the case of spintronic oscillators: it corresponds to the dynamical dependence of the oscillator frequency with an applied current that varies with time. We show that this frequency dependence differs strongly from that of a quasi-static experiment. Finally, we emphasize that the concept of deviation sensitivity differs significantly from the tunability discussed so far in the context of macrospin oscillators [2].

Towards the self-synchronization in arrays of Spin Torque Oscillators (STO), an important question is to understand the role of the phase difference $\Delta\varphi$ between a STO on the main features of the output rf signal. . This issue is not only important to improve the rf properties of STOs but also for the potential implementation of neuro-inspired magnetic memories [1].
Here, we investigate the mechanism of self-injection using a delay line of STOs and notably the influence of $\Delta\varphi$ [2]. In order to re-inject the rf-signal generated from STO into the STO itself, we used the reflection at the close end. A tunable delay line is inserted in the circuit to control the $\Delta\varphi$; $\Delta\varphi=2\pi f_{ini} \Delta t +\pi$, where f_{ini} is the STO frequency without re-injection and Δt is the total delay time of lines. The rf signal generated by the STO after a re-injection is measured through a directional coupler.
The main results are that we clearly observed a 2π dependence with the phase difference $\Delta\varphi$ of the STO frequency, the linewidth, and the emission power as expected from theory [3]. Moreover, we find that when $\Delta\varphi$ is appropriately tuned, the spectral linewidth is strongly decreased and the emitted power increased compared with their respective values without re-injection. This first demonstration of an optimization of rf properties through an optimized delayed self-injection represent a key advance toward the mutual synchronization of two oscillators as the physical mechanisms are equivalent for both synchronizations.

In the last decade, large expectations have been anticipated on how the rich physics of spin transfer nano-oscillators could give birth to a new generation of multi-functional microwave spintronic devices [1]. Indeed, it has been often emphasized that their nonlinear behavior gives a unique opportunity to tune their radiofrequency properties but at the cost of large phase noise, not compatible with targeted applications.
To tackle this issue, a solution would be to rely on their synchronization to a reference external signal [2] or achieve mutual synchronization of multiple oscillators. However the largely reported presence of phase slips in the locked regime has non-controllable impact on these oscillators, and so an associated spectral linewidth that remains in the kHz range. Here we investigate the mechanism leading to a perfectly phase locked double vortex based STNO [3] to an external rf current Fs at multiple integer as well as half integer oscillator frequencies, with an associated phase noise down to -90dBc/Hz at 1 kHz frequency offset.
Furthermore we highlight that the physical mechanisms at play for the oscillator to be locked are very sensitive to the source and the symmetry of the spin transfer forces, allowing fractional synchronization without the presence of any phase slip events. The improved understanding of the locking behaviour gives us the opportunity to present an efficient electrical synchronization of two oscillators in series with a locking bandwidth of a few MHz. These results open the way to an efficient synchronization of multiple spin transfer oscillators which would be a real breakthrough towards applications in advanced rf devices or novel family of neuro-inspired memories.

Spin Transfer Torque Nano-Oscillators (STNOs) are one of the best examples of Spintronic devices exploring the spin transfer mechanism with a strong position to reach real world commercial applications. However, some requirements such as a large output power (Pout ~ 1 μW) and narrow linewidths (Γ < 1 MHz) were not reached yet. Among the many different implementations of STNOs, those based in Magnetic Tunnel Junctions (MTJs) look the most likely to provide large output oscillations thanks to the large tunneling magnetoresistance effect obtained in CoFeB/MgO/CoFeB stacks.

Here, a MTJ stack incorporating a MgO wedge (RA ranging from ~ 50 Ωμm2to below 1 Ωμm 2 over an 8 inch wafer) was deposited with the purpose of clarifying the tradeoffs between endurance to large currents and reliability in ultra-thin and thin MgO barriers. Circular devices with diameters of 200 nm were then fabricated. Upon nanofabrication the static electrical properties of the nanopillars were measured and TMR ratios up to 100% achieved. The dynamic properties of some devices were then studied by measuring the RF emission and extracting key figures of merit (output power, line width, frequency, etc.) as a function of biasing conditions (field and voltage/current) for MTJs in different positions along the MgO wedge covering different ranges of RxA values. Besides oscillations in the RxA region approaching RxA~1 Ωμm2, which is usually the target in MTJ based STNO applications, clear and good quality oscillations were also obtained in devices with intermediate MgO. A Very high output power of the order of 1 μW for 20 Ωμm2 could be achieved.
To the best of our knowledge, this is the largest reported integrated power output obtained from a homogenous nano-oscillator. Besides the large integrated power output, the device also exhibits a reasonable linewidth and tunability in the frequency range.

TU.H.2_I1 - Quantum Critical Behavior in Quasicrystals and Approximant Crystals

N.Sato [1], S. Matsukawa[1], K. Nobe[1], K. Imura [1], K. Deguchi [1], T. Ishimasa [2]

1. Department of Physics, Nagoya University, Japan
2. Department of Applied Physics, Hokkaido University, Japan

Quasicrystals (QCs) are intermetallic alloys that possess aperiodic structures with diffraction symmetries forbidden to the conventional crystals. It is believed that their electronic states are critical, neither extended nor localized. Experimentally distinguishing such the critical state remains a formidable challenge. In the Au-Al-Yb QC, we observed quantum critical phenomena that are characterized by similar critical indices to those of Yb-based heavy fermions [1]. In contrast, no divergence was observed in the Au-Al-Yb approximant crystal (AC), a phase whose unit cell has atomic decorations (i.e., icosahedral clusters of atoms) that look like the QC and forms the body-centered cubic lattice in the present case. These results lead us to suggest that the observed quantum criticality in the QC is related to the critical state unique to the QCs. To gain further information on the physical properties, we studied the substitution effect of constituent elements on the magnetism and found that the Au-Al-Yb QC and AC are located near the border of the divalent and trivalent states of the Yb ion [2]. Recently, we found that there are two ACs with the Tsai-type cluster that show superconductivity at low temperatures [3]. In the presentation, we review the magnetic properties of these novel QCs and ACs. The effect of hydrostatic pressure and magnetic field on the unconventional quantum criticality of the Yb-based QCs and ACs as well as Ce-based ACs will be also presented.

TU.H.2_O2 - Multiple quantum phase transitions in $CeRhIn_5$

H. Yuan [1], L. Jiao [1], Z. Weng [1], Y. Chen [1], F. Steglich[1,2], D. Graf [3], J. Singleton [4], M. Jaime [4], E. Bauer[4], J. Thompson [4]

4. Los Alamos National Laboratory, Los Alamos, United States

CeRhIn5 provides a prototype compound for studying quantum criticality and its interplay with superconductivity. Application of pressure suppresses the antiferromagnetic (AF) order and gives rise to superconductivity [1]. A sharp change of Fermi surface was observed just at the pressure-tuning AF quantum critical point (QCP) [2], which was argued to support the scenario of local quantum criticality [3]. By means of measuring the dHvA oscillations and specific heat in a pulsed magnetic field, we have recently demonstrated the existence of a field-induced AF QCP around Bc0=50T in this compound [4]. A sharp reconstruction of Fermi surface was observed well inside the AF state, i.e., around B0*=31T, which might correspond to a localized-itinerant transition of Ce 4f-electrons attributed to the Kondo effect. These results suggest that multiple quantum phase transitions may exist in CeRhIn5 which can be classified by the measurements of Fermi surface topology[4]. We further explored the multiple QCPs of CeRhIn5 by mapping its pressure-magnetic field phase diagram with measurements of the Hall resistivity and magnetoresistivity under combined extreme conditions of high pressure and high magnetic field.

4. Helmholtz-Zentrum Dresden-Rossendorf, Germany

CePdAl crystallizes in the hexagonal ZrNiAl structure, where the magnetic ions form a distorted kagomÚ lattice. At T_(N) = 2.7 K the onset of antiferromagnetic (AF) order is observed. Neutron scattering experiments [1] revealed a partial frustration in the distorted kagomÚ planes of this structure: two-thirds of the Ce moments form ferromagnetic chains, which are antiferromagnetically coupled, the remaining third do not participate in any long-range order. Along the c-axis the magnetic moments exhibit an amplitude modulation. Accordingly, the kagomÚ planes are stacked on top of each other, resulting in corrugated AF planes parallel to the c-axis formed by the ordered magnetic moments, which are separated by the frustrated moments [2]. The substitution of Pd with Ni in CePdAl tunes the system to a quantum critical point exhibiting an unconventional critical behavior [2].
I will present measurements of the thermodynamic properties, especially of the specific heat and the electrical resistivity, of single crystalline CePd_(1-x)Ni_(x)Al down to very low temperatures as well as neutron scattering experiments, in order to explore the effect of magnetic frustration on the quantum critical behavior and discuss the possible emergence of a partial spin liquid state in CePdAl.

TU.H.2_O4 - Non-Fermi-liquid behavior in the THz response of $CeCoIn_5$

M. Scheffler [1], U. S. Pracht [1], M. Dressel [1], M. Shimozawa [2], R. Endo [2], T. Terashima [3], T. Shibauchi [2,4], Y. Matsuda [2]

1. Physikalisches Institut, Universität Stuttgart, Germany

3. Research Center for Low Temperature and Materials Science, Kyoto University, Japan
4. Department of Advanced Materials Science, University of Tokyo, Japan

Heavy fermions are a prime material class to study the physics of quantum phase transitions. In particular, non-Fermi-liquid behavior related to quantum criticality has been observed in several heavy-fermion compounds. While the charge transport as a function of temperature has been studied in great detail for several quantum-critical heavy-fermion metals, including $CeCoIn_5$, the frequency dependence, directly revealing the charge dynamics, has been studied much less. This is mostly due to the severe experimental difficulties involved, namely optical spectroscopy on highly reflective metals at very low frequencies and temperatures. We overcome these difficulties by THz transmission measurements (detecting amplitude and phase of the THz signal) on high-quality thin films of CeCoIn5. We are particularly interested in the extended temperature range (above the superconducting transition) where the dc resistivity of $CeCoIn_5$ exhibits a linear temperature dependence, which is a signature of non-Fermi-liquid behavior.
We have measured the optical response of $CeCoIn_5$ at temperatures down to 3 K and at frequencies between 0.2 and 1.1 THz, i.e. at matching energy scales of the non-Fermi-liquid regime. We find characteristic metallic behavior in the THz response, and in particular we can follow the transport relaxation rate move through our spectral range upon cooling. Using the extended Drude formalism, we deduce the frequency dependence of relaxation rate and effective mass of the charge carriers. Here we find a strong increase of the relaxation rate with increasing frequency that demonstrates optical non-Fermi-liquid behavior and which even surpasses the temperature dependence at zero frequency. The effective mass also exhibits a strong temperature dependence, which allows us to observe the evolution of the heavy-fermion state upon cooling.

TU.H.2_O5 - Microscopic investigation of electronic inhomogeneity induced by substitutions in a quantum critical metal CeCoIn5

E. Bauer [1], H. Sakai [2], F. Ronning [1], J.-X. Zhu [1], N. Wakeham [1], H. Yasuoka [1], Y. Tokunaga [2], S. Kambe [2], J. D. Thompson [1]

1. Los Alamos National Laboratory, New Mexico, United States
2. Advanced Science Research Center, Japan Atomic Energy Agency, Japan

Chemical substitutions are used commonly to tune a magnetic transition to zero temperature, but the resulting non-Fermi liquid (NFL) behavior is non-universal. CeCoIn5 is an unconventional superconductor that belongs to the CeTIn5 (T=Co, Rh, Ir) family, and is known to lie in close proximity to an AFM QCP at ambient pressure [1, 2]. Due to the high purity of the parent materials we can study how controlled amounts of disorder influence these phenomena. A very small amount of Cd (5s2) substitution for In (5s25p) in CeCoIn5 induces long-range AFM order [3]. Applying pressure to CeCo(In,Cd)5 suppresses the AFM; however, the fluctuations and the signatures at this P-induced AFM QCP are absent [4]. In the case of Sn (5s25p2) substitution in CeCoIn5, magnetic order is not induced, and instead the AFM fluctuations are suppressed as the system is driven away from the AFM QCP [5,6]. In a rigid band picture, changing the electron count by of order ± 1% per unit cell should have a negligible effect on the global band structure, and it, therefore, seems puzzling that two non-magnetic dopants on the In sites could produce vastly different responses at the QCP. Though Sn substitutions introduce a rather homogeneous electronic state suppressing the AFM fluctuations, Cd substitutions intrinsically produce an electronic heterogeneous state. We show here that Cd dopants in CeCoIn5 enhance antiferromagnetic behavior by inducing localized moments in their immediate vicinity. These substituents induce very different local electronic environments as observed by site dependent spin lattice relaxation rates 1/T1 that influence the NFL behavior. The effects found here illustrate the need for care in interpreting NFL properties determined by macroscopic measurements.

TU.H.3_I1 - Dynamics of chiral spin systems: soliton lattices, defects and spinwaves

R. Stamps [1]

1. University of Glasgow, Glasgow, United Kingdom

In this talk, I will discuss unusual features associated with chiral interactions and geometries that lead to chiral ordering. A central theme of the talk will be chirality in spin systemsùits manifestation as skyrmionic and helicoidal textures, the possibility of its emergence in artificially designed structures, and potentials for its application. [1,2] Interface induced Dzyaloshinskii interactions can have significant effects on domain wall structure and mobility in thin ferromagnetic films. Moreover, spin wave propagation can be strongly affected, especially in regards to scattering from magnetic domain walls. [3] Lastly, I comment on new ways of probing chirality in crystals using a type of electronic vortex state. Electrons in these states carry spin and angular momentum, and have great potential for use in electron microscopy as new types of probes. [4]

TU.H.3_O2 - Asymmetric Wave Propagation in Skyrmion String in Chiral Magnets

J. Iwasaki [1], C. Schütte [2], N. Nagaosa [3]

1. University of Toky, Tokyo, Japan
2. Universität zu Köln, Köln, Gemrnay
3. RIKEN, Saitama, Japan

Skyrmion, a topological field configuration first introduced in nuclear physics as a model of hadrons, has now been observed in magnets, known as magnetic skyrmion. In particular, magnetic skyrmion appears ubiquitously in chiral magnets or multi-layered magnets, where the Dzyaloshinskii-Moriya interaction (DMI) due to broken inversion symmetry stabilizes its swirling structure. In the bulk of chiral magnets, two-dimensional skyrmions in xy-plane are stacked up along z-axis, forming a pillar-like object, which we call skyrmion string.
Although there are numerous works on the dynamical properties of magnetic skyrmion such as the dynamics induced by electric current and that by magnons, the most of them focus only on its two-dimensional motion. Here, we move to higher dimension and investigate the dynamics of skyrmion string in three dimensions. We first study, by the micromagnetic simulation based on the Landau-Lifshitz-Gilbert equation, how a wave propagates in skymion string, and find that the waves propagating $+z$- and $-z$-directions are not equivalent. Next, we look into the origin of this asymmetric feature. The simple analysis under the assumption that the skyrmion texture in xy-plane is rigid fails to produce the asymmetry. It is described by the coupling between the skyrmion string and surrounding magnons, which has k_z-linear term in its dispersion relation in the presence of the DMI. Finally, we confirm in the numerical simulation that the wave propagation is symmetric when we artificially switch off the DMI in z-direction.

TU.H.3_O3 - Neutron spin-echo spectroscopy of spin fluctuations in the skyrmion lattice phase of MnSi

F. Haslbeck [1], J. Kindervater [1], A. Bauer [1], W. Häußler[1,2], P. Böni [1], C. Pfleiderer [1]

1. Physics Department, TU Munich, Germany
2. Heinz Maier-Leibnitz Zentrum, TU Munich, Germany

Recent theoretical studies suggest that the skyrmion lattice phase in chiral magnets such as MnSi is stabilised by thermal spin fluctuations [1,2]. We report an experimental study of the quasielastic spectrum of spin fluctuations in the skyrmion lattice phase of MnSi. Using the so called MIEZE spin-echo technique at the spectrometer RESEDA at FRM II we achieved an unprecedented resolution below 1 μeV going well beyond a first preliminary study [3]. Applying a magnetic field parallel and perpendicular to the neutron beam allowed us to study the fluctuations in and out of plane of the skyrmion lattice.

TU.I.1_I1 - Spin-wave logic devices

A. Chumak [1]

1. Fachbereich Physik and Landesforschungszentrum OPTIMAS, Technische Universität Kaiserslautern, Kaiserslautern, Germany

With the fast growth in the volume of information being processed, researchers are charged with the primary task of finding new ways for fast and efficient processing and transfer of data. Spin excitations - spin waves and their quanta magnons - open up a very promising branch of high-speed and low-power information processing. Down-to-nm wavelengths, GHz-to-THz frequency range, Joule-heat-less transfer of spin information, and access to novel wave-based computing concepts allow for the development of a novel technology without drawbacks inherent in modern semiconductor electronics. In my talk, I will discuss exclusively magnon-based processing of digital data. After a brief overview of previous realizations of spin-wave logic gates, recent progress in the field will be discussed on the basis of two novel devices. The first one is a functioning magnon transistor [1], which is required for single-chip data processing solely within a magnonic system (see Fig. 1a). We have demonstrated that a magnon current can be efficiently controlled by another. The second device, which is of large potential for computing, is the magnon majority gate. The first micro-scale design of the majority gate was demonstrated recently using micromagnetic simulations (see Fig. 1b) [2]. A novel design of the majority gate operating with isotropic spin waves in normally-magnetized structure will be presented. A full adder, which consists of 28 transistors in CMOS technology, can be constructed using 3 majority gates only. The potential of magnon-based logic devices will be discussed with respect to miniaturization aspects [3] and the reduced power consumption.

TU.I.1_O2 - Novel paths for rf applications based on spintronics

P. Bortolotti [1], A. Anane [1], M. Collet [1], D. Crete [1], V. Cros [1], O. d'Allivy Kelly [1], E. Grimaldi [1], J. Grollier [1], A. Jenkins [1], J. Kermorvant [1], B. Marcilhac [1], R. Lebrun [1]

1. Unité Mixte de Physique CNRS/Thale, France

Spintronics consists of manipulating electronic spins rather than, or in addition to, charges through electrical currents and/or magnetic fields. This technology has revolutionized the market of read-head applications and other types of magnetic sensors. Recently, a lot of promising studies have been done for active elements such as memories [1], spin transistors and more generally logic spin gates [2]; however, those functionalities are far from being implemented into real devices. Nevertheless, we believe that concerning radio-frequency (rf) applications, spintronics is now mature enough to propose interesting and industrially attractive active functionalities [3] and to foster the development of a new generation of rf devices such as filters, frequency detectors, synthesizers, etcà Here we will present some of our recent works on the subject. 1) A synthesizer based on vortex spin-transfer nano oscillator (STNO): a magnetic tunnel junction (MTJ) where the free layer is in the magnetic vortex configuration. 2) A new type of STNO frequency detector based on vortex core expulsion. 3) Novel STNO-based associative memories; by mimicking the behavior of our brain, we will consider an array of STNOs and take advantage of their mutual synchronization to perform associative memory functionalities. 4) Magnonic devices, i.e., the use of spin wave excitations (magnons) for information treatment. Information can be encoded in the phase of the magnetostatic spin waves and easily manipulated; miniaturized and low energy consumption devices, for both logic and rf functionalities, can indeed be conceived.

Recent developments in magnetic field imaging techniques have demonstrated the advantages of using magnetoresistive (MR) sensors as active element. MR sensors give a direct quantification of the magnetic fields and their dimensions set the measurement's spatial resolution. Still, miniaturizing MR sensors leads to a significant increase in the demagnetizing effects thus decreasing field sensitivity (S). In turn, smaller sensor sizes also lead to large intrinsic noise levels.
We demonstrate a hybrid device with improved sensitivity by placing nanoscale spin-valve (SV) sensors within sub-2um gap magnetic flux concentrators (MFCs), towards downsized magnetic field mapping. The SV stack (deposited by ion beam deposition) consisting of Ta 2/NiFe 3/MnIr 8/CoFe 3.3/Ru 8/CoFe 3.3/Cu 2.5/CoFe 2/NiFe 2/Ru 0.8/NiFe 2.5/Ta 10 (nm) was engineered to deliver improved sensitivity when nanopatterned and was defined by e-beam lithography and ion milling etching (1.3umx500nm), displaying an overall MR~5%. The sensors were then placed in the gap of two 600nm thick CoZrNb MFCs. The MFCs (pole=2um; 100x50um2) were patterned by e-beam lithography and lift-off using PMMA (1.2 um). Our process guarantees that a challenging pole-sensor (P-S) distance down to 400nm is achieved with thick MFCs, thus ensuring maximum field gains. We successfully achieved MFCs with a very clean gap profile and pole geometrical features yielding closure magnetic domain structures, crucial for these dimensions.
NanoSVs-MFCs showed S=0.28%/Oe for P-S=1100nm, increasing to S~0.37%/Oe for P-S=650nm, showing then a maximum value S=0.46%/Oe for P-S=570nm, corresponding to field gains of 15x, 21x and 23x, respectively (compared to isolated sensors). For the smallest P-S=400nm a decrease to S=0.37%/Oe was observed. This suggests the onset of considerable magnetostatic coupling between MFC-poles, which overrides the partial SV guiding effect. In summary, the optimized sensors combine high spatial resolution (500nm) and high field sensitivity (0.46%/Oe) in a small footprint device (100x100 um2).

TU.I.1_O4 - Nanopatterning reconfigurable magnetic landscapes via thermally assisted scanning probe lithography

The search for novel tools for controlling magnetism at the nanoscale is crucial for the development of new paradigms in optics, electronics and spintronics. So far, the patterning of magnetic nanostructures has been mainly achieved through irreversible structural or chemical modifications [1-3]. Here, we propose a new concept, that we call æthermally assisted magnetic scanning probe lithography' (tam-SPL), for creating reconfigurable magnetic nanopatterns by crafting at the nanoscale the magnetic anisotropy landscape of a ferromagnetic layer exchange-coupled to an antiferromagnetic one. By performing a highly localized field cooling with the hot tip of a scanning probe microscope, magnetic structures, with arbitrarily oriented magnetization and tunable unidirectional anisotropy, are patterned without modifying the film chemistry and topography. The proposed technique is straightforward and combines the full reversibility and stability of exchange bias, as the same pattern can be written and reset many times, with the resolution and versatility of scanning probe lithography. In particular, we demonstrate the patterning of arbitrarily shaped domains with dimension down to 250 nm in a continuous CoFeB/IrMn/Ru exchange-bias trilayer grown by magnetron sputtering. By combining magnetic force microscopy, magneto-optical Kerr effect microscopy and micromagnetic simulations we show that, via tam-SPL, it is possible to locally control the micromagnetic configuration and unidirectional anisotropy of the magnetic layer with nanoscale precision. This opens unforeseen possibilities for the development of novel metamaterials with finely tuned magnetic properties as well as reconfigurable computing device architectures. In particular, we discuss the application of our technique to the fabrication of magnonic devices, namely phase shifters and magnonic crystals with controllable and reconfigurable band gaps.

Next information and sensor technology is based on progress in spintronic multilayer design. The interlayer coupling approach used to engineer the magnetization profiles in these systems imposes fundamental limitations on the adjustability of their magneto-electronic response. We demonstrate that oblique incidence deposition (OID) can be used in a facile way to freely adjust the magneto-electronic properties in ultra-thin multilayer devices made from any magnetic material, with any non-magnetic spacer layer. The functionality of these devices is not based on interlayer coupling but solely depends on the magnetic anisotropy of the individual layers. In this new class of layered materials crossed multilayer easy axes with adjustable opening angle and custom-made switching fields (1 - 100 mT) of the individual layers can be precisely realized for the first time. Low and high-field magneto-electronic multilayers and spin-valve systems with tailor-made magneto-resistive functionality can be fabricated in a simple fashion from the same type of multilayer systems (identical layer structure and chemical composition) by adjusting the magnetic properties via oblique incidence deposition.
Irrespective of the interface roughness that goes along with the deposition via OID a very clean and strong magneto-resistive signal is obtained in ferromagnetic/nonmagnetic/ferromagnetic building trilayers that multiplies by simple stacking of such building blocks. Thus new routes are opened up for magnetic multilayer design, and the functionality of spintronic devices can be adjusted to particular applications with unprecedented accuracy [1].

TU.I.2_O2 - Novel ways of shaping magnetic fields with superconducting-ferromagnetic metamaterials

A. Sanchez [1], J. Prat-Camps [1], C. Navau [1]

1. Universitat Autonoma Barcelona, Barcelona, Spain

With the discovery of the transformation optics technique, many new possibilities of generating, transmitting and controlling electromagnetic waves have become possible, including electromagnetic cloaks and perfect lenses. This technique has also been recently successfully applied the case of static magnetic fields. Here in this work we report on how transformation optics applied to static magnetic fields results in a variety of new possibilities for transmission and guidance of magnetic fields and energy. We discuss in particular how magnetic fields can be cloaked [1], can be concentrated in a given space with unprecedented values [2,3], and can even be transmitted to arbitrary long distances through magnetic hoses [4], similar to light transmitted in optical fibers. We also discuss why static magnetic fields make an ideal case for application of these ideas: many interesting designs require extreme values of the material properties (magnetic permeability in this case) and, for the case of magnetic fields, available superconductors and soft ferromagnets exist to provide both extreme permeability values (zero and infinite, respectively), as well as intermediate values. All these novel possibilities for magnetic fields achieved with metamaterials will be also experimentally demonstrated using superconducting and ferromagnetic hybrid systems.

Thin film-based Magneto-Impedance (MI) structures are well suited for developing highly sensitive magnetic microsensors, which can be directly integrated into microelectronic circuits. Permalloy (Py) based structures benefits from well-established preparation procedures and enhanced structural stability over amorphous based sensors. In previous studies we have concluded that sputtered Py (Ni81Fe19) films lose their soft magnetic properties for thickness above a critical value (about 200 nm). Py films below that limit display excellent properties with only slight differences between 50 nm and 100 nm thick films. Thicker (up to 1 micron) multilayer structures keeping soft properties can be obtained by inserting thin spacers between Py layers. Additionally, the MI performance is greatly enhanced in sandwiched structures composed by a non-magnetic conductive layer between two magnetic structures. The best results are expected when the thickness of the non-magnetic layer equals the magnetic ones. In this work we determine the combination of magnetic and non-magnetic layers that maximizes the MI performance, maintaining an open flux configuration (Py not enclosing the central non-magnetic conductor), which permits the fabrication of the complete stack of layers in a single process.
Samples with a sandwiched multilayer structure defined as [Py(100 nm)/Ti(6 nm)]4/Cu(400 nm)/[Ti(6 nm)/Py(100 nm)]4 have been prepared by magnetron sputtering and photolithography, having different dimensions. They were magnetically characterized by magneto-optical Kerr effect, displaying a well-defined transversal anisotropy. The MI was measured in a network analyzer using a microstrip test-fixture. The MI ratio (Z-Zmin)/Zmin Î 100 reaches values of 350 %, the largest ratios reported for thin film Py-based structures. The sensitivity, calculated as the field derivative of the MI ratio, reaches 300 %/Oe. The MI ratio is somewhat lower that the one reported previously for amorphous CoSiB/Ag/CoSiB with closed-flux structure, but the sensitivity is six times larger. These figures compare favorably with wire-based MI devices.

TU.I.2_O4 - Bioinspired Nanocomposite Tactile Sensor

A. Alfadhel [1], J. Kosel [1]

1. Computer, Electrical and Mathematical Sciences and Engineering Division (CEMSE), King Abdullah University of Science And Technology (KAUST), Thuwal, Saudi Arabia

The current progress in fields like robotics or biomedical engineering requires the development of wearable and flexible sensing technologies that combine miniaturization with a high sensitivity and low power consumption. In this context, tactile sensors are required that have a high sensitivity and low power consumption.
We report the fabrication and characterization of a novel tactile sensor that consists of an array of 1 mm long and 200 µm in diameter bioinspired cilia integrated on a giant magneto-impedance (GMI) magnetic field sensing element for a wide range of tactile sensing applications including soft robotics, smart prosthesis, surgical tools, or flow sensing. The cilia are fabricated from a permanent magnetic and highly elastic nanocomposite that is made of iron nanowires (NWs) incorporated into polydimethylsiloxane (PDMS). The permanent magnetism stems from the high magnetization of iron NWs at remanence, which is due to the strong shape anisotropy.
The operating principle of the sensor is based on detecting the change of the stray magnetic field, created by the permanent magnetic cilia when deflected by an external force (e.g. hand touch). A GMI sensor, which offers a good compromise between sensitivity and fabrication complexity, and has potential for wireless operation, is utilized to measure the change in the magnetic field upon the deflection of the cilia.
The tactile sensing element has a high sensitivity of about 11.5 mΩ/mN (46 mΩ/kPa) and a resolution of 1.4 mN (0.35 kPa). Its operating range is between 0-100 mN (0-25 kPa) with an extremely low power consumption of 80 nW. The developed tactile sensor is fabricated on rigid and flexible substrates and it can measure more than one property such as flow, vibration, orientation, or the texture of a contacted object, with easily modifiable performance and operating range.

TU.I.2_O5 - Low Frequency Plasmonic State in FeNi/Cu Hybrid Granular Composite Materials

T.Tsutaoka [1], H. Massango [1], T. Kasagi [2], S. Yamamoto [3], K. Hatakeyama [3]

1. Hiroshima University, Hiroshima, Japan
2. National Institute of Technology, Tokuyama College, Japan
3. University of Hyogo, Japan

Left handed (LH) substances with simultaneously negative values of permittivity (ENG) and permeability (MNG) have been the most popular of the metamaterials due to their property of negative refractive index. The double negative (DNG) electromagnetic properties have been observed in granular composite materials in several GHz range [1, 2]. In this study, the FeNi/Cu hybrid granular composite materials has been prepared to investigate the electromagnetic properties by measuring the relative complex permeability and the relative complex permittivity spectra over the microwave frequency range with the goal to achieve the double negative permeability and permittivity spectra without the external magnetic field. The composite materials $(CuxFeNi_{1-x})yPPS_{1-y}$, where x and y are the volume fraction of particles and PPS denotes the poly-phenylene sulfide resin, were prepared by mixing Cu and FeNi powder with PPS resin powder, heated the mixture at 300ºC and pressing at a pressure of 31.8 MPa in the cooling process down to the room temperature. The samples were shaped in the toroidal form (inner diameter of 3 mm and outer diameter of 7 mm) with the thickness of about 1 mm. The permittivity and permeability spectra were measured by transmission/reflection method using the standard 7/3 mm coaxial airline techniques in the frequency range from 10 MHz to 20 GHz.
The permittivity spectra of $(Cu_{0.24}FeNi_{0.76})0.85PPS_{0.15}$ indicated the Drude type ENG characteristic bellow 4.5 GHz. In this composite, the negative permeability was also obtained by the magnetic resonance of FeNi particles. Hence, combining these two ENG and MNG properties, a DNG characteristic can be obtained in the frequency range from 300 MHz to 1.8 GHz without the external magnetic field.

TU.I.2_O6 - Microwave shape resonance in magnetic microwires tuned by giant magnetoimpedance effect: sensing applications

V. Lopez Dominguez [1], E. Riccardi [2], K. Osiak [3], P. Marin [1], A. Hernando [1]

1. Instituto De Magnetismo Aplicado, Universidad Complutense De Madrid-CSIC-ADIF, Madrid, Spain

Glass-covered amorphous magnetic microwires present a diameter in the range of microns and a magnetoelastic anisotropy influenced by mechanical stress and amorphous microstructure [1-2]. These characteristics besides the strong interactions that present magnetic microwires with electromagnetic microwaves make them ideal candidates for technological and medical applications [3-4]. In our present work we propose a new theoretical framework about the interaction of electromagnetic microwaves and Co-based magnetic microwires exhibiting giant magnetoimpedance effect. Such interaction induces an electrical current along the microwire [5] that depends on its impedance, as well as on the relation between its length and the wavelength of the microwave. Furthermore, our numerical results reveal a direct dependence of the total impedance of the microwire on its magnetic permeability, which can be tuned by an external magnetic field or stress. These theoretical results were compared with the experimental microwave spectrum of Co-based magnetic microwires (radius 33 µm) in the microwave range between 500 MHz and 20 GHz. Particularly, it was measured the relative variations of the scattering coefficient S21 induced by the application of an ac-bias magnetic field. As our theory predicts, depending on the length of the magnetic microwire there are a set of frequencies in which the variations of the scattering coefficient are maxima (shape resonance frequencies). In addition, at the shape resonance frequencies the maximum variation of the scattering coefficient occurs at the coercive field of the microwire (maxima variations of the magnetic permeability). Consequently, a suitable combination of magnetoimpedance effect and shape resonances opens the perspective to use this system as a wireless field and stress micro sensor element.

TU.I.3_O1 - **Evidence of a spin-polarized resonant surface state in (111) $Sm_{1-x}Gd_xAl_2$, a zero-magnetization ferromagnet**

K. Dumesnil [1], M. Bersweiler [1], D. Lacour [1], M. Hehn [1], P. Lefevre [2]

1. Institut Jean Lamour, Université de Lorraine and CNRS, Nancy, France
2. Synchrotron SOLEIL, Gif sur Yvette, France

An important challenge in the field of spin-dependent tunnelling consists in developing materials to design electrodes with specific properties. A material with both high spin-polarization and very small or zero magnetization would thus constitute a perfectly stable electrode. In this context, the $Sm_{1-x}Gd_xAl_2$ (SGA) compound is of paramount interest: it can be considered as a zero-magnetization ferromagnet and a finite TMR value has been namely measured at its compensation point in SGA-based MTJ.
In order to unravel electronic transport properties in such MTJs and to get a deeper understanding of surface electronic properties of this original material, synchrotron-based Angle Resolved- and Spin Resolved-PhotoEmission Spectroscopy experiments have been performed for MBE-grown (111) $Sm_{1-x}Gd_xAl_2$ epitaxial films. Electronic band structure calculations (LSDA+U+SO, Wien2k code) complete this study.

ARPES experiments have evidenced an intense electron pocket, strongly localized around $\overline{\Gamma}$ and close to the Fermi level, with in-plane quasi free electron like isotropic dispersion and much reduced dispersion in the perpendicular direction. This electronic state exhibits a_1 symmetry and its spectral weight is strongly enhanced for an incident photon energy around 34eV. These various characteristics, combined with the observed sensitivity to surface conditions and with electronic calculations (for bulk and surface), strongly suggest the presence of a resonant surface state of 5d character, likely built on the bulk electron pocket developing around L points. First SRPES have evidenced the low temperature positive spin polarization at the Fermi level of this resonant surface state. It also appears to interestingly survive in a MgO (2ML thick)-covered $Sm_{1-x}Gd_xAl_2$ epitaxial film.
Such an electronic state should influence the transport properties of SGA-based MTJ, as it has been reported in other crystalline systems. A specific anomaly, indeed observed in the conductance characteristic, likely originates from the SGA resonant surface state highlighted by photoemission spectroscopy.

TU.I.3_O2 - Ab-initio calculations of Gilbert damping parameters in doped Permalloy systems.

L. Bergqvist [1], F. Pan [1], A. Bergman [2], A. Delin [1]

1. KTH Royal Institute of Technology, Stockholm, Sweden
2. Uppsala University, Uppsala, Sweden

The Gilbert damping is perhaps the most important material parameter for magnetization dynamics. It is a measure of the strength of the dissipative processes in a magnetic dynamical system, for instance spin-flip scattering due to spin-orbit, scattering against phonons and magnons etc. In applications, a low damping is normally wanted to minimize losses. Experimentally it is normally measured using ferromagnetic resonance (FMR) but until recently, ab-initio calculations were scarce due to the complexity of such calculations. However, recent advances and developments in the computational tools, Gilbert damping is nowadays more accessible in calculations for a variety of materials. Here, we present a systematic investigation of Gilbert damping from ab-initio calculations using linear response formalism as implemented within the Korringa Kohn Rostoker (KKR) framework, including analysis of the temperature effects from phonons and magnons as well from the underlying band structure. In particular, we focus on the technologically important material Permalloy (Py), known for its low damping, doped with heavy elements like Au, Ag and Pt and compare the results with recent experimental meausurements. The trends with respect to concentration of doping elements and temperature dependence are found to agree well with each other. By changing element and doping concentration, the Gilbert damping can be varied within a large interval and together with exchange interactions and anisotropy, all material specific parameters in atomistic spin dynamics simulations (ASD) are calculated within the same computational framework. We also present results on Heusler alloys, which is an important class of materials for spintronics applications, due to its intrinsic spin polarization and low damping.

TU.I.3_O3 - Experimental evidences of first-time reported (100) in-plane easy axis in magnetite films grown onto different single-crystal substrates

Magnetite (Fe3O4) is attracting much interest due to its robust ferrimagnetism down to nanometer thickness, good electrical conductivity and presumed half-metal character. Fe_3O_4 films are studied as ideal cases for designing improved bulk magnets [1] and have been tentatively used in spin-valves. Fe_3O_4 presents a low-temperature metal-insulator transition, proposed for spintronic applications. However, an open question is to what extent preparation can affect the detailed magnetic properties, such as the magnetic anisotropy axis.
Most of studies dealing with bulk and Fe_3O_4 films show room temperature (RT) in-plane <110> magnetic easy axis. By contrast, we show in this work the preparation of pure stoichiometric Fe_3O_4 thin films by IR-PLD [2], on different single-crystal substrates, with RT easy axes along the in-plane <100> directions [3], i.e. rotated by 45º respect to previous studies. Substrates of SrTiO3, MgAl2O4 and MgO have been selected.
RT in-plane hysteresis loops were measured by vectorial-MOKE as a function of the direction of the applied field in 0º-360º range. The highest coercivity and remanence are found at 0º, 90º, 180º and 270º (i.e. <100>), thus orthogonal to each other, while the lowest coercivity values are found between them. This results in a well-defined four-fold symmetry indicative of biaxial magnetic anisotropy. In order to verify this result, ferromagnetic resonance (FMR) experiments have been carried out at 9.4 GHz frequency [4]. The angular dependence of the in-plane resonance field at RT proves that the easy axes are indeed the <100> directions. This result is supported by SPLEEM experiments and demonstrates the possibility of tuning the easy axis orientation in Fe3O4 films.

We develop a gauge-independent perturbation theory for the grand potential of itinerant electrons in two-dimensional tight-binding models in the presence of a perpendicular magnetic field. At first order in the field, we recover the result of the so-called* {\it modern theory of orbital magnetization}* and, at second order, deduce a new general formula for the orbital susceptibility. In the special case of two coupled bands, we relate the susceptibility to geometrical quantities such as the Berry curvature. Our results are applied to several two-band -- either gapless or gapped -- systems such as graphene, boron nitride, graphene bilayer, etc. We point out some surprising features in the orbital susceptibility – such as in-gap diamagnetism or parabolic band edge paramagnetism -- coming from interband coupling. From that we draw general conclusions on the orbital magnetism of itinerant electrons in multi-band tight-binding models.

STT-MRAM are about to become a main stream generic technology of non-volatile memories. Indeed, according to the ITRS, STT-MRAM are foreseen as the best contender to replace DRAM and SRAM as working memory in microelectronic circuits. Most of the research and development efforts on STT-MRAM are nowadays focused on out-of-plane magnetized magnetic tunnel junctions (MTJs) which offer better retention, lower write current for a given retention than their in-plane magnetized counterparts. The perpendicular anisotropy in these MTJs arises from the magnetic metal/oxide interface [1] partially balanced by the demagnetizing energy. In this work, the origin of this anisotropy has been clarified by ab-initio calculations and ways to increase it by doping of the bulk of the magnetic storage layer were proposed [2,3]. Single and double barrier MTJs were then prepared and characterized. Double barrier MTJs have the advantages of larger anisotropy and therefore longer retention, better resistance to high temperature anneals thanks to reduced Ta interdiffusion and improved resistance to electrical breakdown. Furthermore, by using two polarizing layers, they allow increasing the STT efficiency for writing and even to modulate the amplitude of the STT by using one of the polarizer as a read/write mode select layer. Finally, the influence of the field-like STT term (perpendicular torque) in the STT switching was also investigated. It is shown that this field-like term does not influence the critical current for magnetization switching which is dominated by the in-plane STT term. However, it influences the switching dynamics by modifying the precessional frequency.

5. CNRS, SPINTEC, Grenoble, France

Magnetic microscopy using Photoemission Electron Microscopy (PEEM) on perpendicularly magnetized Pt/Co(0.85nm)/MgO trilayers revealed a significant increase in magnetic domain size upon irradiation with soft x-rays. Subsequent hysteresis loops taken by focused Kerr magnetometry show a large irreversible increase in coercivity and in remanence for the part of the sample that had been irradiated. The increase of the domain size, together with a decrease in domain wall width deduced from high-resolution PEEM images, are in agreement with an increase of the perpendicular magnetic anisotropy induced by the x-ray irradiation, probably caused by changes at the Co/MgO interface. Charging effects induced by the x-ray absorption can lead to the presence of an electric field at this interface, which is known to modify the anisotropy in this kind of Pt/Co/oxide systems due to electron transfer at the Co/oxide interface. In principle, this effect is reversible and disappears when the electric field is switched off, but it was shown more recently that in some types of Pt/Co/Ox stacks prolongated application of a positive electric field can lead to migration of Oxygen ions to the interface and thus to an increase of the magnetic anisotropy. Taking into account such modifications of the PMA is important when investigating this type of materials for skyrmions or domain wall dynamics using x-ray microscopy or x-ray holography techniques.

TU.J.1_O3 - Exchange bias-like effect in 2D patterned thin films with perpendicular magnetic anisotropy

Patterned magnetic materials with Perpendicular Magnetic Anisotropy (PMA) are interesting systems both, from a fundamental research point of view [1] and also for application purposes [2, 3]. Usually, these systems consist in arrays of structures where the magnetic behavior is studied as a function of shape and/or structures density without changing the intrinsic magnetic properties. The use of extended films with a laterally nano/micro-structured magnetic property, introduce a new degree of freedom to get new building blocks that should be useful in the development of new magnetic devices. In this framework, the presented work shows how to fabricate 2D magnetically hard/soft composites by e-beam lithography plus dry etching techniques, based on sputter-deposited NdCo5 thin films with PMA. The laterally modulated parameter is the thin film's thickness, which leads to the modulation of the in-plane/out-of-plane magnetic anisotropies ratio. Due to this modulation, we are allowed to tune the magnetization reversal processes, leading to reproducible coercive field asymmetries (exchange bias-like effect) depending on magnetic history [4].

Research on transition metal nanoparticles (NPs) embedded in or alloyed with high spin-orbit 4*d* and 5*d* elements aims to the tuning and control of the magnetic anisotropy energy for both the understanding of the physical phenomena and for technological purposes. In previous works we reported the enhancement of the magnetic anisotropy of assembled NPs systems by the type of the surrounding matrix. Capping Co NPs with noble metals like Cu, Ag, and Au (which does not diffuse on Co) results in the increase of the surface anisotropy. Alloyed bimetallic NPs of Co with W or Pt allow the modification of the intrinsic source of anisotropy (Phys. Rev. B 90, 174421, 2014). In the present work, we show that CoPd NPs present strong perpendicular magnetic anisotropy (PMA).
CoPd clusters of ~ 3 nm diameter were produced by sequential sputtering of Co on amorphous alumina and subsequent capping with Pd. This process is repeated *N* times in order to get a granular multilayer system. The particulate morphology was confirmed by HRTEM images, while XANES at the Co *K* edge proved the Co-Pd hybridization. The bimetallic $Co_{50}Pd_{50}$ alloy composition (identified also by XRD) as well as short-range order $L1_0$-like phase have been revealed by EXAFS study at both Co *K* and Pd *K* edges. The collective magnetic behavior is temperature dependent and three magnetic phases are identified: hard ferromagnetic, soft-ferromagnetic and superparamagnetic. Magnetic total moments of about 2.7 m_B and of 0.4 m_B were found by XMCD at the $L_{2,3}$ edges for Co and Pd, respectively. PMA can be improved by increasing the amount of Pd in the sample preparation, since this directly affects the quality of the alloy and the structural properties. The PMA, on the order of 10^7 erg/cm^3 at 5 K, is related to the short-range chemical order found in the CoPd NPs.

TU.J.1_O5 - Correlation between magnetic properties and chemical order in L10 FePtCu thin films studied by EXAFS

Nowadays, magnetic recording is a central technology in information storage, and a large part of the interest in nanoscaled magnetic films has been stimulated by their application to data storage [1]. In this contest, the chemically ordered FePt L10 phase is a material with a very high uniaxial magnetic anisotropy which provides the thermal stability for high density magnetic recording [2]. Furthermore, the addition of third elements allows tailoring the magnetic properties but also the onset annealing temperature for chemical ordering from the as deposited disordered FePt phase is strongly affected [3-5]. In this work we present an Extended X-ray Absorption Fine Structure (EXAFS) characterization of ternary FePtCu alloys at the Cu-K and Pt-LIII edges in order to describe the local environment around these elements and to compare the structural evolution as a function of the Cu content. The study allowed to distinguish experimentally the effects on the chemical order and lattice distortion induced by the Cu. We correlated the determined positions of the Cu atoms in the chemically ordered L10 lattice with the magnetic properties of FePtCu ternary alloys. In particular, the main effect is a linear reduction of the c/a ratio, while the non-monotonic behaviour of the chemical order is consistent with the variation of the magnetocrystalline anisotropy [6].

TU.J.2_I1 - Spin torque oscillators based on perpendicular and tilted magnetic anisotropy materials

J. Akerman [1]

1. University of Gothenburg, Gothenburg, Sweden

Nanocontact spin-torque oscillators (NC-STOs) provide an excellent environment for studying spin transfer torquw (STT) driven nano-magnetic phenomena such as localized and propagating auto-oscillatory spin waves (SWs). While traditionally based on easy-plane anisotropy materials, the inclusion of perpendicular magnetic anisotropy materials have greatly expanded on both the physics and performance of these devices. For example, NC-STOs with perpendicular magnetic anisotropy (PMA) free layers were recently demonstrated, showing high-frequency operation in very low fields [1,2]. At higher fields, the same devices can nucleate and sustain so-called magnetic droplet solitons [3,4], stabilized by a combination of PMA and STT. In pillar STOs based on PMA materials in both the free and the fixed layer, the current dependence in in-plane magnetic fields can also be made very high [5]. To further expand the possibilities of NC-STOs based on easy-plane and PMA materials we recently also fabricated NC-STOs based on tilted anisotropy exchange springs [6].

In my talk I will report on these recent demonstrations, and the important role played by PMA and tilted anisotropies in NC-STOs.

TU.J.2_O2 - Electric-Field-Induced Magnetization Switching in Strained Au/FeCo/MgO Heterostructures

N. Kioussis [1], P. Vu [1]

1. California State University Northridge, Northridge, United States

Voltage-controlled magnetic anisotropy (VCMA) plays a central role in the operation of the next-generation of magneto-electric random access memory (MeRAM). The major challenge in the development of the next-generation MeRAM is the low (< 100 fJ/(Vm)) magnetoelectric (ME) coefficient which in turn leads to high switching bit energy and high write voltage. Employing *ab initio* electronic structure calculations we demonstrate for the first time that epitaxial strain, which is ubiquitous in many heavy metal/ferromagnet/insultor trilayers, has a dramatic effect on VCMA of the Au/FeCo/MgO heterostructure. Strain can give rise to a wide range of novel VCMA behavior where the magnetic anisotropy can change from ⋁- to a ⋀-shape electric field dependence with *giant* ME coefficients which are asymmetric under voltage reversal. By tuning the epitaxial strain the ME coefficient can reach values as large as ∼1800 fJ/(V.m) which in turn lead to magnetic switching in the low-electric-field regime. We will also present results for the nonlinear magnetoelastic coupling and the strain-induced spin-reorientation of the system. The underlying mechanism is the interplay between the modification of the MgO dielectric constant by strain and the changes of the spin-orbit coupled d-states at the interfaces due to the synergetic effect of strain and electric field. These findings open interesting prospects for exploiting strain engineering to harvest higher efficiency VCMA for the next generation MeRAM devices.

TU.J.2_O3 - Development of dual magnetic tunnel junctions with perpendicular anisotropy and double polarizing layers

L. Cuchet [1,2,3], B. Rodmacq [1,2,3], R. C. Sousa [1,2,3], S. Auffret [1,2,3], B. Dieny [1,2,3]

3. CNRS, SPINTEC, Grenoble, France

Magnetic Tunnel Junctions (MTJs) with perpendicular anisotropy have been proved for many years to be attractive devices for STT-RAM applications. Among their numerous advantages, out-of-plane magnetized MTJs allow achieving significantly lower critical current density for spin-transfer-torque (STT) writing than their in-plane counterparts for a given specified retention. In the meantime, planar dual MTJs comprising two tunnel barriers were developed and shown to produce enhanced STT efficiency. Thus, in this study, we aimed at combining the advantages of both systems by developing double barrier MTJs with perpendicular anisotropy and two Synthetic AntiFerromagnetic (SAF) polarizing layers.
The first part of this work consisted in investigating the beneficial effect on the perpendicular anisotropy of the storage layer of sandwiching the latter between two MgO layers. A complete series of junctions with bottom SAF reference and increasing storage layer thickness enabled us to conclude that the effective (corrected from dead layers) critical thickness (out-of-plane to in-plane reorientation of the magnetization) increases from 1.1 to 2.4 nm if the standard Ta capping is replaced by MgO.
After developing junctions with a top SAF reference which transition fields were compatible with the bottom one, we combined them to create a full dual MTJ stack with perpendicular anisotropy. The functionality of such a structure was proved as the transitions of all individual magnetic layers could be clearly identified in the VSM measurements. Parallel and antiparallel configurations of the two polarizing layers can be stabilized which allows tuning the STT efficiency on the storage layer magnetization. Indeed, having antiparallel polarizing layers is equivalent to adding the two STT coming from them, whereas in the parallel configuration they subtract. We also developed composite SAF storage layers, with either Ru or Ta spacers, which are interesting to further reduce the magnetostatic interactions between the various parts of the stack.

TU.J.2_O4 - Evidence for In-Plane Tetragonal c-axis in Mn3Ga Thin Films using Transmission Electron Microscopy

F. Casoli [1], J. Karel [2], P. Lupo [3], L. Nasi [1], S. Fabbrici [1,4], L. Righi [1,5], F. Albertini [1], C. Felser [2]

5. Dipartimento di Chimica, Universitá di Parma, Parma, Italy

Tetragonal Mn3Ga films show exceptional magnetic and electronic properties, i.e., a unique combination of low magnetization, high uniaxial anisotropy, high Curie temperature, high spin polarization and low Gilbert damping, which make them very promising as ferromagnetic electrodes in Spin-Transfer-Torque Magnetic RAMs [1]. A few recent works have demonstrated epitaxial growth of this phase on MgO, SrTiO3 or with Cr or Pt underlayers [2,3].
We have grown MnxGa1-x (x=0.75,0.70) films with thickness 10 – 40 nm by RF sputtering on SrTiO3(100) and fully characterized the films by structural and magnetometric techniques (X-Ray Diffraction – XRD; High Resolution Transmission Electron Microscopy – HRTEM; Atomic Force Microscopy - AFM; SQUID Magnetometry).
For both compositions and in all the considered thickness range the thin films exhibit perpendicular magnetic anisotropy with coercive fields between 1 – 2 T. HRTEM and XRD reveal that 40 nm samples grown at 300-350 °C show predominately the tetragonal phase epitaxial with perpendicular c-axis, but a fraction of in plane c-axes is also present; this structure results in a secondary magnetic component in the perpendicular magnetization. Growth at 300 °C with a reduced thickness or Mn concentration significantly decreases the presence of c-axis in the film plane, thus improving the magnetic properties. TEM is of critical importance in characterizing these materials, since conventional XRD cannot always identify the presence of additional crystallographic orientations although they can still affect the magnetic properties. Our study points to ways that the microstructure of these thin films can be controlled, which is critical for utilization of this material in spintronic devices.

TU.J.2_O5 - Logic gates from out-of-plane magnetized nanowires

R. Mansell [1], A. Beguivin [1], D. Petit [1], A. Fernández-Pacheco [1], J. Lee [1], R. Cowburn [1]

1. Cavendish Laboratory, University of Cambridge, United Kingdom

Electronic devices rely on complex combinations of transistors in order to produce the logic functions which process data. It has been shown for in-plane magnetized systems that domain walls in nanowires can be used to reproduce all the necessary functionality required for logic operations. For perpendicularly magnetized layers implementation of logic gates is more difficult since the relatively large anisotropies cause the magnetization to become Ising-like, reducing the degrees of freedom of the system. However, the large data retention times and fast domain wall speeds of perpendicular materials make them attractive for logic applications. Here, we demonstrate the control of domain wall nucleation in nanowires made from Pt/CoFeB and Pt/Co multilayers simply by changing the width of the wire. By adding end pads we show that the nucleation occurs at the ends of the wires narrower than around 200 nm. This allows us to create asymmetric shaped nanowires where nucleation happens at one end. By placing such elements next to each other, the stray field from one element causes a bias field on the point of nucleation o the other that allows a NOT gate functionality. We demonstrate that a synchronous shift register can be made by chaining individual NOT gates together. For more complex devices we show through micromagnetic simulations how a Y-shaped junction between two nanowires can be used to create either and AND or an OR gate, where the functionality depends on the junction shape. This combination of gates forms the building blocks for complex logic devices in perpendicularly magnetized materials.

TU.J.3_O1 - The key role of thermal motion on the structure and magnetic properties of dithiazolyl-based bistable molecular materials

S. Vela [1,2], M. Deumal [2], M. Shiga [3], J. Novoa [2], Jordi Ribas-Arino [2]

Recent years have witnessed a growing interest in the use of organic radicals as building blocks for bistable materials.[1] The family of 1,3,2-dithiazolyl (DTA) radicals has furnished spectacular examples of materials that undergo spin transitions between a low temperature (LT) diamagnetic phase and a high temperature (HT) paramagnetic phase.[2] The neutral radical 1,3,5-trithia-2,4,6-triazapentalenyl (TTTA) is the most prominent DTA-based compound, not least because its spin transition occurs with a wide thermal hysteresis loop that encompasses room temperature.[3] The LT phase of TTTA presents distorted π-stacks that comprise slipped pairs of nearly eclipsed radicals. The HT phase, in turn, presents regular π-stacks where each radical exhibits a slipped overlap with its two nearest neighbors along the stacking direction. I will explain the results of a recent piece of work, in which, by means of ab initio molecular dynamics simulations, we have demonstrated that the regular π-stacking motif of the HT polymorph of TTTA is not the minimum in the potential energy surface of the material. Instead, it is the result of a fast intra-stack pair exchange dynamics, whereby each radical continually exchange the adjacent TTTA neighbor (upper or lower) with which they form an eclipsed dimer. Such unique dynamics is the origin of a significant vibrational entropic gain and thereby it plays a key role in driving the LT  HT phase transition.[4] The importance of the vibrational motion in this material is not only essential to understand the structure, but also the magnetic properties of its HT-phase. I will demonstrate the need of a dynamic perspective of magnetism, and remark how this improved perspective challenges the usual static approach employed to rationalize the magnetic properties of molecular materials.[5] Finally, I will comment about the strategies that those findings open in the design of new bistable molecular materials.

Metal Phthalocyanines (MPc) are robust planar organic molecules with interesting electronic, magnetic, and transport properties. Therefore, MPcs deposited on a substrate are one of the most studied organometallic materials suggested as building blocks on applications in nanodevices and spintronics. In iron phthalocyanine (FePc), the actual electronic structure of the ground state is still being questioned. This uncertainty affects any model one can construct out of these building blocks for a molecule onto a surface or in an epitaxial film
We have performed an experimental and theoretical study of a thick film of FePc on an Au(111) surface including magnetization measurements, STM and x-ray spectroscopic experiments (XMCD, XLPA) at the N K, Fe L2,3 and Fe K absorption edges
The observation of an anomalous quadrupolar signal in x-ray magnetic circular dichroism (XMCD) at the Fe K-edge of iron phthalocyanine films with an unexpected angular dependence is crucial to the determination of the FePc electronic ground state. Indeed, all ground states previously suggested for FePc are incompatible with the experimental data. Based on ab initio molecular orbital multiplet calculations of the isolated FePc molecule, we propose a new model for the magnetic ground state of the FePc film, which explains the XMCD data and reproduces the observed values of the orbital moments in the perpendicular and planar direction. The computed ground state corresponds to a spin triplet including 3A2g, 3Eg2, and 3Eg1 states.

TU.J.3_O3 - Exchange bias of TbPc2 molecular magnets on antiferromagnetic FeMn and ferromagnetic Fe films

Improving the magnetic stability of single molecule magnets is a key issue facing molecular spintronics. In this study we use element-resolved x-ray magnetic circular dichroism to study the possibility of magnetically coupling TbPc2 to ultrathin FeMn and Fe films. TbPc2 deposited on Fe(4.6ML)/Cu(100) exhibits magnetic hysteresis as a consequence of antiferromagnetic exchange coupling to the interfacial Fe spins. TbPc2 deposited on FeMn(8 ML)/Cu(100) displays magnetic hysteresis and a vertical shift of the Tb magnetization curve, consistent with exchange bias generated by the interfacial uncompensated Fe spins. We demonstrate that the exchange coupling of TbPc2 to Fe and FeMn films can be controlled by doping the interface with electron-donor Li atoms.

TU.J.3_O4 - Spin spectroscopy of single magnetic molecules with a radio frequency scanning tunneling microscope

S. Mullegger [1], S. Tebi [1], R. Koch [1]

1. Institute of Semiconductor and Solid State Physics, Johannes Kepler University Linz, Austria

The aim of this work is to combine the analytic power of magnetic resonance methods with the unrivalled spatial resolution and manipulation capability of the scanning tunneling microscope (STM). For this purpose, we have modified a commercial low temperature STM with a dedicated radio-frequency (rf) generation and detection system. Our STM is capable of adding a variable ac modulation between 10 MHz and 4 GHz to the dc tunneling current [1]. The frequency of the ac component is tuned into resonance with low energy (micro-electronvolt) transitions of the sample under investigation, in particular, spin transitions under a static external magnetic field of the order of 10 mT. The response signal is the dc tunneling conductance between the STM and the rf-excited sample obtained at different excitation frequencies. With our novel technique, we have studied single molecules of the archetypal Tb double-decker single molecule magnet adsorbed on Au(111) at 5 K. We demonstrate the successful resonant spectroscopy of the complete manifold of nuclear and electronic magnetic transitions of single quantum spins in single magnetic molecules within the experimental bandwidth [2]. In particular, we achieve sub-nanometer spatial resolution combined with single-spin sensitivity. The method of resonant radio-frequency scanning tunneling spectroscopy (rf-STS) offers, atom-by-atom, unprecedented analytic power and spin control, which may impact diverse fields of nanoscience and nanotechnology.

WE.A1_O1 - Spin fluctuations in superconducting iron selenide (FeSe) and derivatives

M. Rahn [1], R. Ewings [2], S. Sedlmaier [3], S. Clarke [3], A. Boothroyd [1]

1. Department of Physics, Oxford University, United Kingdom
2. ISIS Facility, STFC Rutherford Appleton Laboratory, United Kingdom
3. Department of Chemistry, Oxford University, United Kingdom

Experiments on iron-based superconductors have shown that spin fluctuations persist into the superconducting state and are linked to superconductivity. Mechanisms involving spin fluctuations are therefore highly attractive and in addition offer a possible route to higher superconducting transition temperatures. Superconductors based on FeSe layers exhibit some very distinct properties, including the ability to raise Tc dramatically by application of pressure, by intercalation with alkali metals and molecular species, and by preparation as a monolayer on $SrTiO_3$.
In this presentation I will describe recent neutron scattering experiments that probe the spectrum of magnetic fluctuations in FeSe [1], and in superconductors built from FeSe intercalated with Cs [2] and with Li(NH2)x(NH3)y [3]. The spin fluctuations in these systems all have different characteristic wave vectors. In the case of FeSe, we observe highly dispersive paramagnon fluctuations emerging from the square-lattice wave vector (π, 0), whereas in the other two superconductors the characteristic wave vector is of the form (π, y) with y ≈ π/2. I will discuss these results in connection with the calculated electronic structure and pairing symmetry.

WE.A1_O2 - Competing Magnetic Phases, and Emergent Defect States as a Source of Resistivity Anisotropy in the Nematic Phase of Iron Pnictides

B. M. Andersen [1]

1. University of Copenhagen, Copenhagen, Denmark

The pronounced electronic anisotropy observed in several experiments probing the iron-based superconductors is currently a topic of great interest and controversy.[1] I will discuss novel disorder effects in the nematic phase above the transition temperature to the (pi, 0) stripe ordered magnetic state but below the orthorhombic structural transition. The anisotropic spin fluctuations in this region can be frozen by disorder, to create elongated magnetic droplets whose anisotropy grows as the magnetic transition is approached. Such states act as strong anisotropic defect potentials that scatter with much higher probability perpendicular to their length than parallel, although the actual crystal symmetry breaking is tiny. From the calculated scattering potentials, relaxation rates, and conductivity in this region we conclude that such emergent defect states are essential for the transport anisotropy observed in experiments.[2] Thus, a full understanding of the transport anisotropy in iron pnictides requires both intrinsic nematic susceptibility and concomitant emergent impurity response. Below the spin density wave transition the nematogens freeze into dimer states that show many characteristics in agreement with STM measurements.[3] Finally, a study of competing non-colinear and non-homogeneous magnetic phases (in addition to the usual magnetic stripe order of the pnictides) will be provided. We map out the general phase diagram and investigate the effects of superconductivity, finding good qualitative agreement with recent experiments on these materials.

WE.A.1_O3 - Synthesis and characterization of new heavy fermion compound CePdIn5

K. Uhlirova [1], J. Prokleska [1], B. Vondrackova [1], M. Kratochvilova [1], M. Dusek [2], J. Custers [1], V. Sechovsky [1]

1. Charles University In Prague, Faculty of Mathematics And Physics, Department of Condensed Matter Physics, Praha, Czech Republic
2. Institute of Physics ASCR, Department of Structure Analysis, Praha, Czech Republic

The family of CenTmIn3n+2m (n = 1, 2; m = 1; T = transition metal) heavy fermion compounds have been intensively studied group of materials due to presence of magnetic order and superconductivity in a broad range of the temperature-pressure phase diagram. Besides the well know $CeTIn_5$ and Ce_2TIn_{11} (T = Co, Rh, Ir) compounds, new materials $CePtIn_7$, Ce_2PtIn_8, Ce_3PtIn_{11}, Ce_2PdIn_8, $Ce_5Pd_2In_{19}$ and Ce_3PdIn_{11} have been discovered recently[1-4].
We report on synthesis and characterization of CenPdmIn3n+2m, compounds with focus on an up to now "missing" compound CePdIn5. Similar to other compounds, single crystals of CePdIn5 we prepared by indium flux growth method. The compounds were characterized by microprobe analysis and single crystal x-ray diffraction. Samples for electrical resistivity measurement were fabricated by focused ion beam method combined with electron beam lithography. CePdIn5 crystallizes in the $HoCoGa_{5\text{-type}}$ tetragonal structure with room temperature lattice parameters a = 0.4693 nm and c = 0.7538 nm. The compound remains paramagnetic down to 0.4 K where it becomes superconducting. Interestingly, following the dimensionality, the series goes from pure superconducting state in $CePdIn_5$ (Tc = 0.4 K) and Ce2PdIn8 (Tc = 0.7 K) via coexistence of superconductivity and antiferromagnetism in Ce3PdIn11 (Tc = 0.4 K, TN = 1.7 K) to pure antiferromagnetic $CeIn_3$ (TN = 10 K) resembling the proposed generic phase diagram [4]. The scenario of coupling evolution of magnetism and superconductivity with dimensionality in the CenTmIn3n+2m compounds will be discussed.

WE.A.1_O4 - Comparative orbital fluctuation study in iron pnictides by spectroscopic methods

Y. Koh [1,49], Y. Kim [2] N, J.Seo [1], M. Eom [3], J. Kim [3], B. Park [4], J. Kim [4], C. Kim [1]

1. Yonsei University, Seoul, Republic of Korea
2. Advanced Light Source, Berkeley, United States
3. Pohang University of Science and Technology, Pohang, Republic of Korea
4. Pohang Light Source, Pohang, Republic of Korea

The most important and still remaining issue in iron based superconductor is on the superconducting pairing mechanism. As well as spin fluctuation, orbital fluctuation has been proposed as a candidate for the pairing in iron pnictides. The mechanism we consider is a pairing mechanism in which spin and orbital order fluctuations coexist and contribute to the pairing. Therefore, investigation of orbital fluctuation will give a valuable hint for understanding the superconductivity in iron pnictides.
In this presentation, we present comparative studies on orbital order fluctuations in doped $BaFe_2As_2$ system. To investigate orbital order fluctuation, X-ray linear dichroism and angle resolved photoemission were performed on doped $BaFe_2As_2$ single crystals. We observed different dyz and dzx orbital in occupations by X-ray linear dichroism and band splitting by angle resolved photoemission. Based on these results, we confirmed the existence of orbital order in doped $BaFe_2As_2$ system. Temperature dependence data were compared to previously reported X-ray linear dichroism and angle resolved photoemission data from electron doped $BaFe_2As_2$. Therefore, we found a weak orbital order fluctuation in isovalent doped $BaFe_2As_2$. This comparative study on orbital order fluctuation can help us understand novel states in which spin and orbital order fluctuations coexist.

WE.A.1_O5 - Nematic-driven anisotropic electronic properties of underdoped detwinned Ba(Fe1−xCox)2As2 revealed by optical spectroscopy

L. Degiorgi [1]

1. ETH Zurich, Department of Physics, Zurich, Switzerland

We collect optical reflectivity data as a function of temperature across the structural tetragonal-to-orthorhombic phase transition at T_S on $Ba(Fe_{1-x}Co_x)_2As_2$ for x = 0, 2.5% and 4.5%, with uniaxial and in-situ tunable applied pressure in order to detwin the sample and to exert on it an external symmetry breaking field. At $T < T_S$, we discover a remarkable optical anisotropy as a function of the applied pressure at energies far away from the Fermi level and very much reminiscent of a hysteretic-like behavior. Such an anisotropy turns into a reversible linear pressure dependence at $T \geq T_S$, suggesting a substantial nematic susceptibility. Moreover, the optical anisotropy gets progressively depleted with increasing Co-content in the underdoped regime, consistent with the doping dependence of the orthorhombicity but contrary to the non-monotonic behavior observed for the dc anisotropy. Our findings bear testimony for an important anisotropy of the electronic structure and thus underscore an electronic polarization upon (pressure) inducing and entering the nematic phase.

WE.A.1_O6 - Orbital-driven nematicity in FeSe

S. Baek [1], D. Efremov [1], J. Mok Ok [2], J. Sung Kim [2], J. van den Brink [1], B. Buechner [1]

1. IFW Dresden, Dresden, Germany
2. Pohang University of Science and Technology, Republic of Korea

An important feature in Fe-based superconductors is that superconductivity occurs in the vicinity of nematic ordering - a lowering of the rotational symmetry preserving time-reversal invariance - as well as of magnetic order. The origin of the nematic symmetry breaking has been heavily debated, because lattice, orbital, and spin degrees of freedom are all directly linked one another from a symmetry point of view, and thus it is challenging to establish which ordering is primary. In this talk, I will present nuclear magnetic resonance (NMR) studies of the high-quality FeSe single crystals, demonstrating that orbital degrees of freedom drives the nematic order [1].

WE.A.2_O1 - Proximity effects is YBa2Cu3O7/[Co/Pt]n heterostructures

C. Visani [1], F. Cuellar [1], A. Verso [2], C. Nail [1], C. Deranlot [1], F.S. Bergeret [2], J.E. Villegas [1]

1. Unité Mixte De Physique CNRS/Thales, Palaiseau, and Université Paris Sud, Orsay, France
2. Centro De Física De Materiales, CSIC/UPV, San Sebastián, Spain

We have investigated proximity effects in heterostructures that combine the high-temperature superconductor YBa2Cu3O7 with either Co/Pt multilayers or single Pt thin films. The study is based on measurements across vertical junctions between those materials. The measurements provide information of the electronic density-of-states changes due to superconducting proximity effects. A large number of junctions have been measured. The presence of certain spectral features in the conductance spectra, such as energy gaps or zero-energy peaks, depends on the interface resistance and thickness of the different materials in the stack. The observed behaviors are explained considering short/long range proximity effects.

WE.A.2_O2 - Magnetic nanoparticles in MgB2: vortex pinning, pair breaking and connectivity

E. Babic [1], N. Novosel [1], D. Pajic [1], Stipe Galic [1], K. Zadro [1] N, D.J. Drobac [2]

1. University of Zagreb, Faculty of Science, Department of Physics, Zagreb, Croatia
2. Institute of Physics, Zagreb, Croatia

Present status of ongoing study of the influence of single-domain magnetic nanoparticles (MNP) with size comparable to the coherence length of MgB2 and superparamagnetic (SP) at/below room temperature on electromagnetic properties (resistivity, magnetization, connectivity, Tc, Jc etc.) of high quality MgB2 wires is reported. In spite of conceptual importance (coexistence of magnetism and superconductivity, magnetic flux pinning) and technological potential (improvement of superconducting parameters) present results for the influence of MNPs on MgB2 are inconclusive [1]. In order to shed more light on this problem we measured over sixty MgB2 wires doped with different amounts of four types of MNPs: elemental magnets, magnetic borides, ferrites and rare earth oxides/borides. Both, coated (carbon, silica or dextrin shell) and uncoated MNPs were used in order to asses the effects of co-doping and interparticle interaction. The influence of the annealing temperature and of shape of MNPs (sphere or rod) were studied, too. The magnetic state of MNPs, both in as-obtained form and inside MgB2 was determined via magnetization and ac susceptibility measurements. Transport and magnetic measurements were used in order to determine reliably characteristic fields and Jc of doped and virgin wires [1]. The competition between detrimental influence of magnetic inclusions (reduced connectivity, pair breaking) and enhanced flux pinning in doped wires leads to deterioration of electromagnetic properties at high MNP contents, whereas at light doping (<3 wt%) an enhancement of these properties was observed for several MNPs. For Ni and dextrin coated $NiFe_2O_4$ MNPs the enhancement of in-field Jc is comparable to that obtained by the best nonmagnetic dopands. In the case of the enhancement of the properties a detailed analysis indicates the contribution of magnetic flux pinning, including the first observation of the matching effects in vortex pinning on MNPs.

Iron superconductors, discovered in 2008, are together with cuprates the two families of high temperature superconductors. As in cuprates, superconductivity emerges upon doping a magnetic state. There are also profound differences between the two families since iron superconductors are multiorbital systems. The Fermi surface has a vortex in the Gamma pocket from the yz and zx orbitals making it topologically non trivial. On the other hand, in the normal state iron superconductors present a nematic state. Nematic signatures have been also found in cuprates. The nematic phase is characterized by an x/y anisotropy and it has been observed by many experimental techniques. There is a strong debate about whether the orbital or the spin is behind the origin of nematicity. Understanding the nematic phase is believed to be key to understand high temperature superconductivity. Nematicity has been mostly described with a Landau model with magnetic origin [1]. However to date there is not an understanding of the role played by the vortex of the Gamma pocket. In this work we derive an effective model from a Hamiltonian and we calculate the spin susceptibility in the nematic phase[2]. We find that orbital fluctuations arise from spin fluctuation making both fluctuations potential candidates for the mechanism of superconductivity. We also find that the vortex at the Gamma pocket is behind the anisotropy observed in the spin susceptibility. The anisotropic spin fluctuation give an anisotropic response in resistivity experiments related to the resistivity anisotropy in the magnetic phase.[3]

WE.A.2_O4 - Colossal superconducting spin valve effect and ultra-small exchange-splitting in epitaxial rare-earth-niobium trilayers

Y. Gu[1]

1. University of Cambridge, Cambridge, United Kingdom

Epitaxial Ho/Nb/Ho and Dy/Nb/Dy superconducting spin valves (SSVs) show a reversible change in the zero-field critical temperature of ~400 mK and an infinite magnetoresistance on changing the relative magnetization of the Ho or Dy layers. Unlike transition metal SSVs which show much smaller change in the critical temperature values, our results can be quantitatively modelled. However, the fits require an extraordinarily low induced exchange splitting which is dramatically lower than known values for rare-earth Fermi-level electrons implying that new models for the magnetic proximity effect may be required.

WE.B.2_I1 - Design of interfaces for tuning magnetism in nanostructures

3d transition metal based magnetic nanowires (NWs) and particles might be suitable candidates for alternative rare-earth free alloys as novel permanent magnets. I will discuss the magnetic hardening of Fe30Co70 nanowires by means of magnetic pinning at the tips of the NWs. We observe that 3 nm FeCo oxide layers in contact with the FeCo NW increases the coercive field by 20%, indicating that domain wall nucleation starts at the tip of a magnetic NW. Micromagnetic simulations support our experimental findings showing that the increase of the coercive field can be achieved by controlling domain wall nucleation using antiferromagnetic capping layer at the nanowire tips. In a second example the design of a ferromagnetic interface within a special type of antiferromagnetic CoO / Co3O4 core/shell nanoparticle [1] is presented.

2. Laboratory for Nanoelectronics and Spintronics, Research Institute of Electrical Communication, Tohoku University, Sendai, Japan

Over the last decade, spin ice systems with their intricate interplay between disorder, frustration and degeneracy giving rise to fundamentally new phenomena like the occurrence of monopole excitations, came to the fore of intensive research interest. Due to the ability to tune the geometric shape and the possibility to access spatially-resolved magnetic properties, artificial spin ice systems, i.e. nanostructured arrays of macroscopic spins, were successfully employed as 2D model systems for their 3D equivalent. Here we present magnetic measurements performed on individual building blocks of artificial square spin ice. For this purpose a cobalt-based spin ice structure was grown by focused electron beam induced deposition (FEBID) onto the surface of a lithographically defined μm-sized Hall-sensor based on a two-dimensional electron gas of an AlGaAs/GaAs heterostructure. This setup provides continuous access to the array's stray field during magnetization reversal. Using relatively simple temperature and magnetic field protocols, individual microstates were prepared and thermally-activated switching was observed. Encouraged by these findings the inter-macrospin interaction was enhanced by growing -in a second deposition step- low energy irradiated nano-granular Pt-C at the lattice nodes. In this material, recently a small magnetic moment was observed at low temperatures[1]. Below T= 20 K we find a strongly enhanced coercitivity of the nanocluster's hysteresis as a result of the altered coupling. The presented results will be accompanied by recent investigations of the magnetization reversal of an isolated non-interacting single macrospin element i.e. the fundamental building block of the investigated nanocluster itself. First order reversal curves (FORC) supported by micro-magnetic simulations were employed to study the inter- and intra-macrospin interactions in a model system with increasingly complex interactions.

WE.B.2_O3 - Tuning the melting temperature of artificial spin ice structures

S. Pappas [1], E. Östman [1], H. Stopfel [1], B. Hjörvarsson [1], V. Kapaklis [1]

1. Uppsala University, Department of Physics and Astronomy, Uppsala, Sweden

Water ice is the archetype of geometric frustration, exhibiting disorder in the arrangement of oxygen -proton bonds [1]. Frustration is observed in many physical systems. Spin frustration in rare - earth pyrochlores is found to mimic the geometric frustration in water ice through the formation of spin ice structures. By mimicking the crystalline spin ice materials, we can create two dimensional arrangements of frustrated interacting nanomagnets, referred as artificial spin ice systems, with characteristic length scales and energies distinguishing them from spin systems frustrated at the atomic level due to competing interactions between the individual spins.
In this work, our goal is to realize and investigate thermally induced transitions in extended artificial square spin ice arrays. At thermal energies above the reversal energy barrier, the particles act as super-paramagnetic entities. The investigation of the thermally induced dynamics in an extended spin ice structure requires the magnetic excitations to be observable under experimental conditions [2,3]. To accomplish this, the magnetic properties of the islands and their interactions need to be adjusted to match the accessible temperature range. This is achieved through the choice of the intrinsic ordering temperature of the island material and the distance between the islands. The islands were made of δ-doped Pd(Fe) thin films and different periodicities for the square spin ice lattice were chosen. Photoemission electron microscopy with X-ray magnetic circular dichroism (PEEM-XMCD) in combination with magneto-optical Kerr effect (MOKE) measurements, confirm a dynamical premelting of the artificial spin ice structure at a temperature well below the intrinsic ordering temperature of the island material. The premelting temperature was found to be dependent on the lattice geometry.

WE.B.2_O4 - Magnetic imaging of honeycomb artificial spin ice at low temperatures

K. Zeissler [1], M. Chadha [1], D. Burn [1], L. Cohen [1], W. Branford [1]

1. Imperial College London, London, United Kingdom

Advances in nanotechnology have enabled the creation of complex single domain ferromagnetic constructs, allowing the study of ferromagnetic interactions influenced by geometry. Artificial spin ice is such a playground which marries geometrical order with magnetic frustration. Recently published measurements have shown unusual features in the magnetotransport signature of cobalt and permalloy honeycomb artificial spin ice below 50 K and 20 K respectively [1,2]. Here we explore the changes in the magnetic reversal of a connected artificial spin ice array fabricated from permalloy below and above this transition temperature using magnetic force microscopy. The imaging shows a change in the magnetic reversal process at low temperatures, which results in a striking number of ice rule violations. These ice rule violations are rare occurrences at room temperature in permalloy arrays where switching occurs via propagation of transverse domain walls [3-5]. We present a link between the domain wall chirality with our low temperature observations.

Patterning of magnetic films into interacting arrays of nanostructures has found employment in both applications such as bit-patterned media [1] and fundamental investigations into fields such as frustrated magnetism via the creation of artificial spin ices [2]. An elegant method to synthesise structured 2D and 3D magnetic arrays is nanosphere lithography, in which well-ordered, close-packed arrays of polystyrene beads are formed into a template which can be backfilled by metal electrodeposition to form an inverse-opal, or nanostructured array of part-spherical concavities [1].
Here, substrates coated with a monolayer of 1000nm diameter polystyrene beads were back-filled by electrodeposition of Cu. After a second electrodeposition step of 20nm Ni and NiFe layers and dissolution of the spheres, we thus obtained 2D hexagonal arrays of suspended triangular magnetic elements; these differ from the more typical kagomÚ artificial spin ices in that the elements sit at the vertices of the lattice [2]. Furthermore, the spacing between the elements was sensitive to the thickness of the Cu underlayer; by altering this thickness from just less to just greater than the spheres' radius, we prepared a sequence of samples of constant magnetic layer thickness in which the magnetostatic interaction between elements varied from weak to strong. We present the results of X-ray magnetic circular dichroism photoelectron emission microscopy (XMCD-PEEM) measurements taken at the I06 beamline of the Diamond Light Source (RAL, UK). These measurements were made challenging by the high topographic changes in our concavity samples, as well as shadowing and multiple scattering effects; samples prepared for XMCD-PEEM are typically therefore confined to a 2D plane. These results highlight XMCD-PEEM as a complementary high-resolution probe for magnetic films on substrates with high 3D texturing.

WE.B.2_I6 - Vortices and antivortices on the move: a powerful tool to probe magnetic states in nanomagnets.

J. Vicent [1,2], J. del Valle [1], A. Gomez [1], E. Gonzalez [1,2]

1. Universidad Complutense, Madrid, Spain
2. IMDEA-Nanociencia, Madrid, Spain

Superconductivity and magnetism are two cooperative effects which compete with each other. Recently, this antagonist behavior has been turned around, since magnetic nanostructures could enhance superconducting properties, among many examples we can notice the so-called domain wall superconductivity. In the present work we have followed the opposite approach; we show that superconductivity is an appropriate tool to probe the magnetic behavior of tiny nanomagnets. We have fabricated on Si substrates hybrid superconducting/magnetic nanostructures using a combination of different techniques as sputtering, electron beam lithography, and reactive ion etching. The hybrid samples are arrays of nanomagnets (Py, Pd/Co multilayers, Co, Fe and Ni) with different shapes embedded in Nb films. These samples are patterned to a cross-shaped bridge which allows magnetotransport measurements with the magnetic field applied perpendicular to the films. We show that moving superconducting vortices and antivortices discriminate among different magnetic states including magnetic vortex states; even they show very small stray magnetic fields. We show that we can explore in details the magnetization states using the dissipation output signals induced by the motion of superconducting vortices, and even more in some of the nanomagnets the remanent states can be measured and fine-tuned using the so-called ratchet effect.

WE.C.1_I.1 - SPIN DEGREES OF FREEDOM IN RELATIVISTIC FERROELECTRICS

S. Picozzi

1. Consiglio Nazionale Delle Ricerche CNR-SPIN, L'Aquila, Italy

By exploiting the interplay between spin and dipolar degrees of freedom via spin-orbit coupling in ferroelectric semiconductors, I will focus on the tight link between k-dependent spin-splitting in the electronic structure, spin-texture and electric polarization. Based on density functional simulations, I will show our theoretical predictions of a giant Rashba spin-splitting in "bulk" GeTe[1], prototype of novel multifunctional materials - labeled as Ferro-Electric Rashba Semi-Conductors (FERSC)[2] - where the chirality of the spin texture is one-to-one linked to polarization. As the latter can be induced/controlled/switched via an electric field in a non-volatile way, the integration of semiconductor spintronics with ferroelectricity is envisaged. In the last part of the talk, the connection between erroelectricity and spin-degrees of freedom will be discussed by providing examples from different materials classes (oxides heterostructures, halides perovskites,[3] chalcogenides,[4] etc), all of them showing strong relativistic effects.

WE.C.1_O2 - Tiny cause with huge impact: polar instability through strong magneto-electric-elastic coupling in bulk EuTiO3

A. Bussmann-Holder [1], P. Reuvekamp [1], K. Caslin [1], R. Kremer [1], J. Köhler [1]

1. Max-Planck-Institute For Solid State Research, Germany

Multiferroic materials with combined polar, magnetic, and elastic orderings are at the forefront of scientific research in view of their multiple interactive couplings: magnetic order can be tuned by strain and an electric field, polar order can be triggered by a magnetic field and strain, and elastic properties are controlled by a magnetic and/or an electric field. Such materials are desirable for multiple applications. Even though the phenomenon of multiferroicity has been predicted long ago [1], its realization remains rare for rather simple reasons: typically polar order is achieved when a transition metal d0 configuration is combined with highly polarizable anions, whereas magnetic order relies on a finite dn configuration. Obviously these two requirements yield a certain incompatibility of the coexistence of the two phenomena which have been tried to overcome by combining magnetic layers with polar ones, by growing composites, and via strain engineering [2, 3]. Even though a rather large number of materials have been shown to exhibit the desired properties, the coupling between magnetic and polar order is either very weak, or the spontaneous polarization/magnetization appears at low temperature only and remains too small to be of technological interest. Here we propose a new strategy to achieve strong magnetic-polar coupling by deriving the soft mode frequency of EuTiO3 as a function of its lattice parameters which exhibits unusual, yet very small temperature dependencies at high and low temperatures [4, 5]. Specifically we develop a route of how to induce ferroelectric order in bulk EuTiO3 (ETO) by combining experimental results with theoretical concepts. We show that marginal changes in the lattice parameter of the order of 0.01% have a more than 1000% effect on the transverse optic soft mode of ETO and thus easily induce a ferroelectric instability.

WE.C.1_I4 - Coupled electricity and magnetism in solids: currents, dipoles and monopoles in frustrated systems and in magnetoelectrics

D. Khomskii [1]

1. II. Physikalisches Institut, Universitaet Zu Koeln, Köln,Germany

The standard point of view is that at low energies Mott insulators exhibit only magnetic properties, while charge degrees of freedom are frozen out. I demonstrate that in general this is not true [1, 2]: for certain spin textures in frustrated magnets there may exist spontaneous circular currents in the ground state of insulators, proportional to the scalar chirality. For other spin structures there may exist spontaneous charge redistribution, which can lead to the appearance of dipole moments and possibly of the net spontaneous polarization. This is a novel, purely electronic mechanism of multiferroic behaviour. In particular I show [3] that such electric dipoles should exist in spin ice materials at every tetrahedra with three-in/one-out or one-in /three-out spin configurations, which are equivalent to magnetic monopoles [4]. Thus there should be an electric dipole attached to each magnetic monopole in spin ice. This leads to electric activity of magnetic monopoles, and opens the possibility to control magnetic monopoles by electric field. I will also discuss unconventional dynamics of magnetoelectric materials, in which there should be a magnetic monopole attached to each electric charge [5], which will then become what is known as a dyon. Several experimental manifestations of this effect will be discussed.

WE.C.2_I1 - Electronic and Magnetic Structure of Actinide Metals

G. Van Der Laan

1. Magnetic Spectroscopy Group, Diamond Light Source, Didcot, United Kingdom

In comparison to 3d or 4f metals, magnetism in actinides remains poorly understood due to experimental complications and the exotic behaviour of the 5f states [1]. In particular, plutonium metal is most especially vexing. Over the last five decades, theories proposed the presence of either ordered or disordered local moments at low temperatures. However, experiments such as magnetic susceptibility, electrical resistivity, nuclear magnetic resonance, specific heat, and elastic and inelastic neutron scattering show no evidence for ordered or disordered magnetic moments in any of the six phases of plutonium. Beyond plutonium, the magnetic structure of other actinides is an active area of research, given that temperature, pressure, and chemistry can quickly alter the magnetic structure of the 5f states. For instance, curium metal has an exceedingly large spin polarization that results in a total moment of ~8 ?B/atom, which influences the phase stability of the metal. Insight in the actinide ground state can be obtained from core-level X-ray absorption spectroscopy (XAS) and electron energy-loss spectroscopy (EELS) [2]. A sum rule relates the branching ratio of the core-level spectra measured by XAS or EELS to the expectation value of the angular part of the spin-orbit interaction [3].

WE.C.2_O2 - UH3 based ferromagnets - new look at old material

L. Havela [1], I. Tkach [1], M. Paukov [1], D. Drozdenko [1], M. Cieslar [1], B. Vondrackova [1], Z. Matej [1], A. V. Andreev [2], N.-T.H. Kim-Ngan [3], I. Turek [1]

1. Charles University, Faculty of Mathematics and Physics, Prague, Czech Republic
2. Institute of Physics, Academy of Sciences of the Czech Republic, Prague, Czech Republic
3. Institute of Physics, Pedagogical University Cracow, Poland

UH3 is the first discovered material with ferromagnetism purely based on 5f electronic states, known for more than half century. Although the U metal is Pauli paramagnet, reduced 5f-5f overlap in compounds allows for moment formation and ordering, typically if the U-U spacing exceed the Hill limit, i.e. about 340 pm. The stable form of UH3, knows as beta-UH3, with is high T_C = 165 K is rather unusual, considering d_U-U = 330 pm. Properties of metastable alpha-UH3 with d_U-U = 360 pm could never be well established. Using the fact that alpha-UH3 is in fact bcc U with interstitials filled by H, we attempted to synthesize alpha-UH3 starting from the gamma-U alloys, with the bcc structure retained to room temperature by doping combined with ultrafast cooling. While up to 15% Zr mixed a contamination by beta-UH3 was obtained, 20% Zr yielded single phase alpha-UH3. The T_C value remains high and very similar to beta-UH3. One can see an increase up to 187 K for 15% , followed by a weak decrease. Magnetic moments remain close to 1 mi_B/U atom. An insight is provided by ab-initio calculations, revealing a charge transfer towards H, depopulating U-6d and 7s states, leaving almost pure 5f character around the Fermi level. The 5f magnetism exhibits a high coercivity (mi_oH_c up to 5.5 T) and large spontaneous volume magnetostriction 3.2*10^-3. Even higher increase of T_C, reaching up to 203 K, can be achieved in analogous Mo stabilized hydrides, which yield an amorphous structure. The compounds represent, together with known hydrides of U6Fe and U6Co, a new group of robust 5f ferromagnet with small d_U-U but high T_C. Although common hydrides are fine powders, some of the new hydrides described as (UH3)_(1-x)T_x remain monolithic, which allows to study transport and thermodynamic properties.

WE.C.2_O3 - Physical properties of an $UFe_{1-x}Sb_2$ single crystal

A.P. Gonçalves [1], M.S. Henriques [1,2], J.C. Waerenborgh [1], I. Èurlik [3], S. Ilkovic [3], M. Reiffers [3], J. Rusz [4]

1. C2TN, Campus Tecnológico e Nuclear, Instituto Superior Técnico, Universidade de Lisboa, Bobadela LRS, Portugal
2. Institute of Physics, ASCR, Prague, Czech Republic
3. Faculty of Humanities and Natural Sciences, University of Presov, Presov, Slovakia
4. Department of Physics and Astronomy, Uppsala University, Uppsala, Sweden

In the present work the crystal structure and electronic properties of the $UFe_{1-x}Sb_2$ compound were studied in a single crystal. XRD confirms that $UFe_{1-x}Sb_2$ crystallizes in the $HfCuSb_{2-type}$ structure. Magnetization, AC susceptibility, specific heat, and electrical transport indicate two consecutive magnetic transitions. According to the AC susceptibility results, the anomalies are connected with an antiferromagnetic state at TN = 25.5 K that changes to a ferromagnetic ground state at TC = 21 K. The specific heat in zero field exhibits a small kink at TN that vanishes with increasing applied magnetic field, which is consistent with the onset of the magnetic transition. All the electronic properties exhibit large anisotropy. First principles calculations of electronic structure show an unusually steep local minimum in the density of states right at the Fermi level, providing a starting point for explaining the strong anisotropy of the material.

WE.C.2_O4 - Phasons, amplitude modes, and spin wave excitations in the amplitude-modulated magnetic structure of PrNi2Si2

J. Blanco [1], B. Fak [2], J. Jensen [3], M. Rotter [4], A. Hiess [5], D. Schmitt [6], P.l Lejay [7]

7. Institut Néel, Grenoble, France

In incommensurate magnetic structures, the only low-energy mode that is expected to be is the pseudo-Goldstone mode of broken translations, known as a phason. This excitation is a purely longitudinal mode associated with the phase of the complex order parameter and represent a modulation of the magnetic moment only. This phason mode is quite unusual, where typically the low energy collective modes are transverse spin waves, which correspond to small rotations of the magnetic moments away from their ordered axes. In the spin-wave theory, longitudinal modes are often expected to be highly damped, and then hard to be observed. For a recent notable exception to this rule is the case of amplitude-modulated magnetic structure of PrNi2Si2. It presents a peculiar magnetic character: it is one of the few examples in nature where the magnetic ions, Pr3+, have a longitudinal amplitude-modulated magnetic structure below TN = 20 K, which is stable down to 0 K. In this way, the material is characterized by an Ising-type magnetic structure, where the magnetocrystalline anisotropy confines the magnetic moments along the c-axis. In most ``equal-moment'' systems the moments saturate at low temperatures, in which case the longitudinal excitations are quenched, allowing only the presence of transversely polarized spin waves. The magnetic excitations in the low-temperature amplitude-modulated magnetic structure of PrNi2Si2 have been investigated by inelastic neutron scattering [1]. The dispersions and intensities of both longitudinal and transverse excitations were measured along the high-symmetry directions. The modulated magnitude of the ordered moments implies that the longitudinally polarized magnetic excitations are more intense and dispersive than the usual transverse spin waves. Several well-defined longitudinal amplitude modes are observed to coexist with the longitudinal phason mode. The experimental results are in good overall agreement with predictions from the random-phase approximation, using exchange and crystal field parameters already established from the macroscopic properties and the paramagnetic excitations. At low energies in the neighborhood of the magnetic zone center, the magnetic phason appears to hybridize with an unidentified dispersionless mode.

3. Kamerlingh Onnes Laboratory, Leiden University, Leiden, The Netherlands
4. University of Amsterdam, Amsterdam, The Netherlands
5. Westfälische-Wilhelms University Muenster, Muenster, Germany

Spin densities in CeRuSn were determined at elevated and at low temperatures using polarized neutron dffraction. At 285 K, where the CeRuSn crystal structure, commensurate with the CeCoAl type, contains two different crystallographic Ce sites, we observe that one Ce site is clearly more susceptible to the applied magnetic field whereas the other is hardly polarizable. This finding clearly documents that distnictly different local environment of the two Ce sites causes the Ce ions to split into magnetic Ce3+ and non-magnetic Ce(4-delta)+ valence states. With lowering the temperature, the crystal structure transforms to a structure incommensurately modulated along the c axis. This leads to new inequivalent crystallographic Ce sites resulting in a re-distribution of spin densities. Our analysis using the simplest structural approximant shows that in this metallic system Ce ions co-exist in different valence states. Localized 4f states that fulfill the third Hund's rule are found to be close to the ideal Ce3+ state (at sites with the largest Ce-Ru interatomic distances) whereas Ce(4-delta)+ valence states are found to be itinerant and situated at Ce sites with much shorter Ce-Ru distances. This transition resembles to the famous alpha-gamma transition in elemental cerium.

WE.C.2_I6 - Coupling lanthanide-based molecular qubits to quantum circuits

F. Luis [1]

1. Instituto de Ciencia de Materiales de Aragón, CSIC-University of Zaragoza, Zaragoza, Spain

The manipulation of quantum superpositions of bit states gives resources to crack tough computational problems, relevant to the design of new chemicals and materials, the safe data protection and communication and the efficient search in large data bases, which are beyond those affordable by any classical device. An outstanding challenge is to scale up quantum computation architectures to a level where they are of practical use. In recent years, magnetic molecular clusters have been proposed as suitable materials for the realization of the quantum hardware. We describe experiments performed at very low temperatures on simple molecules that contain either one or two weakly coupled lanthanide ions. The experiments show that these molecules can perform as, respectively, single qubits and two-qubit CNOT gates, i.e., that they can realize the basic ingredients of a universal quantum computer. Spin decoherence times T2 have been measured on magnetically diluted crystals and frozen solutions, reaching values of the order of 500 ns at liquid Helium temperatures and allowing the observation of Rabi oscillations between different qubit states. We next discuss the coupling of such magnetic molecules to quantum superconducting circuits (SQUIDs and superconducting resonators) and how these hybrid devices can contribute to develop a magnetic quantum processor.

Ferroic phase transitions driven by external magnetic, electric or stress fields promise more energy efficient solid state refrigeration. A key step towards this environmentally friendly technology was the use of first instead of second order phase transitions, which substantially increased the associated entropy change. However, a drawback of first order materials is the transformation hysteresis, which heats up the material and thus reduces or even eliminates the efficiency of a solid state cooling device. Despite this, hysteresis is often ignored when characterizing materials, e. g. by using the Maxwell relation or using only the first direct delta-T measurement instead of a complete cycle.
In this talk the structural and microstructural origin of hysteresis exemplarily for Heusler alloys will be analyzed. Starting point is the transient coexistence of both phases, which requires the formation of interfaces between both phases. As these interfaces disappear when the complete sample has transformed, the associated interface energy contributes to the hysteresis loss. In case that the transformation is associated with a reduction of crystal symmetry, the formation of a nanotwinned microstructure minimizes the interface energy. Accordingly the often observed coarsening process of twins contributes substantially to hysteresis. In addition the formation of a periodic structure requires ordering of nanotwins and thus part of the interaction energy, which drives the ordering process, is dissipated. Last, but not least the elastic energy from the volume change at the transformation is dissipated twice during a cooling cycle. This talk will outline the underlying mechanism, scaling laws, and key experiments, without going into the details of the theories used. These concepts may help to develop new materials and microstructures with reduced hysteresis.

Ni-Mn based Heusler alloys are a class of functional materials closely connected with recent breakthroughs in the areas of ferromagnetic shape memory alloys, magnetocaloric materials and potential halfmetallic materials for spintronics applications. Yet, the functionality of these materials sensitively depends on the alloy's composition and especially the state of atomic order. Ni-Mn based Heusler alloys usually crystallize in the high temperature A2 or B2 phase and undergo at lower temperatures a transition to the ferromagnetic $L2_1$ phase. However, in some promising alloy systems such as Ni_2MnAl, an inherently low degree of $L2_1$ order suppresses ferromagnetism and thereby impedes the fulfillment of their theoretical potential e.g. as ferromagnetic shape memory alloys. In our work, we discuss the ordering kinetics in the Ni_2MnAl system and demonstrate a pathway for tremendously increasing the achievable state of atomic order in these materials [1].In general, the state of atomic order is a complex value consisting of many parameters necessary to do justice to both the long and short range atomic order. We demonstrate in our work the interplay of calorimetric and magnetic measurements in order to obtain a quite local probe for the atomic order adjusted in the alloy. Based on the described measurement routine, the increase of achievable order in the alloy via accelerated ordering kinetics by the usage of quenched-in excess vacancies is discussed. With our method, equilibrium order at temperatures as low as 623 K can be adjusted in Ni_2MnAl, while under equilibrium vacancy concentration order adjustment at these temperatures would take impractically long.

Currently, Ni-Mn-based Heusler alloys are intensively investigated for their multifunctional properties such as magnetic shape-memory, magneto-caloric, and giant magneto-resistance effects, which make them promising materials for technological applications. Especially, the characterization and detailed knowledge of the properties of magneto-structural transition properties of these materials is vital for the correct choice of the temperature ranges of their usage. Our recent studies revealed that the martensitic structure for some compositions of Ni-Mn-Ga and Ni-Mn-Sn alloys cannot be stable on varying temperature conditions. Intermartensitic transitions occur at low temperatures, and the reverse intermartensitic transition does not occur before reaching nearly room temperature, exhibiting a broad thermal hysteresis. On decreasing temperature, the 5M and 7M modulated martensite phases, which are the most important structures for the presence of magnetic shape memory property, tend to transform to the non-modulated L10 martensite phase, as this phase is estimated in calculations to be the energetically more stable ground state. This broad hysteresis effect has to be taken into account in variable temperature environments so that the material can be used with desired capacity.

WE.D.1_O4 - Atomic and magnetic structure and magnetocaloric properties of AlFe2B2

The use of magnetic cooling in refrigerators as a replacement for conventional gas cooling devices could lead to lower power consumption and less hazardous materials in the life cycle of the refrigerator. Recently, a new class of materials based on layered AlM_2B_2 (M = Fe, Mn, Cr) was proposed as a candidate compound for magnetocaloric applications.
Here we report a detailed study on the synthesis and magnetic properties of $AlFe_2B_2$. Single phase samples were prepared using high-temperature synthesis methods gaining high quality samples. Magnetic and crystallographic properties were studied with powder diffraction, Mössbauer spectroscopy and magnetic measurements. The study shows that $AlFe_2B_2$ is a ferromagnetic compound with a magnetic transition at T_c=285K. The saturation magnetization at 10K is 60 Am^2kg^{-1} and $\Delta S_m(5T)$=-4.5$JK^{-1}kg^{-1}$ around room temperature.

Mössbauer spectroscopy confirms a ferromagnetic substance and shows good agreement with the magnetic measurements. Theoretical calculations were carried out using the spin polarized relativistic Korringa-Kohn-Rostoker (SPR-KKR) method. Applying the scalar relativistic full potential (fully relativistic) approach a magnetic moment of 2.67 (2.36) μ_B/f.u. was found. The Curie temperature was estimated to 250 K using a Monte Carlo method implemented in the UppASD code.

WE.D.1_O5 - Study of magneto-elastic properties in shape-memory Heusler alloys by resonant ultrasound spectroscopy

C. Salazar Mejía [1], N. O. Born [1], A. K. Nayak [1], C. Felser [1], M. Nicklas [1], J. Schiemer [2], M. A. Carpenter [2]

2. Department of Earth Sciences, University of Cambridge, Cambridge, United Kingdom

Resonant ultrasound spectroscopy (RUS) is a technique that has been widely used in the area of geosciences to measure the elastic properties of minerals, with direct relevance to the velocities of seismic waves through the earth. Over the last 20 years, it has become a versatile laboratory technique in materials science for measuring elastic constants and ultrasonic attenuation [1]. We have applied RUS to study the magneto-elastic properties in Heusler alloys. Heusler alloys that undergo a martensitic transformation have been shown to exhibit diverse functional properties such as the shape-memory effect [2], magnetic-driven superelasticity [3] and the giant magnetocaloric effect [4], which derive from magnetoelastic couplings. The study of the magneto-elastic properties in these materials is important both from fundamental and application points of view. We have studied polycrystalline Heusler alloys from the Ni-Mn-Ga and Ni-Mn-In families by RUS, in a temperature range that includes the ferromagnetic and the martensitic phase transitions. We have observed fundamental differences in the behavior of the crystal lattice at the martensitic transition, i.e., stiffening versus softening, determined by the presence or absence of a pre-martensitic transition and the relation between the Curie temperature and the martensitic-transformation temperature. We will discuss these results in connection with our previous magnetization [5] and calorimetric data [6].

WE.D.2_I1 - Controlling L10 ordering and microstructures of FePt films

C. Lai [1], S. Huang [1], W. Wen [1], J. Liao [1], B. Yang [1], K. Chang [2]

1. National Tsing Hua University, Taiwan
2. Seagate Technology

The addition of C segregant into L10 FePt films reveals a well-isolated granular structure. However, columnar grains with a high aspect ratio are difficult to obtain due to the accumulation of C at top grain surface. Here, we present two approaches to promote the aspect ratio. We prepared samples with the layer structure of substrate/MgO (10 nm)/FePt-C (0-28 vol%). The FePt-C was deposited at 350 0C. TEM images show the increased C contents promote grain isolation with the inevitable accumulation of C at top grain surface, whose amount is also proportional to the FePt film thickness. To suppress the C accumulation, we decrease the FePt-C layer thickness using the FePt-C (28 vol%) (0 íV 3 nm)/ FePt-B (20 vol%) (7 nm) bilayers. In the absence of FePt-C underlayer, FePt-B reveals no ordering peaks due to the presence of Fe-B bonding. With the 3 nm FePt-C layer, the bilayer structure shows enhanced ordering with perpendicular coercivity of 13.6 kOe. The TEM images of the bilayer show the well-isolated grains with the average grain size of 8.88 nm; the continuous (001) lattice through bilayers was observed in each grain, leading to the aspect ratio of 1.21. The EDX results suggest the diffusion of C into the FePt-B layer. The XPS spectra indicate the FePt-C underlayer reduces the Fe-B bonding and promotes the B-C compounds. The results indicate that this bilayer structure can improve the aspect ratio of grains with the promotion of L10 ordering in the top FePt-B layer. In addition to the bilayer approach, we directly perform the Ar plasma treatment on the FePt-C (28 vol%) (7 nm) film, followed by the deposition of an additional FePt-C (4 nm) layer. The TEM image reveals columnar grains, indicating the post plasma treatment can promote the aspect ratio by removing the C accumulation.

WE.D.2_O2 - Reduction in switching field of perpendicularly magnetized L10-FePt nanodots exchange-coupled with soft magnetic Ni81Fe19 under RF field application

W. Zhou [1], T. Seki [1], H. Imamura [2], H. Arai [2], K. Takanashi [1]

1. Institute For Materials Research, Tohoku University, Japan
2. National Institute of Advanced Industrial Science and Technology, Japan

In order to continue the everlasting increase of magnetic storage density, magnetic materials with high uniaxial magnetic anisotropy (Ku), e.g. L10-FePt, are indispensable to maintain the thermal stability of magnetization in nanoscale. On the other hand, to solve the writability problem due to high Ku, Seki et al. proposed an effective switching method called spin wave-assisted switching [1]. The exchange-coupled bilayer film consisting of a Permalloy (Ni81Fe19; Py) and an in-plane magnetized L10-FePt showed a spatially twisted magnetic structure, and the magnetization of hard magnetic L10-FePt was switched at a low magnetic field by exciting the spin wave in the soft magnetic Py. For practical applications, however, it is important to demonstrate the spin wave-assisted switching in a perpendicularly magnetized configuration, which is the purpose of this study. In this study, perpendicularly magnetized L10-FePt was exchange-coupled with Py. The exchange-coupled film was microfabricated into dots with a diameter around 260 nm, in order to reduce the out-of-plane demagnetizing field and form spatially twisted magnetic structures [2]. A coplanar waveguide and a signal generator were utilized to apply an RF field to the microfabricated dots. The switching fields of the FePt (Hsw) were evaluated from the anisotropic magnetoresistance curves. In case of no RF field, the resistance change was observed due to the twisted magnetic structure, and Hsw was obtained to be more than 8 kOe. When an RF field of 176 Oe was applied, no significant reduction of Hsw was observed with the RF frequency (f) from 6 to 10 GHz. However, Hsw was reduced to about 3 kOe at f = 11 GHz, which is attributable to the excitation of spin wave in Py.

WE.D.2_O3 - Free layer effective anisotropy thickness in high TMR top and bottom pinned perpendicular magnetic tunnel junctions

J. Swerts [1], S.Mertens [1], T.Lin [1], S. Couet [1], Y. Tomczak [1], E. Liu [1], W. Kim [1], G. Sankar Kar [1], S. Van Elshocht [1], A. Furnemont [1]

1. Imec, Leuven,Belgium

Thermal stability of the free layer to ensure data retention is one of the key challenges for sub-20 nm spin-transfer-torque MRAM with perpendicular magnetic tunnel junctions (pMTJ). We have studied the impact of the position of the [Co/Pt]-based synthetic antiferromagnetic (SAF) on the effective anisotropy thickness (keff.t) of the free layer and the tunnel magneto resistance (TMR) in a CoFeB/MgO/CoFeB-based pMTJ. The stacks were deposited by PVD in a 300 mm Canon-Anelva EC7800 on smoothened Ta-based bottom electrodes (BE) (rms roughness ~ 0.05 nm) and they received a 300°C crystallization anneal. The TMR was measured by current in-plane tunneling and the keff.t of the free layer in the thickness range of 0.9 nm-1.5 nm by vibrating sample magnetometry. In the case of the top pinned (TP) stack, i.e. [Co/Pt]-SAF on top of the MTJ, keff.t values as high as 0.45 erg/cm2 were obtained whereas in the case of the bottom pinned (BP) stacks, the maximum in keff.t was 0.25 erg/cm2. The TMR of the TP stack reaches values up to 150 % at area resistance of 5 OhmÁm2 whereas the BP stack reaches TMR values up to 130 %. The roughness induced by the BP SAF at the MgO level reduces the TMR [1]. When reducing the roughness in the BP stack, the TMR increases up to 150 %, but the Keff.t does not increase significantly. Besides, TP pMTJ's deposited on non-smoothened BE (rms roughness 0.6 nm) do not reveal a decrease in free layer keff.t. That indicates that the deposition sequence, i.e. MgO on top of CoFeB in the TP case and CoFeB on top of MgO in the BP case, strongly influences the MgO-CoFeB interfacial properties, and thus leads to different free layer keff.t values.

WE.D.2_O4 - Layer-selective switching of a double-layer perpendicular magnetic nanodot using microwave-assisted switching technique

H. Suto [1], T. Nagasawa [1], K. Kudo [1], T. Kanao [1], K. Mizushima [1], R. Sato [1]

1. Corporate Research & Development Center, Toshiba Corporation, Kawasaki, Japan

Increasing the recording density of hard disk drives by the conventional scheme of shrinking magnetic data bits is expected to reach the superparamagnetic limit. Given these circumstances, three-dimensional (3D) magnetic recording with multiple recording layers has been proposed. The implementation of 3D recording requires a writing method that can selectively switch the magnetization in a specific recording layer. In this study, we report the first experimental demonstration of layer-selective switching by means of microwave-assisted magnetization switching (MAS). We fabricated magnetic tunnel junction (MTJ) nanodot (200Î200 nm) comprising two Co/Pt-multilayer-based perpendicular magnetic layers, a MgO barrier, and two in-plane magnetic layers. The lower perpendicular layer (LL) has higher perpendicular anisotropy than the upper perpendicular layer (UL), and they are antiferromagnetically coupled. The dipolar interaction and antiferromagnetic coupling between the LL and UL is weak enough to allow them to take down or up states individually. The in-plane magnetic layers serve to detect the switching of the LL and UL through the magnetoresistive effect. They are antiferromagnetically coupled to cancel the stray fields and pinned by an antiferromagnetic layer. By applying a perpendicular magnetic field to this sample with both the LL and UL magnetizations being down, the UL reverses first because of its smaller anisotropy. By simultaneously applying an in-plane microwave field, the following complex switching behavior appears. When the microwave frequency is low, the UL still reverses first. As the frequency increases, the UL switching field gradually decreases and then suddenly increases. By further increasing the frequency, the LL starts to reverse stochastically, and in a certain frequency range, selective switching of the LL is realized without fail, showing that MAS can realize layer-selective switching by tuning a microwave frequency. This work was supported by Strategic Promotion of Innovative Research and Development from Japan Science and Technology Agency, JST.

WE.D.2_O5 - Multi-bits memory cell using degenerated magnetic states in a synthetic antiferromagnetic reference layer

A. Fukushima [1], K. Yakushiji [1], M. Konoto [1], H. Kubota [1], H. Imamura [1], S. Yuasa [1]

1. National Institute of Advanced Industrial Science and Technology (AIST), Tsukuba, Japan

A new concept of multi-bits magnetic memory cell is represented. The multi-bits is realized by combining a freedom of the magnetic free layer and that in the antiferromagnetically coupled reference layer in the perpendicularly magnetized magnetic tunnel junction (p-MTJ) [1]. The structure of the reference layer is (FeB/Ta/$[Co/Pt]_3$)/Ru/($[Co/Pt]_6$); the top and the bottom layer are coupled by Ru layer where the reference layer has two degrees of freedom of a head-to-head and a bottom-to-bottom magnetic configuration. A four-state memory cell is realized by combination of both freedom.
However, the states in the reference layer hardly detected by the whole magnetoresistance of the p-MTJ because the magnetoresistance change in the reference layer is negligible small. That means the resistance values are degenerated and two different minor loops exist depending on the different magnetic states in the reference layer. On the other hand, the two minor loops have different switching fields due to the different stray field at the free layer depending on the magnetic configuration of the reference layer.
These magnetic states in the reference layer can be differentiated by the two-step read-out, before and after applying a proper pulse-magnetic field which can identify the initial state in the reference layer. This method is similar to distinguishing different magnetic states in an in-plane magnetized spin-valve element [2]. We demonstrated that four different states in the p-MTJ can be distinguished by the two-step read-out. Unlike conventional multi-level MTJ cells [3], this method is a destructive read-out which means the half of initial states will be changed during the read-out. However, this method can assure practically large operation margins which is the same of that of a single MTJ at a little cost of operation speed.

WE.D.2_I6 - Heat-Assisted Magnetic Recording - Turning Plasmonics and FePt Media into a Product

B. Stipe [1], T. Matsumoto [1], S. Burgos [1], G. Parker [1], M. Grobis [1], B. Terris [1]

1. HGST, A Western Digital Company, San Jose, United States

Heat Assisted Magnetic Recording (HAMR) has the potential to revolutionize the way data is written in HDDs by using a plasmonic antenna to focus near-field radiation from a laser onto a recording disk. The resulting heating of an ultra-high anisotropy and small-grain recording media (such as FePt ordered alloy) defines the location of the written bits and, in principle, allows for dramatically higher storage densities compared to conventional recording. In a typical HAMR head design, a waveguide delivers light from a laser diode to a plasmonic aperture or antenna located at the air-bearing surface. The plasmonic device creates an intense optical pattern in the near-field, heating the disk at the nanometer scale. We have previously shown a head design with a plasmonic transducer, called the “E-antenna” fabricated at the end of a waveguide and then used it for recording on granular media with spinstand and on patterned media with a static tester at up to 1 Tb/in2 [1]. An alternative design, called the “nanobeak” has also been described by us [2]. In this talk, we will explain some of the main challenges remaining before commercialization of HAMR can occur, especially in the areas of antenna reliability and areal density improvement.

WE.E.1_I1 - Spin to charge current conversion in metal/oxide interfaces

Y. Otani [1,2], Y. Niimi [1,2], K. Kondou [2], S. Karube [1,2]

1. ISSP University of Tokyo, Tokyo, Japan
2. RIEN-CEMS, Wako, Japan

Spin Hall effects are commonly utilized as a means to interconvert between charge- and spin-currents. As an alternative mechanism for this interconversion, Rashba-type spin splitting at the Bi (111)/Ag interface was recently used to perform the spin to charge conversion called inverse Rashba-Edelstein (IRE) effect [1].
We here demonstrate that the similar spin to charge conversion can be achieved by using nonmagnetic metal/oxide interfaces. The device typically consists of e-beam depositted $Ni_{80}Fe_{20}$(Py)(5nm)/Cu(15nm)/Bi_2O_3(10nm) trilayer structure with a dimension of 5 μm wide by 3 mm long. The ferromagnetic resonance (FMR) of Py layer was excited by a 9 GHz microwave using the coplanar wave guide with applying external magnetic fields, so that FMR of the Py layer induces the spin pumping to the adjacent Cu layer through which spin currents flow towards Cu/Oxide interface accross a Cu layer, and are converted into charge currents. This is clearly observed as characteristic absorption peaks at the resonance field in the dc voltage spectrum. In contrast the Py/Cu bilayers prepared as a reference exhibit no peaks at the resonance field in the dc voltage spectrum, indicating this conversion is due to the presence of the Bi_2O_3 layer. We have studied both Cu and Bi_2O_3 thickness dependences and found the conversion efficiency λ_{IRE} exhibited the Cu thickness dependence via the quality of a Cu layer which varies as a function of the thickness. Rashba parameter α_R was estimated to be -0.3 eVAngstrom, about 30% of the reported value for Bi/Cu(111) interface [2]. Spin absorption experiments [3] also support the presence of spin to charge conversion in the Cu/Bi_2O_3 bilayer.

4. The Henryk Niewodniczanski Institute of Nuclear Physics Polish Academy of Sciences, Krakow, Poland

Hard magnetic antidot arrays (AA) show promising results in the context of implementation in percolated perpendicular media designing. In this work the technology of hard magnetic FePd and CoPd AA fabrication is presented and correlation between surface morphology, structure and magnetic properties is discussed.
For the first time CoPd AA were fabricated by deposition of Co/Pd MLs on nanoporous Ti_{O2} grown on Ti foil and Si wafers. SEM images indicated that morphology of antidots on the Ti_{O2}/Si is flattened as compared to antidots on the Ti_{O2}/Ti. Therefore improved magnetic characteristics of antidots are discussed with respect to the morphology of initial Ti_{O2} template. XRR and XRD revealed at Co/Pd MLs interface a presence of CoxPd1-x quasi-alloy with stoichiometry and grain sizes dependent on the template type. Systematic analysis of magnetization curves evidenced perpendicular magnetic anisotropy. Coercive field enhancement and change of magnetization reversal mechanism from domain wall motion for continuous films to incoherent rotation for AA is associated with pinning of magnetic moments on antidots.
The FePd AA were formed on porous anodic aluminium oxide templates with bowl-shape cell structure with inclined intercellular regions. FePd ordered L10 structure was confirmed by XRD analysis after successive vacuum annealing of MLs at temperatures 530oC and 600oC. Angular dependencies of magnetization curves showed that continuous FePd film had in-plane magnetic anisotropy, while FePd AA revealed isotropic magnetic properties due to increased contribution of out-of-plane oriented magnetic moments. MFM images of antidots showed more complicated contrast, with dark nanodots and bright nanospheres. Thus, MFM measurements confirmed that in FePd AA the enhancement of out-of-plane magnetization component can be associated with complex distribution of magnetic moments due to developed surface topography.

WE.E.1_O3 - Nuclear Resonant GISAXS: Spatially resolved magnetic ordering and magnetization reorientation in a Fe film with periodically varying thickness.

D. Erb [3], K. Schlage [1], L. Bocklage [1], R. Rüffer [2], H. C. Wille [1], R. Röhlsberger [1]

1. Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany
2. European Synchrotron Radiation Facility ESRF, Grenoble, France
3. University of Hamburg, Hamburg, Germany

We propose to merge Grazing Incidence Small Angle X-ray Scattering (GISAXS) [1] and Nuclear Resonant Scattering (NRS) [2] into a new method providing the magnetic information obtained from NRS with the in-plane spatial resolution of GISAXS. The nuclear resonant signal (carrying the magnetic information) undergoes the same scattering in q-space as the electronic signal (carrying the structural information): photons scattered non-resonantly or resonantly from different structural units of the film are separated due to the sample morphology and can be detected at different positions in the scattering pattern. To demonstrate this principle, we fabricated a sample, in which structural and magnetic heterogeneity are correlated: A substrate with parallel surface facets was prepared by heat treatment of M-plane sapphire. Sputter deposition of 57Fe onto this substrate under non-normal incidence resulted in a continuous hardmagnetic 57Fe film consisting of stripe-like regions with periodically varying thickness: Thicker film regions on the facet surfaces facing the sputtering source alternate with thinner film regions on the facet surfaces avert from the source. We investigated this sample in-situ during 57Fe film growth and studied its response to external magnetic fields ex-situ. During film growth we observed the onset of ferromagnetic first in the thicker regions, then in the thinner regions. Upon applying an external magnetic field the magnetic moments in thick and thin regions are displaced from the easy axis of magnetization to different extents. [3] Thus we have demonstrated that nuclear resonant GISAXS can be a feasible method for obtaining information about the magnetic state of individual parts of a magnetically heterogeneous sample.

WE.E.1_O4 - Towards magnetic tomography of 3D structures at the nanoscale

C. Donnelly [1,2], M. Guizar-Sicairos [2], V. Scagnoli [1,2], M. Holler [2], T. Huthwelker [2], A. Menzel [2], I. Vartiainen [2], E. Mueller [2], E. Kirk [1,2], S. Gliga [1,2], J. Raabe [2], L.J. Heyderman [1,2]

1. Laboratory for Mesoscopic Systems, Department of Materials, Zurich, Switzerland
2. Paul Scherrer Institute, Villigen, Switzerland

Significant developments in a variety of fields including biology, photonics and magnetism have been achieved thanks to recent advances in fabrication techniques to create mesoscopic 3D structures [1, 2]. Further progress in these areas benefits from their full quantitative and structural characterization. We use resonant ptychographic tomography, combining quantitative hard X-ray phase imaging and resonant elastic scattering to achieve ab initio element-specific 3D characterization of a cobalt-coated artificial buckyball polymer scaffold at the nanoscale. By performing ptychographic X-ray tomography at and far from the Co K edge, we are able to locate and quantify the Co layer in our sample to a 3D spatial resolution of 25 nm [3]. With a quantitative determination of the electron density we can determine that the Co layer is oxidized, which is confirmed with microfluorescence experiments. Resonant ptychographic tomography enables element-specific characterization, which can be extended to many elements within a sample by taking additional measurements at their corresponding absorption edges. This combination of tomography with resonant scattering opens the door to the full determination of 3D electronic and magnetic functionality of materials, spatially resolved at the nanoscale.

MnAs thin films are known to present a phase coexistence of regularly arranged ferromagnetic α and paramagnetic β stripes below the Curie temperature, when grown onto GaAs(100) substrates. The observation of the effect in nanostructures whose sizes matched the characteristic length of the α / β arrays allowed us to tune the phase coexistence regime by changing different parameters. In our work, we report the observation of a magneto-structural phase transition induced by magnetic field on MnAs nano-ribbons. The transformation of high-resistance paramagnetic regions into low-resistance ferromagnetic ones explains the sharp resistivity drops that are observed when critical magnetic fields are applied to the samples. The critical field required to induce the phase transition in MnAs, depends of the magnetic history and the temperature. As the temperature of the system increases, higher fields are needed to stabilize the ferromagnetic phase. The phenomenon is hysteretic, highly anisotropic and size dependent.
We show that confinement effects in MnAs ribbons produce extraordinary features in the field dependence of the MR. Our results highlights and provides with unique evidences of the magnetic-field phase-induced transition and its characteristics.

WE.E2_I1 - Towards computational design of correlated materials

R. Valenti [1]

1. Goethe University Frankfurt, Frankfurt, Germany

The combination of ab initio density functional theory with dynamical mean field theory (DFT+DMFT) has been proven to be a powerful approach for describing correlation effects in solid state systems at the microscopic level.
In this talk we will focus on recent progress on this method and its application to known unconventional superconductors such as Fe-pnictides, or organic charge-transfer salts as well as use its predictive power for possible new correlated Dirac metals [1,2,3,4].

4. IFM, University of Linköping, Linköping, Sweden

We have studied theoretically the ferromagnetic cubic alpha and paramagnetic hexagonal epsilon phases of iron using a fully self-consistent ab initio dynamical mean-field theory (DMFT) approach. The equilibrium volumes, bulk moduli, equations of states of both phases, as well as the volume change across the alpha-epsilon transition and transition pressure are obtained in close agreement with experiment. A remarkable improvement is obtained for the epsilon phase, which bulk modulus is strongly overestimated within the standard density-functional-theory framework. A significant magnitude of DMFT corrections in epsilon-Fe is due to rather strong local dynamical correlations in this phase as evidenced by a drastic reduction of the calculated quasiparticle lifetime and enhancement of the effective mass across the alpha-epsilon transition. The calculated electron-electron-scattering contribution to resistivity consequently undergoes a step-wise increase across this transition, as observed in experiment. The calculated magnitude of the jump is, however, significantly underestimated pointing out to probable importance of non-local correlations. The implications of our results for the superconductivity and non-Fermi-liquid behavior of epsilon-Fe are discussed.

WE.E2_O3 - A new tool for analysing systems immersed in a magnetic field: the metric space approach to quantum mechanics

P. Sharp [1], I. D'Amico [1]

1. University of York, Heslington, United Kingdom

Systems subject to external magnetic fields are not simply characterized by their particle densities or their wavefunction, as even their ground states may display a finite current. Current Density Functional Theory (CDFT) is the extension of Density Functional Theory (DFT) for systems subject to external magnetic fields. The core theorem of CDFT, prescribes that ground state wavefunctions are characterized uniquely only by knowledge of both the particle density and the paramagnetic current density (and vice versa).
The metric space approach to quantum mechanics is a new method analysing quantities of physical interest [1]. It is based on deriving from conservation laws 'natural' metrics for quantum mechanical quantities of physical interest, in our case wavefunctions and particle and paramagnetic current densities [2]. We demonstrate the power of this approach by considering many-body systems immersed in a magnetic field, with a finite ground state current. We characterize ground states through the mapping at the core of CDFT between wavefunctions and particle and paramagnetic current densities. This is shown to be a mapping between metric spaces associated to these quantities. We find there are regions of allowed and forbidden distances, a 'band structure' in metric space which directly arises from the conservation of the z-component of the angular momentum. We analyse this band structure both for systems with varying magnetic fields and for systems with a fixed magnetic field but varying confinement potential. In addition, in metric spaces and for the systems considered, the relevant mappings at the core of CDFT display distinctive signatures, including (piecewise) linearity at short and medium distances.
We argue that the uncovered features of the mappings could be used to build or test (single-particle) approximate solutions to many-body problems, e.g., within CDFT schemes.

The new theoretical development on quantum criticality out of equilibrium is studied in a paradigmatic dissipative resonant-level quantum dot subject to a voltage bias. A detailed derivation of a rigorous mapping of our system onto an effective Kondo model is presented. A controlled energy-dependent renormalization-group approach is applied to compute the nonequilibrium current in the presence of a finite bias voltage V. In the linear-response regime V close to 0, the system exhibits as a function of the dissipative strength a localized-delocalized quantum transition of the Kosterlitz-Thouless (KT) type. Fundamental issues are addressed: Does the bias voltage play the same role as temperature to smear out the transition? What is the scaling of the nonequilibrium conductance near the transition? At finite temperatures, we show that the conductance follows the equilibrium scaling for $V < T$, while it obeys a distinct nonequilibrium profile for $V > T$. Our results have direct relevance to experiments on a quantum dot coupled to a resistive environment, such as H. Mebrahtu et al.,[Nature (London) 488, 61 (2012)].

WE.E2_O5 - Unconventional superconductivity in the Hubbard and t-J models: Gutzwiller wave function solution

J. Kaczmarczyk [1,2], T. Schickling [3], J. Bünemann [3], J. Spałek [2]

1. Institute of Science And Technology Austria, Klosterneuburg, Austria
2. Marian Smoluchowski Institute of Physics, Jagiellonian University, Krakow, Poland
3. Fachbereich Physik, Philipps Universität Marburg, Marburg, Germany

The superconducting phase of the Hubbard and t-J models [1, 2] is analyzed within a novel diagrammatic expansion (DE-GWF) method [3]. The method allows one to treat Gutzwiller wave functions (GWF) with unprecedented accuracy. The lowest order of the method reproduces analytically [2] the Gutzwiller Approximation results. With the increasing order of the expansion the results of a truncated DE-GWF method converge to those of the variational Monte Carlo approach. Our method does not suffer from finite-size limitations, which allows us to study the Fermi surface deformations, i.e. nematic ('Pomeranchuk') phases, as well as their coexistence with superconductivity.
The low computational cost of our method allows constructing a detailed phase diagram for the superconducting phase in the Hubbard and t-J models [1, 2]. We obtain agreement with the experimental results: (i) the superconducting gap at the Fermi surface resembles d-wave only around the optimal doping and the corrections to this state are shown to arise from the longer range of the pairing; (ii) the nodal Fermi velocity is almost constant as a function of doping and agrees semi-quantitatively with the experimental results; (iii) the superconducting transition is driven by the kinetic-energy lowering for strong interactions.
It is possible to apply the method to more complicated model systems, e.g., periodic Anderson models, multi-layer Hubbard models, or multi-band Hubbard models. Work in all these directions is in progress. Also the study of non-local interactions and/or correlations should be feasible in the future.

WE.E2_O6 - Correlation-induced d-wave superconductivity within the Anderson-Kondo lattice model: A fully microscopic approach

J. Spałek [1,2], O. Howczak [1]

1. Marian Smoluchowski Institute of Physics, Jagiellonian University, Krakow, Poland
2. Academic Centre for Materials and Nanotechnology, AGH University of Science and Technology, Krakow, Poland

We discuss the appearance of the d-wave superconductivity and its coexistence with magnetism within a fully microscopic Anderson-Kondo lattice model derived earlier [1]. The pairing originates from a competition between the Kondo interaction and the f-f superexchange.
We use the so-called statistically consistent Gutzwiller approximation [2].The coexistence regimes of antiferromagnetism with superconductivity are determined and appear in the vicinity of the Kondo-insulating quantum critical point. We compare our results with those obtained in the Kondo-lattice limit, where the startling f-electrons are localized [3], as well as discuss the valence change [4] accompanying the onset of superconductivity.

WE.E2_O7 - Local-moment magnetism and heavy-fermion superconductivity

Q. Si [1]

1. Rice University, Houston, United States

It is widely believed that quantum criticality underlies unconventional superconductivity in many antiferromagnetic heavy fermions. As such, these systems provide a prototypical setting to study (A) the nature of quantum criticality and (B) how it drives superconductivity. Major efforts in the community over the past decade have been devoted to addressing the first point (A). The central issue has been whether heavy fermion quantum criticality operates within the Landau framework, commonly referred to as being of the spin-density-wave type, or goes "beyond Laudau", in particular taking the form of Kondo destruction [1,2]. This talk will in part summarize the recent theoretical efforts along this direction. The developments above are just beginning to be taken into account in the studies about the second point (B). In particular, the Kondo destruction turns the quasiparticles on the entire Fermi surface to be critical, and it is important to study superconductivity beyond the BCS-Eliashberg approach. I will describe our recent development of the theoretical methods [3,4], which allowed the conclusion for lattice models [5] that the Kondo-destruction local quantum criticality promotes unconventional superconductivity. Implications for systems such as CeRhIn5 and $CeCu_2Si_2$ will be discussed.

WE.F.1_I1 - A unified phase diagram of domain walls in 1d systems, ranging from strips to cylindrical wires

S. Jamet [1,2], N. Rougemaille [1,2], C. Thirion [1,2], J.C. Toussaint [1,2], O. Fruchart [1,2]

1. Univ. Grenoble Alpes, Institut NEEL, Grenoble, France
2. CNRS, Institut NEEL, Grenoble, France

Domain wall (DW) motion under magnetic field or spin current is an important research topic. The knowledge of their micromagnetic inner structure is a prerequisite to understand their motion. The phase diagram of domain walls in flat strips is firmly established, with transverse and vortex walls. In wires (cylindrical or square) micromagnetism predicted either transverse or a new type of wall, called Bloch-point wall; experimental confirmations are only emerging. We provide analytical arguments together with numerical simulations (home-made FeeLLGood software) to sketch a unified phase diagram for a geometry ranging from flat strips to nanowires of (i) square and (ii) circular section. A major aim is to provide a simple view of the important features of DWs. To achieve this we order DWs in terms of their topology, and phase-transitions.
Transverse and vortex walls share the same topology, motivating the name transverse-vortex, with a flux of induction going across the structure (obtained through rotation by pi/2 for a wire). The Bloch-point wall is of different topology, with magnetization essentially parallel to the surface at any location. Transition between these is of first order. We define indicators to quantify the few degrees of freedom such as an asymmetry and a curling, two features resulting from the driving force to decrease magnetostatic energy. For example, vorticity of magnetization around a given direction, either longitudinal or transverse, appears like a second-order transition when one or the two transverse dimensions are larger then circa seven times the dipolar exchange length. An asymmetry of the through-induction in transverse-vortex walls may appear when curling is not possible, eg for the already known transverse walls in flat and wide strips. Finally, analytical scaling laws were derived, eg for the length of walls in wires, scaling like radius squared.

WE.F.1_O2 - Magnetic structure of core-shell iron-iron oxide nanowires

I. Ivanov [1], A. Alfadhel [1], M. Alnassar [1], M. Vazquez [2], J. Kosel [1]

1. King Abdullah University of Science And Technology (KAUST), Thuwal, Saudi Arabia
2. Institute of Materials Science of Madrid, CSIC, Madrid, Spain

Over the past few years core-shell nanostructures have attracted considerable attention due to potential applications as multi-function materials in fields like nanomedicine, smart sensors or spintronics. In particular magnetite (Fe_3O_4) nanowires (NWs) are attractive for biomedical application due to their low-toxicity and biocompatibility. By creating Fe and Fe_3O_4 core-shell NWs, a tunable magnetic moment and controllable magnetic properties can be achieved, while at the same time a passivation layer is present. Polycrystalline and single crystal Fe NWs with 50 nm in diameter have been prepared by electrodeposition into alumina oxide membranes using two different aqueous solutions. NWs have been released from the membrane by dissolving the alumina. Core-shell iron-iron oxide structures have been fabricated by oxidizing the NWs in an oven at 150 ^{0}C for a time between 10 minutes and 72 hours in ambient atmosphere. To observe the evolution of the core-shell structure with annealing time, energy filtered TEM (EFTEM) together with electron diffraction analysis has been utilized. For the polycrystalline iron NWs, increasing the oxidation time results in a gradual decrease of the Fe core and an increase of the iron oxide shell thickness. After 24 hours, the oxidation is practically completed. In contrast, for the single crystal Fe NWs, the formation of the iron oxide shell is much slower. A maximum shell thickness of 12 nm was obtained after 72 hours of annealing time. In contrast to the Fe NWs, the magnetic reversal mechanism of core-shell NWs includes two separate regions, which correspond to the switching of the magnetite shell and the Fe core. Note that the oxidation process creates several pinning sites for domain walls along the polycrystalline core-shell NW. Therefore, the magnetic reversal process includes the formation of a multi-domain state, which remains after removing the field. The magnetic moment measured by electron holography is 2.0 T for the Fe core and 0.25 T for magnetite.

WE.F.1_O3 - Electron holography of magnetic states in cylindrical Co/Cu multilayered nanowires

N. Biziere [1], D. Reyes [1], B. Warot-Fonrose [1], T. Wade [2], C. Gatel [1]

1. CEMES, UPR 8011 CNRS, Toulouse, France
2. LSI, UMR 7642 CEA/CNRS/Ecole Polytechnique, Ecole Polytechnique, Palaiseau, France

We present a complete structural and magnetic characterization of cylindrical Co/Cu multilayers performed combining Energy Filtered Transmission Electron Microscopy (EFTEM), electron holography and 3D micromagnetic simulations.
Nano-layers are grown by template synthesis from a single electrochemical bath. EFTEM allows for a precise geometrical and chemical characterization of the layers. We demonstrate a 10 % amount of Cu impurities in the Co. The layers are shown to grow tilted 10 to 20^{o} about the perpendicular of the nanowire axis. The mean thickness of Co and Cu is 24 nm and 14 nm respectively with a mean diameter of 54 nm. Remanent magnetic states in Co layers are observed by electron holography with a 2 nm spatial resolution. 3D magnetic configurations are deduced from comparison of the experimental and calculated electron phase shift induced by the magnetization. Calculations are performed with OOMMF including structural parameters measured by EFTEM.
We demonstrate that the remanent magnetic states can exhibit two different configurations. The first one corresponds to an antiparallel coupling between the Co layer magnetizations. The second one corresponds to coupled magnetic vortices. We will show that the emergence of each remanent state depends upon the structural characteristic of the layers, with the possibility in some particular cases to switch from one configuration to the other by application of a saturation field in the appropriate direction. A quantitative analysis of the experimental electron phase shift allows determining that the magnetization and exchange values of the cobalt layers are around 15 % smaller than the bulk values, while the anisotropy is only 30 % of the bulk. This study proves the potential of electrodeposition for spintronic applications such as vortex based nano-oscilators.

WE.F.1_O4 - Magnetization reversal of a single modulated magnetic nanowire

C. Bran [1], E. Berganza [1], E. M. Palmero [1], R. P. del Real [1], A. Fraile Rodríguez [2], A. Asenjo [1], M. Vazquez [1]

1. Instituto de Ciencia de Materiales de Madrid (ICMM)-CSIC, Madrid, Spain
2. Departament de Física Fonamental and Institut de Nanociència i Nanotecnologia (IN2UB), Universitat de Barcelona, Barcelona, Spain

The study of spin configuration of a modulated magnetic nanowire and the control over its magnetization reversal process becomes essential for the progress in advanced information storage, logic systems and sensing devices [1-2]. The modulated in diameter Co-based nanowires, electrodeposited into the pores of alumina membranes, have been released from the membranes and studied individually by HRTEM, MFM and XMCD-PEEM. The cylindrical modulated wires are formed by segments with diameters of around 150 nm, separated at every 400 nm by much shorter segments (modulations) with 170nm in diameter. The effect of competing anisotropies on the magnetic domain configuration is analyzed. CoFeCu nanowires present a bcc (110) crystalline structure, with a low magnetocrystalline anisotropy overcome by shape anisotropy, which redirects the magnetization along the nanowire axis. MFM and PEEM images show a strong magnetic contrast at the ends of the wire and a weaker contrast along the wires that seems to match the position of each modulation. Although the easy axis of the magnetization is along the axial direction and the remanent configuration is a single domain state, the magnetization of the nanowires is not homogeneous. The nanowires display contrast along the length due to increase of the stray field at the modulation regions. On the other hand, Co nanowires present hcp (110) crystalline structure with the easy axis of the magnetization perpendicular to the nanowire axis. The MFM and PEEM images show a more complex behavior indicating that, although a competition between anisotropies is expected, the magnetocrystalline anisotropy plays a dominant role in the magnetic domain configuration. Magnetic domains are formed all along the nanowire axis, in good agreement with micromagnetic simulations.

WE.F.1_O5 - Asymmetric spin wave propagation in thin films with Dzyaloshinskii-Moriya coupling

D. Cortés-Ortuño [1,2], N, M. Opazo-Damiani [1], R. Troncoso [1], R. Gallardo [1], P. Landeros [1]

1. Departamento De Física, Universidad Técnica Federico Santa María, Valparaíso, Chile
2. Institute for Complex Systems Simulation, University of Southampton, Southampton, United Kingdom

We have developed a general theory that describes the spin wave spectra of ferromagnetic films with Dzyaloshinskii-Moriya interactions, either of bulk or interfacial nature. In agreement with recent experiments [1], we demonstrate that, in the case that a bias field saturates the film magnetization, the spin wave dispersion relation is asymmetric with wave vector inversion, for a variety of ferromagnetic films with Dzyaloshinskii-Moriya interaction (DMI) and different crystallographic classes [2]. It is also predicted that, for non-zero wave vectors, the resonance frequency and resonance field can increase or decrease depending on the spin wave vector orientation. We provide explicit formulae for the spin wave dispersion relation, for the spin-wave frequency asymmetry, as well as for the dynamic susceptibility tensor for a film under microwave excitation, which can be used to understand Ferromagnetic Resonance (FMR) as well as Brillouin Light Scattering (BLS) experiments in these classes of magnetic thin films. It is proposed that the measurement of the frequency asymmetry can be useful to obtain the strength (D) of the Dzyaloshinskii-Moriya interaction [2]. We also predicted that depending on relative angle between the magnetization and the wave-vector, the asymmetry could be observed or not depending on the type of DMI, which may be used to characterize such magnetic coupling. It is also expected that in the case that the magnetization is perpendicular to the plane of the film, the frequency asymmetry vanish for every kind of DMI. For the case of interfacial DMI the frequency asymmetry is proportional to the sine of the angle between the magnetization and the wave-vector.

WE.F.2_I1 - Superconductivity in the layered iron-germanide YFe2Ge2

M. Grosche [1], K. Semeniuk [1], P. Reiss [1], J. Chen [1], Z. Feng [2], P. Logg [1], Y. Zou [1], G. Lampronti [3]

1. Cavendish Laboratory, University of Cambridge, Cambridge, United Kingdom
2. London Centre of Nanotechnology, University College London, London, United Kingdom
3. Department of Earth Sciences, University of Cambridge, Cambrige, United Kingdom

In the d-electron system YFe_2Ge_2, an unusually high Sommerfeld ratio of the specific heat capacity of order 100 mJ/(molK^2) and a non Fermi-liquid power law temperature dependence of the electrical resistivity signal strong electronic correlations in an anomalous metallic state. Full resistive transitions, diamagnetic screening and heat capacity anomalies observed at the transition suggest that pure samples of YFe_2Ge_2 superconduct below 1.8 K [1]. DFT studies have put forward alternative proposals regarding the pairing mechanism in YFe_2Ge_2 [2].

The electronic structure and superconducting properties of YFe_2Ge_2 are discussed in the context of the closely related alkaline metal iron-arsenide superconductors (K/Rb/Cs)Fe_2As_2, which have similarly enhanced heat capacities as YFe_2Ge_2, and which have recently been shown to superconduct in the pressure-induced collapsed tetragonal structure [3].

WE.F2_O2 - Magnetic-field-induced Lifshitz transitions in heavy fermion materials

G. Zwicknagl [1]

1. Institut F. Mathematische Physik, TU Braunschweig, Braunschweig, Germany

Recent results on the evolution with magnetic field of the Fermi surfaces in various Ce- and Yb-based heavy fermion compounds are reported. The heavy quasiparticles are calculated by means of the Renormalized Band method which explicitly accounts for the field-dependence of the g-factor enhancement and of the quasiparticle mass in a Kondo system [1]. The Zeeman splitting of the Kondo resonance induces a series of Lifshitz transitions. In $YbRh_2Si_2$, the theoretically predicted critical magnetic fields were shown to agree quantitatively with the positions of anomalies in transport properties [2,3]. Of particular interest is the influence of magnetic-field-induced Fermi surface transitions on Spin Density Wave instabilities as reflected in recent neutron scattering results.

5. Laboratoire Nationale des Champs Magnétiques Intenses, Grenoble, France

UCoGe is a ferromagnetic superconductor with a Curie temperature T_C=2.7K and a superconducting transition temperature T_{sc}=0.6K. The Curie temperature decreases with pressure and vanishes at a critical pressure: p_c=1GPa[1]. Superconductivity was observed both below p_c and above p_c with a maximum of T_{sc} just below the critical pressure. At ambient pressure in the ferromagnetic phase the upper critical field as a function of temperature shows an unusual upward curvature [2]. We report magnetoresistance and Hall effect measurements on UCoGe for field along the easy magnetization axis c as function of pressure in the ferromagnetic and paramagnetic states. At ambient pressure we observed several anomalies in the magnetoresistance and in the Hall effect for field up to 34T. These anomalies point to several Fermi surface instabilities as function of field. A clear signature of a Fermi surface reconstruction appears at H=17T where a small quantum oscillation frequency is suppressed and a large frequency appears. Measurements of Shubnikov-de Haas oscillations under pressure up to 2.5 GPa indicate only a small evolution of Fermi surface properties with pressure. No Fermi surface reconstruction has been observed around the critical pressure p_c. Finally, the upper critical field of UCoGe for field along the c axis increases with pressure through the critical pressure p_c. The unusual upward curvature of the upper critical field is also enhanced above the critical pressure, while the ferromagnetic fluctuations are expected to be reduced.

Recently, the technique of fabricating epitaxial superlattices consisting of heavy-fermion compounds and conventional metals has been developed and provides a new research field on f-electron systems[1,2]. For example, superlattice-superconductors $CeCoIn_5$/$YbCoIn_5$ show the strong enhancement of Hc2/Tc[2] where Hc2 is superconducting upper critical field at T = 0 K and Tc is critical temperature. In these superlattices, the heterostructure would play a key role, but its magnetic and electronic properties are have not been explored at the microscopic level. To investigate the magnetic and electronic properties in each block-layer(BL) of the superlattices, we performed nuclear magnetic resonance(NMR) measurement, which is one of the most suitable microscopic probes, on the $CeCoIn_5$/$YbCoIn_5$ superlattices as well as the thin films of $CeCoIn_5$ and $YbCoIn_5$. By comparing the spectra of these samples, we succeeded in identifying the 115In NMR signals arising from the $CeCoIn_5$ and $YbCoIn_5$ layers in the superlattices, separately. We measured nuclear spin relaxation rate(1/T1) in each BL, and found that 1/T1 of Ce-BL is suppressed with decreasing thickness of Ce-BL, although 1/T1 of Yb-BL is essentially unchanged with 1/T1 of the $YbCoIn_5$ thin film. This suggests that each BL is isolated and the proximity of f-electron with magnetic moment to nonmagnetic Yb-BL is unlikely. In addition, we compared the NMR spectra obtained in superlattices with different thickness of Ce-BL, and identified 115In-NMR signals arising from interfaces of heterostructures. From the measurement of 1/T1, we found that antiferromagnetic fluctuations are spatially varied along the c-axis even in the one Ce-BL.

We present resonant inelastic X-ray scattering (RIXS) experiments investigating electronic structural changes in response to the unusual valence transition in $YbInCu_4$. This system features free local moment behavior above the transition (Tv=42K), and strongly screened moments below, implying an order-of magnitude change in the Kondo scale in response to changes in temperature. Our hard X-ray RIXS measurements at the L3 edge of Yb are particularly sensitive to the itinerant states related to Yb 5d orbitals, and directly reveal the existence of a quasi-gap in the itinerant electronic band structure, as well as systematic shifts in spectral features implying movement of the Fermi level as the Yb valence changes. These observations highlight the central role of the itinerant gap influencing transition. Separate soft X-ray experiments at the M_5 edge are particularly sensitive to the localized Yb 4f orbital excitations, and give the first indication that the hybridization scale is apparent in these spectrum. These results, and pending order-of-magntiude improvements in the energy resolution of the RIXS technique portends a new day in the science of heavy fermions and valence fluctuating compounds.

WE.F2_O6 - Classical and quantum criticalities in the itinerant ferromagnet UGe_2: A microscopic interpretation

M. Wysokinski [1], M. Abram [1], J. Spałek [1,2]

1. Marian Smoluchowski Institute of Physics, Jagiellonian University, Krakow, Poland
2. Academic Centre For Materials and Nanotechnology, AGH University of Science and Technology, Krakow, Poland

We present [1,2] a microscopic interpretation of the complete magnetic phase diagram of the ferromagnetic superconductor UGe_2 as a function of applied magnetic field, pressure, and temperature, including its classical and quantum critical points. Our predictions are based on the Anderson Lattice Model tackled by the modified Gutzwiller approximation (SGA [3]). Appearance of two distinct ferromagnetic phases in our approach is associated with change of Fermi surface topology. Our predictions at temperature T=0 of magnetic and electronic properties compare favourably with the experimental findings of UGe_2 as seen in the neutron scattering, the magnetization data, and in the de Haas - van Alphen oscillations. For T>0, we provide a quantitative description of the all critical points observed in this compound [4], namely the critical ending point, the tricritical point, and the quantum critical ending point. Moreover, we propose that a new quantum critical point appears in close vicinity to the spin-triplet superconducting dome. We characterize it as a Lifshitz quantum critical point and suggest that it can be related to the appearance of quantum critical fluctuations near the Fermi-surface-topology instability, and hence is related to the onset of the spin-triplet superconductivity.

WE.F2_O7 - Symmetry of the excitations in the hidden order state of URu_2Si_2

M.A. Measson [1], J. Buhot [1], Y Gallais [1], A. Sacuto [1], M. Cazayous [1], D. Aoki [2], G. Lapertot [2]

1. University Paris Diderot – CNRS, Paris, France
2. Univ. Grenoble Alpes / Tohoku University, Grenoble, France

For three decades, the identity of the ordered phase, the so-called hidden order (HO), found in URu_2Si_2 at temperature below T0=17.5 K has eluded researchers despite intensive experimental and theoretical investigations. We address here the question of the symmetry of the novel excitations emerging from the HO state, a key information to solve the long-standing question of its nature.
We have performed polarized electronic Raman scattering on URu_2Si_2 single crystals at low temperature down to 8 K in the hidden order state and under magnetic field up to 10 T. The hidden order state is characterized by a sharp excitation at 1.7 meV and a gap in the electronic continuum below 6.8 meV. Both Raman signatures are of pure Γ symmetry. By comparing the behavior of the Raman sharp excitation and the neutron resonance at Q0=(0,0,1), we provide new evidence, constrained by selection rules of the two probes, that the hidden order state breaks the translational symmetry along the c axis such that Γ and Z points fold on top of each other. The observation of these distinct Raman features with a peculiar Γ symmetry as a signature of the hidden order phase places strong constraints on current theories of the hidden order in URu_2Si_2.
Symmetry of the Excitations in the Hidden Order State of URu_2Si_2

WE.G.1_I1 - Berry curvature, hall effect and topological edge modes of magnons

S. Murakami [1]

1. Tokyo Institute of Technology, Meguro, Japan

In electronic systems, various interesting phenomena such as spin Hall effect, quantum Hall effect, and topological insulators originate from nonzero Berry curvature of Bloch wavefunctions. This Berry curvature is calculated from the Bloch wavefunction and characterizes a geometric aspect of the Bloch wavefunction in k-space. We theoretically pursue analogous phenomena for magnons (spin waves). Such phenomena for magnons require some sorts of gspin-orbit couplingh. While it was known previously that the Dyaloshinskii-Moriya interaction plays this role, we proposed that the dipolar interaction also gives rise to nonzero Berry curvature. If we consider only the dipolar interaction in a thin-film ferromagnet in a long-wavelength regime, we can calculate an analytic form of the Berry curvature for each magnonic band, and only the magnetostatic forward volume-wave modes (i.e. magnetic field being out-of-plane) have a nonzero Berry curvature. When the exchange coupling is included, the magnonic bands are modified, and there occur a number of band anticrossing points. Around such an anticrossing point, the Berry curvature is enhanced. This Berry curvature gives rise to thermal Hall effect of magnons, and it also gives rise to a shift of wavepackets in reflection or refraction. We explain some experimental attempts to measure this shift. In analogy to the quantum Hall effect and topological insulators for electrons, we can design the magnon band structure to make it gtopologicalh. By introducing some artificial spatial periodicity into the magnet, for example by fabricating nanostructures with two different magnets in a periodic structure or by making a periodic array of nanomagnets, we theoretically propose emergence of topological edge modes, analogous to the edge modes in electronic quantum Hall effect. The edge modes are chiral, and propagate along the edge of the magnet in one way. We call this a topological magnonic crystal.

WE.G.1_O2 - The inverse thickness proportionality of the interfacial Dzyaloshinskii-Moriya interaction on the Pt/Co(CoFeB)/Al_2O_3 inverse symmetry broken structure

J. Cho [1], N.H. Kim [1], S. Lee [1], J.S. Kim [2], R. Lavrijsen [2], A. Solignac [2], Y. Yin [2], D.S. Han [2], N. Hoof [2], H. Swagten [2], B. Koopmans [2], C.Y. You [1]

In magnetic multilayer systems, a strong spin-orbit coupling at the interface between heavy metal and ferromagnetic layers can lead intriguing phenomena such as the perpendicular magnetic anisotropy (PMA), the spin Hall effect, the Rashba effect, and especially the interfacial Dzyaloshinskii-Moriya (IDM) interaction. The understanding of IDM interaction is important not only for the fundamental understanding of magnetic structure but also to spintronic applications based on the spin-orbit torque. Here, we demonstrate a novel experimental technique to observe the IDM interaction, so-called Brillouin light scattering (BLS). The non-reciprocal spin wave dispersions, systematically measured by BLS, allow determining the IDM energy densities. We fabricated Co and CoFeB thin film 1.0 to 3.0 nm, sandwiched Pt and Al_2O_3 layers using DC magnetron sputter. In order to precisely and systematically investigate this interface effect by means of BLS, two different methods (magnetic field dependence and incident angle dependence) as a function of the thickness of the Co and CoFeB are used. The quantitative magnetic layer thickness dependent measurements and careful analysis show the inverse proportionality of the frequency differences and confirm that the IDM interaction is indeed purely interfacial with maximum energy density of 1.2 (0.8) mJ/m^2 for 1.2-nm-thick Co (1.6-nm-thick CoFeB) with the Pt underlayer. Furthermore, two independent measurement methods, the magnetic field dependence and spin wave dispersion relations, allow us to confirm our results are free from artifacts such as different interface anisotropies of top and bottom interfaces.

WE.G.1_O3 - Deterministic magnetization switching driven by spin hall effect in ultrathin magnetic CoFeB/MgO heterostructures with tilted anisotropy

J. Torrejon [1,2], F. Garcia-Sanchez [3], T. Taniguchi [4], J. Sinha [2], S. Mitani [2], J.V. Kim [3], M. Hayashi [2]

4. National Institute of Advanced Industrial Science and Technology (AIST), Spintronics Research Center, Tsukuba, Ibaraki, Japan

In addition to conventional spin transfer torque (STT) [1,2], current-induced torques due to Rashba [3] and Spin Hall effects [4] (SHE) may open new paradigms for highly efficient magnetization reversal. In particular, the perpendicular magnetization switching by in-plane current in ultrathin ferromagnetic layer is attracting great interest owing to its potential for technological applications. However, the underlying mechanism of the switching process is yet to be identified. We report magnetization switching in wires (30 µm length and 5 µm width, respectively) patterned from CoFeB/MgO heterostructures with heavy metal (HM) underlayers: we focus in TaN underlayer however others HMs have been also explored (Hf, Ta and W). Using a Kerr microscopy, we study the threshold current needed to reverse magnetization as a function of pulse amplitude, pulse length and in-plane magnetic field. We observe distinct differences in the in-plane field dependence of the threshold switching current depending on the underlayer thickness. The STT is likely responsible for the switching for the thinner underlayer films whereas the SHE is the dominant mechanism for the thicker underlayer films. In the latter case, the switching process is asymmetric with respect to the initial magnetization state and the current direction. Such asymmetry cannot be explained by the action of the longitudinal (damping-like) and transverse (field-like) components of spin Hall torque. We find that the broken symmetry is ascribed to a slight tilt in the uniaxial anisotropy axis. The tilt develops during the film deposition process and strongly influences the magnetization switching with current[5]. Most importantly, the presence of such symmetry breaking anisotropy enables deterministic magnetization switching at zero external fields [5,6].

Electronic reconstruction at interfaces between different oxides is giving rise to a plethora of new functionalities and novel phenomena. Complex oxides are characterised by a strong interplay of the different degrees of freedom (orbital, spin and lattice) which can be engineered and modified at interfaces and surfaces. For instance, the interface between two insulating non-magnetic oxides (for instance, $LaAlO_3$ and $SrTiO_3$) can be metallic and ferromagnetic. Another example is that of heterostructures involving manganites, in which interfacial orbital and magnetic reconstructions can affect transport properties. This work constitutes a joint theoretical-experimental effort to understand the properties of a multilayer formed by a metallic ferromagnetic manganite oxide ($La_{0.7}Sr_{0.3}MnO_3$) and the insulating $SrTiO_3$. Magnetoresistance has been measured under a magnetic field which rotates with respect to the interface plane. In such a geometry, a peak in the magnetoresistance for a perpendicular magnetic field is expected and has been measured in other systems. However, our heterostructures also show an unexpected peak when the magnetic field is in plane. We have performed calculations of the resistivity in a model system which includes spin-orbit coupling. The results reveal that the unexpected in-plane maximum is due to transport through a two-dimensional ferromagnetic electron gas formed by orbital reconstruction at the manganite interface. These orbital and magnetic reconstructions are supported by X-ray linear dichroism and ab-initio calculations.

This work has been published in Advanced Materials 26, 7516 (2014).

WE.G.1_O5 - Spin-orbitronics: Investigation of the spin-to-charge current conversion by a topological insulator

J.C. Rojas-Sánchez [1,2], S. Oyarzun [3], A. Marty [3], C. Vergnaux [3], G. Desfond [3], S. Gambarelli [3], M. Jamet [3], Y. Ohtsubo [4], P. Le Fèvre [5], F. Bertran [5], A. Taleb-Ibrahimi [5], N. Reyren [1,2], J.M. George[1,2], A. Fert [1,2]

5. Synchrotron SOLEIL, Gif sur Yvette, France

We have used experiments of spin pumping by ferromagnetic resonance (FMR) to investigate the efficiency of the spin-to-charge current conversion (SCCC) by spin-orbit effects in different systems [1-4]. In 3D systems the SCCC can be obtained by the spin Hall Effect (SHE) and is then characterized by the dimensionless spin Hall angle, θ_{SHE} [1-3]. SCCC can also be obtained by the spin-orbit coupling of 2D surface or interface states, as in our recent experimental discovery of the Rashba-Edelstein Effect (REE) [4] at a Rashba interface. With 2D systems, the key parameter that accounts for the efficiency of the SCCC is a length, which is called λ_{IREE} for the REE of Rashba states [4,5].
The largest effects with 2D systems can be anticipated from the exploitation of the surface states of topological insulators. However one fundamental question, which is not yet experimentally answered, concerns the protection of the topological character of surfaces states when other layers such as ferromagnetic or normal metal layers are placed in contact with the topological insulator. I will mainly focus on the case of the topological insulator α-Sn [6], and present our recent ARPES experiment at the Cassiopee beamline at Synchrotron Soleil where we attempted to address this question. I will then present results of spin pumping FMR experiments on the same set of samples demonstrating a highly efficient SCCC.

WE.G2_I1 - Bulk magnon spin-current theory for the longitudinal spin-Seebeck effect

S. Rezende [1], R. Suárez [2], A. Azevedo [1]

1. Universidade Federal de Pernambuco, Recife, Brazil
2. Pontificia Universidad Católica de Chile, Santiago, Chile

The longitudinal spin-Seebeck effect (LSSE) consists in the generation of a spin current parallel to a temperature gradient applied across the thickness of a bilayers made of a ferromagnetic insulator (FMI), such as yttrium iron garnet (YIG), and a normal metal (NM) such as platinum [1]. The LSSE can be detected by two effects: (1) A DC voltage generated along the NM layer due to the conversion of the spin current into a charge current perpendicular to the static magnetic field by means of the inverse spin Hall effect: (2) A change in the magnetic relaxation of the FMI measured by the linewidth of the ferromagnetic resonance absorption or by the attenuation of spin-wave packets propagating along the FMI film. Depending on the sign of the gradient the relaxation rate can be increased or decreased, leading in the latter case to an apparent amplification. We will present a model for the LSSE that relies on the bulk magnon spin current created by the temperature gradient across the thickness of the FMI [2]. We show that the spin current pumped into the NM layer by the magnon accumulation in the FMI provides continuity of the spin current at the FMI/NM interface and is essential for the existence of the LSSE. The results of the theory are in good agreement with experimental data for the variation of the DC voltage with the sample temperature and with the FMI layer thickness in YIG/Pt bilayers. The model also explains the observed control of the magnetic relaxation rate in YIG/Pt under a thermal gradient applied across the thickness of the bilayer.

WE.G2_O2 - Electric-field-induced magnetic anisotropy in a nanomagnet investigated on the atomic scale

J. P. Hermenau [1], A. Sonntag [1], A. Schlenhoff [1], J. Friedlein [1], S. Krause [1], R. Wiesendanger

1. University of Hamburg, Hamburg, Germany

One of the challenges in data storage applications is the control of magnetic anisotropy: To stabilize a magnetic bit against thermal magnetization reversal a large anisotropy is needed, while a low anisotropy is desired when writing information. A possible control mechanism could be the selective application of an electric field that has been shown to modify the surface anisotropy of magnetic thin films [1,2]. However, the influence on a single nano-scaled magnet is so far largely unexplored.
In our experiments we investigate the impact of the electric field by observing the thermally driven switching of an individual atomic-scale magnet with uniaxial magnetic anisotropy. The biased probe tip of a spin-polarized scanning tunneling microscope (SP-STM) allows to apply electric fields up to 6 GV/m to in-plane-magnetized Fe nanomagnets on W(110) consisting of about 100 atoms [3]. The telegraphic signal which reflects the magnetization reversals of the nanomagnet in the tunneling current of an SP-STM is recorded for different bias voltages. The analysis of the telegraphic signals shows that the electric field E can be used to increase or decrease the switching rate, depending on the sign of E. This is attributed to an electric-field induced anisotropy that favors in-plane magnetization for $E < 0$ and out-of-plane magnetization for $E > 0$. The interpretation is verified by changing from the in-plane Fe/W(110) to the out-of-plane Fe/Mo(110) system. [4] The results of our experiments reveal a method to control magnetic properties of individual nanomagnets without exploiting spin or charge currents.

Rectification of microwave using magnetic tunnel junction (MTJ) is the promising candidate for high sensitive microwave detector, as demonstrated in spin-torque diode. [1] However the high detection sensitivity has been observed under only a lower dc bias current than the destabilizing current of the free layer magnetization In this study, we demonstrate enhancement of the rectified voltage using electric-field-induced ferromagnetic resonance (FMR) under a dc bias voltage, and achieved the high-output microwave voltage even in a large input rf power and a dc bias voltage. [2] An MTJ film was prepared by sputter deposition on thermally oxidized Si wafer: buffer layer/IrMn (10 nm)/$Co_{70}Fe_{30}$ (2.0 nm)/Ru (0.7 nm)/$Co_{16}Fe_{64}B_{20}$ (3.0 nm)/MgO (2.0 nm)/$Co_{16}Fe_{64}B_{20}$ (2.0 nm)/capping layer. The film was annealed at 300‹C for 2.0 h in a 600-mT in-plane magnetic field, which defined the direction of exchange-bias on the pinned layer parallel to the long axis of MTJ pillars. We measured the homodyne detection voltage for the input RF frequency of 2.0 GHz as a function of external magnetic field with tilted angle from the film normal direction. Under zero bias voltage, the spectrum with anti-Lorentzian structure was observed in FMR excited by voltage-torque. Under bias voltage application of -1.0 V, the shape of spectrum changes from an anti-Lorentzian structure to a Lorentzian structure, and clear enhancement of the rectified voltage was observed. This can be understood by the non-linear effect due to the asymmetric magnetization-potential in the free layer. This work was partially supported by the Strategic AIST integrated R&D Program, gIMPULSE: Initiative for Most Power-Efficient Ultra-Large-Scale Data Explorationüh, and ImPACT Program of Council for Science, Technology and Innovation (Babinet Office, Government of Japan).

The development of materials that combine magnetic and electric order parameters (multiferroic materials) drives intense research activities since the coupling of both order parameters opens the way to the electric control of magnetization. Composite multiferroics (combining ferroelectric and magnetic materials) are currently developed to optimize order parameter coupling that is often weak in intrinsic multiferroics: the magnetoelectric coupling in heterostructures is achieved either by strain or by modulation of charge carrier density. In the field of charge-driven magnetoelectric coupling, complex magnetic oxides are particularly interesting candidates because of the high sensitivity of strongly correlated magnetic systems to competing electronic ground states.

In this study, the influence of an electric field applied to a $La_{0.67}Sr_{0.33}MnO_3$ (LSMO)/$Pb(Zr_{0.2}Ti_{0.8})O_3$ (PZT)/Nb-doped $SrTiO_3$ (STO) heterostructure on the magnetization depth profile of the LSMO single crystal film has been explored by Resonant X-ray Magnetic Reflectivity (RXMR). First results show that the saturation magnetization (H=1kOe) of ferromagnetically ordered LSMO is not affected by the direction of the electric polarization of PZT. However, in the remanent state (H=0), the ferromagnetic thickness and remanent magnetization of the LSMO film appear to be reduced for the case of hole-charge accumulation at the LSMO/PZT interface.

In order to decouple electric-field induced and possible strain-induced effects from PZT, complementary neutron scattering experiments have been performed: LSMO films directly grown on Nb-doped STO have been submitted to either a bending strain or an electric field. Bending strain was applied to the sample using a four-point mechanical jig, while, in a separate experiment, charge was applied using an electric field produced by a parallel plate capacitor. This investigation shows that the bending strain affects the saturation magnetization, while the electric field affects the remanent magnetization of the LSMO film, thus confirming the electric origin of the effects observed in the LSMO remanent state by RXMR.

WE.G2_O5 - Reversible electric control of magnetic anisotropy in CoFeB/$BaTiO_3$ heterostructures with perpendicular magnetic anisotropy

L. Baldrati [1], C. Rinaldi [1,2], M. Asa [1], M. Cantoni [1], S. Bertoli [1], R. Bertacco [1,2]

1. Department of Physics, Politecnico Di Milano, Milan, Italy
2. IFN-CNR Institute for Photonics and Nanotechnologies, Milan, Italy

The electric control of magnetization represents a viable path to overcome the consumption and miniaturization limits of memory/logic spintronic devices. Magneto-electric coupling (MEC) in heterostructures made of ferroelectric and ferromagnetic materials is a promising route towards room-temperature electric-field-controlled magnetic devices. We have already demonstrated the on-off switching of the ferromagnetism in the interfacial Fe layers of the Fe/$BaTiO_3$ (BTO) system, via an electric field applied across the BTO. [1,2] Here we present recent results obtained on the CoFeB/$BaTiO_3$ interface. Ta(2.0 nm)/ CoFeB(~1 nm)/ BTO(150 nm)/ $La_{0.7}Sr_{0.3}MnO_3$(50 nm) stacks were grown on $SrTiO_3$ (001) substrates. Microcapacitors (100x70 microns) were patterned by means of optical lithography and ion beam etching. LSMO serves as a conducting and lattice matching layer while Ta is used for capping and stabilization of the out-of-plane anisotropy of the CoFeB layer. We found a magnetic coercive field variation up to 80% versus voltage applied to BTO. Noteworthy, the magnetization can be switched from upwards to downwards by reversing the voltage polarity across the BTO in a bias field of -5 mT. Reversing this uniform low bias field and addressing each pad via voltage pulses, allows to reversibly switch the magnetization of individual spintronic devices in a chip.

Magnetization control using an electric field at room temperature [1, 2] will be useful because of its expected ultra-low power consumption and coherent behavior. Magnetic anisotropy control using electricfield at room temperature in all solid-state devices was first done using an Fe ultrathin film grown on Au(001) surface and covered by an MgO layer [2]. The effect was soon applied to switch magnetization coherently [3], to excite FMR [4], and to modulate spin waves [5]. However, theoretical understanding of the effect has not been satisfactory. The size of the effect are in rough agreement with theories, however, even the sign of the effect can be opposite. The main reason of this difficulty is because of insufficient control of interfaces in our samples, although the effect is very sensitive to it. In my talk, I will also address to those difficulties and mention to a recent progresses in understanding the mechanism through XAS and XMCD measurements.

WE.H.1_I1 - Manipulation of magnetic skyrmions with spin-polarized STM

K. von Bergmann [1]

1. University of Hamburg, Hamburg, Germany

The spin textures of ultra-thin magnetic layers exhibit surprising variety. The loss of inversion symmetry at the interface of magnetic layer and substrate gives rise to the so-called Dzyaloshinsky-Moriya interaction which favors non-collinear spin arrangements with unique rotational sense [1,2]. An ideal tool to investigate such systems down to the atomic scale is spin-polarized scanning tunneling microscopy, which has enabled the discovery of spin spirals with unique rotational sense at surfaces [2]. Recently, different interface-driven skyrmion lattices have been found [3,4], which can be viewed as a two-dimensional analogon to spin spirals. Depending on the involved magnetic interactions single particle-like skyrmions can be realized and their writing as well as the deletion based on local spin-polarized current injection has been demonstrated [4]. An external magnetic field is used to tune the energy landscape, and the temperature is adjusted to prevent thermally activated switching between topologically distinct states. Switching rate and direction can then be controlled by the parameters used for current injection. In addition to measurements with spin-polarized currents we demonstrate that skyrmions can be detected with non-spin-polarized currents due to spin-mixing effects in the non-collinear spin texture. The strength of this new magnetoresistive effect correlates with the angle between nearest neighbors. As this is expected to be a general phenomenon we propose to use it as an easy and reliable scheme to detect skyrmions in future spintronics devices.

Magnetic vortices are attracting enormous interests since they have fascinating topological spin structures for fundamental studies of nanoscale spin behavior and offer a great potential as building blocks in advanced magnetic technologies [1]. To realize the practical application of magnetic vortices, a completely reliable control over the vortex spin structure is mandatory but it has been assumed to be hampered by stochastic nature. Therefore, Controlling and understanding stochastic behavior in magnetic vortex systems is premium. So far, most studies have assumed that thermal fluctuations are the main source for stochastic behavior in magnetic processes [2]. In this work, we provide evidence that the ultrafast dynamics in the initial stage of vortex formation process can be a critical factor for the stochastic behavior observed at steady state in asymmetric magnetic disks [3]. It was found that the dynamics triggering the stochastic nature in the vortex formation has a characteristic of chaos, the butterfly effect, where minute changes significantly determine the final outcome of a process. We also demonstrate that the proper design of the geometry in asymmetric disks can lead to fully deterministic behavior. This work would have a significant impact to acquire a deeper and fundamental understanding of nanospin behavior paving a way for potential applications. This work was supported by the Director, Office of Science, Office of Basic Energy Sciences, Materials Sciences and Engineering Division, of the U.S. Department of Energy under Contract No. DE-AC02-05-CH11231. In MnSi the transition from paramagnetism to helimagnetism in zero field is driven fluctuation-induced first-order by strongly interacting chiral fluctuations as described in the Brazovskii scenario [1]. Magnetic fields quench these fluctuations leading to a field-induced tricritical point (TCP) where the transition becomes mean-field second-order [2]. In addition, MnSi gives rise to a regular arrangement of spin whirls, the so-called skyrmion lattice, in finite fields just below the helimagnetic ordering temperature [3]. While it was established that the unwinding of these topologically non-trivial objects into a helimagnetic state is accomplished via emergent magnetic monopoles [4], it is still unkown how they crystallize from a paramagnetic state.

In order to address this question, we report a comprehensive study combing small-angle neutron scattering and neutron spin echo spectroscopy using the MIEZE technique, which allows to measure under applied magnetic field without loss of energy resolution. The quasi-elastic linewidth recorded by means of MIEZE shows a change of the characteristic spin fluctuations at the TCP, providing microscopic evidence for its existence. In the field range of the skyrmion lattice, our data suggest the presence of fluctuations with a skyrmionic character already above the onset of static order. These findings are supported by high-resolution specific heat data, measurements of the longitudinal and the transversal ac susceptibility, as well as by all-electrical broadband spectroscopy showing excitations in the GHz range that may be attributed the gyration of skyrmion-like objects [5].

The characterization of defects in ferromagnetic nanostructures is of special importance for magnetic data storage based on vortices or domain walls moving through nano-devices, since their presence may modify critically the vortex or domain wall dynamics [1,2]. In this paper we study experimentally the temperature dependence of frequency, line-width and power of the vortex oscillations in $Co_{40}Fe_{40}B_{20}$(3nm)/MgO(1.1nm)/$Co_{40}Fe_{40}B_{20}$(2nm)/$Ni_{81}Fe_{19}$(30nm) magnetic tunnel junctions (MTJ) circular pillars (d=460nm,590nm,780nm) in presence of defects. Small power oscillations in MTJs caused by thermal fluctuations [3] are especially sensitive to defects that pin the vortex and change the oscillation frequency [4,5]. When applying an in-plane magnetic field the oscillation frequency exhibits maxima and steep minima at certain field values. While the frequency maxima correspond to the oscillations of the pinned vortex [2], the minima correspond to the field induced depinning of the vortex where the energy landscape becomes flat and large amplitude, high power oscillations occur. The depinning is influenced by thermal fluctuations which help to overcome the energy barrier. We analyze the temperature dependent power spectra by using a Thiele based model including a white noise term and numerically solve the stochastic differential equation. The vortex pinning by defects is taken into account by a Gaussian pinning potential. We find experimentally that at certain field values a Barkhausen-like [6] depinning at low temperatures (<70K) occurs, showing temperature and rate dependent field hysteresis. We attribute these frequency jumps to strong defects (e.g. inclusions). The frequency maxima, which correspond to pinning by small defects (e.g. surface roughness), show a frequency increase up to 1200MHz at 4K (with respect to 450MHz of the unpinned vortex), which corresponds according to our model to pinning potentials of -0.7eV to -0.9eV. The approach shows that the description of magnetization dynamics in terms of vortex core position is consistent with the experimental results also in presence of thermal fluctuations.

WE.H.1_O5 - Observation of magnetic skyrmions at room temperature in ultrathin Pt/Co/MgO perpendicularly magnetized multilayers by XMCD-PEEM

O. Boulle [1], S. Pizzini [2], J. Vogel [2], L. Buda-Prejbeanu [1], O. Mentes [3], A. Locatelli [3], A. Sala [3], G. Gaudin [1]

Magnetic skyrmions are currently attracting lots of attention due to their stability, their poor sensitivity to material defects and the fact that they can be moved by currents with very small densities, which opens a path for novel spintronics data storage devices. So far, magnetic skyrmions in thin films have only been observed on free surfaces under ultra-high vacuum and low temperature, which prevents any use for applications. Here we show that the large Dzyaloshinskii-Moriya interaction in ultrathin magnetic multilayers allows stabilizing skyrmions at room temperature in patterned structures. We carried out XMCD-PEEM magnetic imaging on the Nanospectroscopy beamline in Elettra, Italy in ultrathin Pt/Co/MgO/Ta perpendicularly magnetized multilayers. The high spatial resolution of the technique combined with the larger magnetic contrast for in-plane compared to out-of-plane magnetization allows the observation of the magnetization within the magnetic domain walls (DW). The observation of the multidomain structure in the unpatterned thin film reveals that the magnetization in the DW is oriented perpendicularly to the DW surface, with opposite orientations for up/down and down/up magnetic DW. DW are thus chiral Néel DW which is a signature of the Dzyaloshinskii-Moryia interaction. In patterned sub-micronic squares, we observed 200 nm wide magnetic bubbles delimited by chiral Néel DWs, which are identified as chiral NÚel magnetic skyrmions.

WE.H.2_I1 - Metamagnetism in heavy fermion systems

G. Knebel [1,2], A. Pourret [1,2], D. Aoki [1,2,3], T. Combier [1,2], A. Palacio Morales [1,2], G. Lapertot [1,2], T. D. Matsuda [4], J. Flouquet [1,2]

4. Tokyo Metropolitan University, Hachioji, Japan

In this presentation we will discuss examples of metamagnetism in different heavy fermion compounds. In the first part we will review recent transport experiments on the itinerant 5 f system UCoAl. This is a paramagnet at ambient pressure, i.e. the quantum critical point is located at slightly negative pressure, and presents a canonical compound to study metamagnetic phenomena and the wing structure of the generic T–p–H phase diagram of an ferromagnet. Under field the system undergoes a first order metamagnetic transition to a field-induced ferromagnetic state at the critical magnetic field Hm = 0.7 T. Hall effect, resistivity, and thermoelectric power measurements were performed up to 2 GPa and 13 T on a single crystal of UCoAl. Hall effect measurements indicate a critical pressure near 1.6 GPa and a critical field near 7 T, while the other transport experiment point to a higher critical pressure. The pressure – temperature - magnetic field phase diagram will be discussed in detail. In the second part of the talk we will discuss antiferromagnetic systems where the a Lifshitz-type transition of the Fermi surface occurs when the magnetization reaches a critical value. This will be discussed for the heavy fermion compounds $CeRu_2Si_2$ and $YbRh_2Si_2$. We will discuss different transport properties and compare them to Fermi surface studies with quantum oscillation experiments.

WE.H.2_O2 - Controlling the coupling among many-body Kondo states in atomically designed Co atomic structures

M. Moro-Lagares [1,2], M. Piantek [1,2], M.R. Ibarra [1,2], J. I. Pascual [3], D. Serrate [1,2]

1. INA-LMA, University of Zaragoza, Zaragoza, Spain

3. CIC-Nanogune and IKERBASQUE, San Sebastian, Spain

We investigate the hybridization of Kondo many-body states as interactions through conduction electrons among them are controllably strengthened. As a model system, we use Kondo screened Co adatoms (TK=55 K) over the Ag(111) surface studied by scanning tunneling spectroscopy and atomic manipulation at a base temperature of 1.1 K. We obtain spatially resolved images of the Kondo many-body resonance as a function of proximity to and number of atomic neighbors, which exhibit non-local Kondo screening [1,2] away from the atoms centers for interatomic distances below 8.7 Å. This is interpreted as the formation of hybrid 1-D many-body states, and show distinct features compared to the case of hybridized one-particle wave functions in atomic wires. Increasing the number of neighbors at 5.8 Å, the energy scales of the hybridization and Kondo screening become comparable and, as a consequence, magnetic Ruderman-Kittel-Kasuya-Yosida (RKKY) interactions develop. RKKY correlations lift the spin degeneracy of the isolated Co states, and lead to the energy broadening of the Kondo spectral features[3,4]. The dependence of the broadening on the Co cluster structure is compared with the expected spin splitting from a Heisenberg spin-1/2 ferromagnetic model Hamiltonian, and reveals an RKKY spin coupling constant of about 1.5 meV (about TK/2). With the aid of structural design of atomic scale ensembles, our results show how indirect interactions mediate the transition from Kondo screened isolated impurities to a Kondo lattice, and finally to a RKKY correlated magnetic structure.

WE.H.2_O3 - Ferromagnetic Kondo lattice behaviour of $CeZn(Zn_{0.29}Si_{0.71})2$

H. Michor [1], F. Failamani [2], A. Grytsiv [2], G. Giester [3], E. Bauer [1], P. Rogl [2]

1. Institute of Solid State Physics, Vienna University of Technology, Vienna, Austria
2. Institute of Physical Chemistry, University of Vienna, Vienna, Austria
3. Institute of Mineralogy and Crystallography, University of Vienna, Vienna, Austria

We report on the ferromagnetic Kondo lattice behavior of novel $CeZn(Zn_{0.29}Si_{0.71})2$, which was studied by means of ac and dc magnetic susceptibility, specific heat and resistivity measurements on flux-grown single crystals as well as on sintered bulk samples. The orthorhombic CeNiSi2-type phase $CeZn(Zn_{0.29}Si_{0.71})2$ [space group Cmcm, a=0.42079(1), b=1.765218(3), c=0.41619(1) nm] was identified in the course of an investigation of the phase equilibria in the Ce-Zn-Si system (<33.3 at.% Ce) in Ref. [1]. Field dependent isothermal well as temperature dependent magnetisation measurements reveal ferromagnetic ordering of $CeZn(Zn_{0.29}Si_{0.71})2$ below about Tc=4.4 K with a magnetically ordered moment near 1 µB/Ce at 1.9 K and 6 T. The corresponding specific heat anomaly at 4.4 K displays a significantly reduced magnitude as compared to the value expected from a basic local moment mean-field approach and is analysed in terms of a simple model for a ferromagnetic Kondo lattice system based on the resonant level model by Schotte and Schotte [2], thus, yielding parameters for the ferromagnetic exchange coupling J = 14.6 K and the Kondo temperature TK = 5 K. The effective paramagnetic moment of Ce, µeff = 2.5 µB, obtained from a Curie-Weiss fit suggest that the ground state of Ce-ions in this compound is close to 3+.

$YbNi_4P_2$ is a ferromagnetic Kondo lattice system with a Kondo temperature of 8K and a small Curie temperature of 0.15K. It is close to a ferromagnetic quantum critical point, which can be induced by substitution of phosphorus by arsenic [1]. A magnetic field of 60mT applied along the crystallographic c-axis is also able to suppress the ferromagnetic order, above which $YbNi_4P_2$ is a field-polarized Fermi liquid. We performed thermopower, resistivity, and specific heat measurements to study the evolution of $YbNi_4P_2$ in magnetic fields up to 12T. While we observe signatures of strong fluctuations at small fields, our measurements detect multiple transitions at higher fields between 0.5T and 12T. To analyse the high field behaviour, we explore the validity of the Mott formula, relating the thermopower to electrical conductivity, which gives important information about scattering mechanisms especially around the observed transitions. Using the combination of the transport results with thermodynamic properties, we obtain further insights into the origin of the transitions in $YbNi_4P_2$. Some of them present characteristics similar to those identified as Lifshitz-type in previous studies on the two Kondo lattices $YbRh_2Si_2$ [2] and $CeRu_2Si_2$ [3]. Lifshitz-type transitions mark changes of the Fermi surface topology, but break no symmetries. Kondo lattice systems are ideal materials to study Lifshitz transitions, since the Zeeman energy and the electronic bandwidth are comparable.

The Kondo semiconductor $CeRu_2Al_{10}$ orders antiferromagnetically at TN=27 K in spite of the small ordered moment μord=0.34μB. We have investigated the effect of electron doping (i.e. 3% Si) on the Al site in $CeRu_2Al_{10}$ on the direction and magnitude of the ordered state Ce moment as well as on the spin gap formation using muon spin rotation (μSR), neutron diffraction (ND) and inelastic neutron scattering (INS). Our μSR study shows a strong increase of the electronic relaxation rates and 2/3 drop in the initial symmetry below 19 K, indicating the long range magnetic ordering (at TN=18.5 K) with large internal fields (>800G) at the muon sites. The ND study confirmed a long range magnetic ordering of the Ce-moment with a propagation vector k=[1 0 0]. This is similar to the ordering observed in the parent compound $CeRu_2Al_{10}$, however, the direction of the ordered state moment along the a-axis and its size (μord=1.3μB) are in sharp contrast to the small moment (μord=0.34μB, TN=27 K) observed along the c-axis in $CeRu_2Al_{10}$. The INS study does not reveal any clear sign of spin gap excitations at 5 K, indicating that the spin gap has nearly closed with electron doping on the Al-site. These observations are very similar to those found for electron doping (i.e. Ir/Rh) on the Os/Ru site in $CeOs_2Al_{10}$/ $CeRu_2Al_{10}$ and shows that the effect of electron doping either on the transition mental site (T=Ru, Fe and Os) or on the Al site gives very similar changes in the magnetic and electronic properties of the Kondo semiconductors CeT_2Al_{10}. These results suggest that part of the spin gap excitations should be originating from the electron and hole pockets of the Fermi surface and provide a basis to develop and test realistic theoretical models to understand the physics of these compounds.

WE.H.2_I6 - The importance of orbital occupation in heavy fermion compounds investigated by means of x-ray spectroscopy

A. Severing [1], F. Strigari [1], M. Sundermann [1], W. Thomas [1], H. Maurits W. [2], L. Hao Tjeng [2]

1. University of Cologne, Cologne, Germany
2. Max-Planck Institute for Chemical Physics of Solids, Dresden, Germany

The importance of k-dependent hybridization in heavy fermion compounds has been suggested by several authors (e.g. Ref.s[1-3]) and should be visible in the anisotropy of the 4f ground state wave function. However, standard experimental methods were lacking accuracy so that only recently it was shown with a new experimental approach that the orbital anisotropy correlates with a heavy fermion phase diagram, from magnetically ordered to superconducting [4]. Other theories even suggest orbital transitions as function of hybridization [5,6] but are still waiting to be challenged by experiment.
We investigate the orbital occupation of cerium heavy fermion compounds by means of soft x-ray absorption spectroscopy and hard x-ray non-resonant inelastic scattering. In the former the dipole selection rules of linearly polarized light give access to the ground state symmetry with unprecedented accuracy (see e.g. [4,7,8]). In the latter the multipole selection rules of the double differential scattering cross-section contains information about the orbital symmetry plus they yield information about the rotation of an orbital with fourfold symmetry, thus completing the crystal-field picture [9].
These methods have been successfully applied to several metallic as well as insulating-like heavy fermion compounds. Several examples shall be given and the importance of orbital occupation shall be stressed.

WE.I.1_I1 - Interface-driven chiral spin textures in ultrathin magnetic films

G. Beach [1]

1. Department of Materials Science and Engineering, Massachusetts Institute of Technology, Cambridge, United States

Spin orbit coupling at interfaces in ultrathin magnetic films can give rise to chiral magnetic textures such as homochiral domain walls and skyrmions, as well as current-induced torques that can effectively manipulate them [1-3]. This talk will describe the statics and dynamics of chiral spin textures in thin-film nanowires stabilized by the Dzyaloshinskii-Moriya interactions (DMI) at a heavy metal/ferromagnet interface. We show that the DMI depends strongly on the heavy metal, differing by a factor of ~20 between Pt and Ta [2], and describe the influence of strong DMI on domain wall dynamics [1,2] and spin Hall effect switching [3]. We present high-resolution magnetic imaging of static magnetic textures that directly reveal the role of DMI and allow its strength to be quantified [4]. Finally, we will describe how a gate voltage can be used to control interfacial magnetism and magnetic domain walls in nanowires by manipulating interfacial oxygen coordination and magnetic anisotropy at a ferromagnet/oxide interface [5].

WE.I.1_O2 - Chiral effects in domain wall velocity and nucleation in Pt/Co/MOx films: The influence of the Dzyaloshinskii-Moriya interaction

S. Pizzini [1], J. Vogel [1], S. Rohart [2], L. Buda-Prejbeanu [3], M. Miron [3], G. Gaudin [3], O Boulle [3], E. Jué[3], A. Thiaville [2]

Chiral effects in current or field-driven domain wall (DW) motion in Pt/Co/MOx stacks with perpendicular magnetic anisotropy can be explained by the presence of chiral Néel walls stabilised by the Dzyaloshinskii-Moriya interaction (DMI). We show that the nucleation of reversed domains in a microstructure is also chiral and affected by the presence of DMI. The nucleation of domains in Pt/Co(0.6nm)/MOx (M=Al,Gd) stacks, induced by a z-field in the presence of an x-field, has been studied by Kerr microscopy. Nucleation occurs preferentially at one edge of the sample, normal to the x-field, where the DW magnetisation is parallel to the x-field (S. Pizzini et al. PRL 2014). The edge where nucleation takes place, which depends in a chiral way on the initial domain magnetization and applied field directions, points to Néel walls with left-handed chirality, stabilised by negative DMI. The nucleation field at the edges strongly decreases as the x-field increases, unlike the nucleation within the film. This decrease of the nucleation field is due to the decrease of the DW energy with the x-field in the presence of DMI. The DW energy becomes negative for x-fields around 200 mT, and domains nucleate without a z-field. Fiel- and urrent-driven domain wall motion in Pt/Co/Gd/Ox samples has also been studied. We show that the field driven low speed regime (creep regime) is strongly influenced by the details of the Gd/Co interface and cannot always be explained by the models proposed so far.

WE.I.1_O3 - Electrical switching of the perpendicular magnetization in Pt/[Co/Ni]3/Al multilayers

J.C. Rojas-Sánchez [1,2], J. Sampaio [3], P. Laczkowski [1,2], N. Reyren [1,2], C. Deranlot [1,2], S. Collin [1,2], K. Bouzehouane [1,2], V. Cros [1,2] N, H. Jaffrès [1,2], A. Mougin [3] , A. Fert [1,2], J.M. George [1,2]

2. Université Paris Sud, Orsay, France
3. Laboratoire de Physique des Solides, Université Paris Sud, Orsay, France

Electrical control of the magnetic and resistive states in spintronic nanostructures is highly desirable. The spin to charge current conversions (SCCC) due to spin-orbit (SO) coupling opens the way to manipulate the magnetization by electrical means. In particular, using spin pumping by ferromagnetic resonance (FMR) experiment, we investigated the SCCC induced by spin Hall effect (SHE) in metals such as Pt [1,2] or AuW [3]. We found spin Hall angles that are large enough to drive the magnetization by SHE-induced spin torques.
In the context of an active debate [4-7] about the magnetization reversal mechanism(s) by SO torques, we will present results demonstrating the control of the magnetization in Pt/(Co/Ni)3/Al multilayers with perpendicular magnetization driven by electrical current. Using both the anomalous Hall Effect and Kerr experiments in patterned Hall bars, we are able to establish a scenario for the reversal mechanism involving domain wall motions and SO torques induced by SHE in Pt. In our scenario, the Dzyaloshinskii-Moriya interaction (DMI) at the Pt/Co interface [8] plays only a minor role in the reversal mechanism.

WE.I.1_O4 - Influence of Joule heating on current-driven domain wall depinning

S. Moretti [1], V. Raposo [1], E. Martinez [1]

1. University of Salamanca, Salamanca, Spain

The analysis of the current-induced domain wall depinning (CIDWD) in ferromagnetic strips is not only crucial for the development of logic [1] and storage applications [2], but it is also interesting from a fundamental point of view. Although these depinning processes have been widely studied experimentally [3], the underlying theory of the interaction between a spin polarized current and the local magnetization is not completely understood. Experiments are usually interpreted in terms of a model where the current only generates both adiabatic and non-adiabatic spin-transfer torques (STT) [4]. However, due to the conductive nature of the strips, the current also generates space- and time-dependent Joule heating (JH) which could influence significantly the depinning process, and consequently, result in a different estimation of the STT parameters. In this work we explore numerically the role of the JH on the CIDWD by coupling the magnetization dynamics with the heat transport for a Permalloy strip [5] on top of a Si/SiO2 substrate, as in typical experiments [3]. We study the critical depinning current densities as a function of the applied field. Our results clearly indicate that JH has a strong influence on the depinning process, and in particular, it significantly reduces the value of the critical depinning current and leads to symmetric phase diagrams with respect to the direction of the flowing current, as usually obtained in experiments. This study suggests that thermal effects must be taken into account to extract realistic information about the STT phenomena.

WE.I.1_O5 - Perpendicularly magnetized spintronic memristor

S. Lequeux [1], J. Sampaio [1], R. Matsumoto [2], A. Fukushima [2], K. Yakushiji [2], S. Yuasa [2], V. Cros [1], J. Grollier [1]

2. AIST, Tsukuba, Japon

Memristive devices are tunable nano-resistors which can store and process information [1]. Among their most interesting applications are multi-level memories and plastic synapses in neuromorphic architectures, which both require these devices to present a large number of resistance states. Spintronics offers the possibility to engineer memristors based on purely electronic writing by displacing a domain wall (DW) in the free layer of a magnetic tunnel junction thanks to spin torque [2]. In this case, the number of resistance states is equal to the number of positions where the DW can stabilize [2-4]. Here, we will show how perpendicularly magnetized (PMA) junctions can be engineered to fabricate very efficient, multi-state spintronic memristors. Our systems are FeB/MgO/FeB magnetic tunnel junctions [5] shaped as stripes (~ 0.1 x 1 µm2). As expected for a PMA system, the number of resistance states is largely increased compared to our first generation of memristor [2-4] and is sufficient for bio-inspired applications. We have optimized the width of the stripes in order to accommodate a DW with a magnetic configuration between the Block and Néel DW configurations. This offers the possibility to harness the Slonczewski torque (ST) in addition to the field-like-torque (which is generally smaller than the ST) to move the DW [6]. We will present the numerical 1D model that we have developed to highlight the contribution of each torque in the DW depinning process. In our junctions, we measure that the DW motion occurs for very low current densities (about 1-2 106 A/cm2) under perpendicularly injected current. This observation, together with the general trends for the depinning as a function of field, indicate that indeed, both torques are involved in the DW dynamics. In addition, we observe that the the displacement and depinning of the DW is remarkably stochastic. Supported by our model, we interpret this behavior by the fact that in the hybrid Bloch/Neel DW that we have chosen to enhance the ST contribution, the intrinsic dynamics for the DW is the Walker regime.

This research was partly funded by the French Ministry of Defense (DGA) and the European Research Council (Stg 259068).

WE.I.2_I1 - Spin-caloritronics in magnetic tunnel junction nanodevices

S. Serrano-Guisan [1], N. Liebing [2], T. Böhnert [1], K. Rott [3], E. Paz [1], R Ferreira [1], G. Reiss [3], H.W. Schumacher [2]

3. Universität Bielefeld, Bielefeld, Germany

Spin-caloritronics [1] is a new emerging field of spintronics where thermal gradients developed in nanostructured devices can play an active role to control and manipulate spin-based effects like thermally driven spin currents [2, 3] and heat driven magnetization reversal [4]. Such effects are very promising to improve energy efficiency in future devices as well as to develop novel applications for industry and metrology such as magnetic heat valves. However, to date, many concepts have only theoretical basis and need to be studied experimentally. Moreover, the large current densities involved in spin transfer torque effects in magnetic tunnel junction (MTJ) nanodevices imposes a better knowledge of the interplay of heat, charge and spin currents at such conditions. Here we will present a compilation of the observed spin-caloric properties in MTJ nanodevices like the large Tunneling Magneto-Seebeck (TMS) ratios [5, 6] and its angular dependence [5, 7], the Tunneling Magneto-Thermocurrent [8] and the possibility to explore thermal spin transfer torque effects on magnetization dynamics. We will also discuss the uncertainty of input parameters and its large influence on the calculated temperature profile through the nanostructure (and hence on the derived Seebeck coefficients) [9], and we will show some different approaches to minimize it. Moreover, in order to establish a reliable method to derive Seebeck coefficients different experimental techniques for magneto-thermoelectric measurements in MTJ nanodevices (optical heating [6], electrical heating [5] and ohmic nonlinear correction [10]) will be considered.

WE.I.2_I2 - Spin pumping and magnon-drag effect

M. Costache [1], G. Bridoux [1], I. Neumann [1], S. Valenzuela [1]

1. Catalan Institute of Nanoscience And Nanotechnology (ICN2), Bellaterra, Spain

Spin related effects have been intensivelly studied using electrical transport methods, by measuring the spin diffusing length in metals and semiconductors. In addition to electrical transport, the thermoelectric properties of magnetic materials are increasingly gathering more attention. There, thermal magnons are expecting to play an major role. However, despite intensive studies on the spin transport, the coupling between electrons and magnons in ferromagnetic metals remains poorly known. We demonstrate a conceptually new device that enables us to gather information on magnon-electron scattering and magnon-drag effects[1]. The device resembles a thermopile formed by a large number of pairs of ferromagnetic wires placed between a hot and a cold source and connected thermally in parallel and electrically in series. By controlling the relative orientation of the magnetization in pairs of wires, the magnon drag can be studied independently of the electron and phonon drag thermoelectric effects. Measurements as a function of temperature reveal the effect on magnon drag following a variation of magnon and phonon populations. These results demonstrate the feasibility of directly converting magnon dynamics of nanomagnets into an electrical signal and could pave the way to novel thermoelectric devices for energy harvesting. This research was founded by the Spanish Ministry of Science (MICINN/MAT2010-18065) and by the European Union (FP7/NANOFUNCTION-257375).

Since 2008, some publications have reported a surprising magneto-voltaic signal measured on an electrode in response to a thermal excitation [1]. We show here that the corresponding magneto-voltaic voltage can be interpreted in terms of Magnon Hall and planar Righi-Leduc effects [2], due to the anisotropic temperature difference generated by the heat current. The transverse electrode plays the role of a thermocouple that measures locally the temperature difference. The predicted magneto-voltaic signal DV measured on the transverse electrode in response to a thermal heat current Q, along the (Ox) direction is given by the equation [2] :
$\Delta V = Q\ \Delta S\ [(\Delta r \sin(2\theta)\sin 2\varphi)/2 + r_H \cos\theta]$ (1) where θ and φ are the angle describing the assumed uniform magnetisation of the ferromagnetic layer, ΔS is the amplitude of the thermocouple, Δr is the Planar Righi-Leduc coefficient and r_H is the "magnon Hall" or equivalently "anomalous Righi-Leduc" coefficient. We experimentally checked that our signal follows Equation (1)
On the one hand, the Magnon Hall effect is analogous to the well-known anomalous Hall effect and to the anomalous Nernst effect. On the other hand, a second transverse force is observed, which is generated by the anisotropy of the ferromagnetic excitations. The two forces are due to the same ferromagnetic axial vector, which is responsible for both the anisotropy of the heat resistance and the breaking of the time invariance symmetry. *We conclude that both planar Righi-Leduc and magnon Hall effects should be a priori present in any ferromagnetic materials in the same manner as anomalous and planar Hall effects can be expected a priori in any ferromagnetic conductors.*

There has been a growing demand for efficient means for generating spin currents as it is a key quantity in driving the functionality of spintronic devices. An emerging technique called 'spin pumping' [1], i.e., a spin injection from a precessing feromagnet into an adjacent spin sink, is now established as a versatile method for the spin current generation. The spin pumping has an advantage that it is not accompanied by any charge transfer across the spin injector/spin sink interface and thus free from the impedance mismatch problem which often hinders a spin injection into semiconductors [2]. Here we theoretically demonstrate that, when an itinerant weak ferromagnet near its Curie temperature (Tc) is used as the spin sink, the resultant spin pumping is significantly amplified owing to the fluctuation enhancement of the spin conductance across the precessing ferromagnet/spin sink interface [3]. We also discuss the mechanism of the plasmonic spin pumping recently demonstrated for a Pt/YIG bilayer with Au nanoparticles being embedded [4].

3. I. Physikalisches Institut, Justus-Liebig-Universität Gießen, Gießen, Germany

In recent spincaloritronic research, several groups have observed the tunnel magneto-Seebeck effect (TMS) in magnetic tunnel junctions (MTJs) incorporating CoFe electrodes and MgO tunnel barriers [1, 2]. Semiconducting materials are known to have large Seebeck coefficients. This is mainly attributed to the gap in their band structure and the asymmetric position of the Fermi-level. Accordingly, half-metals with a band-gap for only one spin-channel may have very different Seebeck coefficients for the majority and minority charge carriers. The tunnel magneto-Seebeck effect (TMS) is a powerful tool to investigate such spin-dependent Seebeck coefficients because separate spin-channels can be defined in magnetic tunnel junctions (MTJs). Here, we investigate the spin-dependent Seebeck coefficients of half-metallic Heusler compounds in Heusler/MgO/CoFe MTJs. In comparison to CoFeB/MgO/CoFeB MTJs with TMR ratios of 80 to 230 % and TMS ratios of 5 to 50 % we find for Co_2FeSi as electrode material TMS ratios of up to 100 % with TMR ratios in the same range. Furthermore, we observe an increase in the measured voltage signal from 10 to 30 µV in CoFeB to 3 mV in Co_2FeSi based MTJs when heating with a laser power of 150 mW. In addition, thermocurrent measurements were carried out as a function of applied laser power.

WE.I.2_O6 - Heat production by diffusion of pure spin current

T. Taniguchi [1], W. Saslow [2]

1. National Institute of Advanced Industrial Science And Technology, Kashiwa, Japan
2. Department of Physics, Texas A&M University, College Station, United States

The generation of a pure spin current by spin pumping, the spin Seebeck effect, or the spin Hall effect, has attracted much attention both as fundamental physics and for spintronics device applications. One motivation to utilize a pure spin current, instead of a spin current associated with an electric current, is that it is expected to reduce power consumption in practical applications because of the absence of the Joule heating due to the electric current. In particular, spin pumping has been widely used to generate pure spin current in a ferromagnetic (F)/nonmagnetic (N) multilayer system [1]. However, both spin-flip and spin-diffusion processes within the bulk and across the F/N interface result in an increase of entropy and in heat production. Therefore the heat production is finite even for a system with pure spin current, even in the absence of an electric current. A quantitative evaluation of the heat production, i.e., the dissipation, due to pure spin current therefore is of great significance. This study presents a theory of dissipation due to pure spin current, based on spin-dependent transport theory and thermodynamics [2]. We derive a generalized Joule heating formula that includes both electric current and spin current. The theory is applied to investigate entropy production for spin pumping across an F/N multilayer. Entropy is produced at the interface because spin pumping irreversibly transfers both spin angular momentum and energy from the ferromagnet to the conduction electrons near the interface. We find that the rate of heating production is proportional to the enhancement of the Gilbert damping constant by spin pumping.

WE.J.1_I1 - Novel applications of perpendicular magnetic anisotropy: 3-dimensional MRAM and cancer therapy

Russell Cowburn [1]

1. University of Cambridge, Cambridge, United Kingdom

Most thin magnetic films have their magnetization lying in the plane of the film because of shape anisotropy. In recent years there has been a resurgence of interest in thin magnetic films which exhibit a magnetization easy axis along the surface normal due to so-called Perpendicular Magnetic Anisotropy (PMA). PMA has its origins in the symmetry breaking which occurs at surfaces and interfaces and can be strong enough to dominate the magnetic properties of some material systems. In this talk I describe two novel applications based on the PMA system Pt/CoFeB/Pt. Both take advantage of the strong Brown's paradox present in such materials, i.e. high anisotropy combined with low coercivity. In the first application, we use the PMA material system to design a serial shift register acting between RKKY-coupled magnetic layers which is able to synchronously shift data from the bottom of a heterostructure to the top [1]. Such as shift register could form the basis of a 3-dimensional MRAM cell. In the second application, we lithographically structure a high-moment synthetic antiferromagnet layer system into microelements which we then lift off into solution to form a ferrofluid with carefully designed magnetic properties. This ferrofluid is then used for mechanical-disruption cancer therapy both in-vitro and in-vivo against glioblastoma cancer cells.

3. Seagate Technology, Londonderry, United Kingdom

Electron holography (EH) is an interferometric method using an electron beam particularly efficient for the quantitative studies of local magnetic fields with a resolution of the order of few nanometers over large field of view as large as few microns. We developed a new set-up allowing for the first time to quantitatively map in-situ in a TEM the induction field generated by the write pole in operating of a hard disk drive (HDD) developed by Seagate Technology for perpendicular magnetic recording.
The use of EH allows for a complete mapping of the magnetic fields generated by the writer as a function of the applied electrical current. The resulting quantified field maps demonstrate the key features desired for a writing magnetic pole : low spread of a high magnetic flux over a reduce area. Further, since the writers control electronics are designed to operate at GHz frequencies, we demonstrated the possibility of performing time resolved magnetic dynamic studies to obtain quantitative information about the damping of the magnetic induction as a function of the applied current frequency. The magnetic induction maps obtained by EH for various applied currents have been successfully simulated using micromagnetic simulation using the geometrical parameters of the writer.

WE.J.1_O3 - A development of advanced barium ferrite tape media

O. Shimizu [1], M. Oyanagi [1], Y. Kurihashi [1], A. Morooka [1], T. Harasawa [1]

1. FUJIFILM Corporation, Tokyo, Japan

The total global volume of digital data is increasing at an explosive rate and is projected to reach 44 zettabytes (ZB) by 2020–10 times the volume of data estimated for 2013 [1]. Particulate media-based tape storage systems are widely used for data backup and archiving applications because of their low cost, stability of the recording media for long term data retention, and the reliability of information retrieval and reproduction. Therefore, the continuous increase in the storage capacity of magnetic tapes is important. In order to achieve a higher areal recording density, smaller magnetic particles are essential. We have developed a magnetic tape media using barium ferrite particles as small as 1350 nm^3, which is approximately 30% smaller than those used in LTO6 barium ferrite tape (LTO6B) and less than 50% of those used in LTO6 metal particulate tape (LTO6M). The signal-to-noise ratio (SNR) of our tape was 3.5 dB and 10.5 dB higher than that of LTO6B and LTO6M, respectively, at 300 kfci. Such a high SNR was achieved not only because of the use of smaller magnetic particles, but also by using perpendicular orientation of magnetization and providing a smoother surface to reduce spaces between those particles. Surface roughness (Ra) of this tape was 2.0 nm compared with 2.4 nm in the case of LTO6B. Contribution of particle size, orientation, and surface roughness to SNR is estimated to be 1.5 dB, approximately 1 dB, and approximately 1 dB, respectively. The large increase in SNR from LTO6M is explained by the difference of transition parameter between barium ferrite media and metal particulate media.

WE.J.1_O4 - Circuit architecture for NAND logic operation via STT-MTJ

D. Loy [1], S. Goolaup [2], W. Siang Lew [3]

1. Nanyang Technological University, Singapore

Spin-transfer torque (STT) magnetic random access memory is one of the most promising candidates for next-generation non-volatile memory and logic devices owing to its high endurance, fast read/write speed and low power consumption. The main component of magnetic random access memory is the magnetic tunnel junction (MTJ), which is a magnetic element comprising of two magnetic layers (free and fixed) sandwiching a thin insulating layer. In this work, we present a simplified circuit configuration based on a STT-MTJ structure that is capable of performing NAND logic operations. Our proposed STT-MTJ structure comprises of five terminals, with decoupled reading and writing operations. In this structure, two terminals are used for writing, two are used for reading and the remaining terminal is used for potential tapping. In the two terminals used for writing, magnetization switching of the free layer is carried out by current-induced domain wall motion between two oppositely-charged writing terminals. The three remaining terminals are used to provide complimentary output (reading) and for acting as a potential tap. Two 5-terminal STT-MTJ structures are connected in a circuit and corresponding branches have complementary high and low resistances. PSPICE was used to simulate the circuit architecture with the STT-MTJ terminals represented by their respective high and low resistance using variable resistors. Our simulation shows that in a circuit structure comprising of just two STT-MTJ devices, a NAND logic operation can be performed. The scalability of this logic circuit makes it superior over similar logic devices. In addition, modifications to the circuit logic operations could allow us to achieve different logic operations such as OR, NOT etc.

WE.J.1_O5 - Ferromagnetic tetragonal Heusler thin films for spintronic applications

J Jeong [1], Y. Ferrante [1,2,3], S. Faleev [1], M. Samant [1], C. Felser [4], S. Parkin [5]

1. IBM Almaden Research, San Jose, United States
2. The Graduate School of Excellence 'Materials science in Mainz', Mainz, Germany

4. Max Planck Institute for Chemical Physics of Solids, Dresden, Germany
5. Max Planck Institute of Microstructure Physics, Halle (Saale), Germany

Heusler alloys are class of materials with X_2YZ or XYZ and structure L_{21} or C_1b where X and Y are from transition metals or Lanthanides and Z is from the main group element. Heusler alloys are of great interest both scientifically and technologically due to their nature of multifunctionality and tunability: topological insulators[1], the possible existence of skyrmions[2], and half-metallicity[3] or high spin polarization etc. A subset of Heusler alloys which show high perpendicular magnetic anisotropy originating from the tetragonal distortion of the unit cell are of great importance in spintronic applications. As an example, Mn-based alloys such as Mn_3Ge and Mn_2-xGa have been extensively studied in both bulk and thin films where Mn spin moments between two adjacent planes were coupled antiferromagnetically. In this work, ternary/quaternary Heusler thin films were deposited by cosputtering of various constituting elements on both amorphous (Si/SiO_2) or single crystal MgO(100) substrate with proper choices of buffer layers. These materials were chosen as candidates to have tetragonal distortion with ferromagnetic coupling between magnetic layers predicted by DFT calculation. Magnetization, magnetic anisotropy and the structural property of deposited Heusler alloy films were measured and compared with the property of Mn-based tetragonal ferrimagnetic Heuslers.

During the past two decades, the growth and characterization of ferromagnetic metal/semiconductor have received much attention. In particular, the Fe/Si multilayer magnetic structures are quite interesting since they are compatible with Si microchip technology. Their performance depends on the iron silicides formed at the interfaces since they can affect their physical properties and possible applications. In this work we focus on Fe/Si nanometric multilayer samples, which were prepared by thermal evaporation under ultrahigh vacuum onto a Si(100) substrate1, and on on GaAs(100)/Fe(1 nm)/Ag(150 nm) buffer2. The morphology of the Si-on Fe interface was studied by a combination of scanning transmission electron microscopy, X-ray reflectivity, angle resolved X-ray photoelectron spectroscopy, hard X-ray photoelectron spectroscopy and XMCD 1,2,3. The nterface thickness and roughness were determined. Moreover, the stable and metastable Fe silicide phases formed at both Fe-on-Si and Si-on-Fe interfaces were determined using conversion electron M÷ssbauer spectroscopy on multilayers with well separated Si-on-Fe and Fe-on-Si interfaces and when the Fe layer thickness is several nanometers thick. The reported examples of Fe/Si interfaces are reviewed and compared.

WE.J.2_O2 - Influence of the type of magnetic domain walls on magnetization reversal of bilayer permalloy-niobium nanostructures

L.S. Uspenskaya [1], S.V. Egorov [1]

1. Institute of Solid State Physics RAS, Chernogolovka, Russia

For many years it was studied the problem how would be changed the magnetic domain structure of soft magnetic material under the influence of the vicinity of superconductor [1-5]. Here we report our recent results on the experimental study of low temperature behavior of magnetic domain structure of permalloy in bilayer hybrid films permalloy-niobium. Kinetics of magnetization reversal is studied in bilayer permalloy-niobium hybrid nanofilms by means of a magneto-optic visualization technique [6]. The Nb-sublayer is found to affect the width of magnetic domain walls, the type of the walls, the orientation of the walls, and the kinetics of magnetization reversal in permalloy. Moreover, the low temperature magnetization reversal dependence upon the high temperature prehistory is revealed for a permalloy layer with domain walls of Bloch type. The niobium retains the information about a magnetic pattern freezed in permalloy and causes its reproduction during magnetization reversal. The "memory" is intact under magnetic field cycling as well as under a current flow. The effect demonstrates the efficiency of magnetic pinning and opens a new method for reversible variation of electromagnetic properties of hybrid devices.

WE.J.2_O3 - Comparative study of pair correlations in superconducting-magnetic hybrid systems

A. Bill [1], T. E. Baker [2], A. Richie-Halford [3]

1. California State University Long Beach, Long Beach, United States
2. University of California, Irvine, United States
3. University of Washington, Seattle, United States

The proximity of a superconductor to an inhomogeneous magnetic material induces singlet and triplet pair correlations. The amount of each component and their presence deep in the magnetic material strongly depends on the hybrid structure and in particular on the type of magnetic inhomogeneity. We present a comparative study of pair correlations in a diffusive magnetic Josephson junction involving a multilayer with misaligned magnetization, a cosine-type helical structure and the domain wall of an exchange spring. We demonstrate that the three systems induce qualitatively different mixtures of correlations.
Misaligned homogeneous films and continuously rotating magnetizations do not display the same physical state. The relative weight of different pairing correlations is discussed by analyzing the Gor'kov functions and the cascading proximity effect [1,2]. We find that so-called short range singlet correlations can be found deep in the magnetic material and compete with triplet correlations giving rise to the singlet-triplet 0-pi transition introduced in [2].

WE.J.2_O4 - Flexible magnetic actuator-cum-electrically conducting sheet based on FeNi3-bacterial cellulose nanocomposite

T. Vijayabaskaran [1], S. Vitta [1]

1. Indian Institute of Technology Bombay, Bombay, India

Bacterial cellulose (BC), a highly porous reticulate hydrogel polymer which is biodegradable has been functionalized into a magnetic actuator which is also electrically conducting by the incorporation of FeNi3 nanoparticles. These nanoparticles have been incorporated through an aqueous phase reduction technique and the resulting FeNi3-BC hydrogel is made into flexible sheets by pressing at 65^{o}C under different applied pressures. X-ray diffraction combined with SEM and TEM shows the presence of spherical FeNi3 nanoparticles of size varying between 20 nm and 250 nm distributed in the reticulate BC matrix. The room temperature field dependent magnetization clearly shows a ferromagnetic behavior with saturation magnetization of 18.9 emu/g and a coercivity of 31 Oe, a soft magnetic characteristic of $FeNi_3$. Temperature dependent dc magnetization indicates the presence of superparamagnetic particles with a blocking temperature, TB between 13 and 15 K. Temperature dependent ac susceptibility exhibits a frequency dependent maximum between ~15 and 16 K. The rate at which the susceptibility maximum shifts with applied frequency indicates the presence of interparticle interactions. To determine the extent and nature of these interactions, electrical conductivity was investigated. It is seen that the sheets are conducting with a conductivity of 6.8 S/cm and 41.2 S/cm at 300 K for the two applied pressures 9 and 26 MPa respectively and it increases with decrease in temperature. The conductivity exhibits a temperature dependence which is typical of metals with a positive temperature coefficient of resistivity. These electrical and magnetic studies of FeNi3-BC composite clearly show (i) coexistence of larger ferromagnetic and smaller superparamagnetic FeNi3 particles, (ii) existence of spinglass like behavior at low temperatures and (iii) increase in percolating conducting path with increase in applied pressure which also affects the magnetic behavior.

WE.J.2_O5 - The ultimate hard magnetic MFM tip - a new approach to advanced magnetic force microscopy imaging

V. Neu [1], T. Sturm [1], S. Vock [1], L. Schultz [1]

1. IFW Dresden, Dresden, Germany

A novel magnetic force microscopy (MFM) tip has been developed which has unprecedented high coercivities of up to 2 T. Its largely improved stability against demagnetizing fields allows superior contrast detection when applied in external fields and for the investigation of modern permanent magnet materials with large stray fields.

The MFM tip is based on a 50 nm thin epitaxially grown SmCo5 film with a single orientation of the magnetic easy axis along an in-plane substrate edge. A triangularly shaped piece of film/substrate with base length of 2 µm and height of 15 µm is separated from the as-grown sample by focused ion beam (FIB) and is attached to a Si cantilever.

The imaging performance is tested on (i) a Co/Pt multilayer sample with a fine-scaled band domain pattern (ca. 170 nm), and (ii) a coarse grained Sm_2Co_{17} alloy, which develops a large scaled domain structure (1 – 5 µm) with large stray fields. Tip calibration routines known from quantitative MFM are applied to extract the tip transfer function of the novel MFM tip. It fully compares in imaging quality with commercially available tips concerning sensitivity and resolution. The superiority of these tips shows itself in the ability to observe clear domain contrast on top of the Sm_2Co_{17} magnet. To fully probe the tip's stability against external fields, it has been successively demagnetized and the magnetization state of the tip has been evaluated from zero-field MFM measurements on the two reference samples. The tip reversal is constructed as a function of applied field and was found to occur at above 0.8 T, but also to depend on the reference sample. This seeming discrepancy can be resolved when considering a domain nucleation at the tip apex and a hindered (pinned) domain expansion into the tip interior.

WE.J.2_I6 - Josephson superconductor/ferromagnet/superconductor structures and their possible applications in superconducting digital and quantum logics

V. Ryazanov [1]

1. Institute of Solid State Physics, Russian Academy of Sciences, Chernogolovka, Russia

Josepson hybrids based on superconductors (S), normal metals (N) and ferromagnets (F) attract increasing attention in the last decade. Among the achievements made on SFS sandwiches it should be noted implementation of the pi-junction (superconducting phase inverter) [1] and realization of SFS switches for ultra-low-power, high-density cryogenic memorie [2]. Our recent observations are carried out on planar multiterminal S/F/N structures and related with quasiparticle and spin injection to Josephson junctions. (See [3,4], for example).

Th.A.1_O1 - Spin-lattice coupling and magnetocrystalline transition in $Pr_{0.50}Sr_{0.50}CoO_3$ investigated by x-ray absorption and neutron diffraction

J. Padilla-Pantoja [1], J. Herrero-Martín [2], B. Bozzo [1], C. Ritter [3], J. Blasco [4], J.L. García-Muñoz [1]

1. Institut de Ciència de Materials de Barcelona, Bellaterra, Spain

4. Instituto de Ciencia de Materiales de Aragón, Dep. Física de la Materia Condensada, CSIC-Universidad de Zaragoza, Zaragoza, Spain

Cobalt-based perovskites are attracting much interest as strongly correlated electron systems due to the relevance of the cobalt spin state for their functional properties. The spin state of trivalent cobalt is a key feature in half-doped $Pr_{0.50}Sr_{0.50}CoO_3$ (A: Ca or Sr) perovskites. Here the spin-lattice coupling gives rise to non-conventional magnetic and electronic transitions whose interpretation has been controversial.
The macroscopic properties of $Pr_{0.50}Sr_{0.50}CoO_3$ (PSCO) noticeably differ from those in $Pr_{0.50}Sr_{0.50}CoO_3$ (PCCO), where a spin-state change has been proved to induce a partial Pr3+ to Pr4+ valence shift and a exotic metal-insulator transition around 80 K [1]. Recent works have confirmed the importance of the spin-lattice coupling in PSCO reporting magnetostructural changes at 120K. We have investigated the properties of PSCO (always metallic, and ferromagnetic below TC ~ 230 K) across the unexpected magnetostructural transition at TS ~120 K [2]. X-ray absorption experiments (XAS) at the Pr M4,5 and L3 edges rule out any trace of Pr4+ below TS, and a large density of empty Co t2g states precludes pure nonmagnetic Co3+ ions at low temperature unlike the PCCO compound. In addition, the sudden changes in the magnetization at TS have been investigated by XAS, X-ray magnetic circular dichroism (XMCD) at Co L2,3 edges, and by neutron diffraction down to 5 K, revealing that they are driven by a Imma→I4/mcm symmetry change and spin reorientation of Co moments. They present a significant orbital contribution, and an anomalous ml/ms evolution concomitant to the stretching of CoO_6 octahedra at 120 K. Sudden spin state changes are discarded in this system, whose properties differ from related $Ln_{0.50}A_{0.50}CoO_3$ (Ln: lanthanide) compounds.

Th.A.1_O2 - Magnetic properties of the 3d-5d double perovskite Sr_2FeOsO_6: Microscopic insights from ab-initio density-functional theory study

S. Kanungo [1], B. Yan [1,2], M. Jansen [1,3], C. Felser [1]

1. Max Planck Institute For Chemical Physics of Solids, Dresden, Germany
2. Max-Planck-Institut fur Physik komplexer Systeme, Dresden, Germany
3. Max-Planck-Institut fur Festkorperforschung, Stuttgart, Germany

Using density-functional theory calculations, we investigated the electronic and magnetic properties of the ordered 3d-5d double perovskite Sr_2FeOsO_6, which has recently drawn attention for interesting antiferromagnetic (AFM) phase transitions in experiment. The calculated effective magnetic exchange interactions for reveal the importance of long-range super-super-exchange interactions in this compound.
The competition between the weak ferromagnetic Os-O-Fe shor-range interaction and strong antiferromagnetic Os-O-Fe-O-Os long-range interaction induces strong magnetic frustration along the crystallographic c axis. This frustration is proposed to drive the magnetic phase transition between two AFM phases and related lattice distortion, which were observed in experiment. To understand, whether this is a general trend or not we studied another 3d-5d double perovskite Sr_2CoOsO_6 [2], and this also shows similar type of trend in the magnetic exchange interactions, although in the low temperature Co and Os sub-lattices follow very different spin dynamics. Ab-initio calculations indicate that the weak effective exchange coupling between Co and Os sub-lattices, drives this difference in the ground states and spin dynamics of Co and Os, making Sr_2CoOsO_6 distinct from previously reported double-perovskite compounds.

Th.A.1_O3 - Field-induced spin-structural transition in ising chain CoV_2O_6

M. Nandi [1], N. Khan [1], D. Bhoi [1], A. Midya [1], P. Mandal [1]

1. Saha Institute of Nuclear Physics, Kolkata, India

Recently, the quasi-one-dimensional (1D) spin-chain CoV_2O_6 has received attention to the scientific community due to several interesting features like 1/3 magnetization plateau, large single ion anisotropy etc. Both monoclinic α-CoV_2O_6 and triclinic γ- CoV_2O_6 undergo long-range antiferromagnetic transition below 15 and 7 K respectively and exhibit field-induced metamagnetic transitions at two critical fields H_{c1} and H_{c2}.
We have investigated the temperature (T) and magnetic field (H) dependence of magnetization, specific heat (C_p), and relative sample length change ($\Delta L/L_0$) for understanding the field-induced spin-structural change in CoV_2O_6. Specific heat and the coefficient of linear thermal expansion (α) of monoclinic CoV_2O_6 exhibit a sharp λ-like peak close to transition temperature (T_N) and a huge positive magnetostriction [$\Delta L(H)/L_0$] is also observed below T_N. The large value of magnetostriction below T_N suggests presence of strong spin−lattice coupling in α-CoV_2O_6. With the application of external magnetic field, a sharp and symmetric peak emerges below T_N in both $C_p(T)$ and α(T) due to field-induced ferrimagnetic/ferromagnetic-paramagnetic transitions and the sharp nature of the peak indicates that the transition is first-order.

Th.A.1_O4 - Magnetic phase transitions and magnetic interactions in quasi-two-dimensional complex oxides based on brucite-like octahedral layers

A. Kurbakov [1], A. Kuncevich [1], A. Malyshev [1], V. Nalbandyan [2], E. Zvereva [3]

1. Petersburg Nuclear Physics Institute, Gatchina, Russia
2. Southern Federal University, Rostov-on-Don, Russia
3. Moscow State University, Moscow, Russia

The results of neutron powder diffraction study of the crystal structures and spin configurations in new complex oxides with the layered crystal structure are presented. New layered solid electrolyte $Na_2Ni_2TeO_6$ (*P6₃/mcm*) and quasi-two dimensional honeycomb oxides $Na_3Co_2SbO_6$, $Li_3Ni_2SbO_6$ and $Na_3Ni_2SbO_6$ (*C2/m*) were investigated. The studied substances established structural motives on the basis of edge-related oxygen octahedral layers between which there are alkali metal cations or low charging relatively large cations of d-elements. Magnetic cations in the oxygen-octahedral layers form honeycomb grids that on condition of antiferromagnetic type interaction between nearest neighbors can lead to frustration in the magnetic subsystem and the emergence of unusual types of magnetic moments ordering including non-collinear spiral structure.

The appearance of additional reflections related to antiferromagnetic ordering organization of the samples at T_N below 7K ($Na_3Co_2SbO_6$), 15K ($Li_3Ni_2SbO_6$), 17K ($Na_3Ni_2SbO_6$) and 26K ($Na_2Ni_2TeO_6$) is clearly visible on the low-temperature neutron diffraction measurements. At $T > T_N$ the magnetic susceptibility nicely follows the Curie-Weiss law with positive and negative temperatures: $\Theta \approx$ -25K ($Na_2Ni_2TeO_6$), -10K ($Na_3Co_2SbO_6$) indicating predominance of AFM interaction and +8K ($Li_3Ni_2SbO_6$), +12K ($Na_3Ni_2SbO_6$) with predominance of FM. However at low temperatures long-range AFM order is established at all oxides. Hence there is a delicate balance of competing AFM and FM interactions due to difference in character and sign of exchanges between Co^{2+} (Ni^{2+}) ions within the magnetic layer and between the layers.

Especially as it was possible to expect that primary superexchange interaction via half-occupied Co/Ni e_g (d_z^2, $d_{x^2-y^2}$) orbitals to be FM since within mixed-cation layers of Co/Ni and Sb/Te the Co(Ni) -O- Co(Ni) cation-anion angles are close to 90°.

It is demonstrated that there is a clear correlation between fine specific features and temperature evolution of crystal structures, the corresponding types of low-temperature spin ordering, and physical properties all researched systems.

Th.A.1_O5 - Local magnetic behavior across the first order phase transition of the La($Fe_{0.9}Co_{0.015}Si_{0.085}$)13 magneto caloric compound

C. Bennati [1,2], F. Laviano [1], M. Kuepferling [2], E. Olivetti [2], V. Basso [2], G. Ghigo [1]

1. Department of Applied Science and Technology, Politecnico di Torino, Turin, Italy
2. Istituto Nazionale di Ricerca Metrologica (INRIM), Turin, Italy

La(Fe,Si)13 based compounds [1] are known to show a giant magneto-caloric effect (MCE) due to the first order nature of their magneto structural transitions which can be easily tuned by substitution by Co or Mn. Such substitutions might lead to phase inhomogeneities which can influence drastically the kinetics of the phase transition, an important feature in order to judge the materials performance in refrigeration cycles.
We studied the compound La($Fe_{0.9}Co_{0.015}Si_{0.085}$)13 by a magneto optical imaging technique with indicator film (MOIF) in order to investigate the local magnetic behavior during the temperature driven phase transition. Isothermal hysteresis loops (up to 70 mT) were recorded to spatially resolve the magnetic response of the compound at constant temperatures around the Curie temperature, Tc = 200 K. The magnetic permeabilities in different areas of dimension 10-1000 μm^2 were analyzed statistically and differences between the matrix and isolated grains of secondary phases were found. We observed soft ferromagnetic (FM) grains, which have a constant permeability across the entire temperature range (185-215 K) and, for T < Tc, paramagnetic isolated grains (PM) which show a wide distribution of permeabilities.
The evidence of minor phases at the surface is also confirmed by SEM analysis, where isolated islands of Fe-rich phase (FM grains) and La-rich phase (PM grains) were observed . The correlation and the interaction between the parent phase and the secondary magnetic phases is thus discussed at a local spatial scale. In fact, when sweeping the temperature across the phase transition, we find that (i) the new magnetic phase nucleates in different areas at slightly different temperatures, thus we recognize Co/Si graded grains in the matrix (i.e. Tc-graded grains), (ii) there exists a secondary phase that remains paramagnetic in the whole temperature range. These secondary phases and the Tc-graded grains influence the nucleation of the new magnetic phase (the transition always starts close to one of them) and act as pinning centres for the transition thus influencing the propagation of the transition front [2].

Th.A.1_O6 - Magnetism of sigma-phase Fe-Mo alloys: revealing spin-glass as the ground state

S. Dubiel [1], J. Przewoznik [1]

1. AGH University of Science And Technology, Krakow, Poland

Sigma-phase (space group D144h - P42/mnm) is a member of Frank-Kasper family of phases. Among over 40 known binary alloys in which sigma-phase occurs, only sigma-phase in Fe-Cr and Fe-V alloys was known, until recently, to possess magnetic propertiues. Freshly, magnetism of sigma-phase was discovered in Fe-Re [1] and Fe-Mo [2] alloy systems. To further characterize the magnetism in the latter, an AC magnetic susceptibility study was carried out on a series of sigma-Fe(100-x)Mo(x) (x =47-53) samples. This contribution reports the first ever AC susceptibility results obtained on this kind of alloys. Clear evidence was found that a spin glass (SG) constitutes the ground magnetic state of the alloys and the SG temperature ranges between 34K for x=47 and 16K for x=53. The SG state was found to be magnetically heterogeneous as far as an irreversibility is concerned, and it can be divided into a weak- and a strong-irreversibility domains. Figures of merit are typical of metallic (canonical) spin glasses hinting that the RKKY interaction is responsible for the magnetism. In particular, a relative shift of the SG temperature per decade of frequency ranges between 0.012 and 0.013 and the dynamic exponent, zv, varies between 8 and 10.

4. Laboratoire Léon Brillouin, CE de Saclay, Gif-sur-Yvette, France
5. Charles University in Prague, Faculty of Mathematics and Physics, Department of Condensed Matter Physics, Prague, Czech Republic

$Dy_3Ru_4Al_{12}$ crystallizes in the hexagonal $Gd_3Ru_4Al_{12}$ archetype structure, in which Dy atoms form corner sharing distorted kagome nets. A single crystal was grown and its physical properties were first studied by means of magnetization, neutron diffraction, specific heat and resistivity measurements. It was found that $Dy_3Ru_4Al_{12}$ orders antiferromagnetically at T_N = 7 K in a non-collinear monoclinic magnetic structure with $\boldsymbol{k}$ = (1/2 0 1/2). The transition is of first-order as indicated by the anomalies in the specific heat, resistivity and the intensity of magnetic reflections. Additionally, the magnetic ordering of the Dy atoms presents some fingerprints of geometrical frustration, which is manifested also by metamagnetic transitions in all lattice directions accompanied by large positive magnetoresistance up to 140%. This altogether indicates a complex balance among the RKKY exchange interactions, the crystal-field induced magnetic anisotropy and Zeeman energy.
Thermal expansion and low temperature X-ray diffraction were performed across the magnetic transition, confirming its first-order character. The linear thermal expansion is step-like with a change of $\Delta l/l \approx 3\times10^{-5}$ at the transition, highly anisotropic and hysteretic upon cooling and heating. Structural refinements suggest that there is no symmetry lowering down to 2.5 K, but coupling between the lattice and the spin was disclosed by anomalies in the variation of the lattice parameters with temperature in the vicinity of T_N. Moreover, further data analysis has shown that the distance between the near nearest Dy atoms reaches an absolute minimum close to the critical temperature.

Th.A.2_O2 - Chiral magnetism in rare-earth intermetallic compounds $YbNi_3Al_9$ and $Yb(Ni_{0.94}Cu_{0.06})3Al_9$

S. Ohara [1], H. Ninomiya [1], Y. Matsumoto [1], Y. Kousaka [2], K. Ohishi [3], J. Akimitsu [4]

4. Department of Physics and Mathematics, Aoyama-Gakunin University, Shibuya, Japan

In chiral magnetic materials, the combined effect of symmetric ferro- (or antiferro-) magnetic and antisymmetric Dzyaloshinskii-Moriya (DM) interaction will give rise to a helical or a canted magnetic structure. In recent years, chiral magnets have attracted much attention because they exhibit new spin-configurations, such as a skyrmion in MnSi and a chiral soliton lattice in $Cr_1/3NbS_2$. However, only a few materials have been known for chiral magnets. Moreover, most of the work has been done on 3d transition-metal compounds but very few reports on 4f rare-earth intermetallic. Recently, we have succeeded in synthesizing a new chiral crystal of rare-earth intermetallic compounds RNi_3X_9 (R:rare-earth elements, X:Al and Ga). In this work, we report chiral crystal structure and chiral magnetism of $YbNi_3Al_9$ and $Yb(Ni_{0.94}Cu_{0.06})_3Al_9$. To study the chiral properties in 4f-magnetism, X-ray diffraction, polarized neutron scattering and magnetization measurements have been taken on the single crystalline samples. The crystal structures are identified as the trigonal $ErNi_3Al_9$-type with chiral space group R32. $YbNi_3Al_9$ is a helimagnet below an ordering temperature of Tm=3.4K with a magnetic wave vector q=(0, 0, 0.8). We confirmed that the magnetic satellite intensities depend on incident neutron polarization for $YbNi_3Al_9$. In magnetization process, a metamagnetic transition is observed at a magnetic field of Hm=1kOe with the magnetic field applied perpendicular to c-axis at 2K. We can enhance both Tm and Hm by copper substitution. For $Yb(Ni_{0.94}Cu_{0.06})_3Al_9$, Tm and Hm are 6.5 K and 10 kOe, respectively. The magnetization process in $Yb(Ni_{0.94}Cu_{0.06})_3Al_9$ was very similar to that in uniaxial chiral magnet $Cr_1/_3NbS_2$ and in good agreement with the theoretical result based on the chiral soliton lattice. We conclude that the magnetic ordering in Yb(Ni1-xCux)3Al9 (x=0 and 0.06) can be chiral helical due to combined effect of Ruderman-Kittel-Kasuya-Yosida (RKKY) and DM interactions in the chiral crystal.

Th.A.2_O3 - Observation of large anomalous Kerr rotations in the Skyrmionic Mott insulator Cu_2OSeO_3

R.B. Versteeg [1], S. Schöfer [1], A. Aqeel [2], T.T.M. Palstra [2], P.H.M. Van Loosdrecht [1]

1. University of Cologne - II. Physics Institute, Cologne, Germany
2. Zernike Institute for Advanced Materials, University of Groningen, Groningen, The Netherlands

The Mott insulator Cu_2OSeO_3 has recently gained considerable scientific interest owing to the presence of a Skyrmion lattice phase. The Skyrmion phase is a magnetic topologically protected state, which manifests itself as a hexagonal lattice of spin vortices, and originates from a combination of different magnetic interactions. Together with their topologically protected nature, the nanometer size scale of Skyrmions may potentially allow them to be harnessed as bits in racetrack memory devices. The ability to achieve all-optical control of Skyrmions would add yet another degree of flexibility to Skyrmion-based devices. This, however, requires intimate knowledge of the magneto-optical properties of these materials, but to date, research in this realm has been limited.
Here, we present the first magneto-optical Kerr Effect (MOKE) spectroscopy study of the Skyrmion material Cu_2OSeO_3, in order to lay the foundation for better understanding of the magneto-optical properties of this class of materials. of particular interest is our observation of a surprisingly large anomalous Kerr rotationùas large as 10 degreesùwith a nontrivial magnetic field dependence. The light polarization rotation observed at the intersite-dd and charge transfer transitions allows for the mapping of the magnetic phase diagram of bulk Cu_2OSeO_3. In addition to gaining insight into the nature of the magnetic phases of these materials, our observations open an exciting new avenue on the quest for optical manipulation of Skyrmionic matter.

Th.A.2_O4 - Observation of various magnetic field-induced states in MnGe with cubic B_{20} type structure

R. Viennois [1], C. Reibel [1], D. Ravot [1], R. Debord [2], S. Pailhes [2]

1. Institut Charles Gerhardt, Université Montpellier, Montpellier, France
2. Institut Lumière Matière, Université Claude Bernard - Lyon 1, Villeurbanne, France

Transition metal compounds with the cubic B_{20} crystal are interesting because of their very various and exotic magnetic properties induced notably by the lacks of inversion center and fourfold axis in their cubic symmetry structure. The most important discovery in this class of compound was phases containing skyrmions. Recently, the study of MnGe has shown the presence of helimagnetic ground state below about 170 K with short length helix and large topological Hall effect and Nernst effect below 100 K [1]. However the origin of these two effects is still controversial as recent neutron work has shown [2]. Until now, MnGe seemed to behave differently than other compounds with B20 structure as there is no report of A phases containing skyrmions and located at temperature just below the ordering temperature as e. g. in MnSi [3]. But, to date, no systematic study of the magnetic phase diagram of MnGe has been performed. In the present communication, we report our study of the magnetic phase diagram of MnGe by using ac susceptibility experiments. For the first time, we found the presence of several different magnetic field induced phases. First we found not only the presence of an A phase presumably due to the presence of skyrmions as in isostructural compound MnSi but with much broader existence range in the (H,T) domain. We also found second phase we call B at much lower temperatures whose magnetic signature is very similar to that of A phase. Clearly, further studies on these different new magnetic phases are necessary in order to understand the large topological Hall and Nernst effects in MnGe.

Th.A.2_O5 - The stable magnetic phase of the Gd doped topological insulator, Bi_2-xGdxTe_3

E.H. Shin [1], M.H. Chung [2], M. Kim [1], H. Kim [1]

1. Sookmyung Women's University, Seoul, Republic of Korea
2. Sogang University, Seoul, Republic of Korea

The discovery of three dimensional strong topological insulators (TI) such as Bi_2Se_3, Bi_2Te_3 and Bi_2Sb_3 has intrigued many researchers. The surface metallicity in contrast to the insulating bulk state is known to be topologically protected and robust for impurities and disorders as long as the time reversal symmetry is preserved.
One of TI, Bi_2Te_3 was studied to examine whether topological surface state is robust when the transition metals such as Fe, Mn, and Co are doped. In this presentation, we report first-principles calculations on the crystal of $Bi_{2-x}Gd_xTe_3$ (x = 0.021, 0.042, 0.063, 0.074, 0.083, 0.125) to understand the effect of substitution of magnetic rare-earth element, Gd (Gd_{Bi}) on the surface metallicity and the magnetic property.
A single Gd_{Bi}'s in Bi_2Te_3 crystal(x=0.021) is calculated to carry a spin magnetic moment of 7 μ_B. Two Gd_{Bi}'s in Bi_2Te_3 crystal(x=0.042) prefer to be located in the first nearest neighbor sites in the Bi sublattice on a single Bi atomic layer of the same quintuple layer. The magnetic moments of two Gd_{Bi}'s remain unchanged (7 μ_B) and the antiferromagnetic (AFM) configuration is more stable [ΔE (=E_{AFM}-E_{FM}) is -2.36 meV] due to super-exchange interaction via the intervening Te atoms.
With the increased concentration of Gd, we found that Gd_{Bi}'s favor to be clustered than to be uniformly dispersed. For instance, Gd_{Bi}'s form a linear chain (x=0.083) or a hexagonal ring (x=0.125) in the single Bi atomic layer. In most of the clustered structures, the AFM ordering is calculated to be more stable than the FM ordering. Among the considered configurations, the hexagonal ring is most effective in stabilizing the AFM phase (ΔE=-14.7 meV).

Th.A.2_O6 - Magnetic order and excitations in the Magnetic Dirac Materials (Ca,Sr)$MnBi_2$

A. Princep [1], A. Boothroyd [1], Y. Guo [1], X. Zhang [2], P. Manuel [3], D. Khalyavin [3], I. Mazin [4], Y. Shi [2], A Piovano [5]

5. Institut Laue-Langevin (ILL), Grenoble, France

The electronic spectrum of so-called Dirac materials such as graphene and topological insulators is linear. These linearly dispersing “Dirac cones” and associated pseudospins determine the peculiar properties of Dirac materials such as high electron mobility, an anomalous quantum Hall effect, and a large spin-hall effect. Typical Dirac cones are in general isotropic, but several hamiltonians have been investigated which show (for example) k-linear dispersion in one direction but k^2 dispersion in a perpendicular direction. SrMnBi2 and CaMnBi2 have been determined to host highly anisotropic 2D Dirac fermions in a square conducting layer of Bi, with pseudospin dynamics analogous to those of graphene. These two materials are not quite isostructural, but they show giant magnetoresistance and a large magnetothermopower, related to their unusual low temperature transport properties. This result is particularly exciting because the Bi (or other pnictogen) square net is a building block of many layered materials, and the possibility of coupling Dirac fermions to superconducting or magnetic order parameters (as, for instance, in CeNixBi2 or the hypothetical BaFe*Pn*2) offers a rich playground for the generation and exploration of new physics. Through neutron diffraction and inelastic scattering measurements on single crystal and powder samples, we have shown that both materials exhibit a Neel-type in-plane AFM order with ordered moment of ~3.7 μB (substantially reduced from the free-ion value), broadly consistent with DFT calculations, and that the $MnBi_4$ layers are coupled ferromagnetically in CaMnBi2 and antiferromagnetically in SrMnBi2. The spectrum of excitations shows significant nearest and next-nearest neighbour exchanges, a much weaker inter-plane coupling, and a surprisingly large anisotropy gap. We will discuss the implications of these results, particularly with regard to possible novel ordered phases that could be produced with doping.

Th.A.2_O7 - Magnetism of disordered Heusler alloys

M. Leitner [1], P. Neibecker [1], W. Petry [1]
1. Technische Universität München, Munich, Germany

Heusler alloys constitute a class of systems with great potential for applications. Most of their appeal rests on the diverse aspects of magnetism in these materials, including the ferromagnetic shape-memory effect, the magnetocaloric effects, and half-metallicity. Due to their intermetallic nature, off-stoichiometry and site disorder constitute degrees of freedom additional to temperature. In previous work we have shown that in Ni_2MnAl well-defined states of order can be prepared, which are accessible via correspondingly varying magnetic transition temperatures [1]. Here we report on a detailed characterization of the peculiar magnetic behaviour, e.g. temperature- and field-dependent magnetization for specific states of order, with nearly constant ferromagnetic susceptibilities up to the highest fields. We present a microscopic model of how Mn/Al site disorder and site-specific ferro- and antiferromagnetic interactions of the Mn moments give rise to observed features as a function of field, temperature, and order.

Th.A.3_O1 - High coercivity in rare earth-lean hot-deformed magnets by grain boundary infiltration

G. Hadjipanayis [1], R. Madugundo [1], D. Salazar Jaramillo [2], J.M. Barandiaran [2]

1. Department of Physics and Astronomy, University of Delaware, Newark,United States
2. BCMaterials, Technology Park of Biscay,Derio, Spain

The recent rare-earth crisis led to worldwide efforts to develop rare-earth lean/free permanent magnets. In this report, we present our recent results on the enhancement of coercivity (Hc) in rare-earth lean Pr(Nd)-Fe-B melt-spun ribbons and hot-deformed magnets by grain boundary modification through infiltration using the low melting temperature eutectic alloys Pr-Cu, Pr-(Cu,Co). Alloys with compositions $Nd_{10}Fe_{84}B^{6}$, $Pr_{11.5}Fe_{81.5}Ga_1B_6$ and $Pr_{12.5}Fe_{80.5}Ga_1B_6$ prepared by arc-melting were melt-spun to produce thin ribbons. The ribbons were crushed to small flakes <200 μ and hot-compacted at temperatures between 650-750 C. The compacts were hot-deformed to 75% of their original height at 750 – 850 °C. In $Nd_{10}Fe_{84}B_6$ ribbons, the infiltration was carried out by mixing the ribbon pieces with Pr-(Cu,Co) crushed powder and the mixture was heat-treated at 650°C for 1- 4 hours. In the case of hot-deformed magnets, a thin slice of Pr-Cu alloy, or Pr-(Co,Cu) alloy powder was placed on top of hot-deformed pieces and heat-treated at 650°C for 1 to 4 hours. The ratio of Pr-Cu or Pr-(Co-Cu) alloy to melt-spun ribbon or hot-deformed magnet was 1:5. In $Nd_{10}Fe_{84}B_6$ ribbons, the Hc increases from 5.3 to 23.8 kOe on infiltration with Pr-(Cu,Co) powder for 4 hours. The $Pr_{11.5}Fe_{81.5}Ga_1B_6$ and $Pr_{12.5}Fe_{80.5}Ga_1B_6$ hot-deformed magnets show an increase in Hc from 5.4 to 19.5 kOe and 8.4 to 26.4 kOe, respectively on infiltration with Pr-Cu alloy for 4 hours. The microstructure of the melt-spun ribbons and hot-deformed magnets before and after infiltration are currently being studied and the results will be presented and discussed. Work supported by Siemens and Bizkaia Talent AYD-000-195.

Th.A.3_O2 - Grain boundary modifications of hot-deformed Nd-Fe-B permanent magnets with low melting eutectics

S. Sawatzki [1], C. Kübel [2], S. Ener [1], O. Gutfleisch [1,3]

1. TU Darmstadt, Materialwissenschaft, Darmstadt, Germany
2. KIT, Institute of Nanotechnology (INT) & Karlsruhe Nano Micro Facility (KNMF), Eggenstein-Leopoldshafen, Germany
3. Fraunhofer IWKS, Projektgruppe für Wertstoffkreisläufe und Ressourcenstrategie, 63457 Hanau, Germany

The grain boundary diffusion process (GBDP) increases coercivity in sintered Nd-Fe-B magnets without losing much in remanent magnetization by only using a very small amount of Dy [1]. Here low melting eutectics DyCu, DyNdCu and TbNdCu have been incorporated by two different methods: first, by mixing the powders together with Nd-Fe-B melt-spun ribbons before hot-compaction and hot-deformation and second, by coating the solid state hot-deformed magnet (conventional GBDP). For the first method the distribution of these eutectics within the nano grained sample has been optimized by grinding as well as by ball milling. For the ternary eutectic alloys, an uniform distribution was observed by scanning electron microscopy (SEM). This uniform distribution was attributed to the lower melting point of DyNdCu and TbNdCu compared to DyCu. Additional annealing of the hot-compacted magnets at 600°C leads to a diffusion of Dy or Tb into the Nd-Fe-B flakes, which was observed by transmission electron microscopy (TEM). This diffusion modifies the grain boundary phase and thus enhances coercivity without decreasing remanence. For die-upset magnets coercivity was suppressed due to grain growth nearby the rare earth rich flake boundaries during the deformation process and could not be increased by additional low temperature annealing. In contrast to this, the second method enhances coercivity during low temperature annealing but also reduces remanence.

Th.A.3_O3 - High-coercivity Nd-Fe-B permanent magnets based on the electrophoretic deposition of TbF3

M. Soderžnik [1], K. Üestüener [2], M. Katter [2], S. Kobe [1]

1. Jozef Stefan Institute, Ljubljana, Slovenia
2. Vacuumschmelze, Hanau, Germany

In this study, our aim was to substantially improve the coercivity of Nd-Fe-B magnets, based on the electrophoretic deposition (EPD) of TbF3 powder and subsequent annealing called the grain-boundary diffusion process. In order to retain the remanence as high as possible Nd-Fe-B magnets with a rather low amount of heavy rare earths (HRE) were used as starting material. The overall amount of HRE was 1.6 wt. % (0.1 wt. % of Dy and 1.5 wt. % of Tb). The magnets with the dimensions 12.5 mm × 8 mm × 3.5 mm were evenly coated with TbF3 powder using the electrophoretic deposition. After the magnets were coated with TbF3 powder, they were heat treated in vacuum at 875°C for 10 h followed by aging at 500°C for 1 h. The magnetic properties were measured with a Steingroever permeameter. Since the magnets could not be demagnetized at room temperature, the remanence and the coercivity were determined to be Br = 1.25 T and HcJ = 1580 kA/m at 70°C, respectively. Applying the temperature coefficients TK(Br) = -0.11 %/K and TK(HcJ) = -0,63%/K, the remanence and coercivity are calculated to be 1,32 T and 2080 kA/m at room temperature, respectively. Using the grain-boundary diffusion process, based on the electrophoretic deposition of TbF3, we have successfully enhanced the coercivity at room temperature to more than 2000 kA/m, while the remanence exceeded the ambitious value of 1.3 T.

Th.A.3_O4 - Sintering analysis of NdFeB material

B. Hugonnet [1], C. Rado [1], J.M. Missiaen [2,3], O. Tosoni [1], F. Servent [1]

1. Univ. Grenoble Alpes, CEA, Grenoble, France
2. Univ. Grenoble Alpes, SIMAP, Grenoble, France
3. CNRS, SIMAP, Grenoble, France

NdFeB permanent magnets are used in a broad range of devices including high temperature applications such as electric motors for hybrid cars or wind turbines. Indeed, their high remanence lead to an important weight and size reduction compared to induction magnets. They should contain heavy rare earth (HRE) to conserve enough coercivity at their working temperature. Actually, the use of HRE is a problem because it is a high critical resource and it decreases the magnet remanence. Another possibility to increase the coercivity without using HRE is to work on the microstructure. Indeed, several improvements in magnetic properties of NdFeB magnets have been done since their discovery by decreasing the grain size and by controlling the thickness and the continuity of the grain boundary phase. However, up to date, this solution did not give coercivity required for high temperature application. This could come from the fact that the link between microstructure and coercivity is still empirical. Microstructure could be controlled by a full mastering of the manufacturing process. The steps of sintering and annealing of the NdFeB-aligned powders need to be well understood. The Nd-Rich phase contained in the NdFeB powders plays a role during the sintering and its repartition controls the final magnetic properties. Sintering mechanisms which are responsible for a different shrinkage perpendicular and parallel to the magnetization axis require further investigation. In this work several aspects of NdFeB sintering are discussed based on dilatometric experiments and microstructure observation of sintered magnets. Possible causes of the strong sintering anisotropy have been identified. Calculation of the sintering activation energy has been used to characterize if a liquid phase is present or not at the grain boundary between the magnetic grains. Finally the link between magnetic properties and grain morphology in sintered magnets has been explored.

Th.B.1_I1 - Magnetocaloric effect in type-I $Eu_8Ga_{16}Ge_{30}$ clathrate nanocrystals

H. Srikanth [1], A. Biswas [1,2], S. Chandra [1,3], S. Stefanoski [1,4], J. Blasquez [5], J. Ipus [5], A. Conde [5], M.H. Phan [1], V. Franco [5], G. Nolas [1]

2. Ames Laboratory, Ames, IA, United States
3. EMT-INRS, Quebec, Canada
4. Carnegie Institute, Washington DC, United States
5. Physics Department, University of Sevilla, Sevilla, SPAIN

$Eu_8Ga_{16}Ge_{30}$ type-I clathrates have attracted growing attention owing to their intriguing thermoelectric, magnetic and magnetocaloric properties [1-3]. The presence of Eu makes them interesting from the magnetism perspective and also affords the possibility of combining magnetocaloric and thermoelectric functionalities in the same material. The effect of reduction of particle size on magnetism and magnetocaloric response in these materials is reported. Nanocrystalline samples of three different average particle sizes (~42 , 34 , and 15 nm) were prepared by high energy ball milling [3]. While ferromagnetic materials show a general trend of magnetic entropy change ($-\Delta S_M$) decreasing with reduction in particle size, in this system there exists a unique cross-over temperature (T_{cross}~ 25 K) below which the reduction of particle size enhances $-\Delta S_M$ significantly. The largest value of $-\Delta S_M$ (~ 10 J/kg K for a field change of 5 T at 5 K) is obtained for the sample with particle size of 15 nm, making it a promising candidate for cryogenic magnetic cooling. The observed increase in $-\Delta S_M$ for nanocrystalline samples is attributed to the enhancement of the interactions between Eu ions residing in two different positions in the lattice and responsible for the low temperature transition. Interestingly, the 42-nm particle size sample exhibits a table-like MCE, desirable for ideal Ericsson-cycle magnetic refrigeration.

3. Grupo de Fluidos Complexos, Instituto de Fisica & Instituto de Quimica, Universidade de Brasilia, Brasilia, Brazil

The unique properties of magnetic nanoparticles and their interactions with their environment continue to give rise to innovative and surprising experimental possibilities outside the field of conventional magnetism. One such example is found in the field of magneto-thermal energy science (e.g., magneto-convection and magneto-caloric effects). In this presentation, we will introduce a hitherto underexplored energy application possibility for magnetic nanoparticles; namely, the thermoelectric energy conversion in ferrofluids. More specifically, we have determined experimentally both the thermoelectric (Seebeck) and thermodiffusion (Soret) coefficients of ionically stabilized ferrofluids made of maghemite nanoparticles dispersed in various non-magnetic liquid media (e.g., dimethyl sulfoxide, water and ionic liquids) under a temperature gradient. Both the thermoelectric voltage and the concentration gradient are measured as a function of nanoparticle concentration and analysed using existing theoretical models. The connection between the thermoelectric and thermodiffusion effects is revealed through a common parameter, the Eastman entropy of transfer of nanoparticles. This parameter characterizes the particle-solvent interactions and is generally proportional to the particle size. It is known to give rise to large Soret coefficients in colloidal suspensions including ferrofluids, and it is predicted to influence the Seebeck coefficients of carrier fluids. The values of the Eastman entropy of transfer obtained from both experiments are a few orders of magnitude larger than typical electrolyte ions and are in a quantitative agreement, lending support to the existing theoretical models. Simultaneously, our findings open a new research and technological path for magnetic nanoparticles in thermoelectric device applications.

Th.B.1_O3 - Reproducibility of barocaloric and magnetocaloric effects in $Fe_{49}Rh_{51}$

E. Stern-Taulats [1], A. Gràcia-Condal [1], A. Planes [1], L. Mañosa [1], P. Lloveras [2], M. Barrio [2], J.L. Tamarit [2], S. Pramanick [3], S Majumdar [3], C. Frontera [4]

3. Department of Solid State Physics, Indian Associaton for the Cultivation of Science, Jadavpur, Kolkata, India
4. Institut de Ciència de Materials de Barcelona, Bellaterra, Spain

$Fe_{49}Rh_{51}$ exhibits an antiferromagnetic-ferromagnetic first-order phase transition at 320K displaying subtle changes in magnetization, volume and entropy [1]. Recently, large barocaloric effect has been found [2] to arise in the vicinity of the transition which adds to the previously reported magnetocaloric [3] and elastocaloric effects [4]. Its first-order transition temperature presents unusually high sensitivity to pressure, magnetic field and stress resulting in large isothermal entropy (~12.5 J K-1 kg-1, in absolute terms) and adiabatic temperature (~8 K) changes in a wide temperature span (~20 K) when external fields are applied (2T or 2.5 kbar). Direct and indirect measurements of barocaloric and magnetocaloric effects in $Fe_{49}Rh_{51}$ are provided in order to characterize these caloric effects arising from material's interplay with external fields and their corresponding reversibility which becomes crucial either for applicational purposes such as solid state refrigeration and the understanding of the physical mechanisms involved in the AFM-FM first-order transition. A proper combination of applied fields can result in an optimization of $Fe_{49}Rh_{51}$ thermal response and a practical reduction of hysteresis effects associated to the first-order transition which can be responsible of a substantial loss of material's thermal response when subjected to field cycling.

Th.B.1_O4 - Magnetostructural phase transition in $AlFe_2B_2$ with magnetocaloric potential

L. Lewis [1], R. Barua [1], B. Lejeune [1], E. Stern-Taulats [2], L. Mañosa [2], A. Planes [2]

1. Department of Chemical Engineering, Northeastern University, Boston, United States
2. Departament D'Estructura I Constituents De Matèria, Facultat de Físic, Universitat De Barcelona, Barcelona, Spain

Understanding correlations between composition and crystal structure is key to tailoring the response of functional magnetic materials. In particular, the ferromagnetic $AlFe_2B_2$ compound with the layered $AlMn_2B_{2\text{-type}}$ structure is reported to exhibit a magnetic transition of relevance for magnetocaloric cooling, with a reported entropy change $AlFe_2B_2$ at an applied magnetic field of 2 T. Results derived from magnetic, structural and calorimetric probes confirm a thermodynamically first-order magnetic phase change in $AlFe_2B_2$ in the vicinity of the Curie temperature of ~ 300 K.

Th.B.1_O5 - Giant magnetocaloric effect in alternating magnetic fields

A. Aliev [1], A. Batdalov [1], L. Khanov [1], A. Êamantsev [2], E. Dilmieva [2], A. Mashirov [2], V. Koledov [2], V. Shavrov [2], M. Topic [2]

1. Amirkhanov Institute of Physics of Daghestan Scientific Center, RAS, Makhachkala, Russia
2. Kotelnikov Institute of Radio-engineering and Electronics of RAS, Moscow, Russia

The solid state magnetic working body in the magnetic refrigerators is subjected to a strong alternating magnetic field. That is why the alternating magnetic field behavior is crucial for the properties of the prospective magnetocaloric materials. First of all the giant magnetocaloric effect (GMCE) should express itself in alternating magnetic field. GMCE is mainly observed in the substances where both magnetic and structural phase transitions (PTs) are present and merged in one magnetostructural PT. In these materials the total change of entropy at external magnetic field change may consists of two impacts: magnetic and lattice ones. They can be expected to depend strongly on the frequency of the magnetic field applied. The present work is devoted to the study of the GMCE and magnetostriction in the alloys $Fe_{48}Rh_{52}$, Ni-Mn-In and manganite Sm_1-xSrxMnO$_3$ in alternating magnetic field by the technique described elsewhere [1]. The magnetic-field-induced magnetostructural PTs in these materials (antiferro-ferromagnetic in the cases of $Fe_{48}Rh_{52}$ and Heusler alloy Ni-Mn-In, and para- ferromagnetic in case of Sm_1-xSrxMnO$_3$) are accompanied by the strong lattice volume changes which also gives an impact to entropy.
We report that the correlation is observed of magnetostriction and GMCE in these materials. Both MCE and magnetostriction are negligible in small alternating magnetic fields. Starting from some threshold magnetic field both MCE and magnetostriction express themself. We come to the following conclusions: GMCE is strongly expressed in the alloys where antiferro-ferromagnetic PT is accompanied by lattice contraction (FeRh, and Ni-Mn-In) only in the fields stronger than that of needed for the shift the temperature of PT TN+(H) below the temperature of reverse transition in zero field TN-(0) (at TN+(H) < T < TN-(0)). In substances, like manganite Sm_1-xSrxMnO$_3$, in which ferro- paramagnetic PT is accompanied by the lattice expansion, the GMCE expresses at temperatures higher than TC+ in the regime of zero-field heating and below TC+(H) at TC+ < T < TC+(H)).

4. Instituto de Ciencia de Materiales de Aragón (ICMA), CSIC-Universidad de Zaragoza, Zaragoza, Spain
5. CEA Saclay, Gif-sur-Yvette, France

Bismuth (Bi) films, nanowires and nanoconstrictions result into an exciting playground to investigate uncommon quantum and spintronic effects. This stems from the combination of the extraordinary physical properties of Bi and the low dimensionality of the system. In particular, claims of topologically-protected quantum transport in Bi nanostructures have been reported [1,2], as well as remarkable Spintronic effects due to the Rashba interaction at the Bi/Ag interface [3]. In the present contribution we will report some of the experiments carried out by our group in Bi nanostructures along last years. In particular, we will first stress the existing competition of bulk and surface states and its impact in the magnetotransport properties of Bi-films and nanowires [4-6]. Later, we will describe our results in Bi nanocontacts created by electromigration and by focused ion beam etching, which show sub-quantum-of-conductance transport due to a metal-insulator transition at the constriction long before rupture [7]. Finally, the consequences of the Rashba interaction at the Bi/Ag interface for the spin-to-charge conversion due to Inverse Rashba Edelstein Effect and its competition with the Inverse Spin Hall Effect will be shown [8].

Th.B.2_O2 - Intrinsic conduction through topological surface states of insulating Bi_2Te_3 epitaxial thin films

K. Höfer [1], C. Becker [1], D. Rata [1], J. Swanson [1,2], P. Thalmeier [1], L.H. Tjeng [1]

1. Max Planck Institute For Chemical Physics of Solids, Dresden, Germany
2. University of British Columbia, Vancouver, Canada

Topological insulators represent a new state of matter that open up new opportunities to create unique quantum particles. Many exciting experiments have been proposed by theory; yet, the main challenges for their successful realization are material quality and cleanliness of the experimental conditions. The presences of tiny amounts of defects in the bulk or contaminants at the surface can easily mask these phenomena. We present the preparation, structural and spectroscopic characterization of MBE-grown Bi_2Te_3 thin films which exhibit insulating bulk properties. Moreover, temperature dependent four-point-probe resistivity measurements of the Dirac states on surfaces that are intrinsically clean were conducted. The total amount of surface charge carries is in the order of 10^(12)cm^(-2) and mobilities up to 4600cm^2/Vs are observed. Importantly, these results are achieved by carrying out the preparation and characterization all in-situ under ultra-high-vacuum conditions [1]. In order to preserve the surface integrity of the Bi_2Te_3 thin films during ex-situ experiments, e.g. high field measurements, appropriate capping layers need to be identified. We will show ARPES and transport results of a promising candidate, which provides protection against ambient conditions without influencing the electronic structure at the surface. This also opens a feasible route for future device fabrication.

Topological Insulators (TIs) are a new electronic state of matter which has been amply investigated during the last years due to its unique properties which have great potential for spintronic applications. TIs are materials with a bulk energy gap and metallic surface states, both stemming from non-trivial topology of the electronic structure [1]. Due to time-reversal symmetry and spin-orbit coupling, the surface states behave as Dirac Fermions and exhibit a fully spin-polarised k-dependent spin-texture. As a result, electron backscattering becomes quantum-mechanically prohibited, and topological 2-D surface states are expected to be robust against non-magnetic defects.
A large number of Bi-based ternary compounds have been theoretically predicted and experimentally proved to be topological insulators. Band structure calculations of Bi2Se2Te have predicted a TI state, with an isolated Dirac Point [2]. ARPES measurements of the occupied density of states (DOS) near the Fermi level support these calculations [3]. Here we show low temperature (1.1 K) Scanning Tunnelling Microscopy (STM) and Spectroscopy (STS) measurements on a Bi_2Se_2Te single crystal, gaining large spatial resolution of both the occupied and unoccupied local DOS. Atomically resolved STM images of the crystal surface shows a binary chemical contrast which is likely due to Te and Se segregation in regions of a few nm in size.
Moreover, individual Co atoms were deposited on the crystal surface held at T<6K to prevent atom diffusion. Co adatoms show an atomic resonance peak on the STS spectra at around -550 mV, in accordance with recent works on Bi_2Se_3[4]. Importantly, valence and conduction bulk bands undergo a shift towards lower energies upon Co doping.

Furthermore, an external magnetic field allows us to set a preferential spin direction of the Co magnetic moment. Our energy resolved STS measurements unveil the role of electronic hybridization in the interaction between localised magnetic scattering centres and topological Dirac fermions on the surface.

Th.B.2_O4 - Semimetal-insulator transition in Dirac semimetals induced by long-range Coulomb interactions

A. Sekine [1], K. Nomura [1]

1. Institute for Materials Research, Tohoku University, Sendai, Japan

Dirac semimetals in three dimensions have attracted much attention as a novel phase. They have gapless linear dispersions in the bulk, and the low-energy excitations are described by three-dimensional (3D) massless Dirac fermions. Hence they can be regarded as a 3D analog of graphene. Dirac semimetals such as Na_3Bi and Cd_3As_2 were experimentally observed recently [1,2]. It is notable that there exists large out-of-plane Fermi velocity anisotropy in the Dirac cones. One of the important meanings of the realization of Dirac semimetals is on the point that they can lead to various topological phases, since they lie next to various topological phases in the phase diagrams. In this work, we study theoretically the effects of strong 1/r Coulomb interactions in Dirac semimetals with N nodes. Due to the vanishing density of states near the Fermi level, the screening effect is expected to be weak in Dirac fermion systems. We particularly consider the cases of N = 4 and N = 16. Based on the U(1) lattice gauge theory, we analyze the system from the strong coupling limit. In this study, the dynamically generated mass of Dirac fermions, known as the chiral condensate, serves as the order parameter for the semimetal-insulator transition. It is shown that the Dirac semimetal phases survive in the strong coupling limit when the out-of-plane Fermi velocity anisotropy is weak, whereas the mass gap is generated in the strong coupling limit when the anisotropy is strong [3]. This result can be understood as a kind of dimensional crossover.

TH.B.2_O5 - Spin and charge current driven by magnetization dynamics on disordered surface of doped topological insulators

K. Taguchi [1], K. Shintani [1], Y. Tanaka [1]

1. Department of Materials, Physics And Energy Engineering, Graduate School of Engineering, Nagoya University, Nagoya, Spain

Topological insulator (TI) is a new class of material, which has a gapless surface state, in which the spin and momentum are perfectly locked by the spin-orbit interactions. On the surface of the TI attached ferromagnetic material (FM), the magnetization of the FM plays the role of an effective vector potential for conduction electrons, which is like a vector potential of electromagnetic fields. Owing to the effective vector potential, the time-derivative of the magnetization can be regarded as an effective electric field, and the magnetization dynamics generates charge current on the surface even in the absence of applied electric fields[1-3]. This is called as the spin-charge conversion. The property on the surface of the TI can be applicable for spintronics devices. Existing works of the spin-charge conversion has been done on a clean surface of the TI, namely the ballistic transport regime. However, the actual charge transport on the surface of the TI is in the diffusive regime due to the nonmagnetic impurity scattering. We theoretically study spin and charge generation and transport on a disordered surface of a doped three-dimensional TI/magnetic insulator junction by using Green's function techniques. We show that the charge and spin current are induced not only by local but also by nonlocal magnetization dynamics through the nonmagnetic impurity scattering on the disordered surface of the TI. We also clarify that the nonlocal magnetization dynamics induces spin current, as well as charge density on the surface. Using these results, we discuss the magnetization dynamics due to the ferromagnetic resonance before and after the spin and charge generation on the disordered surface of the TI.

4. Vacuumschmelze GmbH & Co. KG, Hanau, Germany

La(Fe,Si)13 are itinerant ferromagnets with giant magnetoelastic coupling, exhibiting large magnetocaloric effect (MCE) associated with a first-order metamagnetic phase transition. Substitution of Si produces lattice contraction and hybridisation between the electronic orbitals of Si and Fe atoms resulting in elevation of Tc. Substitution of Mn is thought to isovalently enhance antiferromagnetic exchange, lowering Tc. Tc can also be shifted to near room temperature by hydrogen absorption. Theoretical progress has been made to describe the electronic properties and the influence of substitution and interstitial occupancy [1, 2], but detailed comparison with experiment is lacking. Here we measure the Sommerfeld coefficient (gamma) extracted from the low temperature heat capacity in polycrystalline LaFeXMnYSiZ. Changes in magnitude of gamma by 20-30% are observed with Mn substitution and introduction of hydrogen showing that there are significant changes taking place in the density of states at the Fermi level. Interestingly gamma is of the order of 150- 200 mJ/mol K2 significantly greater by about a factor of eight than that determined by recent band structure calculation [3], but similar to experimental reports of related itinerant compounds [4,5]. Mass enhancement in transition metals on the cusp of ferromagnetism is understood to be due to d electron correlation effects brought about by spin fluctuations [6] but detailed understanding in La(Fe,Si)13 is lacking.

The generation of spin currents without movement of charge is of crucial importance in spintronics that could allow computer speed and power consumption to move past limitations of current technologies. The spintronic can also be applied to some traditional technologies as thermoelectric converters. Regardless of the big amount of research in thermoelectrics, the efficiency of such devices has remained low due to the interdependence between the Seebeck effect, the resistivity and the thermal conductivity. Meanwhile, the Joule heating of electronic devices with finite size effect is another obstacle. One promising approach to overcome this set of problems and give versatility to thermoelectric devices is exploiting the spin of the electron, in addition to its charge and transport properties. The discovery of the spin Seebeck effect (SSE) [1] and more particularly its observation in magnetic insulators [2, 3] offers a new approach for thermoelectric energy conversion and sensors. The SSE provides a feasible way to drive a nonequilibrium spin current, as a result of a temperature gradient in magnetic materials. The spin dependent thermal transport of magnetite films on different substrates was studied, taking special care about the heat manipulation of the different substrate material (Al_2O_3, $MgAl_2O_4$, $SrTiO_3$, MgO). In particular, the magneto-thermoelectric characteristics of magnetite film have been investigated by fine manipulation of heat flow. The Anomalous Nernst Effect (ANE) was measured to normalize and distinguish from the SSE signal. The interplay between the magnetization, temperature gradient, structure and nanostructural defects induced by the substrate have shown to have an important influence on the ANE and SSE voltage signals. ANE and SSE signal were maxima in Fe_3O_4/Al_2O_3 and $Fe_3O_4/MgAl_2O_4$, respectively. Nanostructural defects like antiphase boundaries in magnetite films were studied by aberration correction TEM and showed to have different patterning depending on the substrate of growth.

Th.B.3_O3 - Modeling specific heat and entropy change in La(Fe,Mn,Si)13-H compounds

M. Piazzi [1], C. Bennati [1], C. Curcio [1], M. Kuepferling [1], V. Basso [1]

1. Istituto Nazionale Di Ricerca Metrologica (INRIM), Turin, Italy

Two classes of magnetic materials are currently the most promising candidates for room-temperature magnetic cooling: the La(Fe,Si)13 based [1] and the MnFe(P,X) (X=As, Ge, Si) based [2]. Both systems display first-order ferro- to paramagnetic phase transitions with an enhanced magnetocaloric effect (MCE). In hydrogenated La(Fe,Mn,Si)13-H the MCE can be finely tuned by varying Mn content [1]. Modeling the behaviour of these systems is of primary importance for further optimising the materials. In this work we compare La(Fe,Mn,Si)13-H data with a thermodynamic model that, taking into account magnetovolume effects, is able to display both first- and second-order transitions by smoothly varying the strength of the magnetoelastic coupling [4]. The magnetism is treated within the framework of localized electrons mean field theory (MFT) and lattice entropy is explicitly considered. We find that the model successfully describes the experimental entropy change at the phase transition, capturing also the variation from first- to second-order transitions. However the sharp peaks of the specific heat close to the transition temperature are insufficiently reproduced. This is a known problem related to the difficulty of MFT to shape the specific heat behaviour close to the Curie point, where spin correlations play a relevant role. Thus, to go beyond MFT, different strategies taking into account these correlations should be considered. Here we derive the magnetic entropy from the density of states, as obtained by the Wang-Landau sampling algorithm applied to Ising ferromagnet [5]. The resulting model allows to better capture the peculiar shapes of the specific heat peak at La(Fe,Mn,Si)13-H phase transitions.
The research leading to these results has received funding from the European Community's 7th Framework Programme under grant agreement no. 310748 (project "DRREAM").

Th.B.3_O4 - Effect of irreversibility on the magnetocaloric effect of compounds with first-order transitions

R. Burriel [1], E. Palacios [1]

1. Instituto de Ciencia de Materiales de Aragón (ICMA), Zaragoza, Spain

The use of magnetocaloric materials for cooling applications at room temperature requires high values of the magnetocaloric parameters. These high values are found in compounds with first-order transitions. Associated with the first-order character, there is a detrimental effect due to the inherent irreversibility of these transitions.

At the first-order magnetic transitions there is an entropy production due to the irreversibility. The elemental evaluation of the isothermal entropy change upon a field change, ΔS_T, from magnetization, heat capacity, or direct measurements, has an error and its value depends on the physical property used. Estimations of the entropy from heat measurements lack the entropy creation through the first-order transitions. Consequently, the transition entropies derived from heat capacity or direct measurements are not correct and the errors are shown to be proportional to the thermal hysteresis of the compound. In the case of magnetization measurements, the Clausius-Clapeyron equation is used to calculate the entropy of the transition from the magnetization jump and the temperature dependence of the transition field. This calculation lacks an irreversible term that is demonstrated to be equal to the temperature derivative of the free energy jump at the transition. Generally, this correction to the values derived from magnetization is higher than in the case of values derived from heat capacity data.

Apart from these corrections of the transition entropy, accounting for the irreversible entropy creation, there is a much higher spurious effect in ΔS_T values derived from the application of the Maxwell equation to isothermal magnetization data. They result in an unphysical ΔS_T spike that has been referred to as a colossal magnetocaloric effect. The values of the spike are shown to be proportional to the anomalous heat capacity at zero magnetic field. This effect is not related to irreversibility but happens only in compounds presenting thermal hysteresis.

TH.C.1_I1 - Magnetic nanostructures for magnonic and logic applications

A. Adeyeye [1]

1. National University of Singapore, Singapore, Singapore

Magnetic nanostructures have attracted a lot of interest from researchers around the world in the last decade, both from a fundamental viewpoint and because of their potential in a wide range of emerging applications such as ultra high density storage, magnetic random access memory, spin logic and magnonics. The ability to synthesize high quality arrays of magnetic nanostructure with precise dimensionality control is crucial for reproducible magnetic switching processes. Key issues to be considered in the development of any nanofabrication techniques are critical dimension control, resolution, size and shape homogeneity, patterned area and alignment accuracy. With advances in lithographic and other controlled nanofabrication techniques, made possible by developments in nanotechnology, it is now possible to synthesize a wide range of high-quality magnetic nanostructures. The talk will focus on strategies developed in my group over the year for synthesizing high-quality complex magnetic nanostructures using photon based and charge based lithographic processes [1]. In addition, recent results on the static and dynamic properties of magnetic nanostructures obtained using a combination of magneto-optical Kerr effect measurements, magnetic force microscopy, broadband ferromagnetic resonance spectroscopy and Brillouin light scattering (BLS) spectroscopy will be presented. The dynamic behavior of various types of structures made from lithographically defined magnetic nanostructures will be discussed [2]. Results on the direct detection of neighboring dipolar interactions on a single nanomagnet using micro-focused BLS spectroscopy will be presented [3]. It will be shown that magnetic nanostructures can be designed to realize ferromagnetic and antiferromagnetic ground states for logic and magnonic applications [4].

TH.C.1_O2 - Mechanical control of magnetic easy axis in a TbFeCo thin film deposited on a flexible substrate

S. Ota [1], D. Bang [2], H. Awano [2], T. Kozeki [3], H. Akamine [3], T. Fujii [3], T. Namazu [3], T. Takenobu [4], T. Koyama [1], D. Chiba [1]

1. Department of Applied Physics, Faculty of Engineering, The University of Tokyo, Tokyo, Japan
2. Information Storage Materials Laboratory, Toyota Technological Institute, Nagoya, Japan
3. Division of Mechanical Systems, Department of Mechanical and Systems Engineering, University of Hyogo, Himeji, Japan
4. Department of Applied Physics, Waseda University, Tokyo, Japan

Use of the inverse magnetostriction effect is known as one of the effective way to manipulate magnetization direction for magnetic storage devices [1]. The strain-induced change in the magnetic anisotropy in ferromagnetic thin films has been reported by directly bending the substrate [2], or in the configuration where the sample was mounted on a piezo device [3]. In this work, we have achieved to apply larger uniaxial strain over 2% on the thin film made of TbFeCo, one of the famous magnetostriction alloys, by simply stretching a flexible substrate on which the film was deposited. As a result, a clear switching in the easy axis has been observed.
Pt(4 nm)/TbFeCo(6 nm)/Pt(4 nm) layers were deposited on the flexible substrate by magnetron sputtering. The sample was fabricated into Hall bar structure to measure the magnetization curve under the application of strain using the anomalous Hall effect. When the external strain was off, a square hysteresis loop was seen in the curve, indicating that the sample had the perpendicular magnetic anisotropy. We applied a tensile strain ε to the sample by stretching the substrate in the direction parallel to the current direction. As ε increased, both the coercivity and the squareness ratio of hysteresis loop decreased, and the hysteresis disappeared when ε was larger than 2%, indicating that the easy axis switched from the perpendicular to the in-plane direction. After that, by reducing ε to 0%, the coercivity and the squareness ratio returned almost to their initial values. The result evidences that the change in the magnetic anisotropy shown here was reversible.

TH.C.1_O3 - High-sensitivity dc field magnetometer using nonlinear resonance magnetoelectric effect

Y. Fetisov [4], D. Burdin [1], D. Chashin [2], N. Ekonomoov [3]

1. Moscow State Technical University of Radio Engineering, Electronics and Automation, Moscow, Japan

New type magnetometer using nonlinear resonance magnetoelectric (ME) effect in ferromagnetic-piezoelectric (FM-PE) structures is proposed. The magnetometer exploits nonlinear dependence of FM sample magnetostriction ë vs. magnetic field and piezoelectric effect to register the signal. This differs from the fluxgate magnetometers which use nonlinear dependence of FM sample magnetization vs. field and electromagnetic induction.
The magnetometer operates as follows. The FM-PE structure is placed in a low-frequency pumping field h with frequency f and measured dc magnetic field H. In order to avoid influence of the FM layer hysteresis, h should be bigger than saturation field. The signal with frequency 3f generated by the PE layer due to nonlinear ME effect is measured. Magnitude of the signal is proportional to the field H. Acoustic resonance of the structure is used to increase sensitivity of the magnetometer.
A prototype of the magnetometer was fabricated on the structure with dimensions 40x5 mm2 containing 30 um thick Metglas layer and 400 um thick langatite layer. The pumping field of h =20 Oe and f =1.5 kHz was created by a coil. The frequency 3f coincided with the frequency of bending oscillations of the structure 4.5 kHz. In this case the output signal and, respectively, the sensitivity of the magnetometer was increased by acoustic quality factor Q~10^2. Under resonance operation regime the magnetometer allowed registration of fields H =1 mOe - 5 Oe and had sensitivity u/H ~1 V/Oe.
Thus, new type dc field magnetometer using nonlinear resonance magnetoelectric effect in FM-PE structures was suggested and fabricated. The ME magnetometer has ~2 order of magnitude higher sensitivity than well known fluxgate magnetometers.

The research was supported by the Ministry of Education and Science of Russia

TH.C.1_O4 - New susceptibility measurement devices and their calibration

J.L. Mesa Uña [1], M. Pérez [1], A. B. Fernandez [2], M. Maicas [1], C. Aroca [1], M. Díaz Michelena [1]

1. Universidad Politécnica De Madrid, Madrid, Spain
2. Instituto Nacional de Técnica Aeroespacial (INTA), Madrid, Spain

Susceptibility measurements are very important for materials characterization because it is related to intrinsic properties of the matter like the capability to magnetize (real part) and the conductivity or spin relaxation (imaginary part). In order to cover this widely extended technique, we have developed several devices:
1. Laboratory High Resolution Susceptometer. This device can measure with high resolution the magnetic signal produced by a magnetic sample. It is based on a linear actuator and a set of coils: primary and secondary. The principle is similar to a VSM, but the main difference consist in the possibility to determine the ac magnetic permeability in a large frequency range (dc - 100 kHz).
2. Portable Susceptometer for planetary applications. Device based on an electrical resonant ferrite actuator. The measurement technique is based on impedance changes in an inductive core due to the presence of a magnetic material. This device is currently being developed for a Mars lander. Despite the importance of having absolute measurements of the susceptibility, the calibration of the devices is complicated and requires the manufacturing of reference probes. In this work we report on the calibration and latter measurements with the two susceptometers. The calibration of the system has been carried out using a set of reference probes controlling the composition and the concentration of ferro and ferri magnetic materials in a scarcely diamagnetic epoxy. The susceptibility measurements of natural samples (basalt, peridotite, terrace and clays) performed with the portable susceptometer show a good correlation with the results obtained with other well-known techniques (SQUID, VSM), with the advantage that we can perform measurements of the ac magnetic susceptibility at different frequencies. The measurements performed with the laboratory susceptometer demonstrates a high resolution (minimum signal around 10 - 20 Oe) and a good correlation in dc with results obtained with VSM.

TH.C.1_O5 - Magnetostrictive stress reconfigurable thin film resonators in vacuum for magnetic field sensing

P.Finkel [1], M. Staruch [1]

1. US Naval Research Laboratory, Washington DC, United States

The magnetic response of microdevices is significantly enhanced at structural resonance allowing for improved sensitivity and signal-to-noise ratio. The magnetic field resolution of these devices can be further improved when operating in vacuum due to an increase in mechanical quality factor. In this work, free-standing thin film CoFe bridge resonators have been fabricated and investigated. A strong magnetic field dependence of the fundamental resonance frequency is a function of magnetic field orientation due to a large unidirectional anisotropy. Under vacuum, a quality factor of up to 25 times greater than at atmosphere was revealed as well as an increased magnetic field sensitivity. Such stress reconfigurable sensors offer the possibility of broadband sensing with high resolution, and may therefore represent a new approach to fully integrated resonant magnetic field sensing technology.

Th.C.2_I1 - Field-dependent Size and Shape of Single Magnetic Skyrmions

N. Romming [1], André Kubetzka [1], C. Hanneken [1], K. von Bergmann [1], R. Wiesendanger [1]

1. Department of Physics, University of Hamburg, Hamburg, Germany

Magnetism in thin films can significantly deviate from commonly known magnetic configurations in bulk systems due to low dimensionality, hybridization effects, a change of the lattice constant, stacking and broken inversion symmetry at interfaces. This can lead to non-collinear spin states such as spin spirals or skyrmions. Especially skyrmions offer great potential as information carriers in future robust, high-density, and energy-efficient spintronic devices: in addition to their protected topology and nano-scale size, they can easily be moved by lateral spin currents and written as well as deleted by vertical spin-current injection [1]. While numerous theoretical and simulation studies have concentrated on individual skyrmions and their physical properties, no high-resolution experimental characterization of the internal spin structure of skyrmions has been reported up to now, even though the knowledge about their actual size and shape provides the foundation for predictions about the interactions of skyrmions with spin currents or their manipulation by external fields as envisaged in potential skyrmion-based device concepts. Here we investigate the atomic-scale spin structure of individual isolated skyrmions in an ultrathin film in real space by spin-polarized scanning tunneling microscopy. Their axial symmetry as well as their unique rotational sense is revealed by using both out-of-plane and in-plane sensitive tips. The size and shape of skyrmions change as a function of magnetic field. An analytical expression for the description of skyrmions is proposed and applied to connect the experimental data to the original theoretical model describing chiral skyrmions [2]. Thereby, the relevant material parameters responsible for skyrmion formation can be obtained.

Th.C.2_O2 - In-situ TEM study of temperature-dependent dichroism: Application to epitaxial MnAs/GaAs(001)

X.Fu [1], D. Demaille [2], V. Etgens [2], S. Joulié [1], G. Seine [1], R. Arras [1], V. Serin [1], B. Warot [1]

1. CEMES-CNRS, Toulouse, France
2. UPMC (Université Pierre et Marie Curie), Paris, France

Epitaxial MnAs thin films grown on GaAs substrate, have attracted much attention over the last decades due to their magnetic properties and potential spintronic applications. In this work, we focus on investigating the temperature-dependent local magnetic behavior of MnAs/GaAs(001) by TEM (Transmission Electron Microscopy) techniques. Before that, the surface topography and magnetic domain structure are observed using AFM (atomic force microscopy) and MFM (magnetic force microscopy). It demonstrates the coexistence of the α ferromagnetic phase and the β paramagnetic phase, in a temperature range of around 30°C. HRTEM (High resolution transmission electron microscopy) image and EELS (electron energy loss spectroscopy) spectrum have been acquired at room temperature, and the α-MnAs ferromagnetic phase has been identified. The magnetic moment information has been then extracted from the manganese L-2,3 edge with an element-specific technique, EMCD (Electron energy-loss Magnetic Circular Dichroism). The spatial resolution reaches a few tens of nm. Local quantitative magnetic moment information is extracted from the dichroism signal with Sum Rule, and it is compared to DFT calculations. In a second step, the temperature of the sample is increased above 70°C in situ inside the microscope. In this condition, all the hexagonal α-MnAs phases are transformed into the orthorhombic β-MnAs ones. We follow the change of atomic structure and magnetic moment during and after the phase transition.

Th.C.2_O3 - Experimental evidence of ultra-small particles in magnetic metal-insulating nanogranular films

M. Garcia Del Muro [1], Z. Konstantinovic [2], A. Labarta [1], X. Batlle [1]

2. ICMAB-CSIC, Bellaterra, Spain

Since the first work by Morup in 1983 describing a nanoparticles (NP) system where the superspins of all NP were correlated in a ferromagnetic-like way, many efforts have been devoted to completely understand what has been called superferromagnetism (SFM). So far, there is no clear understanding of the interaction leading to the SF order in an ensemble of nanoparticles embedded in a dielectric matrix, although it has been generally assumed that indirect exchange could be mediated by dispersed ions and ultrasmall paramagnetic nanoparticles between the superspin particles (SSP). Thus, it is believed that these so-called glue-particles would cause the magnetic percolation below the physical percolation, but without any direct experimental evidence. In this work, we prepared nanogranular Co-ZrO2 films, and submitted to two subsequent annealings to bring on the nucleation of very small particles from the Co atoms dispersed in the matrix. High resolution TEM images unambiguously show the presence of ultra-small (below 1 nm) regions with crystalline structure, that were attributed to Co by EELS. Those very small particles appear filling the space between the nanoparticles observed by conventional TEM. Our previous work, have revealed that microstructural changes are critical for the ac electrical behaviour, and the usefulness of random R-C models in simulating real complex materials with microstructural disorder: R accounts for the tunneling conduction paths through ultra-small particles, and C for the capacitive conduction through the bigger SSP. In this work, numerical simulations reproduce the ac experimental results and provide physical parameters that are compatible with microstructural changes observed by TEM, strongly confirming the increasing presence of ultra-small particles in between the SSP by subsequent annealings.

Th.C.2_O4 - Low frequency dynamics of magnetic droplet solitons in spin transfer nanocontacts

F. Macia [1], J.M. Hernández [1], S. Lendínez [1], D. Backes [2], A.D. Kent [2]

1. University of Barcelona, Barcelona, Spain
2. New York University, New York, United States

Localized excitations that correspond to reversed dynamically precessing magnetic moments, known as magnetic droplet solitons, were predicted to occur in uniaxial magnets in the absence of damping. However, damping is present in all magnetic materials and suppresses these excitations. It is possible now to compensate damping in ferromagnetic thin films by spin transfer torques through electrical current flow in nanometer scale contacts. Recent experiments [1,2] have shown the existence of these magnetics objects and proved their stability [2]. We explored conditions that allow formation, stabilization, and annihilation of the droplet excitations. We report spectral measurements, on the GHz range, as a function of current and applied field that challenge existing theories. Additionally, we will report low frequency (~300 MHz) excitations associated to the magnetic droplet dynamics. We will show that the droplet hysteretic behavior in current and field, which is related to its stability, is also present in the high and low frequencies spectra. Finally, we will present our recent simulations and compare them with the results and the existing theory. FM is Supported by Catalan Government through COFUND FP7. FM, JMH and SL aknowledge the Spanish Government (grant no. MAT2011-23698). DB and ADK were supported by NSF-DMR-1309202 and in part by ARO-MURI, Grant No. W911NF-08-1-0317

Th.C.2_O5 - Light irradiation-driven modifications of Pt/Co/Pt trilayers

A. Maziewski [1], I. Sveklo [1], J. Kisielewski [1], Z. Kurant [1], A. Bartnik [2], M. Jakubowski [3], R. Sobierajski [3], J. Pełka [3], A. Wawro [3]

3. Institute of Physics, Polish Academy of Sciences, Warsaw, Poland

A series of Pt(111)/Co(001)/Pt(111) trilayer structures was epitaxially grown on Al_2O_3(001) by MBE technique. As-grown films with in-plane magnetization state were selected. Samples were irradiated using various single pulse irradiation sources: (i) femtosecond laser of 800 nm in wavelength, similarly as in Ref. [1]; (ii) 3 ns laser-plasma source of extreme ultraviolet (EUV) with the most intense emission in a relatively narrow spectral region, centered at wavelength 11 nm described in Ref. [2]. Irradiations were performed at a broad range of light energy densities. The highest applied densities modified locally the morphology of studied trilayers due to: (i) sputtering of ultrathin layers using femtosecond pulses and (ii) local melting by EUV. Atomic force microscopy was used to control the surface modifications. Both magneto-optical Kerr microscopy and magnetic force microscopy were used for magnetic properties studies. Using image processing of magneto-optical images, the maximal Kerr rotation, remanence and coercivity were determined as functions of irradiation fluence. Both light sources enabled creation of the irreversible magnetic out-of-plane magnetic state - the irradiation can locally induce the spin reorientation transition. Strong decrease of magnetic domain size was observed while approaching the spin-reorientation transition region. Maximum Kerr rotation increased with the applied light fluence. Investigated light irradiation driven modifications of Pt/Co/Pt trilayers are similar to those induced by Ga+ ions irradiation described in Ref. [3]. The research is supported by: Polish National Science Centre under the project no. DEC-2012/06/M/ST3/00475 and SYMPHONY project operated within the Foundation for Polish Science Team Programme co-financed by the EU European Regional Development Fund, OPIE 2007-2013.

Th.C.3_O1 - Evidence for nodal superconductivity in quasi-one-dimensional $K_2Cr_3As_3$

G. Pang [1], M. Smidman [1], W. Jiang [1], J. Bao [1], Z. Weng [1], Y. Wang [1], L. Jiao [1], J. Zhang [1], G. Cao [1], H. Yuan [1]

The newly discovered quasi-one-dimensional superconductor $K_2Cr_3As_3$ has attracted considerable interest [1]. Its crystal structure consists of double-walled tubes of $[Cr_3As_3]^{2-}$ that run along the c axis. Electronic structure calculations for $K_2Cr_3As_3$ reveal that three bands cross the Fermi level, two of which are one-dimensional and one is three-dimensional [2]. For a transition temperature of $T_c \approx 6.1K$, this compound shows a remarkably high upper critical field ($B_{c2}(0) \approx 31.2T$), far exceeding the Pauli limiting value [1]. In this presentation, we report measurements of the London penetration depth $\Delta\lambda(T)$ and superfluid density $\rho_s(T)$ of $K_2Cr_3As_3$ to probe its superconducting gap structure [3]. Linear behavior of $\Delta\lambda(T)$ is observed for $T<<Tc$, instead of the exponential behavior of conventional superconductors, indicating that there are line nodes in the superconducting gap. Possible pairing states will be discussed by comparing different fits of $\rho_s(T)$. Our results provide strong evidence for unconventional behavior and may provide key information for identifying the pairing state of this novel superconductor.

Th.C.3_O2 - Unveiling the magnetic state of iron in the superconducting pressure region

B. Lebert [1,2], J. Ablett [1], F. Baudelet [1], M. Casula [2], A. Juhin [2], G. Le Marchand [2], P. Munsch [2], A. Polian [2], J.P. Rueff [1], Z. Zhang [1,2], M. d'Astuto [2]

Iron undergoes a martensitic transition at 13 GPa and room temperature from ferromagnetic α-iron to apparently non-magnetic ε-iron. This phase is superconducting between 15 GPa and 30 GPa [1], which cannot be explained solely by conventional phonon pairing mechanisms. There is theoretical evidence that a magnetically mediated mechanism is involved, however the magnetism of ε-iron is disputed to this day. Mössbauer spectroscopy (MS) finds an upper limit of 0.05 μ_B for the local moment [2], while other techniques suggest a larger local moment. For example, a study using Kβ x-ray emission spectroscopy (XES) which found evidence of "remnant" magnetism above 15 GPa in the ε-iron [3].
We have also performed Kβ XES, however using higher statistics and argon as a pressure medium, to explore the phase diagram of iron from 3 to 50 GPa and 4 to 583 K. Our results show the satellite's shape and position are stable in α-iron and then exhibit a sharp decrease in intensity, increase in width, and shift in energy at 15 GPa, coinciding with the onset of superconductivity. Increasing the pressure further, the satellite's intensity continues to decrease and disappears between 30 GPa and 50 GPa. As well, we found that the satellite shows no temperature trend between 4 K and 583 K. These results suggest that the local moments are from an intrinsic magnetism in the ε-iron phase, rather than a "remnant" magnetism from the ferromagnetic α-iron phase. Furthermore, the overlapping pressure existence regions strengthens the case for a magnetically mediated component. Contrasting our results to MS: we are either observing magnetic fluctuations faster than the timescale of MS, or we are observing a proposed anti-ferromagnetic ground state (afmII) known to have very weak hyperfine field [4].

Th.C.3_O3 - Fermi-surface topology and pairing symmetry in bis2-based layered superconductors

T. Hotta [1], T. Agatsuma [1]

1. Department of Physics, Tokyo Metropolitan University, Hachioji, Japan

Recently, new $BiS_{2\text{-based}}$ layered superconductors have been discovered by Mizuguchi et al. This material group has the characteristic structure similar to high-T_c cuprate superconductors. Namely, BiS_2 superconducting layer is sandwiched by insulating blocking layers. Here we pick up $LaO_{1-x}F_xBiS_2$. The mother compound $LaOBiS_2$ is insulating, but by substituting F for O, we can dope electrons into the BiS_2 layer and the system becomes metallic. Then, superconductivity occurs and in particular, at x=0.5, the superconducting transition temperature T_c becomes maximum. Under high pressures, we obtain T_c over than 10 K. The minimum model to describe electronic structure of BiS2 layer is the two-band Hamiltonian composed of Bi 6p_x and 6p_y orbitals on the two-dimensional square lattice, proposed by Usui et al. In this research, we analyze the two-dimensional two-band model including intra- and inter-orbital Coulomb interactions within a random phase approximation to derive the effective pairing interaction among quasi-particles. Then, we solve the gap equation to obtain T_c and the gap symmetry by focusing on the Fermi-surface topology. We find that T_c becomes maximum at x=0.6 and the corresponding gap symmetry is the extended s-wave. In this case, we find a couple of big Fermi-surface curves at the centers of Gamma and M points and the extended s-wave is considered to be preferable. An interesting point is the conversion of the gap symmetry from extended s-wave to d-wave, when we decrease x. At x=0.4, we obtain the d-wave gap, but the disconnected Fermi-surface curves around at X and Y points do not cross the line nodes of the d-wave gap. We emphasize that the variation of the Fermi-surface topology induces the conversion of the gap symmetry in this system.

Th.C.3_O4 - First-order superconducting transition of Sr_2RuO_4 investigated by magnetization and magnetic torque

S. Kittaka [1], A. Kasahara [1], T. Sakakibara [1], D. Shibata [2], S. Yonezawa [2], Y. Maeno [2], K. Tenya [3], K. Machida [4]

1. University of Tokyo, Tokyo, Japan
2. Kyoto University, Kyoto, Japan
3. Shinshu University, Matsumoto, Japan
4. Okayama University, Okoyama, Japan

The first-order superconducting transition, recently discovered in a long-standing candidate for a spin-triplet chiral-p-wave superconductor Sr_2RuO_4, is mysterious because it is not expected within the present scenario of spin-triplet superconductivity [1]. To uncover its mechanism, we have measured the magnetization and the magnetic torque using an ultra-clean single crystal of Sr_2RuO_4 down to 0.1 K [2]. In this study, the magnetic field has been applied parallel to the ab plane with a high precision using a device we recently developed. Although the spin susceptibility has been considered to be invariant for the anticipated spin-triplet state, we observed a sharp magnetization jump of as large as 0.74 G, which is comparable to the prediction on the basis of microscopic calculation for a strongly Pauli-limited spin-singlet superconductor. The present work provides the keystone issues whose resolution is crucial in uncovering a ``hidden'' pair-breaking mechanism within the triplet-pairing scenario, or might urge the reconsideration of the order parameter in Sr_2RuO_4.

4. SP2M, Université Paris-Sud, Orsay, France

Entanglement is a concept that has defied common sense since the discovery of quantum mechanics. Two particles are said to be entangled when the quantum state of each particle cannot be described independently, no matter how far apart in space and time these two particles are. We demonstrate experimentally that unpaired spins separated by several hundred Å entangle through a collection of spin singlets made up of antiferromagnetic spin-1/2 chains in a bulk material. Low-temperature magnetization and specific heat studies as a function of magnetic field reveal the occurrence of very dilute spin dimers and at least two quantum phase transitions related to the breaking of excited local triplets. The mechanism at the origin of the unpaired spins inside the quantum chains is the inter-modulation potential between two sublattices, and may be replicated using well-designed synthetic multilayers. Finally I will show that many different kind of entangled species (more than 6 here !!!) can coexist in the same compound without interfering.

Th.D.1_O2 - Magnetic interactions in the two-dimensional strongly coupled dimer system malachite

M. Enderle [1], E. Canevet [1,2,4], B. Fak [1], R. Kremer [3], J.H. Chun [3]

1. Institut Laue-Langevin, Grenoble, France
2. Laboratoire de Physique des Solides, Université Paris Sud, Orsay, France
3. Max-Planck Institute for Solid State Research, Stuttgart, Germany
4. Paul Scherrer Institut, Laboratory for Neutron Scattering and Imaging, Villigen PSI, Switzerland

The mineral malachite, $Cu_2(OH)2CO_3$, is known since the antiquity as a green pigment and gemstone, but its magnetic properties have only recently attracted attention. No phase transition has been observed between room temperature and 0.4 K, and initially it was assumed that the Cu2+ spins 1/2 form alternating chains. We have studied the magnetic excitations of malachite using inelastic neutron scattering on a fully deuterated powder sample. The neutron scattering measurements show that malachite has a quantum spin-liquid ground state and that the excitation spectrum consists of dispersive gapped singlet-triplet excitations, characteristic of spin-1/2 dimer-forming Heisenberg antiferromagnets. The observed excitation spectrum is well described by a model based on the harmonic triplon approximation. We identify the main interactions which are all antiferromagnetic, and lead to a new two-dimensional dimerized coupling scheme with strong interdimer coupling. This coupling scheme places malachite between strongly coupled alternating chains, square lattice antiferromagnets, and infinite-legged ladders. The geometry of the interaction scheme resembles the staggered dimer lattice, with potential for unconventional quantum criticality.

Th.D.1_O3 - Possible quadrupolar quantum criticality in $PrIr_2Zn_{20}$

A. Sakai [1], K. Matsumoto [2], T. Onimaru [2], T. Takabatake [2], P. Gegenwart [1]

1. Universitat Augsburg, Institut Fur Physik, Experimentalphysik VI, Augsburg, Germany
2. Department of Quantum matter, Hiroshima University, Hiroshima, Japan

Quantum critical points (QCPs), which emerge when magnetic order is suppressed by tuning control parameters like pressure or magnetic field, have attracted much attention. It is quite interesting to search for new types of QCPs such as quantum criticality arising from orbital (quadrupole) ordering.

The cage compound $PrIr_2Zn_{20}$ has the cubic nonmagnetic G_3 CEF ground state and shows antiferroquadrupolar (AFQ) ordering at T_Q = 0.11 K [1]. In addition, it becomes superconducting at T_c = 0.05 K within the AFQ ordered state. The AFQ state is suppressed by application of a magnetic field of 5 T along [100] associated with the anomalous enhancement of Seebeck coefficient [2].

In this presentation, we will present the results of adiabatic magnetocaloric effect measurements down to 50 mK for B // [100]. A peak in the magnetic Grüneisen ratio at B ~ 5 T is observed, suggesting possible quadrupolar quantum criticality.

6. Universite Grenoble Alpes & CEA, INAC-SPSMS, Grenoble, France

Fluctuations around quantum critical points are known to be responsible for many unexpected phenomena, e.g. the discontinuous phase transitions seen in itinerant ferromagnets at low temperatures. Such fluctuation-induced first-order behaviour is a consequence of the interplay between magnetic order parameter and soft electronic particle-hole fluctuations.
Using a fermionic version of the quantum order-by-disorder mechanism, we demonstrate that the ferromagnetic quantum critical point is unstable towards the formation of incommensurate spiral order. The key idea is that certain deformations of the Fermi surface associated with the onset of competing order enlarge the phase space available for low-energy particle-hole fluctuations and self-consistently lower the free energy.
We apply this theory to PrPtAl where spiral order on the border of ferromagnetism is observed in neutron and x-ray scattering experiments. In this system, the coupling of the itinerant electrons to the local Pr(3+) moments leads to magnetic anisotropies which have characteristic experimental consequences.

Th.D.2_I1 - Quantum fluctuations in spin-ice-like $Pr_2Zr_2O_7$

C. Broholm [1]

1. Johns Hopkins University, Baltimore, United States

Spin ice is a magnetic analogue of H2O ice that harbors dense static disorder. Dipolar interactions between classical spins yield a frozen frustrated state with residual Pauling entropy and emergent magnetic monopolar quasi-particles. Introducing quantum fluctuations is of great interest as this could melt spin ice and allow coherent propagation of monopoles. Here we report experimental evidence for quantum dynamics of magnetic monopolar quasi-particles in a new class of spin ice based on exchange interactions, $Pr_2Zr_2O_7$ [1]. Narrow pinch-point features in otherwise diffuse elastic neutron scattering reflects adherence to a divergence free constraint for disordered spins on long time scales. Magnetic susceptibility and specific heat data correspondingly show activated dynamics and residual entropy below 0.1 K. In sharp contrast to conventional ice, however, more than 90% of the neutron scattering is inelastic and devoid of pinch points furnishing evidence for magnetic monopolar quantum fluctuations. The spectrum of inelastic scattering persists to significantly higher energies than expected based on estimates of the exchange constant from thermomagnetic measurements. The absence of wave vector dependence in this scattering indicates it is associated with local physics of the non-Kramers doublet.

Work at IQM was supported by DoE, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering under Award DE-FG02-08ER46544.

Th.D.2_O2 - Spin liquid versus long range magnetic order in the frustrated body-centered tetragonal lattice

S. Burdin [1], C. Thomas [2], C. Pépin [3], A. Ferraz [4], C. Lacroix [5]

1. LOMA, CNRS & Bordeaux University, Bordeaux, France
2. Instituto de Fisica, UFRGS, Porto Alegre, Brazil
3. Institut de Physique Théorique, CEA-Saclay, France
4. International Institute of Physics, UFRGN, Natal, Brazil
5. Institut Néel, Université Grenoble Alpes, Grenoble, France

An SU(n) generalization of the quantum Heisenberg model is studied in the geometrically frustrated body-centered tretragonal lattice (BCT-lattice) with antiferromagnetic interlayer coupling J1 and intralayer first and second neighbor coupling J2 and J3. Using a fermionic representation of the SU(n) spin operators, we study the phase diagramm characterizing the ground state of the system. For small n, we find that the most stable solutions correspond to the three different possible long range magnetic orders that are respectively governed by J1, J2, and J3. For large n, spin-liquid (SL) solutions are stabilized. The SL solution governed by J1 breaks the lattice translation symmetry. This Modulated SL is associated to a commensurate ordering wave vector (1,1,1). For intermediate values of n, we show how competition between J1, J2, and J3 can tune the ground state from a magnetically ordered to a SL state. We then discuss the relevance of this scenario for correlated systems with BCT cristal structure.

Th.D.2_O3 - Emergence of a Connected Family of Chiral Spin Liquids on the Kagome Lattice

K. Essafi [1], L.D.C. Jaubert [1], O.J. Benton [1]

1. Okinawa Institute of Science & Technology, Onna-Son, Japan

Competing interactions in frustrated magnets prevent ordering down to very low temperatures and stabilize exotic highly degenerate phases where strong correlations coexist with fluctuations. We study a general classical anisotropic Heisenberg model on the kagome lattice with all the nearest neighbour interactions allowed by the symmetry of the lattice. We obtain the complete T=0 phase diagram. In particular, we find a connected family of chiral spin liquids (SL) which can be described by a Coulomb gauge theory. Within this family, on one hand, some of the phases appear for relatively simple and realistic couplings which will be compared with experiments. And on the other hand, some of those SL can be mapped onto the well known Heisenberg antiferromagnet, but should not be mingled with it. This allows for a connected picture of spin liquids in kagome. The underlying chiral spin texture is especially promising when coupled with itinerant electrons.

Th.D.2_O4 - The role of interchain coupling and exchange anisotropy for the existence of quantum multipolar phases in strongly frustrated edge-shared CuO_2 chain compounds at high magnetic fields near saturation

S.L. Drechsler [1], S. Nishimoto [1], H. Rosner [2], J. van den Brink [1], R. Kuzian [3], J. Richter [4]

1. IFW-Dresden, Dresdem, Germany
2. Max-Planck-Institute Chemische Physik fester Stoffe, Dresden, Germany
3. Institute of Materials Sciences, Kiyv, Ukraine
4. Institut f. Theoretische Physik, Universitaet Magdeburg, Germany

Based on electronic structure calculations, fitting thermodynamic properties and high-energy spectra, the ferromagnetic nearest-neighbor and antiferromagnetic next-nearest neighbor intrachain as well as interchain (IC) exchange are determined for typical CuO_2-chain compounds: linarite, $LiSbCuO_4$, $LiVCuO_4$, Li_2CuO_2, $Ca_2Y_2Cu_5O_{10}$ etc.. The resulting spin-Hamiltonians including also exchange anisotropies are studied numerically for chain boundles within the DMRG-technique and semi-analytically for infinite number of nematic hains within the hardcore-boson method. The resulting phase diagrams for the IC and exchange anisotropy vs. frustration ratio for various multipolar phases and different realistic IC coupling geometries are established firstly. Except for the first three compounds mentioned above, realistic IC within isotropic models is found to be detrimental for the existence of exotic nematic and higher multipolar quantum phases whereas moderate easy-axis and XYZ-exchange anisotropies can stabilize them. The remaining three candidates are discussed in detail. In particular, from neutron diffraction data for linarite we found evidence for the existence of collinear longitudinal SDW states with short-range correlations of large multimagnon complexes., Epitaxial thin film under tension are proposed to weaken the detrimental IC for the other compounds.

Th.D.2_O5 - Projective symmetry of partons in the Kitaev honeycomb model

P. Mellado [1], O. Petrova [2], O. Tchernyshyov [3]

1. Department of Engineering and Sciences, Adolfo Ibañez University, Santiago, Chile
2. Max Planck Institute for the Physics of Complex Systems, Dresden, Germany
3. Department of Physics and Astronomy, Johns Hopkins University, Baltimore, United States

Low-energy states of quantum spin liquids are thought to involve partons living in a gauge-field background. We study the spectrum of Majorana fermions of Kitaev's honeycomb model on spherical clusters. The gauge field endows the partons with half-integer orbital angular momenta. As a consequence, the multiplicities reflect not the point-group symmetries of the cluster, but rather its projective symmetries, operations combining physical and gauge transformations. The projective symmetry group of the ground state is the double cover of the point group.

Th.D.3_O1 - A new spin-liquid antiferromagnet based on opposite-sign bi-triangles

C. Balz [1,2], B. Lake [1,2], N. Islam [1], Y. Singh [1], S. Toth [3], J. Reuther [1,4], O. Prokhnenko [1], M. Reehuis[1], H. Ryll [1], R. Schoenemann [5], H. Luetkens [3], G. Simeoni [6], E. Wheeler [7], J. Rodriguez [8], T. Guidi [9]

8. NIST Center for Neutron Research, Gaithersburg, United States
9. ISIS, Surrey, United Kingdom

Frustration due to competing magnetic exchange interactions can give rise to exotic ground states and excitations. In extreme cases long-range magnetic order is completely suppressed and fluctuations persist down to the lowest temperatures. Here, we present a new candidate compound for such a spin-liquid ground state built on spin-1/2 Cr5+ ions. In $Ca_{10}Cr_7O_{28}$, long-range magnetic order is absent down to a temperature of 19mK while the excitations are diffuse and gapless as shown by inelastic neutron scattering. Muon spin relaxation and AC susceptibility confirm the absence of static magnetism and reveal that the ground state is fully dynamical. $Ca_{10}Cr_7O_{28}$ can be driven towards long range ferromagnetic order by applying an external magnetic field of 12T. In contrast to the zero-field excitations, the excitations in the saturated state resemble sharp magnon modes, and by fitting their dispersions to linear spin wave theory the exchange constants were extracted. A mixture of FM and AFM interactions were found where the FM interactions are greater than the AFM interactions. The coupling scheme consists of bi-triangles where ferromagnetic triangles lie directly over antiferromagnetic triangles and the intertriangle coupling is ferromagnetic. The frustration arises from the opposite sign of the coupling within the two triangles and neither triangle can realize its intrinsic spin arrangement due to the intertriangle coupling. This motif forms a 2D bilayer structure where in each layer the AFM triangles are coupled to FM triangles via their corners in a kagome like arrangement. FRG calculations confirm the absence of long-range order and the spin-liquid ground state in this new type of frustrated system.

Th.D.3_O2 - Interplay of disorder and frustration in the diamond spin lattice antiferromagnet $CoAl_2O_4$

V. Kataev [1], M. Iakovleva [1,2], E. Vavilova [1,2], H.J. Grafe [1], S. Zimmermann [1,3], A. Alfonsov [1], H. Luetkens [4], H.H. Klauss [3], A. Maljuk [1], S. Wurmehl [1], B. Büchner [1,3]

We present a detailed experimental study with three local spin probe techniques, NMR, muSR and ESR, of magnetic properties of the $CoAl_2O_4$ single crystal where the Co spins form a frustrated spin lattice with the diamond structure. We find that in the studied single crystal the degree of structural disorder due to the Al-Co site inversion is optimally tuned to obtain insights onto its influence on the ground state and on the low energy magnetic dynamics of the frustrated diamond spin lattice. Inhomogeneous broadening of ESR and NMR lines at temperatures below 30 - 50 K indicates the growth of short-range spin correlations. The analysis of the NMR and muSR relaxation rates evidences a critical slowing down of spin fluctuations at a characteristic temperature T*= 8 K which suggests the onset of a quasi-static order at this temperature. Most probably the spin order is short-range and unconventional which is manifested by the overdamped oscillations of the muon spin polarization and a continuous line broadening of ESR and NMR lines below T*. Since in the phase diagram of the diamond spin lattice $CoAl_2O_4$ is located close to the special critical point which separates collinear and noncollinear spin phases, it appears in our results that Al atoms at the Co sites acting as quenched impurities smear the phase boundary between the two phases. This can yield a competition between the two ground states with the low-lying spin spiral excitations responsible for an inhomogeneous magnetic dynamics.
We argue that our experimental findings may have important implications for recent theories of an 'order by disorder' mechanism in the frustrated diamond spin lattice.

Th.D.3_O3 - Neutron diffraction study of uniaxial pressure control of spin frustration in isosceles triangular lattice Ising antiferromagnet $CoNb_2O_6$

S. Kobayashi [1], S. Hosaka [2], H. Tamatsukuri [2], T. Nakajima [2], S. Mitsuda [2], K. Prokes [3], K. Kiefer [3]

2. Tokyo University of Science, Tokyo, Japan
3. Helmholtz-Zentrum Berlin, Berlin, Germany

We have studied the effect of uniaxial pressure on magnetic ordering in an quasi-one-dimensional Ising antiferromagnet $CoNb_2O_6$ by single-crystal neutron diffraction in zero field in order to see a possible pressure control of frustrated exchange interactions of the isosceles triangular lattice. In $CoNb_2O_6$, magnetic Co2+ ions form a quasi-1D ferromagnetic chains along the c-axis and form the frustrated lattice in the a-b plane. In zero field, the system exhibits successive magnetic phase transitions from the paramagnetic (PM) phase to the incommensurate (IC) sinusoidal magnetic phase characterized by the temperature-dependent propagation wave vector Qpropa = (0 q 0) at T1= 3.0 K, and then to the noncollinear antiferromagnetic (AF) phase with Qpropa = (0 0.5 0) at T2=1.9 K. We found that under uniaxial pressure of 400 MPa along the a-axis, the temperature dependence of q in the IC phase is significantly modified. With decreasing temperature, IC peaks show up at T ~ 2.98 K at an incommensurate position of q = 0.411 which is larger than 0.377 of no applied pressure, then shift to the AF position of q = 0.5, and the magnetic phase transition from the IC to AF phases occurs at T=2.2 K, which is higher than 1.9 K at no applied pressure. The energy consideration for an Ising model with exchange interactions up to 2nd neighbors suggests that a ratio of nearest neighbor to next-nearest neighbor interactions on the lattice significantly increases from 1.33 to 1.81 by an uniaxial pressure of 400 MPa. This clearly demonstrates that uniaxial pressure can control spin frustration of the isosceles triangular lattice through the anisotropic deformation of the lattice[1].

TbB4 has a tetragonal structure in which the Tb (J = 9/2) ions network in the c-plane is equivalent to the geometrically frustrated Shastry-Sutherland lattice [1]. In zero-field, two successive antiferromagnetic transitions occur at TN1 ~ 44 K and TN2 ~ 24 K [2]. Remarkably, for T << TN2, TbB_4 exhibits a multistep magnetization process above 16 T when the magnetic field is applied perpendicular to the magnetic easy plane [3]. In order to understand this devil-staircase-like magnetization process, the first ever-made neutron diffraction experiment in pulsed magnetic fields up to 30 T was carried out on the CRG spectrometer IN22 at the ILL in 2008 [4] allowing to propose a magnetic model for the 1/2MS state. Here, we present the re-investigation of the magnetic structures of the plateau phases in TbB_4 using the newly completed pulsed field neutron diffraction set-up developed in collaboration between the LNCMI-Toulouse, the CEA-Grenoble, the ILL and the Institut Néel, Grenoble. This installation consists of a 40 T long pulse rapid cooling magnet mounted inside a specially designed cryostat allowing to cool the sample up to 2 K. The new limits offered by this set-up installed on the spectrometer IN22 provide new opportunities for the study of magnetic materials. In the study of TbB4, several steps, clearly related to the structures of the different plateaus, were now detected at low temperature in the field dependence of the antiferromagnetic (100) reflection thanks to better counting statistics and temperature control. A single crystal of TbB4 enriched with 11B was kindly provided by Nojiri et al.

Multiferroics are compounds that show ferroelectricity and magnetism. $BiFeO_3$, by far the most studied, has outstanding ferroelectric properties, a cycloidal magnetic order in the bulk, and many unexpected virtues such as conductive domain walls or a low bandgap of interest for photovoltaics [1]. While this flurry of properties make $BiFeO_3$ a paradigmatic multifunctional material, most are related to its ferroelectric character, and its other ferroic property - antiferromagnetism - has not been investigated extensively, especially in thin films. In this talk, we will bring insight into the rich spin physics of $BiFeO_3$ through various advanced techniques such as conversion-electron Mössbauer spectroscopy, Raman scattering and nuclear resonant scattering. We will show how the spin orders and the spin excitations can be tuned by epitaxial strain and magnetic fields, and discuss routes to map spin textures in real space and control them by electric fields.

Strain engineering can improve or induce new functional properties in thin films by epitaxial growth, particularly in multiferroic materials such as the terbium manganite. Bulk $TbMnO_3$ exhibits an antiferromagnetic ordering below 42 K and a spin spiral below 27 K, the latter inducing the inversion symmetry breaking that causes ferroelectricity [1]. However, in this work we show that epitaxially-strained $TbMnO_3$ on $SrTiO_3$ (001) grown by Pulsed Laser Deposition induces the formation of a novel chemical and magnetic structure, which orders ferromagnetically at 15 K with magnetic moments up to 0.15 μB/f.u. [2]. This new phase is synthesized at the domain walls (DWs) formed to accommodate the epitaxial strain caused by the large lattice mismatch with $SrTiO_3$. Ferromagnetism is strongly correlated with this strain-induced microstructure. The reduction of thickness induces an increase of the DW density, which scales with the increase of the magnetization [2].
Aberration-corrected Scanning Transmission Electron Microscopy (STEM) imaging combined with Electron-Energy Loss Spectroscopy (EELS) has been carried out in an FEI Titan at 300 kV to characterize locally the structural and chemical properties of this novel phase. STEM imaging evidences the abundance of [001]-oriented DWs and the local strain relaxation at the DWs. Atomic-resolution STEM-EELS chemical mapping demonstrates that the new structure synthesized at the DWs is characterized by the presence of spatially ordered Tb-deficient positions along [001], which are entirely replaced by Mn atoms. The substitution of alternate Tb positions by Mn gives rise to exotic atomic coordinations for these “wall” Mn atoms at the Tb position and first principles calculations demonstrate that the different magnetic parameters of “wall” Mn atoms perturb the local magnetic coupling around the DW to induce long-range ferromagnetism.

Th.E.1_O3 - Magnetoelastic coupling in BiFeO3 (111) thin-films observed by non-resonant x-ray magnetic diffraction

The coupling between ferroelectric and long range magnetic order in multiferroic materials is not only interesting in terms of fundamental physics, but also holds great promise for application in future memory devices. With its room temperature multiferroicity and giant ferroelectric polarisation, BiFeO3 is the most intensely investigated multiferroic and arguably the most promising multiferroic material for application in devices. $BiFeO_3$ thin films, upon which these devices are likely to be based, display a wide range of tuneable functionalities, which are highly sensitive to environmental and growth conditions. Understanding the subtle effects of these conditions is therefore of great importance if $BiFeO_3$ thin film devices are to be realised. We study the domain configuration of cycloidal multiferroic domains in 111(cubic)-oriented $BiFeO_3$ films with non-resonant magnetic x-ray diffraction. Comparing reciprocal space maps and post scatter polarisation analysis with simulations, we find that, contrary to previous reports, the crystal structure undergoes a small monoclinic distortion, unresolvable by any conventional crystallographic diffraction techniques, which splits the film into a coherent set of monoclinic twins related by the three-fold axis of the parent (R3c) rhombohedral phase. The distortion is coupled to the magnetic structure such that each of the three monoclinic twins chooses a corresponding magnetic propagation vector, giving rise to the observed characteristic magnetic diffraction signal. We also propose a twin law based on symmetry arguments and a microscopic model of the coupling between the distortion direction and magnetic propagation vector. Our results put an upper bound on the multiferroic domain size of order microns, which has significant implications for devices that would exploit the magnetic order in this material.

Th.E.1_I4 - Induced magnetism at correlated oxide interfaces

J. Santamaria [1]

1. Universidad Complutense de Madrid, Madrid, Spain

At oxide interfaces electron correlations underlie the nucleation of emerging ground states with exciting responses not appearing in the bulk counterparts of the constituents. This has driven an important effort towards the design of heterostructures with specific functionalities. In this talk I will examine several interface problems in oxide heterostructures with special focus on the possibility of creating novel interfacial magnetic states. They originate at the modification of the orbital occupancy resulting from the modified bonding at the interface. I will discuss the effect of these low dimensional magnetic states in determining the magnetic response of practical magnetic tunnel junctions. I will demonstrate the possibility of designing specific functionalities such as spin filtering or electric field control of interface magnetization. In particular I will show that at $La_{0.7}Ca_{0.3}MnO_3$ (LCMO) - $PrBa_2Cu_3O_7$ (PBCO) interfaces a Cu magnetic state is induced which can be controlled by an electric field [1]. At interfaces combining antiferromagnetic $LaFeO_3$ (LFO) and ferromagnetic $La_{0.7}Sr_{0.3}MnO_3$ (LSMO), we find that a net magnetic moment is induced at the LFO interface [2]. Using X-ray photoemission electron microscopy, we show that the ferromagnetic domain structure of the manganite electrodes is imprinted into the antiferromagnetic tunnel barrier, endowing it with spin selectivity. I will conclude with an outline of interesting future directions.

Multiferroic materials have attracted huge interest for coexistence of ferroelectricity and magnetism, and coupling between them. $BiFeO_3$ is the only example that shows multiferroicity above room temperature. It also has a complex magnetic structure including the cycloid spin structure with an extremely long period. In order to understand the microscopic magnetic interactions, inelastic neutron scattering (INS) experiments were carried out using co-aligned single crystals. The magnon dispersion over the full Brillouin zone was measured for the first time, and the exchange interaction parameters between the nearest and the next nearest neighbors were determined [1]. For the further study on the detailed magnetic excitations at low energy, additional INS experiments were performed using the triple-axis spectrometer $4F_2$ at LLB. The magnon dispersion was also calculated using the Hamiltonian that includes the Dzyaloshinskii-Moriya (DM) interaction and single-ion anisotropy (SIA), which are associated with the distortion of the FeO_6 octahedra. The unusual low-energy excitations in $BiFeO_3$ is understood by examining the interplay of DM interaction and easy-axis SIA, and thermal evolution of the parameters was determined, which agrees with structural changes qualitatively [2].

The quest for magnetoelectric multiferroics is driven by the promise of a novel generation of devices combining the best characteristics of ferromagnetic and ferroelectric materials. These cherished applications require materials displaying a substantial magnetization and electric polarization which are coupled and coexist well above room temperature. These properties are not commonly found in a single phase materials and candidates propelling the development of these technologies are still required. In this contribution, we will report on epitaxial epsilon-Fe_2O_3 thin films grown by Pulsed Laser Deposition on (111) $SrTiO_3$ and present recent data on its structural, magnetic and dielectric characterization. The films are ferromagnetic and ferroelectric at room temperature and display magnetization and polarization values at remanence of about 50 emu/cm3 and 1u C/cm2 with a long retention. A magnetocapacitive response has also been detected indicating that the films present coupling between both ferroic orders. The chemical simplicity of epsilon-Fe_2O_3 represents a major advantage to overcome the challenges of stoichiometry and phase purity control that might be cumbersome in all other known room-temperature multiferroics.

Th.E.2_O3 - Theory of antisymmetric spin-pair dependent electric polarization in multiferroic $BiFeO_3$

S. Miyahara [1], N. Furukawa [2]

1. Fukuoka University, Fukuoka, Japan
2. Aoyama Gakuin University, Tokyo, Japan

In magnetoelectric (ME) multiferroics, there is a strong coupling between magnetization M and electric polarization P and ME effects and electromagnon, electroactive magnon, processes arise. As typical ME couplings, spin dependent electric polarizations due to the exchange striction [1,2], the spin current mechanism [3-5], and the metal-ligand hybridization [6] mechanisms are well known and explain the ME coupling in various multiferroics. However, novel component of the spin induced electric polarization observed in $BiFeO_3$, where an electric polar-ization arises perpendicular to the cycloidal spin structures, cannot be explained by the known mechanisms [7]. We clarify the microscopic origin of a new mechanism, a generic coupling be-tween the electric polarization and antisymmetric spin pair [1,8] and show that such a coupling explains the novel feature in $BiFeO_3$ [7]. Moreover, we discuss dynamical ME effects, i.e., electromangon and toroidalmagnon [9] processes, in $BiFeO_3$ and clarify the selection rule of an absorption due to magnon excitation. The results indicate that various non-collinear magnetic structures show multiferroic behaviors owing to the new mechanism.

$BiFeO_3$ is one of the most extensively studied multiferroic materials owing to its multiferroicity at room temperature. To clarify its fundamentals, we studied magnetic and magnetoelectric properties of mono-domain crystals of $BiFeO_3$ synthesized with using the laser-diode heating floating-zone furnace in pulsed high magnetic fields up to 55 T. In magnetic fields applied normal to the ac-plane of the trigonal lattice, electric polarization along the c-axis steeply changes at the transition field from the cycloidal to the canted-antiferromagnetic phase, which can be simply explained as the spin-driven polarization in the cycloidal state through the spin current mechanism or the inverse effect of the Dzyaloshinskii-Moriya interaction. On the other hand, we found even larger change in the polarization normal to the c-axis in addition to it. This transverse, i.e. normal to the c-axis, polarization appears to change its magnitude once the crystal experiences the field cycle up to about 10 T. Such a non-volatile memory effect was observed even at room temperature, and will be used for the low-power consumption magnetoelectric memory devices in future. Main part of this study was published in M. Tokunaga et al., Nature Commun. 6, 5878 (2015).

Th.E.2_O5 - Suppression of mixed-phase areas in highly elongated $BiFeO_3$ thin films on $NdAlO_3$ substrates

7. Institute for the NanoCentury, KAIST, Daejeon, Republic of Korea

Multiferroic bismuth ferrite ($BiFeO_3$; BFO) has received a great deal of attention because it has both ferroelectric and anti-ferromagnetic properties at room temperature. It also has been discovered that a highly-elongated phase of BFO (T-BFO) can be stabilized by the heteroepitaxial misfit strain between substrate and film.[1] It is expected that the T-BFO has totally different physical properties from bulk BFO (R-BFO) because of the large elongation along the c-axis direction (c/a~1.26).[2] It is needed to grow very thick pure T-BFO films for investigating the physical properties of the new BFO phase in more reliable way with sufficient sample volume. However, if the film thickness is thicker than ~40 nm, mixed phase areas start to appear parasitically and the areas become larger with increasing the thickness as a consequence of strain relaxation. We grew a series of T-BFO films varying film thickness on both lanthanum aluminate ($LaAlO_3$, LAO) and neodymium aluminate ($NdAlO_3$, NAO) substrates and characterized their crystal structures through the x-ray diffraction, the reciprocal space maps and the high-resolution transmission microscopy. The surfaces morphology and ferroelectric domain structures were studied by using piezoresponse force microscopy. We found that the NAO substrates prevent the formation of mixed-phase areas, but the LAO substrates do not. Finally we discussed the fundamental mechanism of phase completion of BFO phase using first principles density functional calculation for the misfit strain dependent total energy.

Th.E.3_O1 - A comparative measurement technique for magnetic hyperthermia in nanoparticle suspensions

K. O'Grady [1,2], J. Zehner [1], F. Halpin [1], G. Vallejo-Fernández [1], J. Flatt [1], J. Timmis [2], V. Patel [2]

1. Department of Physics, University of York, Heslington, York, United Kingdom
2. Liquids Research Ltd, Unit 9 Mentec, Gwynedd, United Kingdom

We describe a new method for the determination of the heating power of magnetic nanoparticle colloids which have potential for application in the remedial treatment of malignant and non-malignant tumours. The method is based upon a comparison between the heating power observed when the colloid is exposed to an RF frequency magnetic field and that which is observed using a resistive electrical heater. A new measurement cell has been designed and constructed which eliminates the effects of convection and ensures that the magnetic field is uniform. The heat losses in the system are the same both under a magnetic field and Joule heating ensuring that the measurement of the heating power is determined accurately. The correlation between the initial heating rate dT/dt and the equivalent power that gives rise to that heating rate is excellent. The relationship shows a high degree of linearity (r2>0.99) so that measurements of dT/dt generated by the action of the magnetic field can be directly converted to an equivalent heating power.

Th.E.3_O2 - Synthesis and unusual magnetic damping effect in silver-cobalt ferrite nanosystem

S. Sharma [1], M. Knobel [1], K. Pirota [1], F. Beron [1], G. Zoppellaro [2], J. M. Vargas [3], D. Altbir [4]

3. Institute of Nanoscience and nanotechnology, Centro Atomico Bariloche, Bariloche, Argentina
4. Universidad de Santiago de Chile (USACH), Santiago, Chile

The synthesis and unusual magnetic anomaly in silver-cobalt ferrite nanosystem prepared by two-steps chemical route is reported. The static and dynamic magnetic response of silver-cobalt ferrite nanosystem is compared to pure $CoFe_2O_4$ nanoparticles. Our silver-cobalt ferrite nanosystem showed significant changes in their magnetic behavior, phenomenon that can be understood with the damping effect of magnetic relaxation due to hybridization of Ag and $CoFe_2O_4$ electronic structures. The observed magnetic properties are explained in terms of superparamagnetic Stoner-Wohlfarth and Neel-Arrhenius/Vogel-Fulcher models through micromagnetics simulations. It was observed that enhancing the phase homogeneity in the hetero nano-system was the leading morphological factor responsible for producing a strong enhancement in the effective energy barrier and reduction of the magnetic hardness.

Th.E.3_O3 - Adjustable magnetic properties of Fe_3O_4/silicon nanocomposites with respect to biomedical applications

P. Granitzer [1], K. Rumpf [1], P. Poelt [2], M. Reissner [3]

1. Karl-Franzens-University Graz, Institute of Physics, Graz, Austria
2. University of Technology Graz, Institute for Electron Microscopy, Graz, Austria
3. Vienna University of Technology, Institute of Solid State Physics, Wien, Austria

In the frame of this work we present a magnetic nanocomposite system which is appropriate to be used for magnetically guided drug delivery. As matrix for the incorporation of iron oxide nanoparticles nanostructured silicon is employed. The used magnetite nanoparticles are superparamagnetic due to their size and they are coated with an organic shell. Both materials are known to be biocompatible which has already been shown previously. Further preconditions of the nanocomposite are a magnetic moment as high as possible and a non-existent remanence when the external magnetic field is switched off. Concerning the adjustability of the magnetic properties of the system the loading of the porous silicon with iron oxide nanoparticles has been elucidated in detail and the growth of iron oxide structures within the pores has been investigated. The magnetic properties, especially the transition temperature between superparamagnetic behavior and blocked state (TB) of the nanocomposite can be controlled by the filling procedure. TB shifts to higher temperatures with increasing magnetic coupling between the particles. Dependent on the packing density as well as on the size of the particles within the pores the magnetic interactions can be modified and thus TB can be tuned. These investigations have been carried out for particle sizes between 4 and 12 nm. An optimization of the magnetization (high filling density as possible) and its correlation with the blocking temperature has been carried out. An assessment of the iron oxide deposition dependent on the template and the chemical parameters as well as of the magnetic properties in dependence on the particle size, inter-particle distance and template morphology of the nanocomposite will be presented.

TH.E3_O4 - Dipolar ferromagnetism of island-like agglomerates of Fe_3O_4 nanoparticles embedded in an epoxy matrix

P. Allia [1], P. Tiberto [2], G. Barrera [3], F. Bondioli [4], C. Sciancalepore [5], M. Messori [5]

5. Universitá di Modena e Reggio Emilia, Modena, Italy

Stable suspensions of magnetite nanoparticles were prepared through solvo-thermal treatment of $Fe(AcAc)_3$ dissolved in different amounts into 2-ethyl-exane-1,3-diol (Ex-diol). Epoxy nanocomposites were obtained by in-situ polymerization of bisphenol A diglycidyl ether (DGEBA) monomers directly within the Fe_3O_4 nanoparticles suspensions. The formulations were prepared by adding the nanoparticle suspensions to DGEBA in the range between 1 and 6 phr of Fe_3O_4 using a magnetic stirrer and an ultrasonic bath. The formulations were cast into silicone moulds with a cationic thermal initiator and cured at 130°C for 3 h. Dried nanopowders were characterized by XRD, Raman spectroscopy, TEM. The powders are composed of almost pure Fe_3O_4; XRD spectroscopy indicates that nanoparticles have a crystalline core surrounded by an amorphous shell. TEM images shows that the particles have spheroidal shape with diameters in the range 10-18 nm depending on the $[Fe(AcAc)_3]$/[Ex-diol] ratio. Epoxy nanocomposites were characterized by TEM, FT-IR and DSC. TEM images show that in all cases the nanoparticles are not evenly dispersed in the matrix and form an island-like structure of well-separated nanoparticle agglomerates; within each agglomerate the individual particles are mostly not in contact. Magnetic measurements were performed using a 70 kOe SQUID magnetometer in the temperature range 10 - 300 K. Flat, almost structureless FC-ZFC curves indicate a highly correlated magnetic response. Magnetization loops exhibit non-negligible hysteresis with a coercivity increasing with decreasing temperature; the low-field susceptibility exhibits a non-monotonic trend with temperature. Detailed comparison of the evidence from different magnetic measurements points to a ferromagnetic-like behavior of the embedded nanoparticles. However, the absence of contact interaction among adjacent nanoparticles in island-like agglomerates rules out the hypothesis of the presence of a standard ferromagnetic phase; the temperature dependence of both coercivity and low-field susceptibility indicate that the agglomerates can be considered as dipolar ferromagnets in the whole temperature range.

Th.F.1_I1 - Multiscale dynamics as the key to all-optical magnetization reversal

A. Kirilyuk [1]

1. Radboud University, Institute For Molecules and Materials, Nijmegen, The Netherlands

In spite of recent extensive work on all-optical switching of magnetization, confusion persists as to its mechanism. Here we demonstrate, using various time-resolved imaging techniques, that this confusion is largely due to the fact that this phenomenon involves behavior on multiple scales, both in space and time. At 100's fs, independent demagnetization of sublattices is observed accompanied by spin diffusive processes at <10 nm distances, as shown by time-resolved X-ray scattering [1]. This is followed by the exchange spring driven behavior [2] with reversal and formation of skyrmion-like domains [3] at a few ps times. Later, very large scale coherent oscillations can be observed that accompany the growth of large domains [4]. Moreover, an extra dimension is added to the problem by the multilayered character [4] and the overall shape of the sample [5]. Therefore, only a combination of high-resolution spatial and time resolved techniques is able to follow these processes both in space and time.

Th.F.1_O2 - Controlling the magnetization dynamics with sequences of picosecond acoustic pulses

J. Kim [1], M. Vomir [1], J. Bigot [1]

1. IPCMS, CNRS, Strasbourg, France

We show that using picosecond acoustic pulses is a versatile and efficient way of controlling the magnetization precession in ferromagnets [1]. Two or three longitudinal acoustic pulses, generated by femtosecond laser pulses, allow suppressing or enhancing the magnetic precession at any arbitrary time by controlling the delays T_{12}, T_{23} and the amplitude ratios E_{12}, E_{23} between optical pulses. We found that when using two acoustic pulses, the control is somehow restrictive because the occurrence of suppression or amplification is related to integers of half (T_{12} = (m+1/2)T_{prec} ; m=integer) or full precession periods (T_{12} = mT_{prec}). However, in the case of three acoustic pulses as shown in Fig. 1(a), at arbitrary delay of T_{12} (for E_{23}=1), it is shown that the suppression of the magnetization precession can be always achieved with the proper T_{23}, producing general relations of T_{12} = (m+1/2)T_{prec}+dT and T_{12} = mT_{prec}+dT for the suppression and amplification, respectively. Figure 1(b) presents, furthermore, that even in case of acoustic pulses with different shapes, above relations are maintained meaning that only the delay dT is the core parameter to determine the coherent control of magnetization precession. These results will be useful for the precise control of magnetization dynamics at will without a restriction about the arrival time of the second pulse and its shape.

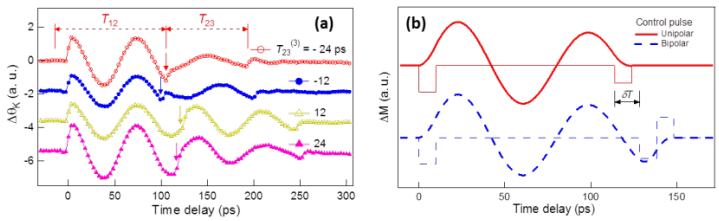

Figure 1. (a) Magnetization dynamics for various delays T_{12} and T_{23} (for E_{23}=1). (b) Simulation results of the magnetization precession with sequences of: two unipolar pulses (top) and unipolar + bipolar pulses (bottom).

Th.F.1_O3 - Femtosecond control of magnetism via resonant optical pumping of Dy ions in multisublattice magnet $DyFeO_3$

R. Mikhaylovskiy[1], T. Huisman[1], A. Popov[2], A. Zvezdin[3], T. Rasing[1], R. Pisarev[4], A. Kimel[1]

1. Radboud University Nijmegen, The Netherlands
2. National Research University of Electronic Technology, Russia
3. Prokhorov General Physics Institute, Russia
4. Ioffe Physical-Technical Institute, Russia

Dielectric magnetic materials such as transition metal oxides appeared to be an excellent playground for the study of the mechanisms for light-spin interactions [1]. Unlike metals the electronic structure of dielectrics is well defined and allows one to trace how and how fast selective pumping of a specific electronic excitation results in magnetic changes. Although many of studied compounds contained rare-earth 4f -ions, their multi-sublattice nature have been often ignored and the experimental findings have been described in terms of off-resonant femtosecond excitation of the transition-metal 3d-ions (Mn,Fe,Co,Ni).

Here using terahertz emission spectroscopy we report that resonant optical pumping of f-f transitions of Dy3+-ions in the antiferromagnet $DyFeO_3$ with circularly-polarized femtosecond laser pulses has a dramatic effect on the laser-induced magnetization dynamics. Analysing the spectrum of the emitted THz radiation, its dependence on the pump polarization and photon energy, we infer that the resonant circularly-polarized optical pumping of Dy3+ magnetizes the ions on a femtosecond timescale. The resonantly induced ultrafast change of the magnetization reaches almost 1 %. We also observe a minimum in the efficiency of the Fe3+-spin-wave excitation for laser photon energies close to the resonance of Dy3+. This fact reveals that the resonant photo-induced magnetization and off-resonant excitation of the Fe3+-spin-waves via the inverse Faraday effect are competing processes.

Th.F.1_O4 - Low Gilbert damping and high magnetic anisotropy in L10-FePd epitaxial thin films grown on MgO and $SrTiO_3$ single crystal substrates

S. Iihama [1], H. Naganuma [1], M. Oogane [1], S. Mizukami [2], Y. Ando [1]

2. WPI-AIMR, Tohoku University, Sendai, Japan

Magnetic materials with a large perpendicular magnetic anisotropy (PMA) are very important for realizing high-density magnetic memory. $L1_0$-ordered alloys, such as $L1_0$-FePt, CoPt, and FePd, have a large PMA to achieve high thermal stability factor. On the other hand, reversal current of current-induced magnetization switching is proportional to Gilbert damping constant α and effective PMA constant K_u^{eff}. Therefore low α materials with large K_u^{eff} are necessary. Reported α of $L1_0$-FePt film and Co/Pt multilayer showed very large, which may be caused by large spin-orbit coupling in Pt atom [1], while α of $L1_0$-FePd has not been investigated intensively compared with that of $L1_0$-FePt film. Here we demonstrate low α and high K_u^{eff} in $L1_0$-FePd epitaxial thin films grown on MgO and $SrTiO_3$ single crystalline substrates [2, 3]. Samples were prepared by magnetron sputtering method. The films were deposited and annealed at various temperature to obtain the films having smooth surface and high chemical ordering. $L1_0$-ordered phase for film with adequate substrate and annealing temperature was confirmed by X-ray diffraction. Magnetization curves for $L1_0$-FePd film showed PMA and maximum K_u^{eff} is ~ 7 Merg/cm^3. External field and field angle dependence of magnetization dynamics by Time-Resolved Magneto-Optical Kerr Effect were measured. Effective damping constant α_{eff} varied with external field and field angle. Very low α_{eff} of 0.007 was observed in particular sample. This α_{eff} is smallest among that of Fe- and Co- based materials with large PMA.

Th.F.1_O5 - Laser control of magnetizations, spin currents and orders in quantum magnets

M. Sato [1]

1. Japan Atomic Energy Agency, Ibaraki, Japan

Recently, laser science has been rapidly developed and we can prepare various lasers in a wide frequency range. This development enables us to observe many sorts of driven quantum states by applying lasers to solid materials. For example, it is predicted that a topological state with a gapless chiral edge mode can appear when we apply a circularly polarized laser to two-dimensional Dirac electron systems [1], and after this prediction, a few experimental evidences for this laser-driven topological insulator have been reported [2]. Including these results, so far many studies for laser-driven systems have been focused mainly on electron systems. By contrast, recently, we have tried to theoretically find new laser-induced phenomena in insulating systems such as spin systems and multiferroics [3,4,5]. In the conference, I would like to show some of our recent theoretical results in this field. In particular, I will focus on the explanation that (i) for general quantum magnetic insulators, their uniform magnetization can be controlled by applying a circularly polarized laser WITHOUT any static magnetic field [3], and (ii) spin currents or spiral ordered states can also be induced by applying a circularly (more generally, elliptically) polarized laser to quantum multiferroic systems with a spin-chirality type magnetoelectric coupling [4].

Th.F.2_I1 - Ultrafast demagnetization induced by hot electrons

N. Bergeard [1], G. Malinowski [1], M. Hehn [1], S. Mangin [1]

1. Institut Jean Lamour, Université de Lorraine – CNRS, France

Ultrafast quenching of magnetization upon femtosecond laser excitation has been extensively studied during the last 20 years. However, possible mechanisms underlying the dissipation of angular momentum are still debated. Initially, direct excitation resulting in the absorption of the laser energy by the electronic system was considered as the only source, resulting in a subsequent loss of magnetization due to different particles quasi-particle interactions. Nevertheless, the role of hot electron transport in magnetic multilayers has been recently highlighted as a possible source for ultrafast demagnetization even though the results were strongly contested. In this work, we study ultrafast demagnetization dynamics in Glass/Ta/Pt/FM/Cu(x)/Pt(2) samples for x varying from 0 to 200 nm and with FM being either a Co/Pt or a Co/Ni multilayers. Both systems have a perpendicular magnetic anisotropy. The experiments were carried out pumping our samples with an 800 nm laser pulse from the front side and probing the induced change in magnetization from the back side (glass) with a 400 nm laser pulse. In order to control the excitation in our systems, we carefully determined the Cu layer absorption as a function of x and we extracted an attenuation length of 22 nm. In the case of the Co/Pt multilayer, a clear modification of the magnetization dynamics between direct optical excitation and excitation by hot electrons is observed when increasing the Cu thickness. However, no modification is measured in the case of the Co/Ni multilayers. These results show that demagnetization induced by hot electrons strongly depends on the nature of the ferromagnet. We infer that the slowing down of the dynamics is mainly due to the presence of the Pt which might increase the scattering of hot electrons.

Th.F.2_O2 - Enhancement of laser-induced ultrafast Demagnetization using localized surface plasmons

H. Xu [1], G. Hajisalem [2], G. Steeves [1], R. Gordon [2], B. Choi [1]

1. Department of Physics And Astronomy, University of Victoria, Canada
2. Department of Electrical and Computer Engineering, University of Victoria, Canada

Ferromagnetic thin films excited by laser pulses undergo ultrafast loss of magnetic order within several hundred femtoseconds, due to rapid energy transfer from thermalized electrons to the spin system. This is followed by a slower recovery over the picosecond timescale as electrons equilibrate with the phonons, and eventually to complete cooling via nanosecond lattice diffusion. The timescale of laser-induced ultrafast demagnetization is orders of magnitude below the limit imposed by conventional switching of magnetic order via magnetic field pulse, and has been the focus of considerable research. In this study we demonstrate that the demagnetization can be significantly increased without increasing the laser fluence by coating ferromagnetic thin films with gold nanorods (AuNRs) dimensionally-tuned to support localized surface plasmons (LSPs) near the peak laser frequency. The effect of plasmon resonance on the transient magnetization was investigated by drop-coating the ferromagnetic films with gold nanorods (AuNR), which support longitudinal surface plasmon resonance near the central wavelength of the pump laser. To independently verify the plasmon resonance effect of the AuNR coating, dark-field scattering spectra of the thin film samples were obtained with a white light source. Laser induced ultrafast magnetization were recorded for a range of pump fluences, $F \approx 0.08 – 0.26$ mJ/cm^2, using a femtosecond Ti:sapphire laser in a pump-probe magneto-optic Kerr effect setup. For all experimental pump fluence used we observed an increased quenching of magnetic order in the AuNR-coated 20 nm thick $Ni_{80}Fe_{20}$ films. At the highest pump fluence (F ~ 0.26 mJ/cm2), the demagnetization signal ($\Delta M_z/M_s$) in the AuNR-coated sample is increased by ~60% compared to the uncoated sample. By extrapolating the linear fit of the data set, it was found that the uncoated sample would require a pump fluence F ~ 0.42 mJ/cm2 in order to achieve the same $\Delta M_z/M_s$ as the AuNR-coated sample at F ~ 0.26 mJ/cm2. The experimental results were qualitatively reproduced with simple model calculations based on mean-field theory.

Th.F.2_O3 - Ultrafast energy diffusivity dependency of all-optical magnetization switching in multi-layer structured GdFeCo thin films

H. Yoshikawa [1], A. Tsukamoto [2]

1. Graduate School of Science And Technology, Nihon University, Chiyoda, Japan
2. College of Science and Technology, Nihon University, Chiyoda, Japan

Femtosecond laser pulse excite an all-optical magnetization switching (AOS) on multi-sub-lattice rare-earth transition-metal ferrimagnet thin films. This AOS phenomena originated from sub-lattice nature is fundamentally different from conventional magnetic field driven switching mechanism[1], [2]. In this study, we show the magnetic domain nucleation on multi-layered structures which have different properties of laser fluence absorption and diffusion, respectively [3]. A single femtosecond laser pulse was irradiated on the magnetic multi-layered thin films, SiN (60 nm)/ $Gd_{22}Fe_{68.2}Co_{9.8}$ (l nm)/ SiN (m nm)/AlTi (n nm)/ glass sub. ({n,m,l } ={20,5,0}, {20,0,10}, {20,5,10}, {30,5,10}). To excite the materials we used regenerative amplified laser pulses at a wavelength of 800 nm. Each pulse had a Gaussian intensity profile, with a full width of a half maximum of 90 fs. The laser excitation create magnetic domains by AOS and/or multi-domains by thermo-magnetic nucleation (TMN) inside the area exceed each laser energy intensity threshold[2]. The time constant and degree of thermalization of electron, spin and lattice systems were changed with layer structure[3]. And, amount of ultrafast demagnetization (UD) is decided by the thickness of continuous metallic layer tmetal[3]. In this result, the domain sizes by TMN are lager in films which has thicker tmetal. UD of both {20,5,10} and {20,5,0} (tmetal=20 nm) are larger than it of {20,0,10} (tmetal=30 nm). However, the domain size of {20, 5, 10} by AOS is similar to it of {20,0,10}, and smaller than {20, 5, 0} ones. Furthermore, UD of {30,5,10} is similar to {20,0,10} ones. But, the magnetic domains werenüft created by AOS on {30,5,10}. These results mean that the created domain size by TMN simply depends on the laser fluence and tmetal. On the other hand, the created domain size by AOS depends on the energy diffusion process with electron, spin and lattice, too.

Th.F.2_O4 - Ultrafast control of the exchange interaction with electric fields

J. Mentink [1,2], K. Balzer [2], M. Eckstein [2]

1. Radboud University Nijmegen, The Netherlands
2. University of Hamburg, Germany

The strongest interaction between microscopic spins in magnetic materials is the exchange interaction J_{ex}. Therefore, ultrafast control of J_{ex} keeps the promise to control spins on ultimately fast timescales, potentially bypassing fundamental speed limits for the control of magnetism with magnetic fields. In this contribution we provide theoretical evidence that the exchange interaction can be manipulated on ultrashort timescales by strong electric field pulses [1,2]. Focusing on the prototype Mott-Hubbard insulator, we find very different effects for resonant and off-resonant photo-excitation. In the former case, the electron distribution is changed and the subsequent relaxation of photo-excited carriers causes an ultrafast reduction of J_{ex}. Conversely, off-resonant driving allows for an ultrafast and reversible control of J_{ex}, i.e., it is active while the field is on, but leaves the electronic state unexcited after the pulse is switched off. In the regime of weak-driving strength the modification of J_{ex} is proportional to the intensity of the electric field and we find that J_{ex} can be enhanced and reduced for frequencies below and above gap, respectively. Furthermore, for strong driving even the sign of the exchange interaction can be reversed and we show that this causes time reversal of the associated quantum spin dynamics.

Th.F.2_O5 - Terahertz-driven ultrafast magnetization dynamics in canted antiferromagnetic $YFeO_3$

J. Lee [1], T. Kim [1], S. Kovalev [2], Y. Tokunaga [3], Y. Tokura [3], M. Gensch [2]

1. Gwangju Institute of Science and Technology (GIST), Gwangju, Korea
2. Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany
3. RIKEN Center for Emergent Matter Science (CEMS), Wako, Saitama, Japan

We investigate the coherent precessional motion of the magnetic moment in the canted antiferromagnetic YFeO3 single crystal after excitation by the transient magnetic field of an ultra-short THz pulse. Time-resolved measurements of the magneto-optical response in the presence of external magnetic fields confirm the exclusive magnetic origin of the interaction between THz pulse and the spin system.. By tuning the spectral component of the input THz pulse around the quasi-ferromagnetic mode located near 0.3 THz, we have experimentally verified that the THz control of the spin state requires resonant excitation. We could confirm these results from the simulation based on the Landau-Lifshitz-Gilbert equation with two sub-lattice model for the canted antiferromagnet. Furthermore, we demonstrate that the spin state can be switched all-optically on a picosecond timescale using THz pulses of square and oscillating shapes. Whereas the oscillating THz pulse with a spectral component resonant with the magnetic excitations is necessary for an efficient magnetization switching, we study the possibility for a further reduction of the necessary THz field strength by examining influences of variations in the anisotropy energy and Dzyaloshinskii-Moriya interaction upon the switching behaviors.

Th.F.3_I1 - Advances in magnetic force microscopy

A. Asenjo [1], O. Iglesias-Freire [1], M. Jaafar [1], E. Berganza [1]

1. Icmm-Csic, Madrid, Spain

During the past twenty years magnetic force microscopy (MFM) has become one of the most powerful general purpose methods for magnetic imaging. Apart from applications in quality control in the batch fabrication of magnetic devices, MFM has proven its relevance in fundamental research to gain information about the magnetic properties of the materials at the nanoscale. MFM can be applied under various environmental conditions and requires only little sample preparation. The quantitative data analysis, the tip-sample influence and the lateral resolution have been the most important challenges of this technique. New developments can be implemented in order to improve its potential. In the present work, MFM-based techniques developed in our group are described. MFM performed in external magnetic has led to a novel method of magnetometry at nanoscale [1,2] that can be used to study reversal magnetization processes in Py nanostripes [3] or CoFeCu nanowires. Regarding the spatial resolution, we show the advantage of using one side coated MFM probes [4] and how high lateral resolution magnetic images can be obtained by studying magnetic dissipation processes in MFM [5].

Th.F.3_I2 - Spin Dynamics of Magnetic Skyrmions and Domain Walls due to spin - orbit effects

M. Kläui [1]

1. Institute of Physics, Johannes Gutenberg University Mainz, Mainz, Germany

Topological spin structures that emerge due to the Dzyaloshinskii-Moriya interaction (DMI), such as chiral domain walls and skyrmions possess a high stability and are of key importance for magnetic memories and logic devices [1,2]. We have investigated in detail the dynamics of domain walls [2] and we find that in addition to conventional spin transfer torque, also spin orbit torques play a key role [3]. By comparing the wall motion with current-induced magnetization switching in our systems, we can deduce the spin-orbit torques independently of the DMI [3] and we find that the motion observed Ta(5nm)/$Co_{20}Fe_{60}B_{20}$(1nm)/MgO(2nm) can be attributed to a DMI that is opposite to such stacks with a magnetic CoFe layer pointing to the B at the interface that governs the sign of the DMI [3]. For skyrmions we demonstrate for the first time that we can move a train of skyrmions in a "racetrack"-type device [1] due to spin-orbit torques reliably [4] and we find skyrmion lattices at room temperature in confined geometries [4]. Finally we study the field - induced dynamics of a magnetic bubble skyrmion [5]. The trajectory of the skyrmion's position is accurately described by our quasi particle equation of motion. From a fit we are able to deduce the inertial mass of the magnetic bubble and find it to be much larger than inertia found in any other magnetic system, which can be attributed to the non-trivial topology [5].

Th.F.3_O3 - Development of 22 T VSM system using novel improvements in HTS conductor

J. Good [1], D. Bracanovic [1], T. Ritman-Meer [1]

1. Cryogenic Ltd, London, United Kingdom

Current research has identified a need for greater magnetising fields during vibrating sample magnetometer (VSM) measurements and other measurement options. We present here the methodology involved in our development of a VSM system with 22 T superconducting magnet, a unique system and the highest field combined with a VSM anywhere in the world. Recent developments in HTS conductors have allowed greater reliability than previous coils made from YBCO and BISCO and thus facilitate the consistent achievement of higher magnetising fields at the sample with operation at 4.2 K rather than 2.2 K. Cryogenic Ltd wind HTS coils in both solenoid and pancake forms with an emphasis on solenoids, since they have been found to give a more reliable performance with less thermal transfer to the surrounding liquid helium. The 22T VSM system has been developed using 2G YBCO coated and BSSCO tape which exhibit critical currents up to 5 times greater than those seen in YBCO and BISCO at 4.2 K.

Th.G.1_I1 - Magnetic degrees of freedom in nanophotonics

R. Carminati [1]

1. ESPCI ParisTech, Paris, France

Controlling the optical response of nanoscale devices using an external parameter is a key issue in active nanophotonics. The use of a magneto-optical (MO) effect, with the external static magnetic field as a control parameter, is receiving increasing attention. We will show that MO effects offer in principle many degrees of freedom to act upon light-matter interaction. They can be used to actively control resonant structures or to modulate field enhancements. Conversely, field enhancements can be used to boost the otherwise weak MO response of usual materials (including ferromagnetics). The discussion will be based on specific examples covering the coupling of an incident beam to surface plasmons [1], the use geometric resonances on periodic gratings to enhance the MO response [2], and fluorescence energy transfer between dipole emitters [3]. We will also report on an experimental technique to quantify the relative importance of electric and magnetic dipole luminescence from a single nanosource. The technique allows one to measure the relative weights of the electric and magnetic contributions to the local density of states, a basic quantity in nanophotonics [4]. This result paves the way towards the full electric and magnetic characterization of nanostructures for the control of single emitter luminescence. I am indebted to H. Marinchio, R. Vincent, A. García-Martín, J.J. Sáenz and L. Aigouy for their key contributions to this work.

A surface plasmon polariton (SPP) is a transverse magnetic mode electromagnetic wave propagating at a metal/dielectric interface, which is evanescently confined in the perpendicular direction to the interface. Similar to electrons in a crystal potential, the dispersion of SPP waves on a flat metal surface folds at the Brillouin zone boundaries to form a band structure when a periodic modulation of the metal surface is introduced, realizing what is called a two-dimensional plasmonic crystal. While in a film SPPs can couple only to p-polarized light in the free space, efficient coupling of free-space light, both p- and s-polarized to SPP waves can be achieved through diffraction in metal surfaces with periodic arrangements of sub-wavelength scale structures. We investigate here a two-dimensional plasmonic crystal with a periodic array of cylindrical holes in a ferromagnetic layer, namely a two-dimensional magneto-plasmonic crystal (2D-MPC). Nanostructured magnetic materials allow for intrinsic cross-coupling of plasmonic modes due to their inherent magneto-optical (MO) activity as demonstrated for localized surface plasmons [1]. The underlying idea explored in this work is that this phenomenon should occur also in 2D-MPCs under proper experimental conditions, namely having the MO coupling acting in the crystal plane. We show that this is indeed the case and demonstrate that magneto-optical activity mediated coupling between SPP waves, in combination with the 2D photonic band structure can be used to design metamaterials with tailored and enhanced MO response, moreover controllable via an external field. Thereby, our results disclose a novel way to exploit the SPPs mediated MO polarization conversion via plasmonic band engineering leading to enhancement of MO signals at desired wavelengths in view of potential applications of such 2D-MPCs as nanoscaled non-reciprocal polarization-dependent optical isolators.

Th.G.1_O3 - Plasmon-mediated large enhancement of magneto-optical activity in colloidal magnetic metals

O. Herranz [1], G. Herranz [1]

1. Icmab-Csic, Madrid, Spain

Magnetic properties may undergo dramatic changes at the nanoscale that, eventually, can be exploited as a basis for enhanced functionality. This is the case that we present here, in which we analyzed the rotation and ellipticity that magnetic nanoparticles exerted on the polarization of light. More specifically, we observed an outstanding increase of the magneto-optical activity at the frequencies of the plasmon resonances of the metallic magnetic nanoparticles, yielding a dramatic increase of the Verdet constant [1]. Furthermore, we have established an innovative theoretical framework in excellent quantitative agreement with the experimental data, endowing our model with a powerful predictive character for the interaction of polarized light with magnetic nanoclusters embedded in dielectric hosts. The relevance of our results goes well beyond the particular case of colloidal metals, as other systems such as metal inclusions in polymers or glasses containing small magnetic clusters can be as well considered. In addition, the observed large Verdet constants allow envisioning the exploitation of light polarization, instead as the commonly used reflectance, as a probe for plasmon-sensing devices. Our results provide new routes for plasmon-based biological and chemical detection.

Magnetotransport phenomena in low dimensional systems have attracted much research attention due to their fundamental and applied importance. The purpose of the present study is to find novel combinational effects in heterostructures of silicon dioxide films containing cobalt nanoparticles SiO_2(Co) grown on n-GaAs substrate. The SiO_2(Co) films with a Co atomic concentration of 45-71 at. % were prepared on GaAs at temperature of 200 C from a composite cobalt-quartz target using the ion-beam deposition technique. We studied magnetic-field-induced photocurrent in these heterostructures in the avalanche regime. A strong photocurrent enhancement is observed for photon energies E above the GaAs bandgap Eg. The photocurrent is increased by a factor of about ten for the photon energy E = 1.5 eV in the magnetic field H = 1.65 kOe for the SiO_2(Co)/GaAs heterostructure with a Co atomic concentration of 60%. This phenomenon is explained by a model describing electronic transitions in magnetic fields with the spin-dependent recombination process at deep impurity centers in the GaAs interface region. We developed a model taking into account the exchange interaction between electrons on the oxygen levels with 3d-electrons of Co nanoparticles via electrons in the accumulation layer and assuming that the exchange interaction is isotropic. In a magnetic field electron-hole recombination is suppressed. This leads to additional free electrons in the conduction band and holes in the valence band. As a result, photo-induced holes are accumulated in the barrier, the photocurrent grows and the avalanche feedback can be manipulated by the light. The photocurrent enhancement caused by applied magnetic field can be used in field-controlled avalanche diodes.

TH.G.1_O5 - Polariton-mediated ultrafast magneto-optical modulation

R. Subkhangulov[1], R. Mikaylovskiy[1], V. Kruglyak[2], T. Rasing[1], A. Kimel[1]

1. Institute for Molecules and Materials, Radboud University Nijmegen, Nijmegen, The Netherlands
2. School of Physics, University of Exeter, Exeter, United Kingdom

Controlling the response of media at the (sub)picosecond time-scale or Terahertz (THz) frequencies is one of the most debated topics in contemporary condensed matter physics and photonics. Aside from a purely fundamental interest in ultrafast processes in condensed matter at the characteristic time-scales pertinent to electronic, spin and atomic motion, the attention to this topic has been continuously fueled by the demands for ever faster information processing. THz magneto-optical modulation at tunable frequencies can be achieved by employing spin resonances. Here we propose a novel approach for an ultrafast tunable magneto-optical modulation by means of a polaritonic excitation launched at the surface of a magneto-optical medium. This excitation together with the surface of the sample act on visible light as partially transparent mirrors, which form an interferometer expanding with a relativistic speed and consequently modulating the total magneto-optical response at THz frequencies. Using Terbium gallium garnet as test sample we succeeded to show the feasibility of such a magneto-optical modulation with frequencies up to 1.1 THz, continuously tunable with the help of an external magnetic field. Besides the novel concept of the ultrafast magneto-optical polarization modulation, our findings reveal the important role which polaritonic excitations can play for the interpretation of pump-probe magneto-optical experiments. We argue that further enhancement of the efficiency of the ultrafast polaritonic magneto-optical modulation is quite possible.

TH.G.2_I1 - Domain wall propagation along cylindrical nanoelenents

The magnetization reversal of two and three-segment cylindrical nanoelements comprising of alternating nanowire and nanotube sections is investigated by means of Montecarlo simulations. By choosing different parameters and materials for the tube and wire segments, the nucleation of vortex and transverse domain walls could be tailored, creating a manifold of different scenarios for the magnetization reversal. Such nanoelements may feature a three-state behaviour with an intermediate plateau in the hysteresis curve due to a metastable pinning of the domain walls at the wire-tube interfaces. In general, when there is only one material the arrival of the domain wall at the interface leads to a local minimum in the differential susceptibility, since the difference in nucleation field across the interface is not large enough to create a plateau. However, when different materials are used to harden (soften) the wire (tube) section, an intermediate plateau is formed due to the large difference of nucleation fields on each side of the interface. In these cases the width of the wall decreases notably as it reaches the interface, regardless of the reversal mode. It is important to highlight the absence of a preferential nucleation site for domain walls in the WTW elements because in these elements the tube ends are fixed to the hard wires, preventing the nucleation of domain walls at the interfaces. Moreover, because the tube is uniform, the wall can nucleate almost simultaneously in different places, opening the possibility of injecting walls simultaneously on both wires by varying the size of the tube. In summary, a novel feature in cylindrical nanostructures was found, which consists of the outward movement of the domain walls from the element body to the element tips. This might give rise to applications in which such nanoelements are used as domain wall delivering structures at its tips.

TH.G.2_O2 - Structural and magnetotransport properties of FexCo(1-x) nanowires prepared by focused electron beam induced deposition with a heteronuclear metal carbonyl precursor

F. Porrati[1], S. Barth[2], F. Biegger[2], C. Gspan[3], H. Plank[3], M. Huth[1]

Focused electron beam induced deposition (FEBID) is an emerging one-step lithographic technique used to prepare nanostructures down to the nanometer scale. In FEBID the molecules of a precursor gas injected in an scanning electron microscope decompose by interaction with the electron beam, forming a sample during the rastering process. Carbonyl precursors like $Fe(CO)_5$ or $Co_2(CO)_8$ are used for the preparation of magnetic nanostructures with potential employment in magnetic nanologic and sensor applications. Recently, it was shown that magnetic alloys could be prepared by FEBID by mixing two homonuclear precursor gases. As a novel, alternative route we show that Fe-Co alloy deposits can be directly obtained by using a heteronuclear precursor. Such a route, known for the preparation of magnetic thin films alloys in chemical vapor deposition, allows to obtain metallic nanostructures with the stoichiometry of the heteronuclear metal carbonyl compound. In the present work, FEBID deposits have been fabricated by means of the $HFeCo_3(CO)_{12}$ precursor gas. The deposits contain up to 80 at% metal, i.e., ca. 60 at% Co, 20 at% Fe, 10 at% C and 10 at% O, as measured by EDX spectroscopy. Nanowires of various size down to a width of 50 nm and a thickness of 10 nm have been prepared and characterized by four-probe magnetotransport measurements. All the nanowires show metallic behavior in temperature dependent resistivity measurements with a resistivity at room temperature of about 44 μWcm for the smallest nanowire investigated. From the analysis of the Hall effect negative and positive values for the ordinary and the anomalous Hall coefficients were derived, respectively. The saturation magnetization is about 1.4 T, similar to Fe and Co based FEBID deposits known from the literature. Finally, the microstructure of the nanowires has been investigated by means of transmission electron microscopy.

TH.G.2_O3 - Investigating the dipolar interactions in assemblies of ferromagnetic nano-objects by Ferromagnetic Nuclear Resonance

I. Camara[1], Y. Shin[1,2], N. Liakakos[3], C. Achkar[3], M. Respaud[3], K. Soulantica [3], T. Blon [3], M. Bailleul[1], C. Meny [1,2]

2. Department of Physics, CNRS-Ewha International Research Center, Ewha Womans University, Seoul, South Korea
3. Laboratoire de Physique et Chimie des Nano-objets (LPCNO), INSA, Toulouse, France

Nano-objects are studied in many research fields, spintronics, chemistry, biology, medicine... The properties of these objects will depend on their size, shape, crystallographic structure and chemical composition. When we consider ferromagnetic nano-objects that are organized in assemblies where they are closely packed, dipolar interactions will also strongly influence the magnetic properties of the system. The system under investigation has been prepared by chemical route and consists of single-crystalline cobalt nano-wires epitaxially grown on a flat substrate to form a hexagonal array of 1×1012 nanowires/cm2 [1]. In this work we show that while Ferromagnetic Nuclear Resonance (FNR, i.e. Nuclear Magnetic Resonance for ferromagnets) has been extensively used for studying the structure and chemical order in thin films [2] and nanoparticles [3] it can also provide direct insight into the dipolar interaction between the nanowires. Indeed by measuring the Co FNR spectra of the sample in its remnant state and in its demagnetized state we observe a shift of the Co FNR lines. This line shift is a direct measurement of the dipolar field resulting from the film shape of the assembly of nanowires. The measured dipolar field is reduced compared to the one expected for a continuous film and is discussed in term of packing factor of the nanowire film.

TH.G.2_O4 - Magnetic anisotropy of (ZnTe)/Co core/shell nanowires grown by MBE

P. Misiuna[1], T. Wojciechowski[1] P. Dłużewski[1] B. Kurowska[1], M. Wiater[1], S. Lewińska[1], A. Ślawska-Waniewska[1], A. Wawro[1], E. Milińska[1], T. Wojtowicz[1], L.T. Baczewski [1]

1. Institute of Physics Polish Academy of Sciences, Warsaw, Poland

A model object for magnetic anisotropy study such as (ZnTe)/Co core/shell nanowires forming a magnetic nanotubes with nonmagnetic core were grown by MBE technique [1]. Arrays of crystalline zinc telluride nanowires obtained by vapor-liquid-solid mechanism were covered with cobalt of different thicknesses. Structural characterization was performed using SEM, TEM and EDX techniques. In-depth structural analysis revealed that deposited cobalt shell is polycrystalline with crystal grains of both HCP and FCC structure. Increment of deposited Co thickness as well as the initial roughness of ZnTe core leads to a quasi-dendritic shape of Co shell. Cross-section study performed by FIB showed a hexagonal shape of the nanowires with an uniform Co shell structure. Vibrating sample magnetometry and magnetic force microscopy experiments revealed that magnetization hard-axis is parallel to the long axis of the nanowires, which is in agreement with other experimental results [2] and theoretical predictions for hollow Co nanotubes. Our experimental results show that exchange bias effect caused by a possible Co oxides formation and suggested by some authors [3] as a possible origin of such anisotropy direction is not responsible for the observed effect. Protection of Co shell against oxidation by Au cover layer does not influence the anisotropy direction of the nanostructures, but causes its slight magnetic softening.

TH.G.2_O5 - Manipulation of transverse domain wall profile for logic devices

R. Maddu [1], S. Goolaup [1], C. Murapaka[1], W. Lew[1]

1. School of Physical And Mathematical Sciences, Nanyang Technological University, Singapore

The dynamics of domain walls (DWs) in magnetic nanowires (NWs) have been studied to be able to use for high-density non-volatile memories and spin logic devices. The success of these technologies will rely inevitably on the precise control and understanding of magnetic DWs in NWs. This has been a challenging task and much research has been devoted to accomplish these. Changes in the DW structure are significant in device applications where DW motion is controlled via interaction with artificial defects, as the detailed spin distribution in the wall affects the nature and strength of the pinning potential. In thin film narrow magnetic nanowires, the transverse DW (TDW) is the stable configuration. TDW has two degrees of freedom; magnetic charge and chirality. Another approach to describing TDW is to view it as a composite object of elementary topological defects. The edge defects have half-integer winding numbers, either + ½ or − ½, representing the spin configuration of the DW at the edges of the nanowire. As such, the topological defects of DW are important parameter for future DW based devices. Although much progress has been made, DW-based devices with high reliability, for industrial applications are still elusive. In this work, we demonstrated a method to perform logic applications via the topological edge defects. We experimentally demonstrate the DW rectification and logical NOT (inverter) operation based on DW topological defects. The rectifier provides a pre-determined topological output independent of the type of the input TDW. On the other hand, the inverter always provides an output which is has opposite edge defects as compared to the input. Experimental verification of our technique was carried out using magnetic force microscopy.

TH.G.2_O6 - Manipulating vortex domain walls with mechanical strain

A. Rushforth [1], R. Beardsley [1], D. Parkes [1], S. Bowe [1], K. Edmonds [1], B. Gallagher [1], T.Hayward [2], J.Wheelwright [2], D. Allwood [2], A. Irvine [3], C. Reardon [4], S. Cavill [4]

4. University of York, York, United Kingdom

Controlling the motion of magnetic domain walls is an important objective for studying their fundamental properties and for potential applications in devices such as Racetrack memory, 3-terminal MRAM and logical processing architectures[1]. In the case of vortex domain walls in planar magnetic nanowires, it has been proposed that the chirality of the wall can serve as the method to encode information[2]. Practical implementations of domain walls in such technologies will require low power methods to control domain walls on the local scale. A promising route to low energy control of magnetisation is to use electric fields. In particular, the application of voltage-induced mechanical strain in hybrid piezoelectric/ferromagnetic devices has received much attention recently[3,4]. Using this approach, we have investigated the effect of a voltage-tunable strain-induced uniaxial anisotropy on the pinning fields and chirality of vortex domain walls in nanowires. Using x-ray magnetic circular dichroism photo-emission electron microscopy (XMCD-PEEM), magneto-optical Kerr effect (MOKE) microscopy and micromagnetic calculations we demonstrate that the chirality of the domain wall can be modified by the voltage induced-strain. Furthermore, we find that vortex domain walls with opposite chirality exhibit different depinning fields and an opposite dependence of the depinning field on the induced anisotropy when interacting with a notch in the nanowire. The behaviour is explained by the deformation of the domain wall at the notch which leads to different depinning mechanisms for the two chiralities. Our results point the way towards a low power design of chirality dependent domain wall gates in schemes for information storage and processing.

Ruthenate-oxide materials attract much attention due to the interesting ground states they exhibit, such as unconventional superconductivity in Sr2RuO4 or Mott physics in Ca2RuO4. The role of electron correlations, Hund's coupling and spin-orbit interactions is still being debated and explored [1,2]. In this talk [3] we present a study on the Ru 4d-orbital occupation and excitations in (Ca/Sr)2RuO4, performed through a combination of X-ray Absorption Spectroscopy (XAS) and high resolution oxygen K-edge Resonant Inelastic X-ray Spectroscopy (RIXS). The ruthenium 4d orbital occupation and excitations were probed through their hybridization with the oxygen p-orbitals. A minimal model, taking into account crystal field splitting and spin-orbit coupling, is presented to account for the observations. Implications on electronic structure, Mott physics and superconductivity are discussed.

The magnetic critical scattering in Sr_2IrO_4 has been characterized using X-ray resonant magnetic scattering (XRMS) both below and above the 3D antiferromagnetic ordering temperature, T_N. The order parameter critical exponent below T_N is found to be β=0.195(4), in the range of the 2D XYh_4 universality class. Over an extended temperature range above T_N the amplitude and correlation length of the intrinsic critical fluctuations are well described by the 2D Heisenberg model with XY anisotropy. This contrasts with an earlier study of the critical scattering over a more limited range of temperature which found agreement with the theory of the isotropic 2D Heisenberg quantum antiferromagnet, developed to describe the critical fluctuations of the conventional Mott insulator La_2CuO_4 and related systems. Our study therefore establishes the importance of XY anisotropy in the low-energy effective Hamiltonian of Sr_2IrO_4, the prototypical spin-orbit Mott insulator.

TH.G.3_O3 - Orbital magnetism and spin-orbit effects in iridium oxides

M. A. Laguna-Marco [1], P. Kayser [2], J. A. Alonso [2], Y. Choi [3], D. Haskel [3]

1. ICMA and Dpto de Física de la Materia Condensada, CSIC-Universidad de Zaragoza, Zaragoza, Spain
2. Instituto de Ciencia de Materiales de Madrid, CSIC, Madrid, Spain
3. Advanced Photon Source, Argonne National Laboratory, Argonne, United States

Element- and orbital-specific L2,3 edge x-ray absorption and magnetic circular dichroism measurements are used to probe the electronic ground state and magnetism of Ir(5d) states in iridium oxides like A_2MIrO_6 (A=Sr, La; M = Mg, Ca, Sc, Ti, Ni, Fe, Zn, In) and (Ba,Sr)IrO_3. All the studied compounds present a significant influence of spin-orbit interactions in the electronic ground state. Besides, comparison between different A_2MIrO_6 compounds indicates that the Ir 5d local magnetic moment shows different character depending on the oxidation state. Ir carries an orbital contribution comparable (or even bigger) to the spin contribution for Ir4+ and Ir5+ oxides while the orbital contribution is quenched for Ir6+ samples. The results for the A_2MIrO_6 system also indicate that Ir carries a sizable local magnetic moment with the value of the much smaller net magnetization strongly dependent upon the structural details in each double perovskite. In a similar way, the 3d-5d magnetic interaction is strongly dependent on the structural details such as bond lengths and angles. Thus, we found that the net moment of Ir orders parallel to the net magnetic moment of Fe and Ni in Sr_2FeIrO_6 and Sr_2NiIrO_6, respectively, whereas it aligns antiparallel in La_2NiIrO_6. The delicate interplay between lattice degrees of freedom, electronic bandwidth and exchange interactions in iridates is further illustrated by the disparate response of the magnetic properties of $BaIrO_3$ to chemical (doping) and physical pressure.

TH.G.3_O4 - Orbital and magnetic orderings in half-doped manganites thin films: the crucial role of strain and bandwidth

D. Pesquera[1], D. Gutiérrez[1], G. Radaelli[2], A. Barla[3], F. Bondino[4], E. Magnano[4], F. Sánchez[1], R. Bertacco[2], J. Fontcuberta[1]

2. LNESS - Dipartimento di Fisica - Politecnico di Milano, Como 22100, Italy
3. Istituto di Struttura della Materia, ISM CNR, S.S. 14 km 163.5, Area Science Park Basovizza (Ts), I-34149, Italy
4. IOM-CNR, S.S. 14 km 163.5, Area Science Park Basovizza (Ts), Italy.

Half-doped manganites La0.5A0.5MnO3 (A=Sr,Ca) have received renewed attention because their ground state (ferromagnetic (FM) / metallic or antiferromagnetic (AF) / insulator) can be radically modified by engineering the bandwidth or the carrier density. This property makes half-doped manganites ideal materials to be integrated in reconfigurable tunneling junctions with potentially large electroresistance [1,2]. Progress in this direction and discrimination between strain and field-effects in ferroelectric/half-doped manganite heterostructures, and the much wanted field-induced metal-insulator transition at the interface [4], require detailed understanding of the epitaxial strain effects on the properties of ultrathin films which may modify or suppress orbital ordering. Here, exploring the temperature and magnetic field dependence of X-ray absorption linear and circular dichroism, we discern the orbital and magnetic orderings of La0.5A0.5MnO3 (A = Ca and Sr) films and its complex evolution with strain and electronic bandwidth. Our results -combined with the structural, magnetic and electrical characterization of these films [3]- provide a guide for material's selection for optimal hybrid half-doped manganite/ferroelectric tunnel junctions.

TH.H.1_I1 - Efficient and safe magnetic iron oxide nanoparticles for biomedicine

M. Del Puerto Morales [1]

1. Instituto De Ciencia De Materiales De Madrid, Consejo Superior De Investigaciones Cientificas, Madrid, Spain

Magnetic nanoparticles based on iron oxides are utilized in vivo investigations, in diagnosis and therapy treatments for their no-toxicity, biodegradability and magnetic properties. Compared to the conventional, non-targeted methods of drug delivery, magnetic nanoparticles with proper surface modification and conjugated targeting ligands/molecules are promising drug carriers due to the better specificity to the target site that can be assisted with a magnet and the reduced adverse effects [1]. Recent efforts are focused in designing new multifunctional magnetic nanoparticles to address the problems found in biomedical applications [2]. For example, to improve the sensitivity and accuracy of MRI, other materials (organic and inorganic) responsible for different imaging modalities are combined with the nanoparticles [3, 4]. Therapeutic efficacy can be also improved by synthesizing MNPs and controlling the nanoparticle assembling [5]. However, biodistribution and metabolism of these new nanoparticles need to be better understood before serving as nanoplatforms for highly efficient diagnostic and therapeutic applications.

TH.H.1_O2 - Magnetic hyperthermia properties of nanoparticles inside lysosomes using kinetic Monte-Carlo simulations: influence of key parameters, of dipolar interactions and spatial variations of heating power

J. Carrey [1], R. Tan [1], M. Respaud [1]

1. Laboratoire De Physique Et Chimie Des Nano-Objets, INSA Toulouse, CNRS, Université de Toulouse, Toulouse, France

Understanding the influence of dipolar interactions in magnetic hyperthermia experiments is of crucial importance for fine optimization of nanoparticle heating power. In this study, we use a kinetic Monte-Carlo algorithm to calculate hysteresis loops that correctly account for both time and temperature. This algorithm is shown to correctly reproduce the high-frequency hysteresis loop of both superparamagnetic and ferromagnetic NPs without any ad-hoc parameters. The algorithm is easily parallelizable which considerably decreases calculation time and enables the study of assemblies of several thousands of NPs. The heating power of magnetic nanoparticles dispersed inside spherical lysosomes is studied as a function of volume concentration, applied magnetic field, lysosome size, NP diameter and anisotropy. Magnetic interactions are shown to increase the coercive field, saturation field and hysteresis area of major loops. However, for minor loops, the heating power as a function of concentration can increase, decrease or display a bell shape, depending on the relationship between the applied magnetic field and the coercive/saturation fields of the nanoparticles. The heating power of a given nanoparticle is strongly influenced by a local concentration involving approximately 20 neighbors. Because this local concentration strongly decreases upon approaching the surface, the heating power increases or decreases in the vicinity of the lysosome membrane. The amplitude of variation reaches more than one order of magnitude in certain conditions. The amplitude and sign of this variation is comprehensively explained. Finally, implications of these various findings are discussed in the framework of magnetic hyperthermia optimization. It is concluded that feedback on two specific points from biology experiments is required for further advancement of nanoparticle optimization for magnetic hyperthermia. The present simulations will be an advantageous tool to optimize magnetic NPs heating power and interpret experimental results.

TH.H.1_O3 - On-chip attomol level detection of proteins using forced magnetic bead transport

R. S. Bejhed [1], B. Tian [1], K. Eriksson [1], R. Brucas [1], S. Oscarsson [2], M. Strömberg [1], P. Svedlindh [1], K. Gunnarsson [1]

Based on their unique properties, magnetic beads are well suited to be used as target labels in biosensor systems. Here, we present a chip-based biosensor system for protein detection comprising lines of micron-sized magnetic thin film elements. Under the influence of a rotating external magnetic field, the elements enable a forced transport of magnetic beads. Both the beads and a section of the chip (the detection area) were functionalized with capture molecules complementary to the target protein. Two approaches were tested, in which the target protein was labeled with the beads either on-chip or off-chip. In the on-chip labeling approach, the sample was incubated on the chip prior to the transport of the beads. In the off-chip labeling approach, the sample was incubated with the beads which were then transported across the chip. In both cases, the target protein will act as a cross-linker between the capture molecules on the beads and the detection area, resulting in the immobilization of beads on the detection area. The immobilized beads were detected using a standard optical microscope. When tested using avidin as capture molecule and biotinylated anti-avidin as target protein, both approaches resulted in a limit of detection (LOD) in the attomol range. The on-chip labeling approach proved to be the more sensitive approach, with a LOD of 1.7 attomol in a 5 Ál sample (target protein in PBS) and a dynamic range of five orders of magnitude for a total assay time of 1.5 hours. When testing the on-chip labeling approach on a sample of target protein in PBS with 10% serum, the LOD shifted to 34 attomol in a 5 Ál sample. The overall performance of our biosensor system compares well to similar systems and our next challenge will be to extend the system for multiplex detection.

TH.H.1_O4 - Towards an on-chip platform for the investigation of cellular functions via magnetic nanoparticles

D. Petti [1], M. Monticelli [1], E. Albisetti [1], D. Conca [1], A. Cattoni [2], M. Lupi [3], D. Parazzoli [4], R. Bertacco [1]

4. IFOM-FIRC, Institute of Molecular Oncology, Milan, Italy

In-vitro tests and analysis are of fundamental importance for investigating biological mechanisms in cells and bio-molecules. The application of controlled forces to activate specific and not well-known bio-pathways, mimicking the role of the cellular environment, is becoming a prominent approach in this field. Methods based on the remote manipulation of magnetic beads, via external magnetic fields, are receiving great attention because magnetic fields are not screened by biological or culture media. Moreover, magnetic nanoparticles manipulation does not involve relevant energy dissipation, which could eventually damage the cell structure. In this work, we present a non-invasive magnetic on-chip platform, exploiting magnetic Domain Wall Tweezers (DWTs) [1], based on the controlled nucleation and displacement of Domain Walls (DWs) in ferromagnetic conduits, for trapping and finely manipulating single superparamagnetic particle properly functionalized. To this scope, nanometric Ni80Fe20 rings are patterned on a chip where cells are afterwards cultured and a pair of DWs, which attract and drag magnetic nanoparticles, are nucleated and displaced trough the application of a rotating in plane magnetic field. In this way, we demonstrate the possibility to handle with high resolution (down to 100 nm) magnetic beads to a target cell in order to assess controlled forces in the range of pN-nN [2] to mechanically and chemically activate relevant cellular pathways (e.g. genes activation) actually under investigation. Furthermore, cellular response to localized stimuli is monitored in real time by means of optical methods like confocal microscopy.

Magnetic nanoparticles have been implemented in biotechnological and biomedical applications related to animal (in particular human) cells and pathologies. However, their use in plant research biology is far less studied, although it could lead to the development of interesting plant biotechnology applications. For this purpose the first stage is to work out the penetration and transport of the magnetic nanoparticles into living plants and plant cells and how they interact with plant cells and tissues [1]. We have synthesized biocompatible suspensions of iron-oxide carbon-coated nanoparticles, obtained by a gas-phase condensation method. They have been injected into pumpkin (Cucurbita pepo) living plants. The graphitic shell of our nanoparticles made possible their visualization into plant cells and tissues, using different microscopy techniques (fluorescence, confocal, light and electron microscopy). Moreover, their magnetic character allowed the nanoparticles to be positioned in the desired plant tissue by applying magnetic field gradients. In the absence of magnetic fields, the nanoparticles can as well travel along the vascular system, reaching different cell and tissues. Nanoparticles have been found both in the cytoplasm and in the extracellular space between cells. A size-based selection mechanism seems to be operating, probably involving cell walls and waxes acting as a barrier. Accumulation of nanoparticles was detected in leaf trichomes, suggesting a way for nanoparticles excretion/detoxification. With respect to cytotoxicity, it has been observed that cells containing nanoparticle agglomerates exhibited a cytoplasm denser than that of cells containing few nanoparticles. Damage at the plant level was not macroscopically evident. Although more studies are necessary to unveil the nanoparticles penetration and translocation mechanisms as well as their cyto- and phyto-toxicity, our results open a wide range of possibilities for using magnetic nanoparticles in general plant research and agronomy.

TH.H.2_I1 - Tumor ablation by exploiting magnetic nanoparticles and magnetic nanoparticle functionalization to achieve heat-mediated drug delivery and antibody tumor targeting

T. Pellegrino [1]

1. Istituto Italiano di Tecnologia, Geneve, Italy

At the tumor, a macroscopically temperature increase above 46°C, can provoke tumor ablation and kill cancer cells in the so called hyperthermia treatment. Lately, we have investigated iron oxide nanocubes prepared by thermal decomposition methods, as heat mediators in magnetic hyperthermia. These magnetic nanoprobes when exposed to an alternating magnetic field can generate heat and retarder the tumor growth (J. Kolosnjaj-Tabi et al. ACS Nano, 2014, 8, 4268). Here, our latest progress on the synthesis and their stabilization in physiological environments of suitable materials for magnetic-based hyperthermia will be presented (P. Guardia et al. J. Mater. Chem. B, 2014,2, 4426).

I will also present an example of surface functionalization of iron oxide nanocubes with a thermo-responsive polymer shell able to release the drug content upon an increase of temperature above the body temperature and under field and frequency conditions that are non-armful for patients. Given the high heat specific absorption rates (SARs) of the nanocubes, their activation under AMF exposure and the consequent heat production, can be exploited to trigger doxorubicin drug release loaded within the polymer shell (H. Kakwere et al, ACS Appl. Mater. Interfaces, 2015, 7 (19), pp 10132–10145).

Finally, an *in vitro* and *in vivo* study of specific targeting of iron oxide nanoparticles towards ovarian cancer cells will be also presented. Upon surface functionalization of spherical magnetic nanoparticles of 20 nm in diameter with an human antibody fragment (MNP-20-AFRA), a better targeting is achieved by directly administration of MNP20-AFRA by loco-regional administration (Quarta A et al., Nanoscale, 2015, 7, 2336–2351). In this context, tumor-specific MNP not only accumulate to a greater extent in the neoplastic lesion, to a level that can be considered appropriate for a therapeutic intervention, but also MNP20-AFRA are retained in the targeted area longer and prevented from a rapid clearance of the nanoparticles out of the tumor tissues than the non-specific control (PEG coated nanoparticles which do not bear the antibody).

TH.H.2_O2 - Real-time analysis of magnetic hyperthermia experiments on living cells under a confocal microscope

V. Connord [1], P. Clerc [2], N. Hallali [1], D. El Hajj Diab [2], D. Fourmy [2,] V. Gigoux [2,] J. Carrey [1]

2. RCTC, INSERM Toulouse, Toulouse, France

Applying a high-frequency alternating magnetic field (AMF) to tumor cells which have internalized magnetic nanoparticles (MNPs) can induce their apoptotic death [1]. However, the mechanisms responsible for this death are currently far from being understood. Their study was made difficult because it was previously impossible to observe cells during the AMF application. Using a new experimental setup we managed to remove this technological bottleneck. To achieve this, a high-frequency miniaturized electromagnet was manufactured [2]. Its small diameter permits its insertion into a cell culture box. It can generate a magnetic field on tumor cells while allowing their observation under a confocal microscope, a standard instrument in cell biology. Using this setup and fluorescence tags, several biological processes were revealed when AMF was applied on a gel containing tumoral cells with or without internalized MNPs. First, cell damages were observed exclusively on cells containing targeted MNPs. Real-time capture of two events suspected to play a key role in cell death induced by the magnetic field treatment were performed: lysosomal membrane permeabilization and ROS generation. These two phenomena were detected after 30 mn of AMF treatment only and thus occur at an early stage in the cascade of events leading eventually to cell death. We have also observed that, in some cells, lysosomes having accumulated MNPs could self-organize into needles under the influence of the AMF. This novel experimental approach is simple to develop and allows getting an insight into the cellular, molecular and physical mechanisms occurring during AMF application on living cells. We hope it will permit to understand the reason why cell death is observed in these magnetic hyperthermia conditions in spite that no increase of global temperature is perceptible.

Hepatocellular carcinoma is a public health burden, which constitutes the third cause of cancer mortality in the world.[1] Nonetheless, only unsatisfactory treatments with major side-effects and high cost are available. As a result, there is a need for new therapies that provide targeted cost-effective treatments that improve patient prognosis. Magnetic iron oxide nanoparticles (IONPs) are a suitable platform for the assembly of targeted entities with multiple functionalities. There is a wide range of methods for their synthesis; however, limited reproducibility, low stability, biocompatibility and limited targeting capabilities, have hampered the translation of these materials into practical tools for medical use. IONPs are commercially available as contrast agents for magnetic resonance imaging (MRI); but interest is now focused on their use as theranostic tools by incorporating a therapeutic capability to these agents. Magnetic hyperthermia (MH) has gained attention for the treatment of malignant tissue due to the possibility of limiting the treated area and enhancing drug efficiency. Herein, 10-30 nm IONPs with different magnetic anisotropies were synthesised and coated with multifunctional dendrons designed for drug loading.[2] These provided stable water suspensions suitable for in vivo use, which were tested for MRI and MH. In vitro tests compared the effect of MH induced drug release against direct drug exposure. Cell internalisation was studied as a function of drug and NPs concentration, as well as under MH treatment. To summarise, we have developed a synthesis and functionalisation method yielding stable drug-loaded dendronised-IONPs water suspensions. This nanoplatform has the potential to fulfil the need for a new theranostic tool for the treatment of hepatocellular carcinoma and other cancers due to its stability and therapeutic properties obtained by combining drug and hyperthermia effects.

3. Dia.Pro Diagnostic BioProbes srl, Milan, Italy

In recent years, the development of fabrication techniques to process materials in micro and nano-scale sized structures has deeply promoted the application of magnetoresistance in the fields of magnetic memories and biosensing. For the latter case, bioassays combining bionsensors based on magnetic tunneling junctions (MTJ) with magnetic markers have been widely developed in order to detect concentration of specific molecules in the medium under inspection. The most widely used scheme relies on the detection of molecular recognition events between the probe molecules, bound onto the sensor surface, and the magnetically labeled target molecules, which bind specifically to the complementary probes [1]. The magnetic stray field of the superparamagnetic labels on the surface of the sensor causes a change in the electrical resistance of the sensor, which is related to the concentration of the immobilized target molecules.

In this work, we demonstrate the detection of natural DNA from different classes of pathogens, precisely Hepatitis E virus (HEV) and Pathogenic bacteria (Salmonella, Listeria monocytogenes) using a highly sensitive biosensing platform based on magnetic tunneling junction (MTJ) [2]. The sensing array consists of 11 MTJ-based rectangular sensors with lateral dimensions 3 x 40 μm^2, a TMR value of 75% and a sensitivity S_0 = 17 %/mT in the linear region. The results show that the platform successfully meets the requirements for the detection of hybridized natural DNA. Moreover, this work represents a fundamental step towards the integration of MTJ-based biosensing platforms in compact Lab-on-a-chip devices for the straightforward detection of pathogens in the agrifood industry and for further medical applications.

TH.H.2_O5 - Optomagnetic read-out system for detection of pathogens based on magnetic nanobead dynamics

R. S. Bejhed [1], T. Zardán Gómez de la Torre [1], M. Donolato [2], M. F. Hansen [2], M. Strömberg [1], P. Svedlindh [1]

1. Uppsala University, Dep. of Engineering Sciences, Uppsala, Sweden
2. Technical University of Denmark, Department of Micro- and Nanotechnology, Lyngby, Denmark

The interest for research on new and improved strategies for the detection of pathogens is continuously growing. One strategy is to label the target entity by binding it to magnetic nanobeads equipped with detection probes. The dynamic behavior of nanobeads exposed to an AC magnetic field will be different for nanobeads with and without bound target. By probing the nanobead dynamics using a laser, this change in behavior can be measured as a modulation of the intensity of light transmitted through a cuvette holding the sample. Here, the complex second harmonic component, V2, of the transmitted light was measured as a function of the AC magnetic field frequency. A DNA target was recognized through padlock probe ligation followed by rolling circle amplification, resulting in micrometer sized DNA coils to which the nanobeads were bound. The read-out system was optimized and a turn-on response was found in the low frequency regime of the phase angle versus frequency spectrum calculated from V2. A limit of detection of 5 pM of Vibrio cholerae DNA coils was found for an assay time of less than two hours. [1] Additionally, a qualitative Escherichia coli/Vibrio cholerae biplex detection methodology was demonstrated.[2] This was accomplished by the binding of two different bead sizes to DNA coils from the two targets. This read-out system has a number of advantages in that it is easy to manage, sensitive, fast and built using inexpensive components therefore being an ample candidate for further research towards commercialization.

TH.H.3_I1 - Spin-dependent thermoelectric phenomena in thin films of $La_{2/3}Sr_{1/3}MnO_3$

C. Bui[1], F. Rivadulla[1]
1. Centro de Investigación en Química Biológica y Materiales Moleculares (CIQUS), Universidad de Santiago de Compostela, 15782-Santiago de Compostela, Spain.

The different density of states and Fermi velocities for the spin up/down population in ferromagnetic metals produce different conductivities for the opposite spin directions [1]. Therefore when the spin lifetime is larger than the momentum relaxation time, a *spin-dependent* Seebeck and Peltier coefficient are predicted, on the basis of the Onsager reciprocities [2]. On the other hand, the observation of a spin Seebeck effect (SSE) in magnetic insulators,[3,4,5] demonstrates that this must be different to the conventional Seebeck effect in magnetic conductors.

In this talk we will discuss the observation of an intrinsic planar Nernst effect (PNE) and anomalous Nernst effect (ANE) in thin films of $La_{2/3}Sr_{1/3}MnO_3$(LSMO). This material shows a fully spin polarized 3d band, and a $T_c \approx 360\ K$, which motivated its extended use as a FM electrode in tunnel junctions. We show that through a very careful control of the thermal gradients in the thin films, the ANE can be completely suppressed and separated from the symmetric PNE response. We further demonstrate that there is a perfect correspondence between the magnetothermal effects and their electrical counterparts in LSMO. Our findings also establish an upper limit for the possible observation of SSE in this system.[6]

TH.H.3_O2 - Switchable field-tuned control of magnetic domain wall pinning along Co microwires by 3D e-beam lithographed structures

C. Blanco-Roldán [1,2], C. Quirós [1,2], G. Rodriguez-Rodriguez [3], M. Vélez [1,2], J. I. Martín [1,2], J. M. Alameda [1,2]

1. Departamento de Física, Universidad de Oviedo, Oviedo, Spain

Modern memory devices based on magnetic domain wall motion require precise control of the domain wall dynamics, making this a fundamental task to achieve in their development process. In this work we present how wall motion in a cobalt wire can be controlled by pinning or de-pinning it due to the effect of the magnetic stray field of a previously magnetized cobalt bridge structure that crosses over it. Co microwires and bridges are both patterned over a Si substrate by e-beam lithography, and grown by magnetron sputtering followed by a lift-off process. Typical sizes are 12 x 3um length and 250nm thickness for the bridges, which rise 200nm on average over the 50 x 3um length and 40nm thickness needle-like shaped wires. Magnetization process has been analyzed by Kerr Microscopy in longitudinal geometry. It can be seen that the Co bridge has a high remanence when magnetized with a 0.53T field in the direction perpendicular to its length, that can induce a pinning effect in the wire below it, even without being in contact. In this way, by changing the remanence state of the bridge coming from negative or positive saturation, pinning of the domain wall motion in the wire can be selected to occur in either the positive or the negative branch respectively of the wire's hysteresis loop when a low magnetic field between 15mT and -15mT is applied along the wire direction, lasting this effect around 2.6±1.0mT. This switchable pinning effect is also very reliable, taking place with a probability of more than 83%, making these 3D structures a good alternative to use as pinning sites because of its novel tunable capacity of selection between pinning and de-pinning effect as required, opening a wider range of options for the user to control domain wall dynamics.

TH.H.3_O3 - Domain wall nanosensors based on ultra-thin CoFeB films

J. Wells [1], J. H. Lee [2], R. Mansell [2], R. Cowburn [2], O. Kazakova [1]

1. National Physical Laboratory, Teddington, Middlesex, United Kingdom
2. Thin Film Magnetism, Department of Physics, University of Cambridge, Cambridge, United Kingdom

Manipulation of magnetic domain walls (DWs) within nanostructures holds great promise for numerous applications, including high density memory, logic and sensor devices. Materials engineered to exhibit perpendicular magnetic anisotropy (PMA) exhibit advantageous properties, including narrow DWs, high thermal stability and low critical currents for DW propagation, which can be implemented in the construction of nanodevices. High sensitivity (down to single particle) detection and manipulation of magnetic nanoparticles (MNPs) is a rapidly developing area of research due to the potential for implementation in metrology and novel medical technologies. Through a variety of studies implementing ultrathin CoFeB(0.6nm)/Pt multilayers, we present a proof of concept for nanodevices based on the controlled nucleation and propagation of DW's through components formed from this PMA material. Reproducible low energy DW injection is demonstrated using precisely tailored device geometry. DW progress through the structures is observed using anomalous Hall effect measurements. These are conducted using both conventional Hall crosses, and also by probing the Hall voltage using overlying gold wires to minimise the disruption to smooth DW motion caused by pinning at Hall crosses in the first type of measurements. Field-driven DW motion modulated via geometrical pinning is demonstrated as a method of initialising the device for the capture of magnetic nanoparticles, and subsequently for probing the interaction between the DW and a MNP located in close proximity to it. The behaviour of clean, as-fabricated devices under varying field orientation is presented. Subsequent measurements of the devices after being decorated with commercially produced 1 micrometer MNPs are contrasted with the pristine devices. A possible method for applying ultra-thin film PMA sensors for single bead detection is evaluated. Further methods for improving the sensitivity of the devices are discussed.

TH.I.1_I1 - Spin-polarization in reciprocal space: analyzing the spin structure of electronic states by quasi-particle interference

M. Bode [1]

1. Wuerzburg University, Würzburg, Germany

The detection of spin-dependent surface properties is an important prerequisite for the understanding of various electron-correlation effects. The experiments presented here evaluate to what extend the observation of interference patterns created by coherent electronic states, so-called quasi-particle interference (QPI), can be used to obtain information on the spin-polarization of electronic bands in k-space. First, ferromagnetic Ni(111) will be used as a test sample for the QPI technique. In the follwoing we will present investigations of surface alloys of some heavy post transition metals with Ag(111), which provide giant Rashba-type spin-splittings, and of magnetically doped topological insulators. In both cases some very complex QPI patterns. The analysis of the energy dispersion of the observed features and the comparison with density functional theory calculations shows how the conservation of spin angular and orbital momentum influences the interference pattern.

Th.I.1_O2 - Eddy current interactions in a Ferromagnet-Normal metal bilayer structure, and its impact on ferromagnetic resonance lineshapes

V. Flovik [1], F. Macià [2], A. Kent [3], E. Wahlstrôm [1]

1. Norwegian University of Science And Technology, Trondheim, Norway
2. Universitad de Barcelona, Barcelona, Spain
3. New York University, New York, United States

In ferromagnetic resonance (FMR) experiments the shape of the absorption line carries valuable information. Recent experiments have used the difference in symmetry of the FMR lines to study spin pumping from a magnetic material to a normal metal. Hence, to interpret correctly experimental data involving FMR it is important to understand how eddy-currents can cause modifications to the measured lineshape. In this study, we investigate the contribution of eddy-currents to the FMR response in a ferromagnet-normal metal (FM/NM) bilayer structure. Eddy-current effects are usually considered negligible for a NM layer thickness below the microwave (MW) skin depth (approx. 800nm for Au at 10 GHz). However, we show that eddy-currents in thin NM layers (10-100 nm Au or Cu) induce a phase shift in the FMR excitation, resulting in an asymmetry of the measured absorption lines. Through systematic studies of how sample geometry and NM thickness affect the coupling between MW fields and eddy-current induced fields, we show that this coupling is tunable through changing the sample geometry and the NM layer thickness.

Th.I.1_O3 - Femtosecond control of spin-polarized photocurrents at the interfaces of metallic ferromagnetic heterostructures using circular polarized light

T. J. Huisman [1], R.V. Mikhaylovskiy [1,] J.D. Costa [2,3], E. Paz [2,] J. Ventura [3], P.P. Freitas [2], Th. Rasing[1,] A. V. Kimel [1]

1. Radboud University Nijmegen, Institute For Molecules And Materials, Nijmegen, The Netherlands
2. International Iberian Nanotechnology Laboratory, INL, Braga, Portugal
3. IN-IFIMUP, Porto, Portugal

Controlling spin-polarized currents using circularly polarized light [1,2] could lead to the development of ultrafast spintronic devices driven by laser pulses operating at the femtosecond timescale. Here we demonstrate that such a helicity dependent photocurrent can be generated at interfaces of metallic heterostructures consisting of a single ferromagnetic layer and a non-magnetic one. In particular, using terahertz emission spectroscopy we show that the direction of the generated photocurrent is controlled by both the helicity of light and the magnetization of the sample. Similarly to the case of noncentrosymmetric semiconductors [1,2] we argue that the helicity and magnetization dependent interfacial photocurrent in metallic multilayers originates from a combination of the spin-orbit interaction and the lack of center of symmetry which is also known as the Rashba spin-orbit coupling.

Pure spin current, flow of spin angular momentum with no flow of charge, is a key physical quantity to realize low-power spintronics devices. The spin Hall effect (SHE) enables one to convert charge current into pure spin current via spin-orbit interaction. Unlike most work, that has focused primarily on the magnitude of the spin Hall angle, the conversion yield between charge and spin currents, we here demonstrate an example of employing the SHE as a probe of a fundamental response of the spin current to the random spin configurations in spin glass systems. For this purpose, we chose CuMnBi ternary alloys [1]. When there is no Bi impurity in CuMn, it shows no SHE in the spin transport but shows a typical cusp structure at the spin glass temperature Tg in the thermo-magnetic curves. Once a small concentration of Bi was added in CuMn, a large SHE was observed as shown in our previous work on Bi-doped Cu [2]. Most remarkable is that the SHE of CuMnBi starts to decrease at about 4Tg and becomes as little as seven times smaller at 0.5Tg. A similar temperature dependence was also observed in anomalous Hall effects in the ternary alloys. These experimental results clearly show that a pure spin current induced by skew scattering at the Bi sites is strongly suppressed by fluctuating spins at the Mn sites even far above Tg, and can be qualitatively explained by the relative dynamics between the localized moment and the conduction electron spin.

Th.I.1_O5 - Mn_2Au, a new material for antiferromagnetic spintronics

V.M.T.S. Barthem [1], C.V. Colin [2], R. Haettel [2], D. Givord [1,2]

2. CNRS/Université Grenoble-Alpes, Institut Néel, Grenoble, France

Mn_2Au crystallizes in the $MoSi_2$ tetragonal structure. In a recent study, it was demonstrated to be an antiferromagnet, with a Mn magnetic moment of around 4 mB and Néel temperature above 950 K, temperature at which the Mn_2Au phase decomposes [1]. The magnetic structure, as determined from powder neutron diffraction, is formed of a stack of ferromagnetic sheets, perpendicular to the uniaxial axis. The moment orientation alternates from one sheet to the next. The Mn moments are confined in the plane of the tetragonal structure. The high Néel temperature in a large moment Mn compound with an heavy element such as Au, where large spin-orbit coupling is expected, suggest that Mn_2Au might be a very promising material for antiferromagnetic spintronics. The fact that the Mn moments lie in the plane of the tetragonal structure is a priori beneficial for possible applications in devices, since the in-plane anisotropy is expected to be much less than the uniaxial one. The possibility to reorient the moments under field remains to be demonstrated. A powder neutron diffraction studies have been performed. Rather than a spin-flop transition, under field, it revealed that the grains rotated under the torque resulting from the anisotropy in the susceptibility. The easy direction, derived form the analysis of the variation in the intensity of the diffraction lines is [110]. To verify the conclusions of this analysis, an X-ray study has been performed, with a powder sample of which constituting grains were previously oriented under field.

Th.I.2_O1 - Current-Driven Magnetization Switching via Spin-Orbit Torque in Perpendicularly Magnetized Hf|CoFeB|(MgO or TaO_x) Films with Structural Asymmetry

M. Akyol [1,2], G. Yu [1], J. G. Alzate [1], P. Upadhyaya [1], X. Li [1], K. L. Wong [1], A. Ekicibil [2], P. K. Amiri [1], K. L. Wang [1]

A charge current flowing inside the heavy metal layer can generate spin-currents flowing into the ferromagnetic layer, which results in SOTs on the magnetization of ferromagnetic layer[1-3]. However, since the SOT cannot switch perpendicular magnetization deterministically due to the symmetric damping-like SOTs in each out-of-plane magnetization state, an external magnetic field along the current direction is needed to assist the SOTs for deterministic switching[2]. Our previous results showed that current-driven perpendicular magnetization switching without external magnetic field is possible in such structures, when they exhibit structural asymmetry along the in-plane direction, in addition to the symmetry breaking along the *z*-direction of the structure[3, 4]. In this work, we study the cap oxide layer effect on the new field-like (FL) torque resulting from this type of symmetry breaking. Specifically, we measure the effective FL-SOTs in the *z*-direction, H_z^{FL} which are perpendicular to current direction, when in-plane current flows in Hall-bar devices with Hf|CoFeB(wedge)|(TaO_x or MgO) material stacks. The results show that although this new H_z^{FL} is observed in MgO-capped samples, a very weak H_z^{FL} is seen in TaO_x-capped samples. The maximum effective FL-SOT, defined as H_z^{FL} per current density, i.e. $\beta_z = H_z^{FL}/J$, were found to be 18.2 Oe/10^7 and 0.8 Oe/10^7 Acm^{-2} for MgO and TaO_x-capped samples, respectively. Depending on the magnitude of H_z^{FL}, we observed zero field magnetic switching with in-plane charge currents in the MgO-capped sample. However, an external magnetic field is necessary to switch the magnetization via in-plane electric current in the TaO_x-capped sample due to the small H_z^{FL}. These results indicate that the top interface between the ferromagnetic and oxide layers affects the generated H_z^{FL} torque significantly, and hence a simplified picture based solely on the choice of the bottom metal layer would not be sufficient to understand the switching behavior of these SOT devices. This is consistent with earlier reported results, which showed that the conventional damping-like and field-like SOTs are also stronger in MgO-capped samples compared to those in TaO_x-capped samples[5]. These new insights are important for the design of magnetic random access memory (MRAM) devices based on SOT switching.

Th.I.2_O2 - Chiral-based spin devices without a permanent magnet

O. Ben Dor [1], Y. Paltiel [1]

1. The Hebrew University of Jerusalem, Jerusalem, Israel

As technology shrinks down in size nano-structures are likely to become primary components of future electronic devices. One such revolution would merge spintronics with standard Si-based technologies. Spintronics, or spin electronics, refers to the role played by electron spin in solid state physics, and to devices that specifically exploit spin properties instead of charge degrees of freedom. This yields a decrease in the device power consumption, an increase in the devices effective speed and allows higher densities. A new phenomenon, called the Chiral Induced Spin-Selectivity effect has become the basis of spin control and manipulation, where organic chiral self-assembled monolayer acts as an efficient spin filter. We are utilizing this phenomenon to achieve high density, low power, Si compatible logic devices. For example, a proof of concept for a new type of chiral-based memory device, without a permanent magnet was realized, whereas vertical spin torque is transferred into a thin ferromagnetic film thus decreasing the required current density in comparison with standard out of plane torque transfer [Nature communications doi:10.1038/ncomms3256]. We also show that local magnetization can be achieved optically. In this work, using chiral molecules and nano crystals, we achieve local spin-based magnetization generated optically at ambient temperatures [Nano Letters DOI: 10.1021/nl502391t]. Through the chiral layer, a spin torque can be transferred without permanent charge transfer from the nano crystals to a thin ferromagnetic layer, creating local perpendicular magnetization. We used Hall sensor configuration and Magnetic Atomic Force Microscopy to measure the induced local magnetization. At low temperatures, anomalous spin Hall effects were measured using a thin Ni layer. The results may lead to Si compatible electrically/optically controlled spintronics logic devices that will enable low power consumption, high density, and cheap fabrication.

Th.I.2_O3 - Spin current conversion in Bi thin films

Spin conversion physics in Bi has been attracting strong attention, since Bi essentially possesses a strongly spin-orbit interaction and an efficiency of the conversion between a pure spin current to a charge current, such as the inverse spin Hall effect (ISHE) can be large [1]. Recently, detection of the inverse Rashba-Edelstein effect (IREE) in Ag/Bi was reported and this new spin current conversion mechanism in Bi is one of the hottest issues in physics of Bi [2,3]. From this motivation, we have investigated interplay between the ISHE and the IREE in Bi on YIG, the magnetic insulator, where a strong Rashba field can be expected at the interface. Spin current was dynamically injected from the YIG into the Bi, and an electromotive force was detected from the Bi. Since the electric current induced by the spin conversion in the Bi exhibited obvious thickness dependence of the Bi, only the ISHE took place in the Bi, i.e., the IREE was missing in the Bi/YIG [4]. Hall measurements of the Bi indicate that electrons are majority carriers, whereas both electrons and holes exist in the Bi, and the polarity of the ISHE is consistent with this result. The spin relaxation mechanism in the Bi was clarified to be the D'yakonove-Perel type from the weak anti-localization measurements and conductivity dependence of the spin-orbit length. The detail of the study is introduced in the presentation.

Being able to create, manipulate and detect pure spin currents is one of the main challenges in the field of spintronics. One of the most promising approaches to generate and detect these currents is by using the spin Hall effect (SHE) and its inverse [1]. These phenomena allow a charge-to-spin current conversion (and its inverse) in a non-magnetic metal with a high spin-orbit coupling. The origin of the effect can be attributed to different intrinsic and extrinsic contributions, although the driving mechanism is still unclear for some materials. In this work, we have studied the spin-to-charge current conversion in platinum (Pt), gold (Au) and bismuth (Bi) using the spin absorption technique in a lateral spin valve geometry. With this technique, we can measure the spin Hall angle (the efficiency to convert spin into charge current) in Pt and Au. Moreover, its evolution with temperature allows us to identify the dominant scattering mechanisms behind the SHE. We have observed that, whereas the intrinsic mechanism dominates in Pt, extrinsic effects are more relevant in Au, including a previously ignored phonon contribution to skew scattering [2]. The spin-to-charge current conversion in Bi is more intriguing: in this case, we observe that spin currents are strongly absorbed at the metallic-Bi surface, creating a 2D charge current due to the inverse Rashba-Edelstein effect (IREE). By analyzing the IREE as a function of temperature, we are able to determine the origin of the effect, which arises from the spin-splitting of the bulk states due to the Rashba effect at the metallic-Bi surface [3].

Th.I.2_O5 - Towards the control of the sign of spin Hall effect in the Cu alloys doped with 5d elements

Z. Xu [1], B. Gu [1], M. Mori [1], T. Ziman [2], S. Maekawa [1,3]

The spin Hall effect (SHE), which converts the injected longitudinal charge current into the transverse spin current via the spin-orbit interaction, is crucial for the development of spintronic devices. The sign of the spin Hall angle (SHA) describes the direction of the induced transverse current. We perform a systematical analysis of the SHE in the dilute Cu alloys doped with a series of 5d elements, by the combined approach of density functional theory and Hartree-Fock approximation. We find out that not only the spin orbit interactions (SOI) in the 5d orbitals, but also the SOI in the 6p orbitals and the local correlations effects in the 5d orbitals of the impurities, are decisive to the sign of the SHA. Including all of these factors properly, we predict the sign of SHA for each alloy in the series, different from the previous theoretical calculations [1,2]. A positive SHA is obtained for CuIr alloys [3,4], which is consistent with experiment [5], while negative SHA are obtained for several alloys including CuOs and CuRe. Furthermore, we analyze the possibility to control the sign of SHA among the Cu alloys doped with 5d elements.

Th.I.2_O6 - Evidence of magnonic charge pumping in single layers of permalloy

A. Azevedo [1], R. Cunha [1], F. Estrada [1,3], O. Alves-Santos [1], J. Mendes [1], L. Vilela-Leão [1], R. Rodríguez-Suárez [1,2], S. Rezende [2]

The generation of a DC voltage in single layers of Permalloy (Py=$Ni_{81}Fe_{19}$) when the magnetization is undergoing ferromagnetic resonance has been recently reported by few groups [1,2]. This phenomenon needs to be well understood because it affects the electrical measurements of the spin pumping voltage in ferromagnet/non-magnetic (FM/NM) metallic bilayers. In order to understand further the origin of the DC voltage generated in single layer of Py we investigated the angular dependence of the voltage for a series of films varying the thickness as described above. As well known in spin pumping experiments using bilayers of FM/NM, the voltage measured along the NM layer can be interpreted as a superposition of the spin pumping contribution (VSP) and the anisotropic magnetoresistance contribution (VAMR). In a previous paper we showed[3] that depending on the angular position, VAMR has symmetric and antisymmetric components in field scan, whereas VSP has only a symmetric component. Here we show that the in-plane dependence of both symmetric and antisymmetric signals cannot be explained as due to galvanomagnetic effects only. The results are well explained by a model that takes into account the addition to the anisotropic magnetoresistance signal the contribution of the recent discovered effect of magnonic charge pumping (MCP)[4] that converts magnetization dynamics into charge current by means of the spin orbit coupling. In our films we have shown that the perpendicular anisotropy field that arises as due to the symmetry breaking at the surface of the films can support the origin of the MCP effect. Research supported in Brazil by the agencies CNPq, CAPES, FINEP and FACEPE, in México by CONACYT and in Chile by the FONDECYT No. 1130705.

Th.I.3_O1 - Self-assembled magnetic nanodot arrays growing on diblock copolymer templates: An in-situ study combining GISAXS and NRS.

D.Erb [2], K. Schlage [1], R. Röhlsberger [1]

1. Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany
2. University of Hamburg. Hamburg, Germany

Large-area nanopatterning via self-assembly has gained considerable interest as an alternative to lithography-based techniques for nanostructure fabrication. We propose a routine for preparing highly ordered metallic nanostructure arrays using exclusively self-assembly processes. Further, we present in-situ structural and magnetic investigations of Fe nanodot arrays during formation by means of synchrotron-based resonant and non-resonant x-ray scattering techniques.
Periodically nanofaceted substrates are produced by high-temperature annealing of M-plane α-Al_2O_3 (sapphire). These substrates provide a preferential direction for the microphase separation of diblock copolymer thin films into surface-perpendicular chemical nanodomains. This results in templates with a periodic chemical surface patterning with a high degree of lateral long-range order [1]. Certain metals such as iron exhibit a pronounced selectivity for one of the copolymer blocks, and will only wet the corresponding template domains during sputter deposition [2]. Thus, the regular chemical surface pattern is translated into a highly ordered array of uniform three-dimensional metallic nanostructures [3].
This bottom-up preparation routine allows for in-situ investigation of structural and magnetic properties of the highly ordered metallic nanostructures during formation by Grazing Incidence Small Angle X-ray Scattering (GISAXS) and Nuclear Resonant Scattering (NRS): For Fe nanodots growing on diblock copolymer templates, in-situ GISAXS data provide the lateral arrangement of the nanodots and the development of their size and shape during Fe deposition. In-situ NRS yields quantitative information on the evolution of magnetic moment dynamics during nanostructure growth. We observe a phase transition from isotropic superparamagnetic fluctuations of the magnetic moments to anisotropic fluctuations with a frequency in the MHz regime. By combining GISAXS and NRS in an in-situ experiment it is thus possible to relate the stage of nanostructure growth to the magnetic state of the nanostructure array. [3]

The understanding how the patterning affects the magnetic phenomena is an important topic for magnetic recording media, sensors and actuators built as nanostructures on patterned substrates. This work presents magnetic behaviour of antidots and dots of Co/Pd thin films, which are suitable materials for high density magnetic recording. Periodic arrays of magnetic nanostructures have been fabricated by depositing Co/Pd multilayers on polystyrene masks prepared on Si wafers. This approach led to highly ordered magnetic arrays of antidots/dots with periods from 200 nm to 800 nm. Change of the preparation conditions allowed to obtain arrays of separated magnetic islands as well as arrays of antidotes with adjustable sizes. Flat, continuous films were simultaneously prepared on Si substrates as reference samples. The magnetic properties and magnetization switching exhibited strong dependence on the island and antidot size and separation distance. The easy axis of magnetization for all samples was normal to the sample plane. The perpendicular coercivity increased with the increase of antidot size, reaching maximum at 3000 Oe for the antidot size of around 80% of the period, and then diminished to the value of 800 Oe characteristic for flat films. The change was more pronounced at low temperatures and it is related to modification of magnetic domain sizes and shapes observed by MFM. For narrow range of nanostructure sizes, the samples have revealed interesting behaviour, in which a morphologically antidot array behaves magnetically as an array of isolated dots. Additionally, field cooling measurements demonstrated significant amount of paramagnetic phase, which can be associated with magnetic dead phase appearing on the edge of nanostructures. The influence of samples morphology on coercivity and magnetization switching characteristics was also confirmed by the micromagnetic modelling, showing similar trend of magnetic properties changes with size and separation of the nanostructures.

Th.I.3_O3 - Anisotropy and dipolar interactions in an ultra-dense array of single-crystalline cobalt nanowires

T. Blon [1], N. Liakakos [1], C. Achkar [1], I. Camara [2], M. Bailleul [2], V. Pierron-Bohnes [2], Y. Henry [2], B. Chaudret [1], M. Respaud [1], K. Soulantica [1]

1. Laboratoire de Physique et Chimie des Nano-objets, INSA, Toulouse, France
2. IPCMS, UMR7504 CNRS-Université de Strasbourg, Strasbourg, France

Up to now, ferromagnetic nanowires (NWs) were mainly synthesized by electrodeposition of metals in nanoporous templates resulting in polycrystalline NWs of relatively large diameters and packed at moderate densities. Recently, we reported the epitaxial solution growth of single-crystalline hcp Co nanowires of 6 nm in diameter. Without any template, they grow vertically on a un-patterned Pt(111) film and are spontaneously arranged in hexagonal arrays of 1012 NWs/cm2 [1]. These properties confer a high interest of this system in future ultrahigh magnetic recording. We present here a detailed magnetic study of such a Co NW array in terms of coercivity, dipolar interactions and magnetocrystalline anisotropy. Despite important dipolar interactions, a high perpendicular anisotropy is obtained due to the combination of the magnetocrystalline and shape anisotropies which both act along the wire axis: at 300 K, the anisotropy is Keff = 2.4Î105 J/m3 with a coercive field Á0Hc = 0.35 T. This coercive field reaches 0.62 T at 4 K, without any Co/Co oxide exchange bias effect. This demonstrates that the NWs are intrinsically oxygen free Co nano-objects. Contrary to electrodeposited nanowires, the measured temperature dependence of Hc cannot be explained by the Stoner-Wohlfarth/Néel-Brown model. On the other hand, the angular dependence of Hc suggests a coherent rotation of the magnetization. The easy axis hysteresis loops are sheared due to dipolar interactions. We demonstrated that the M(H) slope at Hc is related to the packing fraction P=0.38 of the NW array. Also, ferromagnetic nuclear resonance measurements indicate a shift in the Co spectra related to the dipolar field and packing fraction. In an alternative approach to understanding the anisotropy, we used ferromagnetic resonance and magnetic torque measurements. Both underline the important dipolar interactions and reveal a magnetocrystalline anisotropy larger than expected suggesting the presence of a surface anisotropy.

4. Institute of Physics, Universität Basel, Switzerland
5. CIC nanoGUNE, Gipúzcoa, Spain

We present a new method for designing low-cost densely-packed magnetic particle assemblies on 2D curved substrates with perpendicular magnetic anisotropy (PMA) [1]. This process involves the growth of magnetic nanocaps on the back of nanoporous anodic alumina templates (AAO), which is a typical self-ordered nanopore-array material formed by the electrochemical oxidation of Al in acidic solutions. As a proof of concept, we have studied a hexagonally close-packed array of $[Co(0.4nm)/Pt(0.7nm)]_4$ nanocaps deposited on bumps having about 100 nm and 50nm lateral modulation period. During the talk, we will present a carefull study of the magnetization reversal mechanisms in such assembly of Co/Pt nanobumps. Using Extraordinary Hall Effect (EHE) and SQUID-VSM measurements, we will provide macroscopic characterization of reversal mechanisms in terms of the switching fields and switching field distribution (SFD) as a function of field angle and temperature [2]. Then bump-by-bump magnetization reversal mechanism will be proved by high-resolution magnetic force microscopy under magnetic field [2]. The role of inter-bump exchange coupling and dipolar coupling are enlightened. We will show that the magnetic hysteresis loops from flat films and bumpy films are very different because of reduction of direct exchange coupling between bumps and because of the triangular lattice. Then we will focus on isolating the origins of switching field distribution (SFD) in this system, namely dipolar interactions, intrinsic anisotropy distribution and template packing faults [2]. Finally we will further discuss the influence of triangular dipolar frustrations on the energy stability of demagnetized and half-switched states based on an Ising model including local exchange coupling, as well as the impact of intrinsic SFD and lattice defects [2].

TH.I.3_O5 - Magnetotransport in La(2/3)Ca(1/3)MnO(3) thin films with on-surface deposited Py nanostructures

W. Yanez [1], V. Vlaminck [1], J. Hoffman [2], A. Hoffmann [2], D. Niebieskikwiat [1]

1. Universidad San Francisco de Quito, Quito, Ecuador
2. Argonne National Laboratory, Argonne, United States

We study the magnetotransport properties of thin films of La(2/3)Ca(1/3)MnO(3) with Permalloy (Py) nanodots deposited on the film surface, as a function of temperature, magnetic field and the size of the nanodots (100 and 200nm). Results of electrical resistivity show that there is a local proximity effect of the Py nanodots on the manganite film, associated to an interface exchange interaction. To some extent, this effect can be regarded as an applied magnetic field, i.e. electrical resistivity is reduced and the insulator-to-metal transition is shifted to higher temperatures.

Th.J.1_I1 - Advances in Magnetic Structure Determination. Instruments and Methods

J. Rodriguez-Carvajal [1]

1. Institut Laue-Langevin, Grenoble, France

Magnetic Crystallography concerns the description and determination of the magnetization density in solids. A magnetic structure is a particular spatial arrangement of magnetic moments setting up below the ordering temperature. The determination of magnetic structures is mainly done using neutron diffraction (powder and single crystals) and in special cases the use of polarized neutrons is necessary to solve ambiguities in the interpretation of neutron diffraction data. The importance of magnetic structures for understanding the electronic and magnetic properties of condensed matter is testified by the huge number and impact of scientific papers appearing from the beginning of the nineties concerned with spin ordering in superconductors, giant magnetoresistance compounds, frustrated magnets and multiferroics. The symmetry properties of magnetic structures are traditionally described using two different approaches: the magnetic Shubnikov groups [1] and the group representation analysis [2-3]. Contrary to the major part of periodic arrangement of atoms, many magnetic structures are non-commensurate: the periodicity of the magnetic moments is not commensurate with the underlying crystal structure; this is one of the reasons why the representation approach is presently dominant. In this talk we shall describe briefly how these approaches work and the advantages of the new trend towards the use of magnetic superspace groups [4]. A review of the most important methods in magnetic neutron scattering as well as in the symmetry concepts will be presented. The current analytical tools and methods for determining magnetic structures and their symmetry will briefly be described.

Th.J.1_O2 - A case study in magnetic pair distribution function (mPDF) analysis: local magnetic structure of MnO

B. Frandsen [1], S. Billinge [2,3]

The magnetic pair distribution function (mPDF) has recently been introduced as a method for quantitatively investigating local magnetic structure through neutron total scattering measurements. In analogy with the more familiar atomic pair distribution function (PDF), this technique involves Fourier transforming Bragg and diffuse scattering to access both short- and long-range correlations directly in real space, providing a highly intuitive view into the local magnetic structure of a material. Here, we present neutron total scattering measurements of the canonical antiferromagnet MnO as the first experimental demonstration of this new technique. Our analysis successfully recovers the known antiferromagnetic structure of MnO, thus verifying the recently derived mPDF equations. Combined atomic and magnetic PDF refinements suggest a local monoclinic distortion at low temperature with a preferred spin axis along the pseudocubic [11-2] direction. We have also conducted temperature-dependent measurements to investigate quantitatively the temperature evolution of the magnetic correlations in this material, including the short-range correlations that persist well above the Neel temperature. The successful application of the mPDF technique to MnO is a promising development and suggests that this technique can be a valuable tool for studying local magnetic structure in a wide class of materials.

Th.J.1_O3 - Magnetic behavior of a $Mn_{0.85}Co_{0.15}WO_4$ multiferroic crystal investigated by Resonant magnetic x-ray scattering

J. Herrero-Martín [1,2], A.N. Dobrynin [3], C. Mazzoli [4], P. Steadman [3], P. Bencok [3], R. Fan [3], A.A. Mukhin [5], V. Skumryev [6,7], J. L. García-Muñoz [2]

Magnetically frustrated $MnWO_4$ (Hübnerite) and the $(Mn,Co)WO_4$ extended family are considered reference models where to study the mutual interaction between spins and polar orders and to investigate the magnetic control of the electric polarization. In Mn1-xCoxWO4 improper multiferroics (MFs) Co favors a strong competition between its magnetocrystalline anisotropy (McA) and the Mn-Mn exchange interactions, stabilizes the ferroelectric (FE) behavior of MnWO4 and produces an extraordinarily rich T-x phase diagram with a large number of different FE phases and magnetic structures. This family of MFs is intrinsically inhomogeneous since the two different magnetic ions (Mn and Co) occupy the same crystallographic position. In this work we investigate the precise magnetic behavior of a MF crystal of the critical composition $Mn_{0.85}Co_{0.15}WO_4$ above its FE transition. Resonant x-ray magnetic scattering (RXMS) experiments have allowed us to study the collinear AF4 phase of $Mn_{0.85}Co_{0.15}WO_4$ beyond the average description provided by neutron diffraction. Thanks to RXMS chemical selectivity we have observed that Co moments arrange antiferromagnetically following their own strong uniaxial McA, although the collinear order of Mn spins point to a different direction. This implies intrinsic remarkable deviations of the spin arrangement at local scale from the description extracted from neutron data. These element-resolved magnetic results call for reexamining the phase diagram of this model family of MFs beyond the average descriptions previously used.

Th.J.1_O4 - Disentangling the spin and orbital moments in the heavy fermion system $CeRu_2Al_{10}$ using polarised x-rays

P. Dean [1], P. Hatton [1], A. Dobrynin [2], T. Takabatake [3], Y. Muro [3]

1. Department of Physics, Durham University, United Kingdom
2. Diamond Light Source, Harwell Science and Innovation Campus, Didcot, Oxfordshire, United Kingdom
3. Institute for Advanced Materials Research, Hiroshima University, Hiroshima, Japan

Non-resonant magnetic x-ray scattering (NRMXS) is a technique that is sensitive to both the orbital and spin magnetic moments of a system, however NRMXS is very weak so very high quality crystals are required. NRXMS can be used to determine the ratio of spin and orbital moments[1][2]. Resonant x-ray scattering (RXS), taking advantage of the polarisation dependence of magnetic scattering and can be used to determine complex spin (spin-orbit coupled J moment) structures in systems as it is highly directionally sensitive and small spin cantings can be measured and quantified. RXS has the advantage of element selectivity as well as a many-fold increase in the observed signal[3][4][5]. By combining these two techniques a number of other parameters can be determined as well as the spin-orbit ratio we can now experimentally verify the sign of the spin-orbit coupling. We are also able to determine a spin and orbital magnetic structures. We have studied $CeRu_2Al_{10}$ that has a complex cagelike structure surrounding the cerium atoms with large bond distances. From the Ce-Ce separation the magnetic transition temperature (as predicted by the RKKY interaction) is expected to be around 2 K, in reality transitions are observed close to 30 K[6]. $CeRu_2Al_{10}$ is a Kondo semiconducting heavy fermion system, which displays similar properties in its phase transitions to those of the hidden order transition in the heavy fermion superconductor URu_2Si_2[7][8]. Many systems studied to date using NRMXS have been 3d transition metal oxide perovskite structures in which the orbital moment is quenched by the crystalline electric field. In CeRu2Al10 the cerium orbital moment is expected to be largely unquenched as the nearest neighbors are separated by >3Å so any crystal field quenching will be minimal this is compounded by the fact that the magnetism is contained within the highly localized f-orbitals which are screened by the outer electrons.

Th.J.1_O5 - First-principles molecular spin dynamics study on the magnetic structure of mn-based alloys with Cu_3Au-type crystal structure

T. Uchida [1], N. Kimura [1], Y. Kakehashi [2]

1. Hokkaido University of Science, Hokkaido, Japan
2. University of the Ryukyus, Okinawa, Japan

The Mn-based ordered alloys Mn3X (X=Pt, Rh, Ir) with a Cu_3Au-type crystal structure are known as three-dimensional frustrated itinerant magnets in which anti-ferromagnetic Mn local magnetic moments form an octahedron. Neutron diffraction experiments suggest that below the Neel temperature Mn_3Rh and Mn_3Ir exhibit a single ordered phase: triangular magnetic structure, while Mn_3Pt exhibits two ordered phases: triangular magnetic structure for $T < 400K$ and collinear antiferromagnetic structure for $400K < T < 475K$, the latter phase accompanying tetragonal distortion with volume expansion. The physical origin of their magnetic structure has not been clarified yet. In order to understand the magnetic structure from the theoretical point of view, we have investigated the magnetic structure by means of the first-principles Molecular Spin Dynamics (MSD) method [1,2]. The theory is based on the first-principles TB-LMTO Hamiltonian combined with the functional integral method and the isothermal MSD technique, and allows us to determine automatically the magnetic structures of itinerant magnets at finite temperatures. In the present analysis, we have adopted 4*4*4 Cu_3Au unit cells for MSD calculations, and fixed the volume to their room-temperature values. Numerical results at 25 K for Mn3X (X=Pt, Rh, Ir) show triangular magnetic structure, being consistent with experiment. With increasing temperature from 25 K, Mn_3Pt exhibits first-order transition to a low-moment phase around 350K accompanying the development of Mn-Eg DOS peak at Fermi energy, while Mn_3Rh and Mn_3Ir show no such transition below the Neel temperature. We present detailed results of analysis of the magnetic structure by means of the MSD using site-dependent effective medium.

Th.J.2_I1 - On the dual fermion approach to charge order, spin frustration, and transport

S. Kirchner[1]

1. Center For Correlated Matter, Zhejiang University, Hangzhou, China

Self-consistent dynamical approximations for strongly correlated fermion systems are particularly successful in capturing the dynamical competition of local correlations. In these, the effect of spatially extended degrees of freedom is usually only taken into account in a mean field fashion or as a secondary effect. As a result, critical exponents associated with phase transitions of the model have mean field character. Here, we demonstrate that a particular diagrammatic multi¡scale method, the dual fermion method[1], anchored around local approximations are indeed capable of capturing the non mean¡field nature of the critical point of the lattice model and to correctly describe the transition to mean field like behavior as the number of spatial dimensions increases [2]. In spin models with frustrated interactions, relevant to a wide range of materials, e.g. the charge-transfer salts, the layered cobaltates, the delafossites, this approach is able to capture the dynamic interplay between electronic correlation and geometric frustration [3]. The dual fermion method can be extended to tackle systems far from equilibrium and has recently been used to interpret nonlinear transport data in strongly correlated nanostructures[4,5]. Strongly correlated electron systems, dynamical mean field theory and its extensions, dual fermions.

Th.J.2_O2 - Colossal thermopower deep inside the SDW state of $(TMTSF)_2PF_6$

Y. Machida [1], X. Lin [3], K. Izawa [1], W. Kang [2], K. Behnia [3]

1. Tokyo Institute of Technology, Tokyo, Japan
2. Ewha Womans University, Seoul, Republic of Korea
3. ESPCI, Paris, France

We present a study of low-temperature Seebeck coefficient of $(TMTSF)_2PF_6$, the first pressure-induced organic superconductor. At ambient pressure, the system undergoes a Spin-Density-Wave transition at T_{SDW} ~ 12 K. In the ordered state, the opening of the gap leads to an activated electric conductivity and a large thermoelectric response. Below 1K, the resistivity saturates in the Variable Range Hopping (VRH) regime. By extending for the first time the Seebeck coefficient measurements below 1K, we uncovered an extraordinary large thermoelectric response in the VRH regime. The Seebeck coefficient was found to attain the colossal value of S ~ -40 mV/K. This is by far the largest Seebeck coefficient reported in any system in this temperature range and points to an unidentified source of entropy available to hopping electrons not seen in other semiconductors.

Th.J.2_O4 - Determination of the sign of the Dzyaloshinskii-Moriya interaction in crystals

Andrei Rogalev [1], V. E. Dmitrienko [2], F. de Bergevin [1], E. N. Ovchinnikova [3], F. Wilhelm [1], J. Kokubun [4]

1. ESRF, Grenoble, France
2. Institute of Crystallography, Moscow, Russia
3. Moscow State University, Moscow, Russia
4. Tokyo University of Science, Tokyo, Japan

Dzyaloshinskii-Moriya (DM) interaction, which is characterized by the so-called DM vector, is the key element in the physics of multiferroics, that's why so many efforts are devoted to its theoretical and experimental studies. However, the value and the sign of DM vector are not determined by symmetry and depend on details of magnetic and electronic structures. There were very sophisticated ab-initio calculations of the DM vector [1] but they are still waiting for experimental proof. Recently it was shown [2] that the DM sign could be deduced from resonant X-ray scattering experiment but interpretation relies on results of very sophisticated calculations. Another method using X-ray diffraction was recently suggested [3] to measure the sign of the DM vector in crystals. It is based on the interference between non-resonant magnetic scattering and multiple wave diffraction (which acts as a reference wave) which makes this approach model independent. However to make the interference observable one has to use circularly polarized X-rays at photon energies chosen to be far from an absorption edge. We have applied this new technique to a hematite Fe_2O_3 single crystal in which absence of local inversion symmetry gives rise to DM interaction which in turn leads to a small canting of Fe spin magnetic moments. The obtained experimental results show astonishingly good agreement with those of multiple-wave calculations and allow us to unambiguously determine the sign of the Dzyaloshinskii-Moriya interaction in hematite. The developed technique can be used even for not very perfect crystals.

Th.J.2_O5 - Spin excitons in heavy fermion semi-metals

P. Riseborough [1]

1. Physics Department, Temple University, Philadelphia, United States

Recently, a spin exciton dispersion relation has been observed in the paramagnetic semi-metal $CeFe_2Al_{10}$ via inelastic neutron scattering. The dispersion relation exhibits a characteristic minimum at the same reciprocal lattice vector that characterizes the antiferromagnetic stye of a related compound. This coincidence, suggests that the spin exciton is a signature of pre-critical fluctuations. We investigate a theoretical model which describes a Lifshitz transition between the heavy fermion semi-conducting and the heavy fermion semi-metallic states. We relate the DOS states to the DOS inferred from experiments and investigate the effect of doping on the magnetic states.

Th.J.3_I1 - Anatomy of Dzyaloshinskii-Moriya Interaction at Co/Pt Interfaces

H. Yang [1], A. Thiaville [2], S. Rohart [2], A. Fert [3], M. Chshiev [1]

1. Univ. Grenoble Alpes, INAC-SPINTEC, Grenoble, France; CNRS, SPINTEC, Grenoble, France; And CEA, INAC-SPINTEC, Grenoble, France
2. Laboratoire de Physique des Solides, Univ. Paris-Sud, Orsay , France
3. Unité Mixte de Physique CNRS/Thales, Palaiseau, France and Univ. Paris-Sud, Orsay, France

Dzyaloshinskii-Moriya Interaction (DMI) [1] is recognized recently to play a crucial role at ferromagnetic (FM) and heavy nonmagnetic metals (NM) interfaces to create magnetic skyrmions [2]. DMI also plays an essential role for fast domain wall dynamics driven by spin-orbit torques [3]. Here, we clarify the main features and microscopic mechanisms of DMI in Co/Pt bilayers by ab-initio calculations. We find that the large anticlockwise DMI of the bilayers has a predominant contribution from DMI pair couplings between the spins of interfacial Co layer. This DMI between the interface Co spins is directly related to the change of the SOC energy in the adjacent Pt layer when the Co spin chirality is reversed consistent with Fert-Levy picture [4]. We found next that DMI does not extend significantly into other Co layers and is very weak between the proximity-induced spins in Pt. It was suggested [5] that DMI at FM/NM interfaces is directly related to the proximity induced moment in NM. However, we find the opposite result, i.e. Pt moment reduction slightly increases the DMI [6]. We performed calculations for other bilayers and found DMI of clockwise chirality for Co/Au and Co/Ir interfaces. The finding of opposite chiralities for Pt and Ir when both are below or both above Co leads to the interesting prediction of additive effects and large DMI when Co is between Pt and Ir.

TH.J.3_O2 - Thermodynamic Properties of Pr_1-x$DyxCoO_3$ Perovskite

N.K. Gaur [1], R. Thakur [1]

1. Barkatullah University, Bhopal, Madhya Pradesh, India

The interest in $LaCoO_3$ cobaltates is associated with an occurrence of thermally induced transitions from low-spin (LS) to high-spin (HS) or intermediate-spin (IS) state as well as with a possibility to vary the transport and magnetic properties by heterovalent substitution on the La and/or Co sites. The parent compound lanthanum cobaltate $LaCoO_3$ shows an insulating ground state based on the diamagnetic LS state of Co^{III} ions. At room temperature $LaCoO_3$ and lanthanum gallate $LaGaO_3$ possess rhombohedrally distorted crystal structure of perovskite. The main focus of the present paper is to investigate the effect of isovalent substitution in $LaCoO_3$ of diamagnetic gallium ions Ga^{3+} with a completely filled 3d shell ($3d^{10}$) for paramagnetic ions Co^{3+} with a partially filled 3d shell ($3d^6$) on the elastic and thermal properties formed $LaCo_{1-x}Ga_xO_3$ as promising materials for fabricating membranes and other articles for electronic technology.

The specific heat and thermal expansion coefficient of $LaCo_{1-x}Ga_xO_3$ ($0.01 \leq x \leq 1$) has been studied as a function of temperature ($10K \leq T \leq 1000K$) by means of a Rigid Ion Model (RIM) after modifying its framework to incorporate the van der Waals interactions. In this paper the functional relation between charge and size mismatch and the thermal properties is determined and compared with the available reports. The Debye temperatures obtained from the lattice contributions are found to be in somewhat closer agreement with the available experimental data. The thermal expansion and specific heat values revealed by using MRIM are in closer agreement with the available experimental data for some concentrations (x) of $LaCo_{1-x}Ga_xO_3$. In addition, the results on the bulk modulus (B), cohesive energy (ϕ), molecular force constant (f), Reststrahlen frequency (u_o) and Gruneisen parameter (γ) are also discussed.

Th.J.3_O3 - Stoner Magnetism in an Inversion Layer

D. Golosov [1]

1. Dept. of Physics and the Resnick Institute, Bar-Ilan University, Ramat Gan, Israel

Motivated by recent experimental work on magnetic properties of Si-MOSFETs, we perform a calculation of magnetisation and susceptibility of electrons in an inversion layer, while taking into account the co-ordinate dependence of electron wave function in the direction perpendicular to the plane. It is assumed that the inversion-layer carriers interact via a contact repulsive potential, which is treated at a mean-field level, resulting in a self-consistent change of profile of the wave functions. We find that the results differ significantly from those obtained in the pure 2DEG case (where no provision is made for a quantum motion in the transverse direction). Specifically, the critical value of interaction needed to attain the ferromagnetic (Stoner) instability is decreased, and the Stoner criterion is therefore relaxed. Results are discussed in the context of the available experimental data.

Fr.A.1_I1 - Magnetic Properties of $FeCo_2B$ and the effect of doping by 5d elements

A. Edström [1], M. Werwinski [1], J. Rusz [1], O. Eriksson [1], K.P. Skokov [2], I.A. Radulov [2], S. Ener [2,] M. D. Kuz'min [2], J. Hong [2], M. Fries [2], D.Y. Karpenkov [2], O. Gutfleisch [2], P. Toson [3], J. Fidler [3]

1. Uppsala University, Uppsala, Sweden
2. Technische Universität Darmstadt, Darmstadt, Germany
3. Vienna University of Technology, Wien, Austria

We present a thorough investigation, combining electronic structure theory and experiments, into the magnetic properties of the tetragonal $(FeCo)_2B$ system. This system is interesting e.g. in the context of novel permanent magnet materials due to relatively large magnetocrystalline anisotropy energy (MAE) in a certain range of alloy concentrations. We briefly discuss challenges in obtaining a good description of the alloy from the theory perspective. After obtaining a good understanding of the ternary $(FeCo)_2B$ system, we address the question of how to further improve the MAE of this material. We show, using density functional theory based calculations, that the MAE can be increased substantially by doping small amounts, 2.5-5 at.%, of certain 5d elements on the FeCo site which is then verified in experiments.

Fr.A.1_O2 - Magnetic field effects on reaction-sintering of MnBi

Y. Mitsui [1], K. Abemstsu [1], R.Y. Umetsu [2,] K. Takahashi [2], K. Koyama [1]

1. Graduate School of Science And Engineering, Kagoshima University, Kagoshima, Japan
2. Institute for Materials Research, Tohoku University, Miyagi, Japan

Ferromagnetic compound MnBi has known to have a large magnetic anisotropy above room temperature. It is reported that in-field heat treatment realized the change of phase equilibrium and anisotropic microstructure of Bi-Mn alloy [1,2]. In addition, recently, we found that the solid-state reaction sintering process from Mn + Bi to MnBi was also influenced by magnetic fields [3]. In general, liquid-state sintering is denser than solid-state sintering. Therefore, investigation of magnetic field effects on liquid-state sintering is also necessary for improving the magnetic properties of Bi-Mn alloy. In this study, magnetic field effects on solid-state and liquid-state reaction sintering of MnBi were investigated. Crystal orientation, fraction of the ferromagnetic MnBi phase, and magnetic properties were evaluated by X-ray diffraction and magnetization measurements. It is found that reacted fraction of MnBi were enhanced by the application of magnetic field of 15 T for solid-state sintering. In contract to this, the enhancement of reaction was not observed clearly for liquid-state sintering. The fraction of ferromagnetic MnBi phase synthesized by in-field heat treatment was 80wt.%. Both of in-field solid-state and liquid-state sintered samples realized the highly crystal orientation of MnBi phase along the magnetic field direction. The Lotgering factor of the MnBi phase reached to be ~1. Due to the crystal orientation, anisotropic magnetic properties exhibits for in-field sintered samples. The anisotropy field of the sample was evaluated to be 4 T.

Fr.A.1_O3 - The importance of strong electronic correlations in rare-earth free hard magnets

F. Ronning [1], J. Zhu [1], M.Janoschek [1], R. Rosenberg [2], J. Criginski Cezar [3], E. Bauer [1], C. Batista[1], J.Thompson [1]

1. Los Alamos National Laboratory, United States
2. Advanced Photon Source, Argonne National Laboratory, United States
3. Laboratório Nacional de Luz Síncrotron, Brazil

Correlated electron effects, which are normally underestimated in band-structure calculations, play a crucial role in the development of the orbital component of the magnetic moments in many materials. Because magnetic anisotropy arises from this orbital component, the ability to include correlation effects has profound consequences on our predictive power of the magneto crystalline anisotropy energy (MAE) of strong magnets. We show that incorporating the local effects of electronic correlations with dynamical mean-field theory provides reliable estimates of the orbital moment (measured by XMCD), the mass enhancement (measured by heat capacity), and the MAE of YCo_5 [1]. In addition, due to the importance of electronic correlations on the MAE we argue that one can adopt a 'molecular' type approach to designing new hard magnet materials. One such material we investigate is Fe_3GeTe_2, which despite its low Curie temperature is useful to test design principles. XMCD and heat capacity measurements illustrate that electronic correlations are again effective in producing a large MAE in Fe_3GeTe_2, and suggest additional routes to develop new materials.

4. Institute for Energy Technology, Kjeller, Norway

The increasing demand of permanent magnets has boosted research to reduce the use of rare earths in their production [1]. A number of studies have been carried out to obtain biphasic materials composed of a hard magnetic phase and a soft one, coupled by exchange magnetic interaction. [2, 3] In this work, we have fabricated hybrid isotropic nanocomposites made of Sr-ferrite and ferromagnetic metals. We have used $SrFe_{12}O_{19}$ (Hc=4550 Oe and Ms(2T)=70 emu/g) as hard phase and Fe and FeCo-rich milled nanocrystalline powder (Hc=3-70 Oe, Ms(2T)=150 and 200 emu/g) as soft phase. A high energy ball milling procedure has been developed to obtain a homogeneous dispersion. Structural properties of the individual phases are preserved during milling. No amorphization or decomposition in secondary phases was observed. The average particle size of the soft phase is well above the critical threshold for effective exchange-coupling, nevertheless, magnetic properties were surprisingly improved in the nanocomposite. An enhancement of 27% in maximum energy product was reached as a consequence of 14% increase in remanence value, 17% increase in magnetic saturation and 28% decrease in coercivity. Recoil and DC demagnetization curves were carried out in order to elucidate the nature of the magnetic interactions between hard and soft phases, observing some of the typical features of exchange-spring magnets. For instance, a higher slope was observed in nanocomposites recoil curves as compared with pure Sr-ferrite. Susceptibility values were 2.4-10-4 for $SrFe_{12}O_{19}$ and 4.8 • 10-4 for the hybrid nanocomposite. In addition, the remanence to intrinsic coercitivity ratio was 1.25. Finally, single phase behaviour was confirmed by analysing the switching field from the derivative hysteresis loop at 5K. These results suggest the possibility of improving the magnetic properties in hard-soft composites without the need for average particle sizes of the soft phase below the critical threshold.

Fr.A.1_O5 - Magnetism of ferromagnetic bulk MnBi phases made from MnBi nanoparticles

E. Skoropata [1,2], J. Freeland [3], M. Rowe [2], J. van Lierop [1]

1. University of Manitoba, Winnipeg, Canada
2. Toyota Research Institute of North America, Chicago, United States
3. Argonne National Laboratory, Lemont, United States

Due to MnBi having the unique quality of an increasing magnetic anisotropy with rising temperature, for over fifty years MnBi-based systems have been investigated for fundamental interest, and recently pursued aggressively as a rare-earth replacement in permanent magnet composites. To date, the required low-temperature phase (LTP) has been produced mainly in small quantities using laborious methods such as melt spinning followed by numerous grinding and heating processes. We have developed a novel synthesis for large (gram-scale) quantities of MnBi nanoparticles using a wet chemical method, followed by a single hot press sintering to create bulk MnBi. Hysteresis (M(H)) loops of the as-made MnBi indicated a ferromagnetic phase with a small saturation magnetization and coercivity (MS = 0.084 emu/g and HC = 170 Oe; BHmax = 1x10-3 MGOe at 400 K), and HC(T) which decreased with increasing temperature; a non-LTP ferromagnetic phase. Hot pressing nanoparticles at 150^{o}C to 160^{o}C for 1 to 4 hours resulted in bulk samples with large Hc's having the LTP's requisite positive Hc(T); HC = 11.7 - 15.4 kOe and BHmax = 0.2 - 3.4 MGOe at 400 K. Interestingly, M(H) shapes indicated multiple ferromagnetic phases whose preferential formation resulted from pressing conditions. X-ray absorption spectra over the Mn L3,2 edges showed octahedrally coordinated Mn with clear d5 configuration multiplet features, indicating electron localization. This suggested that a change in stoichiometry or microsctucture, rather than Mn coordination environment, was the source of the changes in the overall magnetism. X-ray magnetic circular dichroism (XMCD) spectra of the as-made MnBi show virtually no detectable signal, indicating a very weak Mn magnetization, while the pressed MnBi samples all exhibited XMCD spectra at 10 K in 25 kOe; results consistent with the substantial improvements to the overall magnetism between as-made and hot pressed systems. Our novel synthesis and processing approach produces high anisotropy LTP MnBi, providing a new and simple route to preparing this highly desirable magnetic material.

Fr.A.2_I1 - Micromagnetics of rare-earth efficient permanent magnets?

T. Schrefl [1, 2, 3, 4, 5]

Through the advance in computer methods classical experiments in permanent magnets can be explained by micromagnetic simulations. We show that the angle dependence of coercivity in hot deformed Nd_2FeB based magnets may be attributed to surface defects with a thickness of 1 nm to 3 nm. The grain size dependence of the coercive field of permanent magnets was found to be a result of local demagnetizing field that cause the nucleation of reversed domains near the edges of the grain. Using micromagnetic simulations we investigate the potential of multiphase nano-structured permanent magnets that show excellent magnetic properties with a reduced rare earth content. Based on micromagnetic simulations we propose a magnet with a grain size of around 100 nm. Each grain has a core-shell structure. The shell with a thickness of around 3 nm to 4 nm is made of $N_2Fe_{14}B$. The core might be a single semi-hard phase made of $(FeCo)_2B$ or a nano-structured mixture of $Nd_2Fe_{14}B$ and FeCo. In the later case an optimal structure consists of about 20 nm sized FeCo cubes embedded in a $Nd_2Fe_{14}B$ matrix whereby the thickness of the matrix phase is 4 nm to 5 nm. We apply non-zero temperature micromagnetic simulations which take into account thermal fluctuations, in order to compute the remanence, the coercivity, and the energy product of different structures. Hard shell ($Nd_2Fe_{14}B$) - single phase core ($(FeCo)_2B$) magnets show an energy product of 225 kJ/m at 450 K. Replacing the core with a nano-structured hard / soft mixture the energy product was calculated to be 380 kJ/m. In this magnet the volume fraction of $Nd_2Fe_{14}B$ was reduced by 40 percent as compared to a single phase $Nd_2Fe_{14}B$ hot deformed magnet. Work supported by MagHEM.

Fr.A.2_O2 - Micromagnetic simulations on the role of grain-boundary phase in Nd2Fe14B magnets

M. Yi [1,2], O. Gutfleisch [1], B. Xu [1]

1. Technische Universität Darmstadt, Hessen, Germany
2. Beihang University (BUAA), Beijing, China

In the fields such as hybrid electric vehicles and wind turbine generators whose maximum operating temperature is typically ~160 oC, the coercive field of Nd-Fe-B magnets is reduced to an unacceptably low value. One way to obtain high coercive field at elevated temperature is to add the heavy rare-earth elements Dy or Tb, however, conventionally at the cost of remanence. Dy and Tb are scare natural resources. This has motivated extensive research on enhancing the coercivity and keeping the remanence while minimizing the Dy or Tb usage. 'Grain boundary diffusion process' (GBDP) has been developed, whereby Dy is considered to diffuse through the grain boundaries and a $(Nd,Dy)_2Fe_{14}B$ shell forms around the $Nd_2Fe_{14}B$ core. The $(Nd,Dy)_2Fe_{14}B$ shell is generally thought as the origin for the enhancement in coercivity, as magnetization reversal is delayed to larger critical opposing field. In this contribution, three-dimensional micromagnetic simulations multigrain model based on experimental observation are performed to investigate the effect of microstructure on the coercivity of Dy-diffused Nd-Fe-B sintered magnets by micromagnetic simulation. In the model, the grain boundary, the triple junction, the $(Nd,Dy)_2Fe_{14}B$ shell, the $Nd_2Fe_{14}B$ core, and the defect region will be considered. The size and properties of these phases are tuned to optimize the effect. It is found that if both the grain boundary and triple junction are non-ferromagnetic, a very thin $(Nd,Dy)_2Fe_{14}B$ shell is enough to remarkably increase the coercivity. The defect region, which is ferromagnetic but with much decreased magnetocrystalline anisotropy, can significantly reduce the coercivity through the nucleation or de-pinning of domain during the reversal process. Moreover, the effect of microstructure on the temperature dependent coercivity is also explored.

Fr.A.2_O3 - Optimization of permanent magnets performance by means of micromagnetic modelling

D. Berkov [1], S. Erokhin [1]

1. General Numerics Research Lab E.V., Jena, Germany

Our new methodology for micromagnetic simulations of magnetic nanocomposites [1] has enabled the in-advance optimization of permanent magnets performance, whereby magnetic characteristics of a magnetic nanocomposite material consisting of two magnetic phases can be predicted before its actual manufacturing. Large magnetization of the “soft” phase material is supposed to be combined with a high coercivity due to the presence of magnetically 'hard' inclusions. Both phases should be exchange coupled in the optimal way to obtain a hysteresis loop with shape close to the rectangular one. Our method allows to study the dependence of macroscopic magnetic properties of such materials on structural and magnetic parameters of their constituting phases. We are able to model systems containing up to ~ 1000 hard grains, including the analysis of a non-trivial magnetization distribution in every grain. This approach leads to a very high statistical reliability of results. In our talk we present results concerning the dependence of hysteresis loops and energy products on magnetic and geometric parameters of nanocomposite materials, in particular, volume fractions of phases, grain shape and sizes, exchange weakening on intergrain boundaries. Our methodology also allows to study nanocomposites containing a considerable amount of pores, which are unavoidable by many production techniques. In particular, we show that both for the volume fraction of the 'soft' phase and the degree of the intergrain exchange weakening there exist optimal values, for which the maximal energy product is achieved. Another important question studied here is the single-domain critical size of magnetically soft grains. Only the 'soft' grains with sizes not exceeding this single-domain limit give significant contribution to the energy product of a magnet made of this material. We present corresponding results for several magnetic materials.

Fr.A.2_O4 - First-principles study of the effect of Cu and NdOx in $Nd_2Fe_{14}B$ magnets

Y. Tatetsu [1], T. Ozaki [2], S. Tsuneyuki [1,2], Y. Gohda [1,3]

1. ESICMM, Department of Physics, The University of Tokyo, Tokyo, Japan
2. Institute for Solid State Physics, The University of Tokyo, Tokyo, Japan
3. Department of Materials Science and Engineering, Tokyo Institute of Technology, Tokyo, Japan

For the development of technologies, such as high performance computers, hybrid cars, etc., strong magnets are needed to enhance those performances. Among them, $Nd_2Fe_{14}B$ is the strongest magnet so far. Recent experimental studies tells us that understanding of interactions between grain boundaries and main phases in Nd-Fe-B magnets might be important in order to know the mechanism of its coercivity and magnetic anisotropy energy (MAE). Until now, improvement of coercivity has been reported because of the existence of Nd oxides (NdOx) with fcc Nd sublattice[1]. Furthermore, the coercivity of Nd-Fe-B magnets are enhanced by the Nd-Cu grain boundary diffusion process[2]. From this study, Cu is supposed to be around the main phases. To clarify the mechanism of the enhancement of the coercivity of Nd-Fe-B magnets, Nd_2-$yCuyFe_{14}B$/NdOx system is a suitable system for the first step calculation by the density functional theory. We calculate this system using the computational code OpenMX[3]. Nd atoms are performed by open core potentials due to the well-localized 4f electrons and for computational costs. First, we calculated $Nd1.75Cu0.25Fe_{14}B$ where one Nd site is substituted for Cu, and found that substituting Nd for Cu at the 4g site is more stable than at the 4f site from the comparison of total energies of these two phases. We determined the metastable structure of NdOx as Nd4O (x = 0.25) with the zinc blend structure, which is in good agreement with the previous research[4]. We will also present how Cu existing at grain boundaries affects to the magnetic moments in bulk compared to $Nd_2Fe_{14}B/Nd_4O$.

Fr.A.2_O5 - Molecular field and CEF single ion calculation of the finite temperature intrinsic magnetic properties of $R_2M_{14}B$ intermetallic compounds (R=rare earth, M= Fe, Co)

M. Ito [1,2], M. Yano [2], N. M. Dempsey [1], D. Givord [1,3]

1. CNRS/Université Grenoble-Alpes, Institut Néel, Grenoble, France
2. Advanced Material Engineering Div., Toyota Motor Corporation
3. Instituto de Fisica, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil

The hard magnetic properties of the "R-M-B" (R=rare earth, M=mainly Fe) magnets derive from the specific intrinsic magnetic properties encountered in the $R_2M_{14}B$ compounds. These are a large magnetization and high magnetocrystalline uniaxial anisotropy occurring at room temperature and above. The reference ternary phase used in these magnets is $Nd_2Fe_{14}B$. However, material optimization very often involves the partial substitution of another R element for Nd and that of Co for Fe. It is of special interest in such cases to be able to predict what will be the impact of a given atom substitution on the values of the magnetization and anisotropy and on their temperature dependence. The properties of all $R_2Fe_{14}B$ compounds across the rare-earth series (lanthanides + Y) have been previously studied as well as those of a number of $R_2Co_{14}B$ compounds. The temperature dependence of the transition metal magnetization may be approximated by a phenomenological expression and the rare-earth magnetism may be described within a model, in which the R-M interactions on the rare-earth sites are treated as a molecular field arising from the M atoms, and the magnetocrystalline anisotropy is attributed to the crystalline electric field acting on single ions. In the present study, this has been applied to the calculation of the magnetic properties of all ternary $R_2Fe_{14}B$ compounds. Good agreement with measurements demonstrates the applicability of the hypotheses made. The model has been extended to the calculation of the magnetic properties of pseudo ternary $(RR')_2(FeCo)_{14}B$ compounds. For compounds of which properties are experimentally known, very good agreement with calculation is obtained. Such calculations may constitute a powerful tool for optimizing the chemical composition of the hard magnetic phase used in real magnets, without the need of systematically studying the experimental magnetic properties of the compounds involved.

Fr.A.3_O1 - Permanent magnet demagnetization process considering the inclination of the demag field

S. Tizianel [1], N. Novello [1]

1. LEE Srl., Milan, Italy

ABSTRACT: Computer simulations of the magnetizing process have been carried out by applying a numerical model to the theory of magnetization for magnetic materials. The numerical model is able to calculate the magnetization/demagnetization of the permanent magnet material according to its B-H curves[1]. This numerical model is combined with an existing finite element method model.

The aim of this work was to develop a tool able to simulate the behavior of an anisotropic sintered permanent magnet during the demagnetization process. The permanent magnet material that has been studied in this work is sintered Nd-Fe-B and it was modeled taking into account an average misalignment angle related to the magnet easy axis [2]. This model also takes into account different demagnetizing filed directions, such as a demagnetizing field perpendicular to the orientation direction. A gaussian distribution of the average misalignment angle in the permanent magnet material is also taken into account as well as its variation. Demag curves have been calculated varying the misalignment angle and the intensity and direction of the external magnetic field. The simulations results are in perfect agreement with the $1/\cos\theta$ law [3]. The model can be applied in many magnetization and magnetic tuning applications.

Multilayer films consisting of exchange-coupled hard and soft magnetic layers have a potential to achieve high energy products and have been studied for permanent magnet applications. Sm17Co85 (at.%) ordered alloy with RT5 structure and Fe65Co35 alloy with bcc structure are typical high Ha and Ms materials, respectively. In order to investigate the basic structural and magnetic properties, it is useful to prepare epitaxial films on single-crystal substrates by employing a molecular beam epitaxy (MBE) system equipped with a reflection high-energy electron diffraction (RHEED) facility. In-situ RHEED can reveal the crystallographic properties of films during formation. In the present study, Sm17Co83/Fe65Co35 multilayer films are prepared on MgO(110) single-crystal substrates at 500 °C by MBE. The film layer structures are [Sm17Co83(x nm)/Fe65Co35(40-x nm)]2/MgO (x = 10-30) and [Sm17Co83(40/n nm)/Fe65Co35(40/n nm)]n/MgO (n = 2-4). The structure and the magnetic properties are investigated by RHEED, XRD, and VSM. 1st Sm-Co/Fe-Co bi-layer grows epitaxially on the substrate in the crystallographic orientation relationship of Sm-Co(1-100)[0001] || Fe-Co(211)[01-1],[0-11] || MgO(110)[001]. The Fe-Co layer consists of two bcc(211) variants whose orientations are rotated around the film normal by 180° each other, while the Sm-Co layer is a single-crystal of RT5 ordered structure with the c-axis lying in the film plane. 2nd Fe-Co layer of bcc(211) orientation also grows epitaxially on the 1st Sm-Co layer. However, 2nd Sm-Co layer formed on the 2nd Fe-Co layer involves amorphous and crystals with structures other than RT5. The crystallographic quality degrades with increasing the repetition number of n. As the Sm-Co layer thickness of x increases, the Hc value increases, whereas the Ms value decreases. On the other hand, the Hc value decreases as the repetition number of n increases. The magnetic properties are delicately influenced not only by the multilayer structure but also by the crystallographic properties of Sm-Co layers.

Fr.A.3_O3 - Magnetization reversal process of Nd-Fe-B sintered magnets observed by magnetic very small angle neutron scattering

There have been strong interests in the mechanism of high coercivity in Nd-Fe-B sintered magnets due to increasing demands for automotive applications. Motors used in hybrid and electric vehicles are operating at high temperature and approximately more than 30% of Nd is substituted with Dy in the current Nd-Fe-B sintered magnets for automotive motor applications to increase the anisotropy field. Since Dy is comparatively rare natural resources with supply risks, a new technology that can increase the coercivity of Nd-Fe-B sintered magnets is strongly desired. Magnetic Small Angle Neutron Scattering (SANS) is very powerful to observe bulk magnetic microstructures of Nd-Fe-B nanocrystalline magnets [1-4]. The length scale of standard SANS instrument is not suitable for sintered magnets, i.e. magnet used for motors and industrial applications, since the grain size of sintered magnets is a few micrometer. The use of Very Small Angle Neutron Scattering (VSANS) is indispensable for sintered magnet. In this study, we performed VSANS experiments for Nd-Fe-B sintered magnet at KWS-3 in FRM-II, Munich, Germany. We observed clear changes in magnetic VSANS patterns for Nd-Fe-B sintered magnet in the q-range of 0.003 ~ 0.03 nm-1 during magnetization reversal process. It is suggested that the change in magnetic microstructure inside the bulk sintered magnet is occurred with the size of 200 ~ 2,000 nm. We also found that there are two different origins for the change in magnetic VSANS intensity. In lower q region, magnetic scattering is mostly affected by macroscopic magnetization. On the other hand in higher q region, magnetic scattering is mostly caused by a formation of magnetic domains. This work was partly supported by the JST under Collaborative Research Based on Industrial Demand High Performance Magnets: Towards Innovative Development of Next Generation Magnets.

Fr.B.1_I1 - Size-induced enhanced magnetoelectric effect in chromium oxide nanoclusters

D. Halley [1], N. Najjari [1], L. Joly [1], B. Doudin [1], Y. Henry [1]

1. CNRS/Université de Strasbourg, Strasbourg, France

Magnetoelectric materials give the opportunity of controlling the magnetic dipole of a device by applying an electric field. This explains the renewed interest for magneto-electrics materials within the field of magnetic memories and spintronics. Nevertheless, the scarcity of the magneto-electric materials and the smallness of the magnetoelectric effects up to now prevent the expected application of these materials. Different ways to enhance the magneto-electric coefficient are therefore investigated: for instance, theoretical predictions of a magneto-electric effect enhancement under strain have recently been put for. We recently showed* a proof of-principle experiment proving that large strains due to nanoscale size reduction are very efficient for increasing magnetoelectric coefficients by orders of magnitude. We studied the archetype magnetoelectric material, Cr_2O_3, which was deposited in the form of epitaxial clusters in a MgO matrix that induces a large epitaxial strain in the clusters. The MgO layer is thin enough to behave as a tunnel barrier: electrons can be injected from a Fe magnetic electrode into the Cr_2O_3 clusters by tunnel effect. This enables us to measure the tunnel magneto-resistance effect and by this way to probe the magnetisation of those nanometric clusters under voltage. This original technique showed that the highly strained clusters exhibit an unprecedented 600% change in magnetization magnitude under 1V applied to the MgO tunnel barrier: this effect is due to the enhancement of the magneto-electric coefficient of three orders of magnitude relative to bulk Cr_20_3. Furthermore, a multiferroic phase, with both permanent magnetic and electric polarizations, is evidenced in those clusters, while bulk Cr_20_3 is antiferromagnetic and paraelectric.

Bulk magnetite presents a characteristic sudden change in the structure and electrical conductivity around 120 K, the so-called Verwey transition [1]. In this work we have focused on the study of this transition in magnetite nanoparticles and its dependence with the particle size. However, magnetite nanoparticles are especially sensitive to oxidation and the resulting stoichiometry changes influence Verwey transition, making difficult to find any relation with the size. In the present work, we have used magnetite nanoparticles biosynthesized by magnetotactic bacteria Magnetospirillum gryphiswaldense. This kind of nanoparticles, also called magnetosomes, are surrounded by a 3-4 nm lipid bilayer and present a high structural and chemical quality with well-determined properties thanks to the highly precise biological control. Aiming to know the dependence between the Verwey temperature and particle size, we have followed and stopped the biomineralization process of these magnetosomes at different times after the bacterial incubation in a medium containing Fe(III)-citrate, performing a time-resolved study [2]. By XAS analysis, we have proved that the stoichiometry of the nanoparticles remains constant for the different stages of the biomineralization process, allowing us to study the relation between the particle size and the Verwey transition. TEM analysis shows a size evolution from 15 nm, in early stages of biomineralization, to 45 ± 3 nm with a narrow size distribution, around 8 nm, at the end of the process. Verwey temperature has been obtained performing zero field cooled - field cooled DC magnetization curve and AC-susceptibility. We have observed an increase in the Verwey temperature from approximately 80 K, for fifteen-nanometer particles, to 107 K at the end of the biomineralization process.

Recently, magnetic nanoparticles (MNPs) have become a subject of intense research in a myriad of different fields, from catalysis and pattern formation to MRI contrast agents and for diagnoses in magnetic biosensors [1,2]. A feature common to both superparamagnetic and ferromagnetic MNPs is the addition of correction factors, which must be included when calculating their magnetisation compared to the expected bulk value. These factors are predominantly explained as accounting for finite size effects; however, the nature of these effects is as yet, unresolved [3]. The anomalous appearance of a ferromagnetic moment in nominally antiferromagnetic nanoparticles has been known about since Néel, but never well understood. We present proof of the core/shell model of magnetism in antiferromagnetic NiO nanoparticles (NP) using neutron diffraction. Nickel oxide nanoparticles were produced in a large quantity by a novel continuous hydrothermal flow synthesis method. The antiferromagnetic nature of the nanoparticles allowed the structural and the magnetic diffraction peaks to be completely separated. Using both the microstructure option in 'Fullprof' microstructure fitting suite and convolution techniques, we determined the NP consisted of an ordered antiferromagnetic core 5.2(2) nm in diameter surrounded by a disordered shell 0.7(2) nm thick. Further magnetic measurements showed that this disordered shell possess a significant polarisable magnetisation, up to a fifth that of pure nickel. They also indicate that two magnetic transitions occur between 400 and 10 K; around 350 K, there is a broad transition from paramagnetic to a form of superparamagnetism, then near 30 K there is a transition to a higher anisotropy state. Differences in field cooled and zero field cooled hysteresis loops were found, though with no evidence of exchange bias effects.

The possibility of tuning the magnetic behaviour of nanostructured 3d transition metal oxides has opened up the path for extensive research activity in the nanoscale world. In this work we report on how the antiferromagnetism of a bulk material can be broken when reducing its size below a given threshold [1]. As antiferromagnetic (AFM) systems need a high degree of symmetry in order to maintain a balanced magnetic structure, the magnetic frustration arising from size reduction is especially pronounced. We have combined the use of neutron diffraction, x-ray absorption spectroscopy and magnetic measurements in order to study the influence of NP diameter reduction on the microstructure and magnetism of NPs composed of materials that are AFM in their bulk forms (NiO, Cr2O3, CuO, MnO). Our findings reveal that size effects such as average undercoordination, bond relaxation and static disorder, induce surface spin frustration, which competes with the expected antiferromagnetism, giving rise to a threshold diameter for the nucleation of the AFM phase. Hence, the magnetic microstructure of the NPs changes from a core(AFM)/shell(spin-glass) morphology to a completely disordered magnetic state below a critical NP diameter. Finally, we have explored the link between the NP morphology and the emergence of the exchange bias effect, which arises as a consequence of the exchange interaction at the interface between two magnetic phases with different anisotropy energies.

Fr.B.1_O5 - Sorption study water contaminants by magnetic nanoparticles: a theoretical approach based on DFT calculations

S. Baltazar [1], M. Salgado [1]

1. Departamento de Física, CEDENNA, Universidad de Santiago de Chile, Santiago de Chile, Chile

The study and application of magnetic iron nanoparticles for cleaning contaminated water have attracted a lot of attention during the last years in several regions around the world. In particular, the mechanism of arsenic and lead sorption from water using iron nanoparticles [1] has become increasingly interesting due to its applications in natural environment. The characterization of the materials, before and after the sorption processes, is considered in order to identify the new structures as a function of pH. In this context, a theoretical approach can be used to identify the interactions between Arsenic compounds and iron oxide nanoparticles performing ab initio calculations based on density functional theory [2] with the VASP package. In this case we considered the DFT+U method suitable for the study of strongly correlated systems such as iron oxides surfaces. In this work we present a theoretical study of the interaction of arsenic complexes in contact with different iron oxide surfaces such as Fe3O4 and FeO, which can be associated to the oxidation states found on iron nanoparticles. A detailed analysis of the structural changes, due to the interaction between arsenic compounds and the surface of magnetite, is presented. In particular electronic and magnetic properties such as charge density and magnetic dipolar momentum are reported as a function of the arsenic sorption process. We acknowledge the support of FONDECYT under grants 11100439, Conicyt Grant 79090022, ICM P10-061-F by Fondo de Innovaci¾n para la Competitividad-Minecon.

The interactions arising at the interface between multilayers from complex oxides with strongly correlated electrons are subject of intense research. A prominent example of these interactions is the coupling between the antagonistic superconducting and ferromagnetic orders. In particular, the phenomena observed in superlattices made of high-T_c cuprate superconductors and ferromagnetic manganites, which comprise electronic and magnetic proximity effects (MPE), are yet to be fully understood. These effects are thought to be closely related to the strong electronic correlations and the intimate coupling between the magnetic, orbital and lattice degrees of freedom. For this reason, the study of these interactions and orders in the angstrom scale, with element specificity and with sensitivity to magnetic, orbital and charge orders is vital.
Here, we study the element specific magnetic depth profiles of $YBa_2Cu_3O_7/La_{0.7}Ca_{0.3}MnO_3$ (YBCO/LCMO) superlattices using Soft X-ray Resonant Magnetic Reflectometry (XRMR). In YBCO/LCMO superlattices, the MPE is characterized by the occurrence of a depleted layer on the manganite side of the interface and a small induced magnetization in the Cu atoms (0.25 μ_B per interfacial Cu ion) [1-3]. Using the element specific depth profiling capability we confirm that the Cu moments reside on the YBCO side and originate from the CuO_2 layer that is located right at the interface. We also show that the suppression of the Mn moment on the LCMO side is only a partial effect with interfacial Mn moments of 0.9 μ_B/Mn as compared to 2.4 μ_B/Mn near the center of the LCMO layer. Finally, our study confirms a strong asymmetry of the MPE, between the YBCO/LCMO and LCMO/YBCO interfaces, that was previously reported from polarized neutron reflectometry measurements.

Fr.B.2_O2 - Study of strong electronic correlations and superconductivity for KFe_2As_2 under pressure and for intercalated FeSe

H. O. Jeschke [1], D. Guterding [1], S. Backes [1], R. Valenti [1]

1. Goethe-Universität Frankfurt, Frankfurt, Germany

We use density functional theory combined with dynamical mean field theory (DFT+DMFT) to study the effect of electronic correlations in KFe_2As_2. We show that at ambient pressure, the Fermi surface that is seen in ARPES experiments can only be obtained if correlations are treated correctly [1]. In the recently discovered collapsed tetragonal phase of KFe_2As_2 at very high pressure, however, electronic correlations play a negligible role [2]. Within a random phase approximation spin-fluctuation approach we calculate the superconducting order parameter in the collapsed tetragonal phase. We suggest that the change of Fermi surface between low and high pressure is consistent with a change of superconducting order parameter from d-wave to s ±. In a study of ammonia intercalated FeSe, we try to separate the effects of dimensionality (3D versus 2D) from the effects of charge doping. Our theory can explain the trends of Tc in this material [3].

Superconductivity in iron pnictides was discovered in 2008 [1] and a lot of effort has been devoted in order to explain their unconventionality. As in other high temperature superconductors (HTSC), magnetism and superconductivity (SC) exhibit proximity, competition and/or coexistence in the phase diagram [2]. This indicates a strong connection between such phases and paved the way for the use of theories explaining SC as arising from magnetic fluctuations [3]. In this context the experimental characterization of static and dynamic magnetism is of vital importance in constraining theoretical models. The NaFe1-xCoxAs series represents a contrasting case with the most studied BaFe2-xCoxAs2 compounds because of their much lower magnetic moment (ca 0.1 uB for NaFeAs vs. ca 1.3 uB for $BaFe_2As_2$) [2,4]. However, the Tc of their Co-doped compounds is pretty similar (21 K at x = 0.025 vs. 22 K at x = 0.2 for NaFe1-xCoxAs and $BaFe_2$-x$CoxAs_2$, respectively [2, 4]). This situation turns out to be extremely interesting in order to elucidate the relation between static magnetic moments and spin fluctuations and eventually with superconductivity. Resonant Inelastic X-ray Scattering (RIXS) has proven to be a powerful spectroscopy for probing high energy spin fluctuations in HTSCs [5, 6, 7]. We present a high resolution Fe L3 RIXS study of parent and superconducting NaFe1-xCoxAs. Spectral shape decomposition reveals the persistence of broad dispersive magnetic excitations for all doping levels. In contrast to previous RIXS experiments on hole-doped $BaFe2As_2$ compounds [6] the energy of such modes is not strongly affected by doping and the magnetic weight per iron atom of such excitations remains constant. However, renormalized per formula unit the magnetic weight decreases with doping. We argue that cobalt-doping is mainly tuning the electronic correlations without affecting the dispersion range of the magnetic excitations, only reducing their spectral weight.

Since 2009, NaFeAs has attracted much attention for its notable superconducting dome upon electron-doping with Co, Cu, and Ni. In 2013, a Mott-insulating state was detected in highly overdoped $NaFe_{1-x}CuxAs$, unlike the metallic state in overdoped $NaFe_{1-x}CoxAs$ and $NaFe_{1-x}NixAs$. An STM investigation by Wang [1] on overdoped $NaFe_{1-x}CuxAs$ found signatures similar to those of underdoped cuprates, which have antiferromagnetic parent compounds. Subsequent magnetic susceptibility measurements of $NaFe_{1-x}CuxAs$ indicate possible static magnetic ordering (SMO) in systems with Cu concentrations exceeding 25%, and recently, Song et al., [2] reported antiferromagnetic order in the 44% system from neutron scattering. We performed muon spin relaxation (MuSR) measurements on single crystals of $NaFe_{1-x}CuxAs$ with x = 6, 15, 25, and 44% at TRIUMF. The asymmetry spectra observed in zero field (ZF-MuSR) revealed SMO in the 15, 25 and 44% systems. The 25% and 44% specimens show sharp transitions at TF ~ 20K and 60K, respectively, below which SMO rapidly develops in the entire volume fraction. The 15% compound possesses a gradual transition starting below 20K, with phase-separated paramagnetic and magnetically ordered volumes. This compound achieves SMO in a volume majority by 2K, with the moment size an order of magnitude smaller than those of the 25 and 44% systems. The 6% compound is paramagnetic down to 2K. The absence of sustained precession signals from ZF-MuSR, together with magnetic susceptibility cusps and history dependences, suggest possible spin-glass-like freezing in the 15, 25, and 44% compounds. Evolution from the Mott insulator to the superconducting dome involving a spin glass intermediary phase is reminiscent of the behavior of high-TC cuprates. The present investigation in NaFe1-xCuxAs demonstrates the first case of a Mott transition in iron-based superconductors.

Fr.B.2_O5 - Successive AF-SC-AF phase transition and the quantum criticality in LaFeAsO1-xHx studied by nuclear magnetic resonance

N. Fujiwara [1], N. Kawaguchi [1], Y. Yamakawa [2], H. Kontani [2], S. Iimura [3], S. Matsuishi [3], H. Hosono[3]

1. Kyoto University, Kyoto, Japan
2. Nagoya University, Nagoya, Japan
3. Tokyo Institute of Technology, Tokyo, Japan

The prototypical iron-based high-Tc superconductors LaFeAsO1-xHx can accept high electron doping, which leads to two novel phenomena in the electronic phase diagram: (i) H doping leads to superconducting (SC) phase with double domes following a stripe-type antiferromagnetic (AF) phase, and (ii) further H doping leads to a second AF ordering [1] following double SC domes. We performed 75As nuclear magnetic resonance in the heavily H-doped regime to investigate the second AF ordering in a microscopic viewpoint and the quantum criticality around the AF phase boundary (x=0.49). We found from the 1H linewidth and relaxation rate, 1/T1 of 75As that the SC phase is segregated from the second AF phase in the electronic phase diagram [2]. In the second AF phase, the relaxation rate divided by temperature, 1/T1T exhibits a SDW-like gap: the gap decreases with decreasing H doping level and becomes almost zero at the AF phase boundary. Furthermore, the doping dependence of 1/T1T exhibits the maximum at the AF phase boundary. These results suggest that the AF phase boundary corresponds to the quantum critical point.

4. TU Dresden, Institute of Theoretical Physics, Dresden, Germany

We present Mössbauer spectroscopy and muon spin relaxation experiments on $Ca_{1-x}Na_xFe_2As_2$ (x = 0.35, 0.50, and 0.67). The parent compound $CaFe_2As_2$ shows spin-density-wave order below T_N = 165 K [1]. The magnetic phase transition is accompanied by a structural transition from a tetragonal to an orthorhombic structure [2]. Increasing the Na amount in $Ca_{1-x}Na_xFe_2As_2$, the magnetostructural phase transition is suppressed [1].
Our microscopic study proves this suppression of the magnetic transition temperature as well as the magnetic order parameter with increasing x. For x = 0.50 we find a microscopic coexistence of magnetic and superconducting phases accompanied by a reduction of the magnetic order parameter below the superconducting transition temperature T_c.
A systematic comparison with other 122 pnictides reveals a linear correlation between the magnetic-order-parameter reduction and the ratio of the transition temperatures, T_C/T_N, which can be understood in the framework of Landau theory.
In the optimally doped specimen with $T_c \approx 34$ K, the temperature dependences of the penetration depth and of the superfluid density were obtained, which prove the presence of two superconducting s-wave gaps.

From a cursory investigation of phase relations in the systems {Th,U}-Pt-B at 900°C we observed the formation of novel compounds $AnPt_3B$ of which $ThPt_3B$ (a=0.4383(2) nm; Pm-3m) is a representative of the perovskites and UPt_3B (a=0.38906(3), c=0.52241(5) nm; P4mm) is isotypic with the non-centrosymmetric structure of CePt3B. Characterization of physical properties for $ThPt_3B$ reveals a superconducting transition at 0.75 K and an upper critical field at T = 0 below 0.6 Tesla. For non-superconducting UPt_3B a metallic resistivity behaviour was found in the entire temperature range. At lowest temperatures, spin fluctuations become evident and non-Fermi liquid features are observed from resistivity data. DFT calculations carried out for both compounds provide information about the electronic and phonic structure of these novel compounds.

Fr.B.3_O2 - Colossal thermoelectric effect due to Berry phase fluctuation in chiral superconductors

S. Fujimoto [1], H. Sumiyoshi [2]

1. Department of Materials Engineering Science, Osaka University, Suita, Japan
2. Department of Physics, Kyoto University, Kyoto, Japan

In chiral superconductors such as Sr_2RuO_4(class D topological superconductor), and URu_2Si_2(Weyl superconductor), Cooper pairs possess nonzero total angular momentum, breaking time-reversal symmetry. The chiral pairings accompanying the nontrivial Berry curvature give rise to exotic transverse transport such as the anomalous thermal Hall effect below the transition temperature Tc. It is naturally expected that even in the superconducting fluctuation regime near but above Tc, anomalous transverse transport may be raised by chiral superconducting fluctuations, which induce the Berry phase fluctuation. Here, we discuss this possibility [1]. We found that in the fluctuation regime above Tc, the anomalous Nernst effects can be raised by dynamical skew-scattering due to chiral superconducting fluctuations. This mechanism is in analogy with the skew-scattering mechanism of the anomalous Hall effect without Lorentz force. However, an important difference is that the skew-scattering due to chiral fluctuations is the dynamical Andreev scattering. Furthermore, this anomalous Nernst effects can be gigantic for cleaner samples. Our scenario successfully explains the recent experimental discovery of the colossal Nernst signal for URu_2Si_2 above T_c, which can not be understood within conventional theories of superconducting fluctuations [2]. We also comment on the application to Sr_2RuO_4,and other topological superconductors with broken time-reversal symmetry.

Fr.B.3_O3 - Quasiparticle interference in chiral superconductors and hidden order phase

P. Thalmeier [1], A. Akbari [2]

1. Max Planck Institute For Chemical Physics of Solids, Dresden, Germany
2. Asia Pacific Center for Theoretical Physics and Department of Physics, POSTECH, Pohang, Gyeongbuk, Republic of Korea

The technique of Bogoliubov quasiparticle interference (QPI) has recently been successfully used to investigate the symmetry of unconventional superconductors, in particular of heavy fermion compounds. It was demonstrated that QPI can distinguish between the d-wave singlet candidates of superconducting $CeCoIn_5$. A similar important system is URu_2Si_2 where presumably a chiral d-wave singlet superconducting (SC) state exists inside a multipolar hidden order (HO) phase. We develop a theory of QPI in the HO and coexisting SC phases using the exact solution of a multiorbital model for the heavy 5f quasiparticle bands. We show that hidden order leaves an imprint on the symmetry of QPI pattern that may be used to determine the essential question whether HO in URu_2Si_2 breaks the in-plane rotational symmetry or not. We also demonstrate that the chiral d-wave SC gap leads to a crossover to a quasi-2D QPI spectrum below Tc which sharpens the HO features. We compare the QPI signature in the HO phase with existing STM experimental results. Furthermore we predict the QPI spectrum for the multiband chiral p-wave triplet superconductor Sr_2RuO_4 [2] which is fully gapped on the active band and has nearly nodal gaps on passive bands. We show that this multigap structure should lead to a characteristic change oft he QPI pattern as function of the bias voltage which can be used to confirm the nodes and minima postitions of the gap structure.

Fr.B.3_O4 - Superconductivity of Icosahedral Yb Approximants with Tsai-type Clusters

K. Deguchi [1], M. Nakayama [1], S. Matsukawa [1], K. Imura [1], K. Tanaka [2], T. Ishimasa [2], N. Sato [1]

1. Department of Physics, Graduate School of Science, Nagoya University, Nagoya, Japan
2. Division of Applied Physics, Graduate School of Engineering, Hokkaido University, Sapporo, Japan

Quasicrystals (QC) have been quoted as the 3rd solid because they possess long-range, quasi-periodic structures with diffraction symmetries forbidden to crystals. Instead of extensive studies on the electronic structure, no long-range magnetic ordering has been observed although there are a few reports on superconductivity. For a periodic approximant crystal (AC), a phase whose composition is close to that of the QC and whose unit cell has atomic decorations similar to those of the QC, there are some reports on ferromagnetic or antiferromagnetic orderings. However, superconductivity has not been discovered thus far to the best of our knowledge.
Recently, a new type of magnetic QC and AC was discovered: the Au-Al-Yb QC exhibits novel quantum critical behaviour as observed in Yb-based heavy fermion materials with intermediate Yb valence, while the Au-Al-Yb AC shows heavy Fermi liquid behaviour. Since the diverging behaviour of the magnetic susceptibility as $T \rightarrow 0$ was only observed in the QC, the quantum critical state might correspond to an electronic state unique to the QCs, a critical state that is neither extended nor localized.
In the course of our research, we investigated Au-Ge-Yb system belongs to the 1/1 AC of a Tsai-type icosahedral QC. We have found two types of the Au-Ge-Yb ACs, which show superconductivity with transition temperatures T_c of 0.68 K and 0.36 K. The Tsai-type cluster center is occupied by Au and Ge ions in the former approximant, and by an Yb ion in the latter. For magnetism, the latter system shows a larger magnetization than the former. We present our low-temperature experiments on the electrical resistivity, magnetization, ac magnetic susceptibility, and specific heat of the Au-Ge-Yb ACs. We also discuss the relationship between magnetism and superconductivity in these new systems.

Fr.C.1_O1 - Topological surface states and double berry monopoles in the heavy fermion superconductor UPt_3

A. Nevidomskyy [1], P. Goswami [2]

1. Department of Physics and Astronomy, Rice University, United States
2. Condensed Matter Theory Center, University of Maryland, United States

The concept of topological states of matter has captured the imagination of physicists in the last decade, with possible applications to quantum computing. Traditionally, such topological phases are predicted to occur in fully gapped insulating or superconducting materials and are characterized by topologically protected gapless excitations on the surface. Here, I will demonstrate a generalization of this concept to metallic materials with gapless bulk excitations, focusing in particular on the B-phase of the heavy fermion superconductor UPt3. Recent phase sensitive measurements provide strong evidence for the triplet, chiral pairing symmetry, which endow the Cooper pairs with orbital angular momentum Lz = ± 2 along the c-axis. Such pairing supports both line and point nodes of the superconducting gap, and both types of nodal quasiparticles possess nontrivial topology in the momentum space. In particular, the point nodes located at the intersections of the closed Fermi surfaces with the c-axis are the double monopoles and anti-monopoles of the Berry curvature (referred to as 'double-Weyl points'). Consequently, we predict that the B phase should support an anomalous thermal Hall effect, various magneto-electric effects such as the polar Kerr effect, in addition to two topologically protected Fermi arcs on the (1,0,0) and (0,1,0) surfaces. The line node at the Fermi surface equator acts as a vortex loop in the momentum space and gives rise to the zero energy, dispersionless Andreev bound states on the (0,0,1) surface. At the transition from the B-phase to the A-phase, the time reversal symmetry is restored, and only the nodal ring survives inside the A-phase.

Fr.C.1_O2 - Superconductivity and antiferromagnetism in the half-Heusler compound HoPdBi

A. Nikitin [1], X. Mao [1,2], Y. Pan [1], Y. Huang [1],B. Yan [3], A. de Visser [1]

1. Van der Waals - Zeeman Institute, University of Amsterdam, Amsterdam, The Netherlands
2. Jimei University, Xiamen, China
3. Max-Planck-Institut für Chemische Physik fester Stoffe, Dresden, Germany

Half-Heusler compounds crystallize in a cubic structure. They attract ample attention because of their flexible electronic structure. Furthermore, electronic band structure calculations show selected half-Heusler compounds have an inverted band order, which makes them candidate topological semimetals or insulators (for a review see Ref. 1). Yet another interesting feature is that selected topological half-Heusler compounds, such as LaPtBi, YPtBi, LuPtBi and LuPdBi [1], are superconductors with Tc ~ 1 K. The band inversion, as well as the non-centrosymmetric crystal structure, is expected to give rise to unconventional superconductivity and theory predicts a mixed-parity Cooper-pair state. Recently, we reported a new member of this family: ErPdBi with a Tc of 1.22 K [2]. Moreover, ErPdBi shows antiferromagnetic order with a NÚel temperature TN = 1.06 K [2]. Here we report superconductivity in the presence of antiferromagnetic order in the related compound HoPdBi. Single crystals were prepared out of Bi flux. Transport measurements show superconductivity occurs below Tc = 1.8 K. The upper critical field, Bc2, has an unusual quasilinear temperature variation and reaches a value of 1 T for T->0. The Ho moments order antiferromagnetically with TN = 2.0 K [3] and the AF phase boundary is located at BM ~ 3.6 T for T->0. Thermal expansion measurements show a pronounced peak at the antiferromagnetic phase transition. Ac-susceptibility measurements indicate a superconducting volume fraction of 30 %, which suggests superconductivity and local-moment magnetism compete. Electronic structure calculations show HoPdBi has a topologically nontrivial band inversion. In the course of this work we learned that the occurrence of antiferromagnetism and superconductivity is a general feature of the rare earth palladium bismuthides [4].

Fr.C.1_O3 - Linear magnetoresistance, weak antilocalization and Shubnikov-de Haas oscillations in the putative topological superconductor LuPdBi

O. Pavlosiuk [1], D. Kaczorowski [1], P. Wisniewski [1]

1. Institute of Low Temperature and Structure Research, Polish Academy of Sciences

We present electronic transport and magnetic properties of single crystals of the half-Heusler phase LuPdBi, having theoretically predicted band inversion requisite for non-trivial topological properties [1]. The compound becomes superconducting below a critical temperature of 1.8 K, with a zero-temperature upper critical field of 2.3 T. Although superconducting transition is clearly reflected in the electrical resistivity and magnetic susceptibility data, no corresponding anomaly can be seen in the specific heat [2,3], alike reported for a few related superconductors: LuPtBi, YPtBi [4-6] and HoPdBi [7]. Temperature dependence of the electrical resistivity suggests existence of two parallel conduction channels: metallic and semiconducting, with the latter making negligible contribution at low temperatures. The magnetoresistance shows a weak antilocalization effect in small magnetic fields. In fields above about 1.5 T, the magnetoresistance becomes linear and does not saturate in fields up to 9 T, where it exceeds 200%. The linear magnetoresistance is observed up to room temperature. Below 10 K, it is accompanied by Shubnikov-de Haas oscillations revealing charge carriers with effective mass of 0.06 me and Berry phase very close to 1/2 expected for Dirac-fermion surface states, thus corroborating topological nature of the material [2].

Fr.C.1_O4 - Discovery of superconductivity in Bi_2Te: evidence of universal behavior in an infinitely adaptive series under compression

R. Stillwell [1], J. Jeffries [1], S. McCall [1], Z. Jenei [1], S. Weir [1], Y. Vohra [2]

1. Lawrence Livermore National Laboratory, Livermore, United States
2. University of Alabama at Birmingham, Alabama, United States

The end members of the infinitely adaptive $(Bi_2)n(Bi_2Te_3)m$ series, Bi and Bi_2Te_3, can be experimentally tuned to display topological surface states or superconductivity under appropriate conditions. An intermediate member of the series, Bi_2Te has been found to superconduct under similar conditions, transitioning from a semiconductor at ambient conditions to a metallic superconductor with a maximum Tc = 9.1 K at 14.5 GPa. This represents a move towards universal behavior in the infinitely adaptive $(Bi_2)n(Bi_2Te_3)m$ series in which all of the superstructures converge into a metallic, superconducting state at high pressure.

Fr.C.1_O5 - Quantum oscillations in high magnetic fields, Berry phase, quantum Hall effect and superconductivity in Cu- doped bismute selenide single crystals

S. I. Vedeneev [1], T. Romanova [1,2], D. Knyazev [1,2], A. Sadakov [1,2]

1. Lebedev Physical Institute of Russian Academy of Science, Moscow, Russia
2. International Laboratory of High Magnetic Fields and Low Temperatures, Wroclaw, Poland

The discovery of a new class of materials 3D topological insulators (TIs) and topological superconductors (TSs) have generated a lot of excitement in condensed matter physics. Bi_2Se_3 attracted particular attention, because the intercalating copper between fivefold layers induces superconductivity below ~ 4 K. The surface electron modes of a TI are arranged in a single Dirac cone - the linear dispersion that describes massless particles. The circulating structure of the spins contributes a Berry's phase of pi to the electronic wave function. Berry phase can be experimentally assessed by analyzing the Landau-level fan diagram of the Shubnikov-de Haas (SdH) oscillations due to the fact that longitudinal resistivity oscillates as $\Delta\rho_{xx} \sim \cos[2\pi(F/B_N)+\beta]$, where - $2\pi\beta$ Berry Phase. Careful study of the π-Berry phase gives one of the key pieces of evidence for the Dirac nature of quasiparticles in TIs. Question about the value of the Berry phase in TI is still open, as there is no unambiguous experimental data in literature. In our experiment we tried to fix the question of the Berry phase value in TIs by means of magnetotransport measurements of high-quality single crystals of Bi_2-x$CuxSe_3$ in high magnetic fields up to 20 T and at temperatures down to 0.3 K. The 2D nature of the SdH oscillations in our samples was confirmed by sample rotation in magnetic field. From our data we assume that 2D SdH oscillations originating from several parallel 2D conducting channels in a Bi_2-x$CuxSe_3$ crystal. Also we show that quantum Hall effect can be observed when effective thickness of the conducting layer is less than fivefold layer in crystal structure. We also present experimental study of superconductivity in $Bi_{2-x}CuxSe_3$ single crystals. We have shown that the superconductivity in this 3D TI is well described by the extended Tinkham model for conventional thin-film superconductor.

Fr.C.1_O6 - Surface damage of SmB_6 through ion-irradiation

N. Wakeham [1], Y. Wang [1], Z. Fisk [2], F. Ronning [1], J. Thompson [1]

1. Los Alamos National Laboratory, New Mexico, United States
2. University of California, Irvine, California, United States

SmB_6 is a Kondo insulator, but there is strong evidence for an intrinsic conductive surface state at low temperatures. Theoretical work indicates that SmB_6 may be a topological Kondo insulator with a topologically protected surface state that is robust against time-reversal invariant perturbations. To investigate this robustness, we have used non-magnetic ion-irradiation to damage the (001) surfaces of SmB_6 single crystals to varying depths, and have measured the resistivity as a function of temperature for each depth of damage. We observe a reduction in the residual resistivity with increasing depth of damage. Our data are consistent with a model in which the surface state is not destroyed by the ion-irradiation, but instead the damaged layer is poorly conducting and the initial surface state is reconstructed below the damage. This behavior is consistent with a surface state that is topologically protected. Investigations of time-reversal symmetry breaking perturbations of the surface layer, with magnetic ion-irradiation, will also be discussed.

Fr.C.2_I1 - Kondo Insulators: magnetism meets topology

P. Coleman [1,2], O. Erten [1]

1. Center For Materials Theory, Dept Physics And Astronomy, Rutgers University, United States
2. Department of Physics, Royal Holloway, University of London, Egham, Surrey, United Kingdom

The electrons in Heavy fermion materials are subject to spin-orbit coupling interactions that greatly exceed their Kinetic energy. It has long been known that the spin orbit coupling stablizes new kinds of heavy fermion metals, superconductors and 'Kondo insulators' against the competing state of magnetism. I will discuss the latest realization that spin orbit coupling can changing the topology of Kondo insulators, sometimes giving rise to Topological Kondo insulators[2,3] with surface Dirac cones. We'll specifically discuss SmB6, a KI discovered 45 years ago, predicted to be topological in 2010[2], and tentatively confirmed to be so in a series of experimental studies of the past year[3,4,5]. I'll discuss a simple model for a topological Kondo insulator and discuss how Kondo breakdown at the surface has the effect of tuning the topological edge states from 'heavy' to 'light'. We'll review the status of the most recent measurements, including tentative spin polarized ARPES[5], de Haas van Alphen[6] and high field measurements that appear to support the idea that this is a strongly interacting topological insulator.

Metals can turn into insulators when correlations become sufficiently strong. This is captured in the Mott-Hubbard model, where onsite Coulomb repulsion leads to the opening of a gap at the Fermi energy for a half-filled band. This insulating state is realised for instance in the parent compounds of cuprate superconductors. Whereas cuprates are turned into metals by controlling the filling via doping, the metallic state may also be recovered by controlling the ratio of Coulomb repulsion and kinetic energy, for instance by applied hydrostatic pressure. In proximity to the metal-insulator-transition the metal is strongly correlated and is expected to have a large Fermi surface comprising the full electron count in accordance with Luttinger's theorem. With the charge carrier count unchanged, the insulating state is predicted to be realised by localisation of electrons via divergent effective mass [1]. Here, we report resistivity and quantum oscillation measurements on the pressure-induced insulator-to-metal transition in the Mott insulator NiS_2. We demonstrate the quality of our single crystals and discuss the phase diagram for our samples. Our x-ray analysis as well as our high-pressure transport studies reveal an exceptionally low level of vacancies and impurities, a common challenge in the synthesis of NiS_2. The high quality of our crystals enabled us to perform quantum oscillation measurements for the first time in the high-pressure metallic phase of a Mott insulator. Our results on NiS_2 are consistent with the large Fermi surface obtained in DFT calculations and suggest a strong mass enhancement. We discuss these results in relation to models of NiS_2 inlcuding band-width controlled, filling controlled, and charge-transfer metal-to-insulator transitions.

Fr.C.2_O3 - Pressure effect on the ferromagnetic-metal to ferromagnetic-insulator transition in $K_2Cr_8O_{16}$

Y. Ueda [1], T. Yamauchi [2]

1. Toyota Physical And Chemical Research Institute, Nagakute, Japan
2. Institute for Solid State Physics, University of Tokyo, Tokyo, Japan

There exists the general relation between magnetism and electronic transport properties that insulating transition metal oxides are typically antiferromagnetic, and ferromagnetism, particularly double-exchange (DE) ferromagnetism, goes hand in hand with metallicity. The chromium hollandite, $K_2Cr_8O_{16}$ is a DE ferromagnetic metal (FM). We found that this DE-FM phase transforms to an insulator, retaining fully polarized ferromagnetism [1]. We also revealed from the precise structure analysis and electronic structure calculations that this transition is caused by a Peierls instability in the quasi-one-dimensional column structure made of four coupled Cr-O chains rather than the double chains, namely the transition is a very rare example of the Peierls transition of fully spin-polarized electron systems [2]. The effect of opening of the band gap on DE-FM has been theoretically studied, which predicts novel ground state phase diagram [3]. Motivated by the theoretical study we have investigated the pressure effect on the ferromagnetic metal-insulator transition in $K_2Cr_8O_{16}$. The DE-FM phase is sharply suppressed, while the Peierls ferromagnetic insulator (FI) phase is considerably robust. As a result, the transition temperatures meet at approximately 3.5 GPa and 80 K. Above 3.5 GPa, the ferromagnetism disappears and the ground state becomes antiferromagnetic (AFI) or paramagnetic (PI). The magnetization and magnetoresistance measurements under high pressure suggest an intermediate insulator phase with partial spin polarization between the FI and AFI (PI) phases, which seems to realize the theoretical prediction.

The hallmark of a Mott insulator is a metal-insulator transition (MIT) upon cooling, which is often accompanied by the appearance of antiferromagnetic (AF) order. Frequently, the MIT and AF order can be suppressed by doping or pressure, resulting in a zero-temperature quantum phase transition. Here, we present detailed muon spin relaxation (muSR) measurements of three families of Mott insulators chosen from 3d, 4d, and 5d transition-metal oxides—$RNiO_3$ (R=Sm, Nd, Pr, La), $(Sr,La)_2IrO_4$, and $(Ca,Sr)_2RuO_4$—to elucidate generic and system-specific behavior in the vicinity of the quantum critical point. We exploit the unique capability of muSR to independently determine the magnetically ordered volume fraction and the ordered moment size to examine first- and second-order behavior of the AF order. In all systems studied, we find that the magnetic order is suppressed near the quantum critical point through reduction of the ordered volume fraction, displaying a “stretched” Mott transition with significant phase separation between magnetic and paramagnetic regions over a wide temperature interval. We also find that the ordered moment size near the critical point remains constant in the nickelates but is gradually diminished in the other systems, in parallel with the reduced volume fraction. Finally, systems for which the MIT and AF transition coincide in temperature show first-order behavior of the moment size upon cooling, whereas systems for which the MIT and AF transition are decoupled show second-order behavior.

These observations may aid in gaining a deeper understanding of Mott physics.

Fr.C.2_O5 - A population inversion observed in surface Dirac cone of topological insulator Sb_2Te_3

K. Sumida [1], S. Zhu [1], M. Taniguchi [1,2], Y. Ishida [3], M. Ye [4], K. Kokh [5,6], O. Tereshchenko [6,7], S. Shin[3], A. Kimura [1]

Topological insulators (TIs) show various properties such as a suppression of backscattering and spin-polarized massless Dirac fermion at the surface or interface. These properties are caused by topological surface states protected by time-reversal symmetry and a strong spin-orbit coupling. Therefore TIs are expected next-generation spintronic devices utilizing dissipationless spin current transport. Among so-far predicted binary chalcogenides, Bi_2Se_3 and Bi_2Te_3 have been experimentally established to be TIs possessing surface Dirac cones by using angle-resolved photoemission spectroscopy (ARPES). However, the topological characteristics of Bi_2Te_3 has not been sufficiently understood because the surface Dirac cone is almost located in the unoccupied state region due to its p-type character, which cannot be accessed by ARPES. Since Bi_2Te_3 is predicted to have a relatively large energy gap and an ideal massless Dirac surface state in sharp contrast to Bi_2Se_3 and Bi_2Te_3, it is crucial to understand its Dirac Fermion characteristics from the electronic structure standpoint. Here we focus on time- and angle-resolved photoemission spectroscopy (TrARPES) implementing the pump-probe method. It allows us to observe not only unoccupied electronic state but also hot carrier dynamics. The TrARPES experiments were performed with linearly polarized pump (1.48 eV) and probe (5.92 eV) pulses caused by Ti:sapphire laser system at Institute of Solid State Physics in University of Tokyo. We have studied the Sb-rich [$Sb_{2.01}Te_{2.99}$ (ST#1)] and the Te-rich [$Sb_{1.98}Te_{3.02}$ (ST#2)] crystals, the former has the smaller hole carrier concentration than the latter. We have clearly observed the surface Dirac cones with Dirac points located at 188 meV and 218 meV for ST#1 and ST#2, respectively. For both samples, we observe a population inversion below and above the Dirac point. Moreover, it becomes clear in ST#2 that the decay time is shorter than ST#1 reflecting the difference in the size of the Fermi surface.

Fr.C.3_O1 - Magnetism of disordered Heusler alloys

M. Leitner [1], P. Neibecker [1], W. Petry [1]

1. Technische Universität München, Germany

Heusler alloys constitute a class of systems with great potential for applications. Most of their appeal rests on the diverse aspects of magnetism in these materials, including the ferromagnetic shape-memory effect, the magnetocaloric effects, and half-metallicity. Due to their intermetallic nature, off-stoichiometry and site disorder constitute degrees of freedom additional to temperature. In previous work we have shown that in Ni_2MnAl well-defined states of order can be prepared, which are accessible via correspondingly varying magnetic transition temperatures [1]. Here we report on a detailed characterization of the peculiar magnetic behaviour, e.g. temperature- and field-dependent magnetization for specific states of order, with nearly constant ferromagnetic susceptibilities up to the highest fields. We present a microscopic model of how Mn/Al site disorder and site-specific ferro- and antiferromagnetic interactions of the Mn moments give rise to observed features as a function of field, temperature, and order.

Magnon is a fundamental and long-lived quasiparticle in solid, and so it is rather rare to observe them to decay. It has so far only been seen in a very limited case like one dimensional magnets or quantum magnets. However, it has been recently suggested theoretically [1] that such a rare event of magnon decay can occur even for classical spin systems when it meets certain conditions, i.e. noncollinear antiferromagnetic structures. This nonlinear magnon interaction is also predicted to be strongest for a two-dimensional triangular lattice. In this work, we have studied the spin dynamics of several such triangular lattice systems in the form of hexagonal magnanites, $RMnO_3$. $RMnO_3$ is one of extensively studied multiferroic materials, and was found to have a strong spin-lattice couple at the antiferromagnetic transition around 80 ~ 100 K [2]. Below the transition, it forms one of the so-called 120-degree structures, making it an ideal system to study the nonlinear magnon interaction. By measuring the spin waves over the full Brillouin zone, we have examined the fine details of the spin dispersion curves to find out that our data reveal the three key signatures of the nonlinear magnon interactions theoretically predicted [3]. More recently, we have extended this work to study a possible magnon-phonon coupling in our spin waves [4]. We will use our experimental results to test these two unusual interactions. Moreover, we will give not only qualitative but also quantitative descriptions of the two interactions in our data.

Fr.D.1_I1 - The AC Wien effect and non-linear non-equilibrium susceptibility in spin ice

P. Holdsworth [1], V. Kaiser [1,3], S. Bramwell [2], R. Moessner[3]

1. Ecole Normale Supèrieure De Lyon, Lyon, France
2. London Centre for Nanotechnology, UCL, London, Great Britain
3. Max Planck, Dresden, MPIPKS, Germany

We show that the Coulomb fluid of magnetic monopoles in spin ice (a ''magnetolyte'') exhibits the second Wien effect in the presence of an AC magnetic field [1]. This involves an increase of the monopole density -- a universal and robust enhancement for Coulomb systems in an external field [2] which in turn speeds up the magnetization dynamics. We predict that the monopole density increase is directly related to the non-linear magnetic response providing a signal of the Wien effect that is specific to magnetic systems. The non-linear non-equilibrium susceptibility is treated analytically within a phenomenological model. Through this study, we gain new insights into the AC version of the classic Wien effect. One striking discovery is that of a frequency window where the Wien effect for magnetolyte and electrolyte are indistinguishable, with the former exhibiting perfect symmetry between the charges as well as a new low-frequency regime where the growing magnetization counteracts the Wien effect and hinders any permanent currents. We discuss conditions required to observe our predictions of the AC Wien effect in the non-linear susceptibility of $Dy_2Ti_2O_7$.

2. Institut für Festkörperphysik, TU Dresden, Dresden, Germany
3. Faculty of Mathematics and Physics, Kanazawa University, Kanazawa, Japan

The frustrated balance of competing spin-spin interactions leads to a wide spectrum of fascinating physical properties in the two pyrochlore compounds, $Ho_2Ti_2O_7$ and $Dy_2Ti_2O_7$. Their rare-earth magnetic moments obey the “ice rules” by mapping spin configurations which resemble the proton configurations in water ice, organize as interweaving networks of aligned dipoles, i.e. Dirac strings, and constitute thermally-excited point defects which behave as magnetic monopole charges at far separated string ends. Here we present a detailed investigation of the $Ho_2Ti_2O_7$ spin-ice compound by means of dc-magnetization, magnetic ac-susceptibility, as well as dielectric polarization measurements. Data have been taken both in a wide magnetic-field (up to 14 T) and temperature range (down to 30 mK). The dynamic magnetic susceptibility of $Ho_2Ti_2O_7$ shows a distinct maximum at the spin freezing temperature, T_f = 1.3 K, accompanied by a huge increase of the spin viscosity deduced from the ratio of imaginary and real susceptibility components. At the same temperature, we observe a decrease of the dielectric constant. Its temperature dependence below 1 K suggests the assumption that the dielectric properties of the pyrochlore compound are directly related to the density of magnetic monopole excitations. The magneto-electric coupling in $Ho_2Ti_2O_7$ emerges clearly by applying a symmetry-breaking magnetic field which allows for a manipulation of the density and orientation of Dirac strings. Our experiments provide a detailed insight into the magnetic-monopole physics of spin ice compounds and illustrate a manifold duality of spin and charge degrees of freedom in these materials.

Fr.D.1_O3 - Magnetic charge crystal phase embedded in a disordered spin lattice in thermally-active artificial spin ice

4. Elettra - Sincrotrone Trieste S.C.p.A., S.S: 14 km 163.5 in AREA Science Park, Basovizza, Trieste, Italy

Artificial spin ices (ASI) are systems designed to explore the intriguing physics observed in magnetically frustrated materials. Generally fabricated by using lithography techniques, they offer almost infinite possibilities to construct a wide variety of spin models which can be accessed experimentally in a controlled manner [1]. ASI systems have been the subject of intense research in the last few years and have allowed the investigation of a rich physics and fascinating phenomena, such as the exploration of the extensively degenerate ground-state manifolds of spin ice systems, the evidence of new magnetic phases in purely two-dimensional lattices, and the observation of pseudo-excitations involving classical analogues of magnetic monopoles. In this contribution, we investigate magnetic frustration effects in thermally active ASI. Starting from a paramagnetic state, the system is cooled down below the Curie temperature of the constituent material. The resulting magnetic configurations show that our arrays are locally brought into a novel magnetic phase characterized by a magnetic charge crystal embedded in a disordered spin lattice. By studying our arrays on a larger scale, we find the unambiguous signature of an out-of-equilibrium physics that reveals the spin kinetics which lead to this exotic spin texture [2].

Fr.D.1_O4 - Magnetic crystallography and 'jellyfish' structure of monopoles in spin ice

L. Jaubert [1], M. Udagawa [2], C. Castelnovo [3], R. Moessner [4]

1. Okinawa Institute of Science And Technology, Japan
2. University of Tokyo, Japan
3. University of Cambridge, United Kingdom
4. MPI-PkS Dresden, Germany

Pyrochlore materials have proven to be fertile soil for the emergence of exotic physics such as magnetic monopoles in Dy_2Ti2O_7 or the spontaneous Hall effect observed in $Pr_2Ir_2O_7$. In this talk, we shall review some of the recent developments in the physics of magnetic monopoles in spin ice, especially when magnetic and electric degrees of freedom are coupled together. As shown by Khomskii (Nature Comm. 2012), the spin texture of magnetic monopoles allow them to carry an electric dipole moment. We will show how such magneto-electric coupling opens the path for a magnetic analogue of crystallography by stabilizing long-range ordered crystals of magnetic charges. Here, this crystal takes the form of a double-layer structure of monopoles, reinforced by a magnetic field. This structure has been observed in $Tb_2Ti_2O_7$ under large [110] field which allows us to extract the typical size of electric dipole moments in rare-earth oxides. Furthermore, when coupled to itinerant electrons, magnetic moments are expected to interact via RKKY interactions. We will explain how, for some specific range of parameters, the resulting effective interaction between monopoles gives rise to a new kind of branching structure made of same-sign monopoles, which we figuratively name 'monopole jellyfish'. This jellyfish structure supports an emergent chirality able to encode time-reversal symmetry breaking which could be related to spontaneous Hall effect.

Fr.D.1_O5 - Magnetic phases up to 120 T in a triangular-lattice antiferromagnet $CuCrO_2$

A. Miyata [1], K. Ohgushi [1], S. Takeyama[1]

1. ISSP, Univ. of Tokyo, Tokyo, Japan

A delafossite oxide $CuCrO_2$ is one of the typical multiferroic compounds in triangular-lattice antiferromagnets [1] and has shown a rich magnetic phase diagram under high magnetic fields due to the geometrical spin frustration [2, 3]. However the full magnetic phase diagram of $CuCrO_2$ has not yet been obtained due to its strong magnetic interactions (Curie-Weiss temperature is about -210 K [1].) We investigated the magnetic phases of $CuCrO_2$, using magnetization and magneto-optical measurements under ultrahigh magnetic fields of up to 120 T. A 1/3 magnetization plateau was newly observed around 100 T. Magneto-optical spectroscopy revealed the other distinct anomalies below and above the 1/3 plateau phase showing rich magnetic phases due to the interplay of its geometrical spin frustration and magnetic field.

Fr.D.2_I1 - First principles design of complex magnetic oxides

A. Ernst [1]

1. Max Planck Institute of Microstructure Physics, Weinberg, Germany

The ability to predict material properties is a fundamental requirement for scientific and and technological advancement. One of our most important research fields is the computational material design of oxidic materials. First-principles design of oxides is one of most ambitious challenges in modern computational physics. The electronic and magnetic properties of these materials are substantially affected by strongly localized electrons, complex crystalline structures, and mixed valencies of magnetic ions. To describe these specific features of oxides we develop ab-initio concepts that are put in state-of-the-art computer codes. Using efficient numerical algorithms and modern supercomputers we can simulate experiments and study properties of realistic systems. More specifically, our research on oxides is currently focused on study of crystalline structures of complex oxidic materials and their electronic and magnetic properties. A detailed description of these systems often involves a large number of degrees of freedom, especially when periodic surfaces or interfaces with large unit cells result from surface instabilities or mis?ts at interfaces. In my talk, I present our first-principles approach to design magnetic oxides, which are highly attractive for spintronic applications. The approach is based on the multiple-scattering theory and provides explicitly the Green function, which can be used in many applications such as spectroscopy, transport and many-body physics. Combined with the coherent-potential approximation this method can be used as well for the description of alloys and pseudo-alloys. An important feature of our method is the treatment of electronic correlation effects, which can be substantial in many complex oxydes. In particular, we combine several approaches, designed for strongly correlated materials, to compute measurable quantities, which can be compared with available experiments. A such direct comparison enables us to adjust several important parameters such as the degree of electronic correlations, the oxidation states and the chemical composition of the investigated system. The efficiency of our approach will be illustrated by studies of several complex oxides, which are attractive for spintronic applications.

Fr.D.2_O2 - Half metallicity with huge room temperature spin polarization in the ferromagnetic Heusler compound Co_2MnSi

A. Kronenberg [1], J. Minar [2], J. Braun [2], S. Chadov [3], B. Balke [4], A. Gloskovskii [5], M. Kolbe [1], H. J. Elmers [1], G. Schönhense [1], H. Ebert [2], C. Felser [3], M. Kläui [1], M. Jourdan [1]

1. Physics, Mainz University, Germany
2. Chemistry, LMU München, Germany
3. MPI-CPfS, Dresden, Germany
4. Chemistry, Mainz University, Germany
5. DESY, Hamburg, Germany

The magnitude of the room temperature spin polarization of ferromagnetic materials is a key property for their application in spin transport-based electronics. Thus Heusler compounds, due to their predicted bulk half-metallic properties, i.e. 100% spin polarization at the Fermi energy, are in the focus of interest. However, for most applications it is not the bulk but the surface or interface of the material, which is relevant. Investigating optimized thin films of the compound Co_2MnSi by in-situ spin-resolved UPS, we were able to demonstrate for the first time half-metallicity in combination with directly measured 93% spin polarization at room temperature in the surface region of a Heusler thin film [1]. Our novel band structure and photoemission calculations including all surface-related effects [2] show that the observation of a high spin polarization in a wide energy range below the Fermi energy is related to a stable surface resonance in the majority band of Co_2MnSi extending deep into the bulk of the material. Spin-integrated ex-situ HAXPES with a photon energy of 6 keV on Co_2MnSi thin films and spin-integrated in-situ UPS was carried out. The UPS and the HAXPES results fundamentally agree although the information depth of both experiments varies from less than 1 nm to 20 nm. Nearly quantitative agreement of the calculations with the experiments for both, UV and hard X-ray photon energies was obtained.

In this presenstation, I will report our recent measurements of quantum oscillations in La-doped $Sr_3Ir_2O_7$. The layered perovskite iridates are correlated insulators have recently attracted great interest since they are sharing key structural and electronic properties with the high-Tc cuprates. Intriguingly, many iridates systems that are predicted to be metallic or even superconducting theoretically turn out to be insulators. Studies on the electronic states of these system are still rare due to lack of metallic candidates. With our successfully prepared the metallic $(La_xSr_{1-x})_3Ir_2O_7$ x=0.03-0.08 samples, we carried out torque measurement with the high magnetic field at High Field Lab Nijmegen Netherlands. Quantum oscillations from the torque signal have been observed, giving us a direct evidence of the existence of Fermi pockets in these gapless samples. The features of Fermi surface are highly dependent to the doping level, which also reflects in the energy gap and metal insulation transition. Our quantum oscillation results are in good agreement with our previous results on the Angle-resolved photoemission spectroscopy (ARPES) and LDA+U calculations [1].

Fr.D.2_O5 - Discrete atomic-like crystal-field states in LaCoO3 , K_2CoF_4 and CoO MOTT insulators

R. Radwanski [1,2], D. Nalecz [1], Z. Ropka [2]

1. Institute of Physics, Pedagogical University, Krakow, Poland
2. Center of Solid State Physics, Krakow, Poland

CoO, K_2CoF_4 and $LaCoO_3$ are considered as prototype oxides with very strong electron correlations, not well theoretically described so far. We provide a first-principles consistent description of these monoxides, which reconciles their insulating ground state and a strong magnetism related to 3d electrons in the incomplete 3d shell. We work in the strongly-correlated crystal-field approach with forbidden charge fluctuations (large U). From really first-principles calculations we have evaluated a full set of the crystal-field coefficients accounting for lattice and local distortions for all these compounds. They are real potentials, in the atomic scale, in contrary to pseudopotentials usually introduced in modern theories. We have calculated the electronic structure both in the paramagnetic and magnetic state and the temperature dependence of the specific heat in 0-800 K range, reproducing the lambda-type peak at TN. For the formation of the magnetically-ordered state the spin-orbit coupling is fundamentally important. We have reproduced values of the magnetic moment and its direction in the crystal structure. We have found that small lattice off-octahedral distortions (tetragonal in case of CoO and K_2CoF_4) determine the direction of the magnetic moment. For these compounds we have found a quite substantial orbital magnetic moment, of 0.5-1.0 uB. Nonmagnetic state of $LaCoO_3$ can be also regarded as originating from the orbital magnetism. The discrete atomic-like states have been found by EPR experiments to be very thin in a sharp contrast to band theories. The maximal energy of the spin waves (40 meV) observed in CoO is, according to our calculations, the splitting of the ground-state doublet by magnetic interactions. According to the developed Quantum Atomistic Solid-State Theory (QUASST) we claim that the conventional crystal-field interactions should be evaluated the first for any meaningful description of magnetic and electronic properties of any 3d/4f/5f compound.

Fr.D.3_O1 - Prediction of magnetic ordering in layered technetium perovskite Sr_2TcO_4

A. Horvat [1], L. Pourovskii [2], M. Aichhorn[3], J. Mravlje [1]

1. Jozef Stefan Institute, Ljubljana, Slovenia
2. Ecole Polytechnique, Palaiseau, France
3. TU Graz, Graz, Austria

Technetium perovksites are scarcely investigated due to the radioactivity of Tc. Few years ago strong antiferromagnetism with transition temperatures reaching 1000K has been observed in cubic Tc perovskite. Magnetic properties of layered compound Sr_2TcO_4 have not been measured so far. By combination of density functional theory with the dynamical mean field theory we extract the exchange interactions and predict the ordering to be of the checkerboard type. The frustration in the bct lattice would suppress magnetic ordering if it was not for the dipole-dipole interactions. Including the dipole-dipole interactions we predict the ordering temperature to be 500K. We discuss the role of the Hund's rule coupling for strong magnetism in Tc perovskites and speculate on the possible superconductivity in doped Tc perovskites.

Fr.D.3_O2 - Inherent orbital-selective tunneling in a STM measurement

Y. Takahashi [1], K. Ienaga [1], N. Kawamura [1,2], T. Miyamachi [1], A. Ernst [3], F. Komori [1]

1. ISSP, Univ. of Tokyo, Japan
2. STRL, NHK, Japan
3. MPI, Halle, Germany

Surface morphology of materials is widely discussed based on the topographic image obtained by the scanning tunneling microscopy (STM) measurement. What should be taken care is that its image does not necessarily correspond to an actual atomic coordination at the surface, because it just reflects the electron tunneling provability between the tip and the surface states. In most cases, bias voltage V is the only parameter which causes the image change. In some compounds, however, it has been reported that the topographic images become totally different depending on the tip-surface distance d. Although it is another important parameter for the tunneling process, systematic experimental study on a d-dependent change of the images has not been conducted in any systems so far. For revealing the influence of d on the topographic images, we took a series of d-dependent topographic images of monoatomic-layer iron-nitride islands fabricated on Cu(001). When the tip became closer to the sample surface, topographic images changed to show a dimerized structure rather than a dot one. This investigation links two incompatible topographic images previously observed for iron nitrides of the same surface symmetry [1,2]. Accompanied by this image change, dI/dV spectra also showed the d dependency. These results imply that the surface states detected by the tip shifted from s/p to d due to a different decay length of each state.

Fr.D.3_O3 - The magnetism, energetic stability and magneto-optical properties of the Rh_2Mn-Bi-Al and Ir_2Mn-Bi-Al alloys

D. Legut [1], J. Kudrnovsky [2], J. Hamrle [1]

1. VSB-Technical University of Ostrava, Czech Republic
2. Institute of Physics ASCR, Prague, Czech Republic

We have performed first-principle calculations to investigate structural, electronic, magnetic, and optical properties of Rh2MnAl and Ir_2MnAl Heusler alloys using density functional theory [1]. In contrast to the Refs. [2,3,4] where only the ferromagnetic ordering were considered, here we anticipated also antiferromagnetic ordering along [001] and [111] crystal axis. In accord with the experimental data our calculation showed that the Rh_2MnAl posseses the most stable spin ordering to be antiferromagnetic along [111] crystal axis[5], whereas in the case of the Ir_2MnAl in contrast to the Ref. [5] we obtained as the most stable spin configuration the ferromagnetic ordering. We found that the ferromagnetic ordering could be induced by a strain of a few percent. The enhancemenet of the MO effects is done by a substitution of heavier element Bi instead Al, i.e. Rh_2MnBi and Ir_2MnBi. However, at the same time the system comes to the verge of the thermodynamic stability [2]. Therefore, we investigated a mixed phases, i.e. Rh_2Mn(Al/Bi) and Ir_2Mn(Al/Bi) as well as the disorder of the pure Rh_2MnAl(Ir_2MnAl) and Rh2MnBi(Ir_2MnBi) phases. The influence of the substitution as well as the disorder vs. ordered compound on the MO effects were investigated. The origin of the enhancemenet of the MO effects by the Bi subsituted Heusler alloys is predominatly by the hybridization and increase of the spin-orbit interaction (SOI). The work was supported by the Grant Agency of the Czech Republic, project reg. No. 13-30397S.

Fr.D.3_O4 - Origin of non-monotonic concentration and temperature dependence of magnetocrystalline anisotropy in $(Fe_{1-x}Co_x)_2B$ alloys

K. Belashchenko [1], I. Zhuravlev [1], L. Ke [2], M. Daene [3], L. Benedict [3], V. Antropov [2]

1. University of Nebraska-Lincoln, Lincoln, United States
2. Ames Laboratory, Ames, United States
3. Lawrence Livermore National Laboratory, Livemore, United States

Magnetocrystalline anisotropy energy K in $(Fe_{1-x}Co_x)_2B$ alloys exhibits an unusual, non-monotonic variation with concentration and temperature [1]. The origin of this behavior is elucidated using a detailed first-principles electronic structure analysis. Both chemical and spin disorder are treated within the coherent potential approximation. We find that concentration [2] and temperature dependence of K is reproduced in all important details. These features include three spin reorientation transitions as a function of concentration, a temperature-driven spin reorientation transition at the Fe-rich end, and non-monotonic temperature dependence at the Co-rich end. To understand the origin of these features, we analyze the electronic spectral functions as well as the spin and wave vector-resolved contributions to K. We find that the unusual variation of K is due to the varying occupation of the minority-spin bands as a function of x and T, spin-orbital selection rules, and band broadening induced by substitutional and thermal spin disorder. The latter effect is particularly important near the Co-rich end where a large positive contribution to K is made by a pair of nearly degenerate bands. We also find that at the optimal Co concentration of 30%, K depends strongly on the tetragonality and doubles under a modest 3% increase of the c/a ratio. This suggests that the magnetocrystalline anisotropy can be further enhanced using epitaxial or chemical strain.

4. Transpyrenean Associated Laboratory for Electron Microscopy (TALEM), CEMES-INA, CNRS-Universidad de Zaragoza, Zaragoza, Spain

Electron holography (EH) and Lorentz microscopy (LTEM) are powerful TEM methods particularly efficient for the quantitative studies of local electrostatic and magnetic fields with respective spatial resolution of the order of few nanometers for EH and few tens of nm for LTEM and over fields of view as large as few microns. In addition, both allow performing in-situ measurements for the analysis of magnetic reversal processes as function of external applied field or electric current at various temperatures The basics of EH and LTEM will be presented and illustrated by recent results obtained on the size dependence of Fe nanocubes magnetic configurations at remanence for sizes varying between 15 to 30 nm and on the complete mapping of the magnetic fields generated by a Hard Disk Drive writer as a function of an applied electrical current in situ in a TEM [1]. In a last part, latest in-situ LTEM results on the reversal magnetization mechanisms obtained on magnetic Co antidot arrays of 160 nm when applying the magnetic field along the easy and the hard axis [2] will be presented. These local EH and LTEM magnetic measurements are comforted by successful micromagnetic simulationsthat will be presented .

By measuring the change in the depinning field of a domain wall (DW) trapped in magnetic nanodevices it is possible to detect small magnetic moments, *e.g.* from magnetic beads (MB), and use such devices as nanosensors in metrological and biomedical applications [1,2]. Changes in the magnetic state of these structures and, hence, presence/absence of a DW can be detected by measuring the electrical resistance of the device due to the anisotropic magnetoresistance effect (AMR)[1,2].
To study sensitivity of DW nanosensors to small magnetic moments, we present scanning gate microscopy studies of the interaction between a micromagnet and a DW nanosensor. The electrical resistance of an L-shaped permalloy DW-device with the width of 75 nm is measured in correspondence to a 3D position of the scanning probe. The custom-made probe comprises an NdFeB microsphere (∅ 1 μm) attached to a non-magnetic AFM tip [3–6].The presence/absence of a DW in the corner of the nanostructure is controlled by an in-plane external magnetic field. We demonstrate the stray-field mediated interaction between the micromagnet and the DW, which appears as the change in the AMR signal measured in the close proximity of the probe to the DW position (~ 100 nm lateral distance).

Using this method, we reconstruct a 3D sensitivity map of the device, which provides a route for characterization of the device performance to non-uniform magnetic fields.

Financed by the EU FP7 NMP project NanoMag.

Fr.E.1_O3 - Domain wall pinning in cylindrical nanowires

I. Ivanov [1], A. Chuvilin [2], J. Kosel [1]

1. King Abdullah University of Science And Technology (KAUST), Thuwal, Saudi Arabia
2. CIC nanoGUNE Consolider, San Sebastian, Spain

Magnetic nanowires (NWs) growing inside of an isolating template perpendicular to the substrate are promising candidates for biomedical applications, sensors or to realize new types of 3D magnetic memory devices. In context of the later, it is crucial to have a possibility for controlled manipulation of domain walls (DWs) by periodic energy potentials. In order to realize such potentials, a local variation of the magnetocrystalline anisotropy can be used; for instance, multilayered Co(hcp)/Ni(fcc) cylindrical NWs. Recently, the possibility to grow single crystal hcp Co NWs with strong easy axis in-plane of the NW diameter has been demonstrated. In contrast, the magnetic behavior of Ni NWs is determined by the shape anisotropy; hence, the easy axis is parallel to the length of the Ni NW. Multilayer NWs with 45 nm in diameter have been prepared by the electrodeposition of Co and Ni into anodic alumina membranes by using two different aqueous electrolytes. The electroplating conditions for the Co segments were chosen to yield the magnetocrystalline anisotropy to be in-plane of the NW diameter. The length of the segments was controlled by the deposition time. NWs with 2, 4 and 5 layers have been prepared. Electron diffraction confirmed a very good crystal quality of the NWs, which allows us to grow multilayer NWs with single crystal Co and Ni segments. A sharp interface without the presence of oxygen between Co and Ni segments has been confirmed by electron energy loss spectroscopy (EELS) mapping. Our electron holography studies together with the magnetic force microscopy (MFM) showed the presence of an asymmetric stray field at the Co/Ni interface which might effectively pin the domain wall after the reversing of the magnetization of one of the segment. So the possibility to control DW propagation in cylindrical NWs by local variation of the magnetic anisotropy was successfully demonstrated.

Fr.E.1_O4 - Mechanomagnetic spectroscopy: an ultrasonic method to study magnetostriction

S. Kustov [1,2], M. Ll. Corró Moyà [1]

1. Departament De Física, Universitat De Les Illes Balears, Palma, Spain
2. ITMO University, St. Petersburg, Russia

A technique for mechanomagnetic spectroscopy (MMS) [1] based on the Piezoelectric Ultrasonic Composite Oscillator Technique (PUCOT) [2] has been developed to study the reversible inverse magnetostriction (reversible Villari effect, RVE) over a wide range of periodic stress, temperatures and polarizing magnetic field H. The technique allows us to study simultaneously also elastic and anelastic properties. Measurements of RVE can be performed as a function of cyclic applied field at constant temperature or as a function of temperature at fixed H. Ultrasonic resonant oscillations near 100 kHz are induced in a piezoelectric oscillator which includes the sample. Due to the magnetoelastic coupling, the oscillatory stress produces a variation of the induction in magnetically ordered samples, which is measured by a small pickup coil. The amplitude and the phase of the stress-induced induction with respect to elastic strain/stress are determined. Based on the Maxwell relation, an algorithm is developed to estimate the static magnetostriction versus H from the RVE. Experimental studies were performed in a variety of materials, including well-known ferromagnets (Fe, Ni) as test objects [3], ferromagnetic polycrystalline and single crystalline shape memory materials (Ni-Fe-Ga) [3,4] and pure element (Dy) in ferro- and antiferromagnetic states. In contrast to other macroscopic techniques, MMS is not based on the measurement of total static strain, which includes thermal expansion. This important advantage allows us to study very weak magnetoelastic coupling, like in the antiferromagnetic phase of Dy, or for extremely weak at magnetic fields as low as the Earth's one (spontaneous magnetostriction).

5. Material Systems for Nanoelectronics, Chemnitz University of Technology, Germany

Expanding 2D systems into the third dimension allows for modifying conventional or launching novel functionalities by tailoring curvature or shape of the magnetic 3D surfaces. These systems possess striking novel properties originating from curvature-driven effects, such as magnetochiral effects and topologically induced magnetization patterns due to a Dzyaloshinskii-like exchange interaction. A nanometer spatial resolution is required to image details of the magnetic domain pattern even if the curvature radii of these 3D surfaces is in the micrometer range. In this respect, neither magnetic neutron nor electron tomography can be applied. On the other hand, magnetic x-ray tomography (MXT) relying on x-ray magnetic circular dichroism (XMCD) with full-field microscopy has the potential to become a powerful tool to study these novel classes of 3D magnetic objects. We demonstrate its capabilities by reconstructing the 3D magnetization textures in hollow tubular objects. These objects are fabricated by rolling up planar nanomembranes with well-defined magnetic properties, i.e. in-plane or out-of-plane magnetic easy axes. The magnetic domain patterns are retrieved from a set of 2D images by applying reconstruction algorithms taking into account the vector property of the magnetization. By these means, the impact of the number of windings and of surface angles with respect to the initially applied magnetic field on the domain morphology (size and shape) is studied.

Fr.E.2_I1 - Studies of magnetic structures and magnetization dynamic using scanning transmission x-ray microscope

T. Tyliszczak[1]

1. Advanced Light Source, Lawrence Berkeley National Laboratory, Berkeley, United States

There are many microscopic techniques used to analyze magnetic structures and dynamics of magnetization. One of the most versatile for characterization of bulk magnetic properties is soft x-ray transmission microscopy. It combines good lateral resolution and sub 100 ps time resolution with high sensitivity to magnetization. Magnetization sensitivity is due to X-ray Magnetic Circular Dichroism (XMCD) effect on absorption of circularly or elliptically polarized x-ray by metals. There are two types of x-ray transmission microscopes: full field microscope (often noted as TXM) and scanning transmission x-ray microscope (STXM). Both are used in magnetization studies but they offer somewhat different characteristics. The talk is based on the results obtained using STXM. The Scanning X-ray microscopes with magnetization measurements capabilities are operating at many synchrotron centers. Presented results are from the beamline 11.0.2 of the Advanced Light Source. Beamline 11.0.2 delivers linearly or elliptically polarized light in energy range from 80 eV up to 2000 eV. The scanning x-ray microscope can focus this beam to the size of about 30 nm using Fresnel zone plate. Samples are imaged by recording transmitted intensity as a function of sample position. Images can be recorded as a function of x-ray energy and/or x-ray polarization allowing for spectral analysis at given point of the image. The x-ray beam at the ALS has periodic structure of 500 MHz with a time uncertainty of about 70 ps. By using a fast avalanche photodiode detector it is possible to use the time structured x-ray beam to study dynamics. At the ALS STXM two different modes are used: “pulse-and-probe” and spatially resolved ferromagnetic resonance. The “pulse” is either magnetic or current fast pulse; the x-ray probe time response of magnetic layers. In SR-FMR experiments, the magnetization of the sample is excited by a continuous RF sine wave. In that way spin precession modes (in the GHz frequency range), modes of magnetic vortex movements (in the sub-GHz frequency range) or motion of domain walls can be studied. The frequency of the excitation has to be phase synchronized with the x-ray flashes of the synchrotron. Thus only multiples of the synchrotron bunch frequency can be addressed. Flexible field of view of STXM imaging allows to efficient studies of magnetic structures in different shape and thickness of magnetic nanostructures or complexes like spin ice structures. Latest development in combining transmission imaged and recording scattering patterns (Diffraction Enhanced STXM - ptychography) is significantly improving spatial resolution of x-ray imaging. Presently, at the ALS we can image magnetic structures with a resolution better than 10 nm. Although, dynamic measurements in this mode are more difficult, first results will be presented. Technical aspects of both methods will be presented by discussing examples of latest studies: imaging of spin transfer switching, and magnetic vortex core reversal by excitation with bursts of an alternating field2.

Fr.E.2_O2 - A nanopaleomagnetic study of the early solar system by means of X-ray PEEM

J. Herrero-Albillos [1], J.F.J. Bryson [2], C. I. O'Bryen Nichols [2], R.J. Harrison [2], F. Kronast [3]

1. Centro Universitario de la Defensa, Zaragoza, Spain, Zaragoza, Spain

3. Helmholtz-Zentrum Berlin, BESSY II, Berlin, Germany

Time-resolved records of the Earth's planetary magnetic field have been essential in understanding the dynamic history of our planet. Although most rocky planets, moons and asteroids of the solar system do not generate magnetic fields nowadays, they are thought to have generated dynamo fields in the early solar system. The nature and temporal evolution of those fields has remained enigmatic but its understanding could provide a unique insight into planetary evolution. In the case of asteroids, our foremost source of information regarding magnetic fields comes from meteorites. Meteoritic metallic material contains micro and millimeter size magnetic phases. Unfortunately, those phases are magnetically soft, and therefore they are not thought to provide accurate records of magnetic fields. However, regions containing nano-scale islands of tetrataenite (chemically ordered FeNi), found within the metal, have been recently proposed as reliable remanence carriers. In order to extract the information potentially recorded in those nano-islands, X-ray Photoelectron Emission Microscopy (PEEM) has been performed in a series of meteorites. This technique allows obtaining both magnetic and chemical maps with a spatial resolution down to 40 nm, in a field of view of 5 micrometers. A comparison of the magnetic signals and compositional maps furthers the understanding of the magnetic properties of the nano-islands and their interaction with the surrounding matrix. On the other hand, the experimental magnetization maps are compared with nano-magnetic simulations, giving rise to a time-resolved reading of magnetic remanence of the parent asteroids. The results suggest that an unconventional mechanisms acted in the early solar system giving rise to a long-lasting and widespread epoch of dynamo activity among small bodies in the early solar system, and might help to explain the long-lived magnetic activity observed in larger bodies, such as the moon.

Fr.E.2_O3 - Direct observation of the magnetocrystalline anisotropy axes in Fe_3-xO_4 nanoparticles by MFM

C. Moya [1], Ó. Iglesias-Freire [2,3], N. Pérez [1], X. Batlle [1], A. Labarta [1], A. Asenjo [2]

1. Departament de Física Fonamental, Institut de Nanociència i Nanotecnologia, Universitat de Barcelona, Barcelona, Spain
2. Instituto de Ciencia de Materiales de Madrid (ICMM-CSIC), Cantoblanco, Madrid, Spain
3. Department of Physics, McGill University, Montreal, Canada

Magnetic nanoparticles have potential applications in fundamental magnetism, biomedical applications and ultra-high density magnetic recording. Thermal stability of the particle magnetization is a crucial issue in most of those applications, so that direct observation of the magnetization reversal becomes of great interest to check the validity of models and theoretical assumptions. Despite several attempts found in the literature [1], [2], unambiguous correlation of the magnetic domain orientation to the crystalline structure is yet to be achieved. In our work, we present direct experimental imaging by variable-field magnetic force microscopy of the magnetic domain configuration in individual, cubic Fe_3-xO_4 nanoparticles of about 27 nm in size and high crystal quality [3]. Single domain structures have been shown, whose orientation and polarity result from both the magnetocrystalline easy axes of the particles and previous magnetic history. As the main result, we report on the direct observation of the easy axes in individual ferrimagnetic nanoparticles. Furthermore, the changes in the domain orientation with an external magnetic field have given evidence of a particle magnetization reversal mediated by a coherent rotation of the particle spins that has also been supported by micromagnetic calculations. This work was supported by Spanish MINECO (MAT2012-33037, CSD2010-00024 and MAT2013-48054-C2) and Catalan DURSI (2009SGR856, 2014SGR220).

Fr.E.2_O4 - Ghost imaging protocol for magneto-optical applications

A. Caprile [1], A. Meda [2], I. R. Berchera[2], I. P. Degiovanni [2], A. Avella [2], A. Magni [1], M. Genovese [2], M. Pasquale [1]

1. INRiM - Electromagnetism Division, Torino, Italy
2. INRiM - Optics Division, Torino, Italy

In this work, we develop a new approach to perform magneto-optical imaging, applying for the first time a high resolution Ghost Imaging (GI) protocol to reconstruct the image of Weiss domains within a magnetic sample. Thermal light GI is a technique that exploits intensity correlations between light beams to reconstruct the image of an object. Considering two intensity-correlated multi-speckles light beams, the first one illuminating an object and observed with a "bucket" detector (i.e. without any spatial resolution), the second one, that has never interacted with the object, revealed by a spatial resolving detector (like a CCD camera), the image of the object can be retrieved by correlating the outputs of the two detectors. Glauber's second order correlation function normalized to the fluctuations of the beams is used to reconstruct the image of the sample. An imaging setup, implemented in order to obtain a spatial resolution sufficient to perform an efficient imaging of magnetic domains within an yttrium iron garnet (YIG) sample, has been realized. The outstanding magneto-optical properties of YIG, which possesses one of the highest Faraday rotation angle, make it the perfect material for a feasibility investigation of this new technique. The sample used here is a film of YIG of chemical composition $(YSmCa)_3(FeGe)_5O_{12}$ grown on gadolinium gallium garnet substrate. Ghost image reconstructions of domains of average size of 60 µm with opposite magnetization have been successfully retrieved. The investigated approach opens to the development of interesting innovative setups for magneto-optical microscopy, allowing operations in small volumes such as e.g. in cryostats, since no actuators to scan the sample or CCD close to the sample are needed, where, in perspective, the image of the domains can be obtained just inserting a tiny bundle of optical fibers in the proximity of the sample.

Fr.E.2_O5 - Neutron scattering in magnetic fields up to 26 teslas

O. Prokhnenko [1], M. Bartkowiak [1], W. Stein [1], N. Stuesser [1], H. Bleif [1], K. Prokes [1], M. Bird [2], P. Smeibidl [1], B. Lake [1]

1. Helmholtz-Zentrum Berlin, Germany
2. National High Magnetic Field Laboratory, Tallahassee, United States

This year the user instrument suite of the Helmholtz-Zentrum Berlin (HZB) has been strengthened by a unique high-field facility for neutron scattering. Its main components are the High Field Magnet (HFM), the most powerful DC magnet for neutron scattering in the world, and the Extreme Environment Diffractometer (EXED), the dedicated neutron instrument. Built in collaboration with NHMFL (Tallahassee), the HFM is a horizontal field hybrid magnet. With help of resistive insert coils mounted in the room temperature bore of a superconducting solenoid, fields as high as 26 T can be obtained. The magnet operation requires complex technical infrastructure which comprises the 4 MW power supply, the water-cooling system for the resistive coil and the Helium-refrigerator for cooling the superconducting coil. Because of this infrastructure and magnet dimensions, the HFM is permanently installed on EXED. A special feature of the HFM is a pair of 30 degree conical openings at the ends of the resistive insert envisaged for neutron scattering access. To cover a sufficient Q-range in such a restricted geometry, EXED uses the time-of-flight (TOF) technique. It compensates the limited angular access by the extended wavelength range. Combined with 15 degree magnet rotation, it enables gapless coverage of Q-range from about 0.01 up to 12 Å-1 for diffraction and small angle experiments. In addition to elastic capabilities, the instrument is being upgraded to direct TOF spectrometer mode. It will enable inelastic neutron scattering experiments over a limited Q-range < 1.8 Å-1 with an energy resolution of a few percent and Ei < 25 meV. In this contribution the present status and capabilities of the HFM-EXED user facility will be presented together with the established procedures for planning the experiments and applying for the beamtime.

Fr.E.3_O1 - Domain wall on a magnetic helix with easy-tangential anisotropy

O. Pylypovskyi [1], D. Sheka [1], V. Kravchuk [2], D. Makarov [3], O. Schmidt [3], Y. Gaididei [2]

1. Taras Shevchenko National University of Kyiv, Kyiv, Ukraine
2. Institute for Theoretical Physics, Kyiv, Ukraine
3. Institute for Integrative Nanosciences, IFW Dresden, Dresden, Germany

Here, we demonstrate the curvature- and torsion-induced effects on the magnetization and the magnetic domain wall structure in 1D magnetic helices [1]. Coiling of a magnetic wire with the easy-axis anisotropy along the wire axis into a helix leads to an easy-tangential anisotropy and results in the following effects: (i) Appearance of an effective easy-plane anisotropy in a tangent-binormal-plane and rotation of the axis of the easy-axis anisotropy; (ii) Appearance of the effective Dzyaloshinskii term in the expression for the magnetic energy, which is proportional to the torsion and curvature of the wire [2]. Such a geometrical deformation from a straight wire into the helix can result in values of the Dzyaloshinskii constants comparable with estimations of surface induced ones in multilayer structures [3]. Domain walls in this curved system are described in the Frenet-Serret frame of reference offering the advantage that the magnetic anisotropy assumes the simplest form. The nonzero torsion results in the tilt of magnetization in the domain wall. This effect is similar to the one reported for structures with the intrinsic Dzyaloshinskii interaction [4]. The nonzero curvature results in coupling of the domain wall type (head-to-head or tail-to-tail) and the rotation of magnetization in the domain wall. All these effects are described analytically and confirmed by customized spin-lattice simulator SlaSi [5].

Fr.E.3_O2 - Multi-vortex magnetic nanoparticles: a twin-functionalized agent for magnetomechanical cancer-cell destruction and hyperthermia

D. W. Wong [1], N. Liu [1], Y. Yang [2,] W. Liang Gan [1], C. Boon Tan [1], M. Ramu [1,] Jun Ding [2], W. Siang Lew [1], G. Sarjoosing [1]

1. Nanyang Technological University, Singapore
2. National University of Singapore, Singapore

Magnetic nanoparticles show great potential for magnetic biomedical applications, such as magnetomechanical cancer-cell destruction and magnetic hyperthermia. The key advantage over the conventional cancer therapy is the non-invasive and localization of treatment of the cancer tumor, which minimizes the harmful side effects experienced by the patient. In this study, we prepared NiFe magnetic nanoparticles, with various thicknesses of 50 - 500 nm, via template-assisted pulsed electrodeposition and differential chemical etching technique. Our micromagnetic simulations have revealed that NiFe magnetic nanoparticles, with thickness of > 300 nm, forms a frustrated triple vortex state which produces a higher net magnetization that is stronger than the single vortex state. Therefore, a greater magnetic torque can be actuated, beneficial for various magnetic torque-based biomedical applications, such as magnetomechanical cell destruction. The magnetic torque have been verified by the light transmissivity dynamics of a suspension of magnetic nanoparticles, which shows a much higher magnetic moment for nanoparticles with thickness of 500 nm. In addition, we show that applying a small amplitude and low frequency magnetic field for only a few minutes was sufficient to initiate HeLa cells destruction in vitro. The observation of the loss of HeLa cell membrane integrity can be attributed to the targeted membrane rupture or magnetomechanical induced cell destruction. Among the different thicknesses tested, magnetic nanoparticles with a thickness of 500 nm had significant Specific absorption rate (SAR) values in clinical conditions and reached SAR values up to 2256 W/g at 366 kHz and 48 kA/m. Within a small amount of time (approximately ~251 s) and low iron concentration of 0.024 mg/mL, the temperature can be raised to 42^{o}C, reducing the viability of the cancer cells. Hence, we demonstrate the capability of our magnetic nanoparticles as a twin-functionalized agent for magnetomechanical cancer-cell destruction and magnetic hyperthermia.

Fr.E.3_O3 - Nonlinearity of dynamic magnetization in a superparamagnetic clustered-particle suspension with regard to particle rotatability under oscillatory field

S. B. Trisnanto [1], Y. Kitamoto [1]

1. Tokyo Institute of Technology, Tokyo, Japan

Inhomogeneous particle size distribution which includes cluster formation or local particle aggregation in a polydispersive magnetic-suspension is associable with high nonlinearity of magnetization response, owing to the significance of dipolar magnetism and other inter-particle interactions between neighboring particles. However, the nonlinearity arising from how magnetic nanoparticles suspended in a liquid medium interact with alternating magnetic field, cannot be sufficiently explained from exclusively understanding field-strength dependence of equilibrium susceptibility or the corresponding change in effective magnetic-moments. Additionally, the possibility of individual particles and even the clustered-particles to rotate under oscillatory magnetic field should potentially contribute to shaping curve of magnetization versus magnetic field. To characterize particle rotatability, we, therefore, concerned about rotational relaxation losses in correlation with imaginary part of magnetization. A superparamagnetic clustered-particle suspension which contains ~7 nm iron oxide nanoparticles coated with carboxydextran and dispersed in water so that the measured hydrodynamic-size was ~65 nm, was placed in a magnetosusceptometer and subjected to 0-65 Oe-rms of magnetic field strength with applied frequencies of 0.3, 3, 30, and 300 kHz, to initially measure its complex magnetic susceptibility. From further numerical analyses, we found that a typical nonlinear-curve of dynamic magnetization in the function of field strength at 300 Hz tends to be linear at 300 kHz, and highly field-dependent equilibrium-susceptibility at 300 Hz appears to be relatively-independent at 300 kHz, as well as the effective magnetic-moments. These generally demonstrate that magnetically-induced particle dynamics of the suspension is frequency-dependent. Furthermore, since the rotating particles generate friction losses which is comparative to the dissipation of magnetic energy, their existence should be observable as imaginary part of magnetization M'. Our important finding is that at lower frequency, M' reaches its saturation at lower field strength. This indicates that Brownian relaxation losses are constant after the saturation, thus emphasizing a confinement of particle rotations.

Fr.E.3_O4 - Insight into magnetic configurations in Fe nanocubes by micromagnetic simulations and electron holography

F. Bonilla [1], C. Gatel [2], L. Lacroix [1], A. Meffre [1], B. Warot-Fonrose [2], E. Snoeck [2], T. Blon [1]

1. Laboratoire de Physique et Chimie des Nano-objets (LPCNO), Toulouse, France
2. CEMES-CNRS, Toulouse, France

Magnetic configurations in nanoparticles result from the competition between different magnetic terms. Such terms can arise from intrinsic parameters like composition, crystallinity, lattice deformations, and extrinsic parameters like size, shape and external fields. Here we present a theoretical and experimental study of the magnetic configuration dependence on intrinsic/extrinsic parameters for single ferromagnetic nanocubes with cubic magneto-crystalline anisotropy. First, we performed micromagnetic simulations with the OOMMF-3D package using bulk magnetic parameters of known materials with cubic anisotropy. By varying the nanocube size between 20 and 30 nm, the single domain limit (SDL) has been investigated. Thereby we observed a transition from the single-domain (SD) to the vortex state, where we found intermediate states like the <111> vortex (vortex-core along the cube <111> direction) or <111> SD. In another approach, we considered the extrinsic parameters like shape and applied magnetic field: we demonstrated that a deviation from the cubic shape affects the single domain limit and, furthermore, that magnetic history of nanocubes has a strong impact on the magnetic configuration at remanence. A second part of the presented work deals with the experimental evidence of magnetic configurations in ferromagnetic nanocubes. The particles studied were Fe nanocubes with controlled shape, composition, size and crystallinity [1].These nanoparticles appear as a model system in nanomagnetism, nonetheless, experimental evidence of their SDL is a real challenge considering the small size range. Using electron holography (EH) we mapped the phase shift of the electron beam in a TEM corresponding to the magnetic induction in and outside the nanoparticles [2]. Thus, by combining EH and micromagnetic simulations, we have demonstrated the SDL in isolated Fe nanocubes with sizes ranging from 20 to 30 nm: as the size decreases, the magnetic configuration evolves from the vortex state to the SD one through the intermediate <111> vortex.

Fr.F.1_I1 - Designer Nanomagnets

J. Rossier [1]

1. Inl, Braga, Portugal

Progress in scanning tunneling microscopy (STM) makes it possible to assemble and probe with atomic precision structures made of one or a few magnetic atoms on a surface. Inelastic tunneling permits to probe the spin excitations of these designer nanomagnets, and spin-polarized STM permits to probe the atomic magnetization. In this talk I will discuss the fascinating properties of spin chains made of a few Fe atoms on top of Cu_2N/Cu(100) surface, paying attention to the interplay between magnetic anisotropy and Kondo interactions and the conditions for this type of system to behave classically or quantum mechanically.

Fr.F.1_O2 - Strange correlations in symmetry protected topological phases

P. Sengupta [1], K. Wierschem [2]

1. Nanyang Technological University, Singapore
2. National Taiwan University, Taiwan

Recently, a “strange correlator” has been proposed as a direct probe for the topological character of interacting Symmetry Protected Topological (SPT) phases. Using projective quantum Monte Carlo, we are able to directly access the strange correlator in a variety of phases, as well as to examine its critical behavior at the quantum phase transition between trivial and non-trivial symmetry protected topological phases. After finding the expected long-range behavior in these two symmetry conserving phases, we go on to verify the topological nature of two-leg and three-leg spin-1 Heisenberg antiferromagnetic ladders. This demonstrates the power of the strange correlator in distinguishing between trivial and non-trivial symmetry protected topological phases.

Fr.F.1_O3 - Electronic properties of transition metal atoms on Cu_2 N/Cu(100): a comparative study

A. Ferrón [1], J.L. Lado [1], J. Fernández-Rossier[1]

1. International Iberian Nanotechnology Laboratory, Braga, Portugal

We study the electronic and magnetic properties of individual transition metal atoms (Ti, V, Cr, Mn, Fe, Co and Ni) deposited on a Cu_2 N/Cu(100) surface by means of spin-polarized density functional theory (DFT) and CI calculations. We focus our work on a comparative study of the various quantities, such as magnetic moment, orbital occupation, structural properties, hybridization with the substrate and spin polarization of the substrate, paying attention to the trends as the transition metal is changed. In addition we construct a multi-orbital Anderson Hamiltonian for the N electron problem in the open shell of the magnetic atom allowing charge fluctuation with the surrounding atoms, including both effects of spin-orbit and Coulomb repulsion. In this work we try to go beyond existing theoretical works by providing a comprehensive and comparative study of the electronic, magnetic and structural properties of these seven atoms including also Ni, for which there are no published calculations to the best of our knowledge. In the case of Mn, Fe and Co, we connect our results with the existing scanning tunneling microscope experiments.

Fr.F.1_O4 - Magnetism in rare earth quasicrystals: RKKY interactions and ordering

S. Thiem [1], J. Chalker [1]

1. University of Oxford, Oxford, United Kingdom

We study magnetism in simple models for rare earth quasicrystals, by considering Ising spins on a quasiperiodic tiling, coupled via RKKY interactions. Computing these interactions from a tight-binding model on the tiling, we find that they are frustrated and strongly dependent on the local environment. Although such features are often associated with spin glass behaviour, we show using Monte Carlo simulations that the spin system has a phase transition to a low-temperature state with long-range quasiperiodic magnetic order.

Fr.F.1_O5 - Spin and orbital contributions to relativistic magnetic interactions in strongly correlated systems

A. Secchi [1], A.I. Lichtenstein[2], M.I. Katsnelson[1]

1. Radboud University Nijmegen, Institute For Molecules And Materials, Nijmegen, The Netherlands
2. Universitat hamburg, Institut für Theoretische Physik, Hamburg, Germany

The theory of magnetism is based on the effective description of a magnetic material in terms of a system of spins, coupled to external fields and interacting between themselves via magnetic interactions. The interactions' strengths are related to underlying microscopic electronic processes that can be fully captured only by considering realistic electronic models, including both single-particle and interaction terms. The complexity of the electronic processes leads to non-Heisenberg effects in magnetic metals and semiconductors, i.e., the lengths of magnetic moments and values of exchange parameters depend on the spin configuration for which they are computed, requiring ab-initio expressions. We present our theory of magnetic interactions in strongly correlated systems [1], a method that allows to compute the complete relativistic exchange tensors (including Dzyaloshinskii-Moriya interactions and anisotropic contributions to exchange) for the generalized multi-orbital Hubbard model, in the presence of arbitrarily strong relativistic couplings (such as spin-orbit and magnetic anisotropy) and external electromagnetic fields. The multi-orbital Hubbard model allows to describe relevant magnetic systems such as d and f materials, and we do not assume quenching of the orbital moments. The expressions for all the terms of the exchange tensors are given in terms of equilibrium electronic single- and two-particle Green's functions, which have to be computed from the electronic model, e.g., with the methods of Dynamical Mean-Field Theory. We show that the intrinsic spin and orbital degrees of freedom of the electrons, as well as their interplay, give distinct contributions to the strengths of the magnetic interactions, which can be separately accessed within our formalism. This is expected to be a relevant development in the study of rare earth magnets, where spin-orbit coupling is strong beyond perturbative approaches.

Fr.F.2_I1 - Topological defects in quantum spin-nematics

Y. Akagi [1], H. Ueda [1], N. Shannon [1]

1. Okinawa Institute of Science And Technology, Okinawa, Japan

Topological defects play an important role in the theory of nematic phases in liquid crystals. However, relatively little is known about their role in quantum spin nematic phases which have no long-range dipole order and break only spin-rotational symmetry [1,2,3]. Here, we consider the topological defects in these nontrivial states. The model is the spin-1 bilinear biquadratic model on the triangular lattice [4,5,6]. We classify the defects by homotopy theory and numerical optimization approach, simulated annealing. We also discuss new type defects at particular point, which has global SU(3) symmetry.

Fr.F.2_O2 - Quantum molecular magnetism

S. Brechet [1], F. Reuse [1], K. Maschke [1], J. Ansermet [1]

1. EPFL, Lausanne, Switzerland

Our theoretical description of quantum molecular magnetism is based on the quantum master equations, where the system consists of the electronic spin degrees of freedom and the bath consists of the remaining degrees of freedom. The system is weakly coupled and weakly correlated to the bath, which is at equilibrium on an appropriate time scale. The electrons satisfy the exclusion principle, which requires the tensorial product of the spin and orbital parts of the state to be antisymmetric under permutation. However, the symmetries of the parts of the state taken separately are determined by the irreducible unitary representations of the permutation group. The structure of the quantum master equations is also determined by these representations. The coupling between different isotypic components of the permutation group appearing in the quantum master equations leads to a description of magnetic dissipation at the molecular level and defines molecular spin selection rules. Thus, this theoretical description is expected to bring new and fundamental insight for molecular magnetism. In particular, it is expected to predict the non-trivial deflection of molecular clusters in a field gradient.

Fr.F.2_O3 - Micromagnetic simulations of three dimensional magnonic crystals

L. Spinu [1], A. Maksymov [1]

1. AMRI & Physics, University of New Orleans, United States

Magnonic crystals (MC) are artificial assembly of “man-made” building blocks with tailored properties via their geometrical shaping and compositional modulation. This fact makes possible the confinement of solid state excitations and formation of a discrete spectrum of the allowed modes. Magnonic crystals open huge possibilities for device application as the frequency and strength of resonances related to the propagation of the magnons can be controlled by the geometry and magnetization configuration of meta-atoms.
In this work we use micromagnetics simulations to find the spectra and spatial profiles of collective spin-wave excitations in various three-dimensional (3D) arrays of magnetic nanoelements. Complicated shapes of magnetic elements forming three-dimensional magnonic crystals determine a rather complex structure of a spin wave spectrum of these individual nanosized elements. Thus, full scale micromagnetic simulations that go beyond the macrospin approximation are needed to accurately evaluate the structure of spin wave modes in these elements. The magnetization dynamics in nanosized magnetic elements is described by the Landau Lifshitz-Gilbert (LLG) equation that is solved using a Finite Difference Time Domain method.
A static magnetic field selects different ground states of the system while a transverse picosecond exponential magnetic pulse determines the magnetization dynamics in the system. The frequency response of 3D MC was extracted from the spatially and temporarily resolved data produced by micromagnetic simulations. A special attention was paid to the influence of the magnetic system ground state on the properties of the collective resonance modes, i.e. the possibility to dynamically reconfigure a ground state of 3D MCs.

Fr.F.2_O4 - Remote qubit manipulation by magnetic solitons

A. Cuccoli [1,2], D. Nuzzi [1,2], R. Vaia [2,3], P. Verrucchi [1,2,3]

1. Universitá Di Florence - Dipartimento Di Fisica E Astronomia, Florence, Italy
2. INFN - Sezione di Florence, Florence, Italy
3. Istituto di Sistemi Complessi del CNR, Roma, Italy

One of the major difficulties met when solid-state realizations of quantum computers are proposed, is that of addressing and manipulating the single qubits of a quantum register without affecting the neighbouring ones. We here describe and discuss the proposal of using magnetic solitons propagating along spin chains as a suitable mean for qubit manipulation. Solitons are constant-profile, non-linear excitations, well localized in space and time, and their robustness against external perturbations, like thermal noise, makes them natural candidates for the faithful transmission of signals between distant parties. Mathematically, classical spin chains, in the limit of continuous support, are well known physical models for soliton propagation; experimentally, the observed thermal properties of quasi one-dimensional magnetic materials clearly display distinctive features which can be unambiguously interpreted as the contribution of soliton-like excitations, possibly renormalized by quantum corrections. In view of the possible use of solitons for qubit manipulation, we firstly propose a practical scheme to generate soliton-like excitations in discrete classical Heisenberg chains by applying a time-dependent magnetic field at the chain edge. We present a numerical investigation of the resulting dynamics of the discrete chain, showing the effective injection and propagation of solitons, and their robustness against thermal disorder. Moreover, we propose a setup where the generated soliton, travelling along the chain, eventually reaches a distant qubit, physically realized as a localized magnetic moment of spin 1/2, coupled to the chain, effectively acting on it as a time-dependent magnetic field able to manipulate its quantum state. Numerical results confirm that by a proper choice of the soliton shape and speed, and of the chain-qubit interaction, solitons are indeed suitable for the required task, giving the possibility to effectively control the qubit state by a non-dissipative mechanism, an additional beneficial property of the proposed scheme with respect to more conventional ones.

FR.F.2_O5 - Energy efficient thermally induced magnetization switching by tailoring the electron and phonon dynamics

T. Ostler [1], U. Atxitia [2,3], O. Chubykalo-Fesenko [4], R. Chantrell [1]

1. Department of Physics, The University of York, Heslington, United Kingdom
2. Fachbereich Physik, Universität Konstanz, Konstanz, Germany
3. Zukunftskolleg, Universität Konstanz, Konstanz, Germany
4. Instituto de Ciencia de Materiales de Madrid, CSIC, Cantoblanco, Madrid, Spain

The recently discovered thermally induced magnetization switching (TIMS) in ferrimagnets has received a lot of attention as it proceeds on the time-scale of picoseconds and occurs without the need for other slower additional external sources, such as a magnetic field. Whilst the energy per bit required to reverse the magnetization is low, the system temperature after the application of a pulse remains rather high for a few hundreds of picoseconds. In some cases the final temperature after the pulse is near the Curie temperature of the magnetic material and the heat transfer out of the system is governed by slower phonon processes. Thus, lowering the fluence required to reverse the magnetic state of a material by the TIMS mechanism is a key challenge since it could allow one to (i) realize an ultra-low power magnetic bit-recording scheme and (ii) avoid long lasting elevated temperatures. In considering the optimal set of physical characteristics we must first note that whilst TIMS is a magnetic process, it relies strongly on the underlying physics of the electronic and phononic systems. The focus of this work is to address, at least partially, this issue by demonstrating the properties of a candidate material that would give rise to a significant reduction of the laser power required to excite TIMS. Using large-scale computer simulations based on the stochastic Landau-Lifshitz-Gilbert equation, we have performed extensive analysis of the optimal physical quantities both electronic/phononic and magnetic for example; electron-phonon coupling, amount of rare earth and thermal bath coupling required for low energy TIMS. Significantly, we have shown that by optimizing the combination of the composition and the electron phonon coupling the fluence can be reduced by an order of magnitude. Our results can be used as a recipe to find potential materials exhibiting low energy TIMS.

Fr.F.3_I1 - Inelastic electronic transport in single-layer graphene and at the surface of topological insulator Bi_2Se_3

J. F. Sierra [1], M. V. Costache [1], I. Neumann [1], S.O. Valenzuela [1,2]

1. ICN2 - Institut Catala de Nanociencia i Nanotecnologia, Campus UAB, Bellaterra, Barcelona, Spain
2. ICREA - Institució Catalana de Recerca i Estudis Avanþats, Barcelona, Spain

Understanding of the heating, energy flow and relaxation of two-dimensional Dirac carriers in graphene and topological insulators is essential for the design of electronic devices based on these materials. Elastic scattering by disorder imposes a limit to the conductivity at low temperatures; nevertheless, as disorder is reduced, the limit at finite temperatures will be ultimately set by the intrinsic electron-phonon (e-ph) coupling. In this talk, I will discuss our current understanding about the e-ph coupling in graphene and in the Bi_2Se_3 family of materials. In particular, I will describe recent results on electric-field and temperature-dependent transport measurements in exfoliated thin Bi_2Se_3 crystals and on the generation of thermoelectric voltages due to hot electrons in graphene. In contrast to conventional metals with large Fermi surfaces, 2D Dirac electrons are largely decoupled from acoustic phonons leading to relatively low electron-lattice cooling rates. Temperature and bias dependent measurements reveal the presence of specific optical phonon modes that dominate the electronic response, with similar phenomenology in graphene and Bi_2Se_3. However, the large difference in the energy of the relevant modes (200 meV and 8 meV, respectively) results in dramatically different bias and temperature dependent transport characteristics. While in Bi_2Se_3 the resistivity changes strongly even at low temperatures (<100 K), reflecting inelastic scattering due to the thermal activation of optical phonons, the restriction of the acoustic phonons that can scatter off electrons in graphene leads to very long cooling times and unconventional high-order cooling pathways assisted by disorder in the same temperature range.

Fr.F.3_O2 - Study of the field-induced virgin effect in Mn-Fe-P-Si room temperature magnetocaloric compounds

A. Bartok[1], M. Kustov[2], L. F. Cohen[2], A. Pasko[1], K. Zehani[3], L. Bessais[3], F. Mazaleyrat[1], M. LoBue[1]

1. SATIE ENS-Cachan, France
2. Imperial College London, London, United Kingdom
3. ICMPE-CMTR, CNRS, France

Hexagonal Mn-Fe-P-Si compounds are known to represent a promising rare-earth-free road to room temperature magnetic refrigeration [1]. The giant magnetocaloric effect (MCE) has been studied in this system with particular emphasis on the tuning of critical temperature and magnitude of the entropy change as a function of the composition [2]. Many materials where the first-order transition is associated with a strong magneto-elastic coupling show a peculiar phenomenon referred as “virgin effect” [3, 4] consisting in a lower transition temperature Tc upon first cooling and in a different slope of the magnetization versus temperature curve. To separate extrinsic aspects (i.e. synthesis route, micro-structure) from the intrinsic ones (i.e. the composition) we focus our attention on the influence of sintering technique on the virgin effect in Mn-Fe-P-Si compounds. Powders with composition Mn1.3Fe0.65P0.5Si0.5 have been prepared by ball milling and solid-state reaction methods and consolidated using conventional and SPS sintering. Magnetic and calorimetric measurements show important differences upon first cooling, and slight differences on second cooling between the samples prepared by different synthesis routes. Further measurements using Hall-probe imaging in high magnetic field have been carried out. Virgin samples have been cooled down just above the critical temperature, and the first phase transition has been induced by application of a magnetic field. Bulk samples show staircase isothermal magnetization curves whereas powders show a smoother transition curve. Partial phase transitions have been observed by Hall-probe technique.

This research has received funding from the European Community's Seventh Framework Programme FP7/2007-2013 under grant agreement n 310748 (DRREAM).

Fr.F.3_O3 - Giant Magnetocaloric effect and thermopower in multiferroic Eu1-xBaxTiO$_3$

R. Mahendiran [1], K. Rubi [1]

1. National University of Singapore, Singapore

The cubic perovskite $EuTiO_3$ is an antiferromagnetic quantum paraelectric. Partial replacement of the divalent Eu by the divalent Ba induces ferromagnetism and ferroelectricity. We have investigated magnetocaloric effect and thermopower in Eu1-xBaxTiO$_3$ series ($0 < x < 1$). Specific heat and thermal conductivity were also measured on selected composition. It is found that the parent compound $EuTiO_3$ exhibits the largest magnetic entropy change of 45 J/kg.K for a field of 5T at its Neel temperature (5.5 K) and an adiabatic temperature change of 16 K. The magnitude of the magnetic entropy change decreases with increasing Ba content. However, even the most diluted compound x = 0.9 shows an appreciable magnetic entropy change of 9 J/Kg.K at the cryogenic temperature. Thermopower is negative and large (S = 200-400 microvolt/K) in all these compounds and it increases in magnitude with increasing temperature. The giant magnetocaloric effect is attributed to suppression of spinfuctuations of Eu:4f moments.

Fr.G.1_I1 - Spin-transfer torque for nano-magnonics

S. Demokritov [1], V. Demidov[1], S. Urazhdin [2]

1. University of Muenster, Germany
2. Emory University, Atlanta, GA, United States

We discuss recent experiments on utilization of spin-transfer torque for excitation and amplification of spin waves propagating in microscopic magnonic guiding structures. We demonstrate a novel approach enabling efficient integration of spin-torque nano-oscillators with magnonic waveguides enabling directional transmission of spin waves excited by the spin-polarized electric current. We also show that the spin-transfer torque exerted by pure spin currents generated due to the spin-Hall effect can be used to reduce propagation losses of spin waves in microscopic magnonic waveguides

Fr.G.1_O2 - Direct microscopic observation of spin wave modes in nanoscaled antidot lattices

J. Gräfe [1], A. Gangwar [2], M. Noske [1], H. Stoll [1], C. H. Back [2], G. Schütz [1], E. J. Goering [1]

1. Max Planck Institute For Intelligent Systems, Stuttgart, Germany
2. Department of Physics, University of Regensburg, Regensburg, Germany

Magnonic crystals are nanostructured metamaterials with periodically alternating magnetic properties, similar to photonic crystals, which have gained significant scientific interest. These nanostructures have great potential for technological applications in data processing and storage, and spintronics. A periodic variation is achieved by creating holes in a magnetic host material to form a so-called antidot lattice (ADL). The introduction of the artificial ADL allows to alternate the spin wave dispersion in the material and to form a spin wave guide or filter. The spin wave dispersion can be tuned by variation of antidot size and distance, and the externally applied magnetic field. However, reaching technologically relevant higher frequencies and short-range filtering requires nanosized ADLs. As the spin wave propagation in nanoscaled ADL cannot be visualized by time resolved Kerr microscopy, typical investigations use all electrical spin wave spectroscopy or Brillouin light scattering and are unable to directly image the propagation of spin waves in nanometer sized magnonic crystals. Here, we present results from advanced time resolved x-ray microscopy (MAXYMUS@BESSY) of spin wave propagation and the mechanisms behind selective transmission or damping in these magnonic crystals. Therefore, magnon modes spanning from 250 MHz up to 8 GHz were resonantly excited and the influence of a variable applied field was investigated. These measurements allowed the direct observation of the individual modes, their interaction with the ADL, and their respective localisation within the lattice. Furthermore, we deduce and visualise the mechanisms behind the tailorable band structure of this class of magnonic crystals and the selective transmission or damping. Understanding this mechanism allowed tuning the magnon propagation length within the ADL ranging from 0.5 to 15 Ám. Additionally, our spin wave movies indicate that these mechanisms in magnonic crystals can be exploited to focus magnons laterally.

Fr.G.1_O3 - Unidirectional spin-wave edge modes in perpendicularly magnetized permalloy structures

B. Leven [1], F. Ciubotaru [1], A. V. Chumak [1], V. I. Vasyuchka [1], A. A. Serga [1], B. Hillebrands [1]

1. Fachbereich Physik And Forschungszentrum Optimas, TU Kaiserslautern, Germany

The continuous increase of data transfer capacity and processing speed in information technology requires a permanent evaluation of the underlying processes. However, the currently established techniques in CMOS technology and even spintronic applications seem to approach their limits. Here, using spin-wave information processing - so-called magnon spintronics - offers a high potential for future technology solutions. The advantage of this field is that information transport is conducted solely by the spin system without electron transport, thus preventing Ohmic losses and allowing for lower energy consumption than in conventional technology. New concepts using spin waves in micro- and nano-sized magnetic structures have shown promising results for application in magnon spintronic devices, as e.g. the magnon transistor or spin-wave interference logic gates. In this field, out-of-plane magnetized magnetic structures offer an essential benefit compared to the in-plane magnetized structures used so far: in perpendicularly magnetized films the spin-wave dispersion is isotropic, as the propagation direction is always perpendicular to the magnetization direction. Therefore, even in geometrically complex spin-wave conductors the propagation control of spin waves can be easily achieved. Employing micromagnetic simulations we demonstrated the controllability of a unidirectional propagating spin-wave mode excited in an isotropic perpendicularly magnetized Ni81Fe19 medium which allows for information transport even if the symmetry of the sample geometry is broken. Even the propagation around a corner of 90 ° is feasible. We showed that by controlling the excitation frequency the character of the spin-wave emission can be tuned between isotropic and anisotropic. Even for the volume waves an anisotropic spin-wave emission with respect to the excitation antenna can be achieved. These results show the high potential for the realization of magnonic circuits based on perpendicularly magnetized spin-wave conductors.

5. Kotel'nikov Institute of Radioengineering and Electronics, Russia

The dispersion of spin waves in the magnetostatic in dipole exchange regimes is inherently anisotropic [1]. We have used the time-resolved scanning Kerr microscopy [2] and micromagnetic simulations to study the propagation of spin waves across a T-junction of 5 µm wide Permalloy waveguides. The T-junctions were biased by a magnetic field applied at an angle to its symmetry axis. We demonstrate that the non-uniformity of the internal magnetic field and magnetization inherent to patterned magnetic structures creates a medium of graded refractive index for propagating magnetostatic spin waves and can be used to steer their propagation in magnonic architectures. This results in the T-junction structure acting as a field-controlled magnonic multiplexor. The character of the magnetisation and effective field non-uniformities can be tuned and potentially programmed using the applied magnetic field. Thus, our findings suggest a possibility of using the principles of the graded-index magnonics within a novel reconfigurable magnonic computing technology.

Fr.G.1_O5 - Effective way of spin-wave excitation in YIG-Pt structures

A. Serga [1], M. Agrawal [1], V. Vasyuchka [1], B. Hillebrands [1]

1. Department of Physics and State Research Center OPTIMAS, University of Kaiserslautern, Kaiserslautern, Germany

The field of magnonics deals with the transfer and processing of information through the utilization of spin waves and their quanta, magnons. One of the main challenges for this field is the limited lifetime of magnons even in such a low-damping material as single crystal yttrium-iron-garnet (YIG). One possible way to overcome this issue is the compensation of the spin-wave damping via injection of a spin transfer torque to a magnetic medium using a spin-polarized electron current in an adjacent non-magnetic metal layer. The decrease in the damping of travelling spin waves in YIG-Pt bilayer-based waveguides connected to a dc current source has already been demonstrated. However, the absolute value of spin-wave attenuation in a Pt-covered YIG film is still unacceptably high for practical applications. To understand the nature of this decay we performed a systematic study of the influence of a thin Pt film on the spin-wave propagation in a 6.7 Ám thick YIG waveguide. Spin waves were excited and detected by 50 Ám wide microstrip antennas at frequencies around 7 GHz. Using different excitation geometries, we have found that the observed Pt-related decrease in a spin-wave amplitude is caused not by magnon relaxation processes, but by a reduction in a spin-wave excitation efficiency due to the electromagnetic shielding of microwave Oersted fields induced by the antennas. The shielding effect is strong even if the thickness of the Pt layer (2-10 nm) is significantly smaller than the microwave skin depth. By using of a novel excitation geometry, where the Pt layer faces the ground plane of a microstrip line, we have eliminated the shielding effect and achieved, thus, a drastic (up to 100 times) increase in the excitation efficiency of the Damon-Eshbach surface spin wave.

In a prototypical diluted magnetic semiconductor (DMS) (Ga,Mn)As, substitution of Mn^{2+} and Ga^{3+} leads to a very small chemical solubility, availability of specimens limited to metastable thin films, and high sensitivity to heat treatment. In 2007, we applied MuSR to study (Ga,Mn)As films grown by MBE method [1], and demonstrated development of homogeneous ferromagnetic order in the full volume with a rather sharp transition below Tc for specimens with proper heat treatment. Subsequently we succeeded in synthesizing new DMS systems Li(Zn,Mn)As ([2] ferromagnetic Tc up to 50 K), (Ba,K)$(Zn,Mn)_2As_2$ ([3] Tc up to 200 K), and (La,Ba)(Zn,Mn)AsO ([4] Tc up to ~ 50 K). These systems have similar/identical crystal structures with those of FeAs superconductors LiFeAs, (Ba,K)Fe2As2, and LaFeAsO with a very good matching of lattice parameters. Thanks to isovalent (Zn,Mn) substitutions, these new DMS systems can be obtained as bulk specimens, with spin doping and charge doping achieved independently with each other. We performed MuSR studies in bulk specimens of these new DMS systems [2-4] and confirmed development of ferromanetism in the full volume fraction, and found a linear correlation between spatially averaged ordered moment size and ferromagnetic Tc followed both by (Ga,Mn)As and the new DMS systems with a common slope. The linear correlation suggests common origin and mechanisms of ferromagnetic exchange interaction in all these four DMS systems. The only exception to this behavior was found in (Sr,Na)(Zn,Mn)2As2 (Tc up to ~ 20 K) [5] which has a hexagonal crystal structure different from that of (Ba,K)Fe_2As_2.

Fr.G.2_I2 - Magnetic order at the (111) polar surfaces of $SrTiO_3$: a non-magnetic insulator

J. I. Beltrán [1,2], M. C. Muñoz [1]

1. Instituto De Ciencia De Materiales De Madrid (ICMM) Consejo Superior De Investigaciones Científicas (CSIC), Madrid, Spain
2. Departamento de Física Aplicada III, Universidad Complutense de Madrid, Madrid, Spain

We show that intrinsic confined magnetic phases are realized at the two possible terminations of the (111) $SrTiO_3$ surface. $SrTiO_3$ is a transparent non-magnetic wide-band gap insulator, which crystallizes in the cubic perovskite structure, along the (111) direction it consists of alternating stacks of Ti and SrO_3layers. Via ab-initio density functional calculations, we prove that the ideal terminated $SrO_3$and Ti surfaces become metallic and magnetic. A confined half-metallic two dimensional hole gas is formed at the SrO_3 surface, while the Ti termination sustains a two-dimensional electron gas (2DEG). The breaking of translational symmetry at the surface generates a polar discontinuity -of opposite sign at the two different terminations-, which induces the electronic reconstruction. At the SrO_3 surface, the creation of confined oxygen 2p-holes in the otherwise full valence band of the oxide, induces the development of a spontaneous spin-polarization and the stabilization of the ferromagnetic ground state. Contrary, the 2DEG at the bare Ti surface, is formed by conduction Ti t2g d-electrons. Associated with the metallic state a large spin-splitting and long range magnetic order develop. The two Ti surface layers, which form a buckled honeycomb lattice, couple antiferromagnetically. Our, results evidence the crucial role of the confinement crystal direction, which determines the orbital ordering and related electron localization in real space. Quantum confinement is determinant for stabilizing the two-dimensional magnetic phase, and thus shaping the unconventional intrinsic magnetism. The confined magnetic phases at the SrTiO3 surfaces hold interesting analogies with the oxygen 2p hole-induced ferromagnetism recently reported in non-magnetic oxide heterostructures [1,2].

FR.G.2_O3 - Defect induced magnetism in SiC

S. Zhou [1], Y. Wang [1], Y. Liu [1], S. Gemming [1], M. Helm [1]

1. Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany

Defect-induced magnetism is attracting intensive research interest. It not only challenges the traditional opinions about magnetism, but also has some potential applications in spin-electronics. SiC is a new candidate for the investigation of defect-induced ferromagnetism after graphitic materials and oxides due to its high material purity and crystalline quality [1, 2]. In this contribution, we made a comprehensive investigation on the structural and magnetic properties of ion implanted and neutron irradiated SiC sample. In combination with X-ray absorption spectroscopy and first-principles calculations, we try to understand the mechanism in a microscopic picture.

For neon or xenon ion implanted SiC, we identify a multi-magnetic-phase nature [3]. The magnetization of SiC can be decomposed into paramagnetic, superparamagnetic and ferromagnetic contributions. The ferromagnetic contribution persists well above room temperature and exhibits a pronounced magnetic anisotropy. By combining X-ray magnetic circular dichroism and first-principles calculations, we clarify that p-electrons of the nearest-neighbor carbon atoms around divacancies are mainly responsible for the long-range ferromagnetic coupling [4]. Thus, we provide a correlation between the collective magnetic phenomena and the specific electrons/orbitals.

With the aim to verify if a sample containing defects through its bulk volume can persist ferromagnetic coupling, we applied neutron irradiation to introduce defects into SiC [5]. Besides a weak ferromagnetic contribution, we observe a strong paramagnetism, scaling up with the neutron fluence. The ferromagnetic contribution only occurs in a narrow fluence window or after annealing. We speculate that defect-induced ferromagnetism rather locally appears in particular regions, like surface/interface/grain boundaries.

Spintronics, which allows electrical manipulation of magnetization, is not only of scientific interest, but also of importance for realization of non-volatile memory devices based on ferromagnetic nanostructures. Spin-transfer torque is one of the most important concepts in spintronics. In the standard understanding of spin-transfer torque, an external electric field generates an electrical current which interacts with local magnetization and in turn induces dynamics of magnetization. Thus, spin-transfer torque is usually considered as a current-induced effect. In this work, we study a system with a continuously varying magnetic texture and demonstrate a novel type of spin-transfer torque which originates from an applied electric field but not a current. In this sense, the result of this work is electric-field-induced rather than current-induced. Although both of them are proportional to the applied electric field, the most important difference between the two is that a current-induced contribution is proportional to electrical conductivity while an electric-field-induced contribution is not. We illustrate that our result is closely related to a recently reported electric-field-induced spin-orbit torque from Rashba spin-orbit coupling [1], even though it is derived from a system without spin-orbit coupling. We also demonstrate that the electric-field-induced spin-transfer torque has the same form as current-induced non-adiabatic spin-transfer torque in most practical cases. It is known that the non-adiabaticity usually originates from extrinsic origins such as spin scattering, however, our result gives a non-adiabatic spin-transfer torque only from an intrinsic origin. Since the non-adiabaticity is an important parameter for spin torque efficiency, our theory opens another possibility for enhancing spin torque efficiency.

We analyse light-polarization dependent domain wall (DW) motion induced by fast optical spin-transfer torque (oSTT) pulses [1, 2] . In our experiments, a single coherent domain wall is geometrically pinned [3] on the entrance of a microscopic Hall cross patterned from an epitaxially grown (Ga,Mn)(AsP) film with perpendicular magnetic anisotropy. The strength of the oSTT is determined by the polarization dependent minimum laser fluency required to overcome the in-situ tuneable geometrical pinning barrier. Position and displacement of the DW are monitored by anomalous Hall and magneto-optical Kerr microscopy measurements. Our experimental method allows us to separate light-polarization independent thermal effects from oSTT and shows that the oSTT is the dominant mechanism at laser-light wavelengths where the spin polarization of the photo-carriers is high. We confirm by micro-magnetic calculations based on the Landau-Lifshitz-Bloch equation [4] that continuous DW motion is realised by very fast oSTT pulses. In our experiments, the pulse duration is limited dominantly by the ~ 10 ps life-time of the photo-carriers which is much shorter than the ~ 1 ns reactive precession time of the DW magnetisation. Moreover, the continuous DW motion evidences the inertia of the DW because the ~ 10 ps short oSTT pulses are applied only every ~ 10 ns.

Control of magnetic domain wall motion by electric fields has recently attracted scientific attention because of its potential for magnetic logic and memory devices. Here, we report on a new mechanism for reversible and deterministic motion of magnetic domain walls using an electric field only. Full electric-field control over the magnetic domain-wall velocity in the absence of a magnetic field or spin-polarized electric current is demonstrated using epitaxial Fe films on single-crystal $BaTiO_3$ substrates with alternating in-plane (a domains) and out-of-plane (c domains) ferroelectric polarization [1]. The magnetic domain walls of the Fe film are strongly pinned onto the a-c boundaries of the $BaTiO_3$ substrate by abrupt changes in the symmetry and strength of magnetic anisotropy as a result of strain transfer and inverse magnetostriction [2]. Repeatable back-and-forth motion of a ferroelectric a-c boundary and a pinned magnetic domain wall is realized by the application of positive and negative out-of-plane voltage pulses. The domain-wall velocity is varied over 5 orders of magnitude by adjusting the electric-field strength. Patterning of the magnetic film reveals that near-180^o transverse magnetic domain walls can be stabilized in magnetic nanowires on top of BaTiO3 due to competing shape anisotropy. Moreover, the driving mechanism is not affected by pinning centers such as grain boundaries or notches that usually affect the motion of magnetic-field or electric-current driven magnetic domain walls.

Fr.H.1_I1 - Multiple quantum critical points in a cubic heavy fermion system

S. Paschen [1]

1. Vienna University of Technology, Wien, Austria

Quantum criticality is a key organizing principles for strongly correlated electron systems. In heavy fermion compounds different kinds of quantum critical behavior have been observed experimentally. To classify them, a global phase diagram has been suggested [1]. Magnetotranport measurements on tetragonal $YbRh_2Si_2$ revealed a Kondo breakdown quantum critical point (QCP) between an antiferromagnetic and a paramagnetic phase [2], as predicted for systems with reduced dimensionality [3]. More recently, similar magnetotransport signatures were observed in the cubic heavy fermion compound $Ce_3Pd_{20}S_{i6}$ as the lower of two consecutive phase transitions is suppressed to zero [4]. Here, however, the QCP separates two different ordered phases. Indeed, in the 3D case, a Kondo breakdown QCP is expected between ordered portions of the global phase diagram [3,4]. Our investigations now focus on a second putative QCP in this system [5]. We acknowledge financial support from the European Research Council (ERC Advanced Grant No 227378) and the Austrian Science Fund (project I623-N16).

3. Department of Physics, University of California, San Diego, La Jolla, California, United States

Intermetallic compounds containing Ce or Yb atoms are archetypes for quantum critical behavior close to long-range magnetic order. $Yb_2Fe_{12}P_7$ is characterized by a low magnetic transition temperature of TN approx. 1 K and the breakdown of Fermi-liquid behavior [1]. These properties suggest the proximity to a quantum critical point (QCP) caused by the subtle competition between Kondo and RKKY interactions. The non-Fermi-liquid behavior, however, extends to magnetic fields far beyond the range of the magnetically ordered phase and does not conform to the standard QCP scenario described by the Hertz-Millis-Moriya theory. We measured thermal expansion, magnetostriction and magnetization to determine the phase diagram for fields perpendicular to the c axis. The pressure dependence was studied up to 15 GPa using resistivity measurements in hydrostatic piston cylinder and diamond anvil cells. A comparison with specific-heat measurements reveals that in $Yb_2Fe_{12}P_7$ only a small fraction of the Yb moments participate in the long-range magnetic order. The Grüneisen ratio does not diverge for T zero temperature indicating that the non-Fermi-liquid behavior is not related to a nearby pressure-induced quantum criticality. Likewise, the tiny pressure dependences of the Sommerfeld coefficient and TN argue against a magnetic order that is weakened by the Kondo effect. In view of the unusual noncentrometric crystal structure, our observations might point to geometric frustration of the magnetic moments.

3. Max-Planck-Institut für Chemische Physik fester Stoffe, Dresden, Germany
4. Department of Physics and Astronomy, Rice University, Houston, United States

Quantum criticality represents an established means for generating non-Fermi-liquid properties of an electron fluid. Spectroscopic studies in the heavy-fermion compound CeCu6-xAux have provided evidence that spatial anisotropy influences the nature of the quantum critical point. To establish this feature as a robust effect, directional probes of thermodynamic properties are called for. Here, we introduce the notion that the anisotropic stress Grüneisen ratios constitute a direct measure of the presence and strength of thermodynamic singularities. We demonstrate this new approach to quantum criticality in CeCu5.9Au0.1, uncover the scaling behavior of the associated singularities, and reveal the rich entropy landscape in the vicinity of the quantum critical point.

Fr.H.1_O4 - Non-fermi liquid behaviors and distinct metal insulator transitions in perovskite $SrIrO_3$ epitaxial films

Y. H Jeong [1], Y, A. Biswas [1]

1. Dept of Physics, POSTECH, Pohang, Republic of Korea

Understanding of metal insulator transitions in a strongly correlated system, driven by Anderson localization (disorder) and/or Mott localization (correlation), is a long standing problem in condensed matter physics. The prevailing fundamental question would be how these two mechanisms contrive to accomplish emergent anomalous behaviors. Here we have successfully grown high quality perovskite $SrIrO_3$ thin films, containing a strong spin orbit coupled 5*d* element Ir, on various substrates such as $GdScO_3$ (110), $DyScO_3$ (110), $SrTiO_3$ (001) and $NdGaO_3$ (110) with increasing lattice mismatch, in order to carry out a systematic study on the transport properties. We found that metal insulator transitions can be induced in this system; by either reducing thickness (on best lattice matched substrate) or changing degree of lattice strain (by lattice mismatch between film and substrates) of films. Surprisingly these two pathways seek two distinct types of metal insulator transitions; the former falls into disorder driven *Anderson* type whereas the latter turns out to be of unconventional *Mott-Anderson* type with the interplay of disorder and correlation. More interestingly, in the metallic phases of $SrIrO_3$, unusual non-Fermi liquid characteristics emerge in resistivity as $\Delta\rho \propto T^{\epsilon}$ with ϵ evolving from 4/5 to 1 to 3/2 with increasing lattice strain. We discuss theoretical implications of these novel phenomena to shed light on the metal insulator transitions.

Fr.H.1_O5 - On the superconducting instabilities of metals near quantum critical points

S. Raghu [1]

1. Stanford University, California, United States

We study the dynamics of a metal near a quantum critical point. We study both the intermediate regime where the Landau damping of the boson can be neglected and the strongly overdamped regime where the order parameter is strongly Landau damped. Using renormalization group and large N analyses, we consider controllable regimes in which superconducting instabilities are enhanced near continuous quantum phase transitions. We present renormalization group treatments of singular enhancement of superconductivity in the Cooper channel due to the exchange of a gapless (critical) order parameter field. The resulting log-squared and higher order divergences are treated in systematic fashion. We also discuss regimes in which superconductivity develops out of a normal state that consists of ill-defined quasiparticles.

Fr.H.2_I1 - Conductive atomic force microscopy of magnetic tunnel junction nanopillars

S. Majetich [1], S. Piotrowski [1], S. Oberdick [1], M. Bapna [1], A. Abdelgawad [1], M. Matty [1]

1. Carnegie Mellon University, Pittsburgh, Pennsylvania, United States

Conductive atomic force microscopy (C-AFM) enables scanning magnetoresistance measurements of individual nanostructures. Here we describe the application of C-AFM to CoFeB/MgO/CoFeB magnetic tunnel junctions as a function of their diameter. The CoFeB films were < 1.2 nm so that they exhibited perpendicular anisotropy. Electron beam lithography and nanoparticle masking were used with reactive ion etching to pattern CoFeB/MgO/CoFeB tunnel junctions with diameters down to 10 nm. After scanning electron microscopy was used to determine the nanopillar diameters, the samples were imaged with the C-AFM. Topography and conductivity maps of the nanopillar patterns were collected simultaneously. Measurements of resistance as a function of magnetic field and voltage bias were made with the Pt-coated probe tip in stable contact with individual nanopillars. When resistance-area product was unchanged by the patterning process, field-dependent switching was reliably observed. Major and minor hysteresis loops were collected as a function of the applied magnetic field to determine the effective anisotropy of the free layer. At fields close to the coercivity the tunnel current showed random telegraph noise, and the effective anisotropy was also calculated from the switching statistics and comparison with Landau-Lifshitz-Gilbert modeling of the magnetization dynamics. Voltage induced switching of the free layer was observed in devices larger than 80 nm. The regimes of magnetization reversal by coherent rotation and domain wall nucleation are discussed.

Fr.H.2_O2 - Ferritin-based multifunctional nanoparticles for magnetic fluid hyperthermia

Magnetic nanoparticles (MNP) are fundamental building-blocks for developing innovative nanodevices with multi-fold therapeutic and diagnostic activities, including magnetic fluid hyperthermia (MFH), Magnetic Resonance Imaging (MRI) and targeting of tumor cells. Iron oxide MNPs mineralized within human H chain ferritin protein, HFt, represent a viable platform to achieve this goal as they offer multiple advantages. However, a major limitation is that their size cannot exceed the protein shell inner diameter (ca. 8 nm), which is not large enough to produce a significant MFH effect. In order to overcome this drawback while still exploiting the advantages provided by HFt, we developed two different approaches: first, we increased the magnetic anisotropy of 6-7 nm NPs@HFt by doping with small amount of Co2+ ions (Co-NPs@HFt) [1]; the second approach was based on HFt-NPs constructs obtained by conjugation with apo-HFt of larger, chemically synthesized, magnetite NPs (15-18 nm). In vitro tests showed that both constructs were highly biocompatible. The hyperthermic properties of Co-NPs@HFt and HFt-NPs were investigated through calorimetric technique and related to the structural and magnetic properties. A doping of 5% was found to enhance the hyperthermic efficiency of Co-NPs@HFt and to induce a significant reduction of cell viability when exposed to an alternating field, with clear indications of an advanced stage of apoptotic process. On the other hand, the same treatment performed with HFt-NPs had no effect on cell viability, despite their much larger hyperthermic performances with respect to Co-NPs@HFt. Confocal microscopy measurements performed on rhodamine labeled samples, showed that the different hyperthermic efficiency should be related with a different level of cell internalization, pointing out the fundamental role of cell-nanoparticles interactions with respect to large hyperthermic efficiency.

Fr.H.2_O3 - Efficient, safe and fast magnetic targeting of stem cells in spinal cord injury

V. Zablotskii [1], O. Lunov [1], D. Tukmachev [2], E. Sykova [2], S. Kubinova [2], A. Dejneka [1]

Cell transplantation represents a promising therapy for the treatment of different diseases, including spinal cord injury (SCI). To achieve a significant therapeutic effect, the number of cells in the lesion should be a large enough [1]. We propose a new magnetic system consisting of two cylindrical magnets placed on a ring-shaped folder with the poles facing each other. First, we studied general patterns of different superparamagnetic iron oxide nanoparticles (SPIONs) engulfment by living cells and verified endocytosis mechanisms involved in SPIONs uptake. Second, SPION-labelled mesenchymal stem cells were subdurally transplanted and targeted by a magnetic field to the lesion site in a rat model of SCI. The calculated magnetic forces exerted on the transplanted cells in the lesion site correlated with the cell distribution found by histological analysis. We succeeded in efficiently delivering stem cells to lesions within the animal anaesthesia time period, 2 hours. In our experiments, in contrast to the control non-magnetic groups, the SPION-labelled cells were able to migrate from the trapping area to the lesion site. It is worth noting that the efficacy of conventional stem cell transplantation to the lesion site is low and variable, with typical delivery time to SCI varying from 12 to 24 h [2]. The efficacy of the proposed magnetic targeting strategy and the possibilities of reaching therapeutic concentrations were assessed together with physiological and biological factors that decrease the number of captured live cells at the lesion site, e.g., because of cell death in the target area, macrophage activity and/or the possible further removal of cells due to cerebrospinal fluid flow. A minimally invasive magnetic targeting strategy enabling fast cell retention after intrathecal transplantation was designed and tested in vivo. Its main advantage is the ability to reach a significantly higher concentration of SPION-labelled stem cells into the vicinity of a lesion site. Supported by MEYS of the CR (LO1309).

Fr.H.2_O4 - Regulation of mesenchymal stem cell adipogenesis by oscillating high-gradient magnetic fields

Biological effects of magnetic field on intracellular molecular mechanisms attract significant interest [1,2]. Here, we show that oscillating HGMF and mechanical vibration affect adipogenic differentiation of mesenchymal stem cells (MSCs) by the transmission of mechanical stress to the cell cytoskeleton, resulting in F-actin remodelling and subsequent down-regulation of adipogenic genes. Our findings propose an insight into the regulation of cellular nanomechanics, and provide a basis for better controlled down-regulation of stem cell adipogenesis by HGMF, which may facilitate the development of challenging therapeutic strategies suitable for the remote control of biological systems.
The adipogenesis was significantly down-regulated after 2 days and completely blocked after 7 days of HGMF as well as mechanical vibrations [3].Furthermore, our study of the effects of mechanical and magnetic vibrations on the differentiation pathway of MSCs may give a first hint as to a force value that could be responsible for changes in cell fate. Down-regulation of adipogenesis of MSCs by oscillating high-gradient magnetic fields and mechanical vibration was caused by small mechanical forces 0.1-1 pN transmitted through the cytoskeleton to the nucleus and DNA. These force values are just above the thermal fluctuation forces of f-actin.[3] Nevertheless, two days' worth of exposure of the MSCs to mechanical vibrations and oscillating magnetic induced alterations of adipogenic gene expression. We suggest a mechanism involving the following consequence of events in the transformation of MSCs upon oscillating HGMF: external magneto-mechanical stress → enhancement of actin filament tension → enhanced tension of the cell nucleus and DNA → change of gene expression→ change in the differentiation pathway. Furthermore, we suppose that, this mechanism can be reversible due to the ability of cells to deform elastically in the operating ranges of the mechanical loading [4,5].

Fr.H.2_O5 - Halbach arrays consisting of cubic elements optimized for high field gradients in drug delivery applications

L. Barnsley [1], J. Owen [1], D. Carugo [1], E. Stride [1]

1. Institute of Biomedical Engineering, Department of Engineering Science, University of Oxford, Oxford, United Kingdom

Magnetic drug targeting (MDT) has received a significant amount of attention from researchers as a method for highly localized delivery of therapy in a range of diseases, including cancer and stroke [1]. While MDT has significant advantages because it is non-invasive and magnetic fields can permeate the human body without being attenuated by tissue, there are a number of challenges that must be overcome before the technique is clinically viable [2]. Of particular importance is the need to develop systems that can deliver sufficient magnetic forces at useful tissue depths to overcome the hydrodynamic forces of blood flow in the targeted region [3]. In this paper, we present a series of designs of Halbach arrays optimized to retain magnetically tagged agents at distances up to 50 mm. By considering assembly forces, and field and force profiles, a particular design was selected and constructed. In vitro experiments to test the assembled array's capacity to retain magnetic microbubbles against flow demonstrated a factor of two increase in the relative intensity of retained microbubbles at 15 mm from the magnet when compared with a conventional, linear Halbach array. We propose that these designs are viable as light-weight, inexpensive options for MDT, particularly for applications for which size and portability are limiting factors, e.g. thrombolysis and combination therapies.

We report a combined spin-polarized scanning tunneling microscopy (SP-STM/S) and *ab initio* calculations of the magnetic state of individual nm small biatomic-layer-high Fe islands on Cu(111). Our study reveals a one-dimensional helimagnetic spin order, with a period of 1.28 nm, in Fe nanoislands where the topmost Fe is located in bridge-site of the surface Fe layer [1]. Energy-resolved SP-STS mapping provides spatially-resolved and spin-dependent electronic structure of this spin order. The wave vector describing the spin order remains constant in the energy range -0.8 to +0.6 eV, whereas the spin contrast varies and changes its sign near the Fermi energy. We discuss this energy dependence in view of the electronic structure associated with the helical spin density wave. Our results point at a novel aspect of SP-STM/S to characterize complex spin order with respect to its spin-dependent electronic density of states.

Domain wall propagation in magnetic nanostructures with in-plane magnetic anisotropy is strongly affected by the presence of edge topological defects [1] (half vortices and antivortices) that can be tuned by the system geometry (antidots, notches in nanowires, bifurcations, à). Nanostructured weak perpendicular anisotropy materials, with comparable in-plane and out-of-plane magnetization components, introduce an additional complexity in which in-plane half-vortices can become coupled to topological defects in the out-of-plane magnetization stripe pattern (dislocations and disclinations) [2]. In this work we have studied domain wall propagation in magnetic bifurcations of weak perpendicular anisotropy amorphous Nd-Co alloy. The samples have been fabricated by a combined e-beam lithography, cosputtering and lift-off process on Si_3N_4 membranes and Si substrates. Samples were patterned in an "Y" geometry, 50 nm thick, 1 micron wide and 10 micron long. Magnetization reversal has been studied by magnetic Transmission X-ray Microscopy, Kerr microscopy and Magnetic Force Microscopy. First, a large in-plane field is applied along the "Y" symmetry direction in order to define in-plane easy axis. Then, a series of transverse field pulses allows us to nucleate and propagate a vortex wall in the nanostructure. This process results in an asymmetric configuration of each "Y" branch and modifies stripe domain configuration at the bifurcation due to the coupling between in-plane and out-of-plane topological defects.

Fr.H.3_O3 - Suppression of transition from antiferromagnetic to weak ferromagnetic state in (0001) oriented α- Fe_2O_3 film by Ir doping

S. Prakash Pati [1], N. Shimomura [1], H. Hoshino [1], T. Nozaki [1], K. Mibu [2], M. Sahashi [1]

Antiferromagnets with high ordering temperature have attracted the attentions due to their potential application in spintronics devices. In this context, corundum structured hematite α-(α- Fe_2O_3) is a most promising antiferromagnet having high Neel temperature (TN, 950K). But, a well-known spin reorientation from the [0001] axis to the (0001) basal plane occurs at Morin temperature TM, 263K [1].This spin re-orientation is explained by the competition between magnetic dipolar anisotropy (KMD, in-plane anisotropy) and single-ion anisotropy (KFS, perpendicular anisotropy) [2]. The origin of weak ferromagnetism above TM is the Dzyaloshinskii-Moriya (D-M) interaction, where asymmetric exchange interaction between two neighboring spins results in aweak net magnetic moment in the (0001) plane.In this study, the successful observation of weak in-plane magnetic moment above TM in (0001) oriented Fe_2O_3 thin films and its suppression by Ir-doping is reported. This suppression of weak ferromagnetism leads to a conclusion of enhancement of Morin transition temperature. Fe_2O_3 and Ir-doped α- Fe_2O_3 films are fabricated by reactive sputtering of metal target using RF magnetron sputtering. A clear increase of in-plane magnetization for Fe_2O_3 film has been observed indicating Morin transition, while that was not observed for Ir-doping case. These results indicate that by Ir-doping, TM of Fe_2O_3 is dramatically enhanced. To clarify this assumption, conversion electron M÷ssbauer spectroscopy (CEMS) study has been employed at room temperature.The results for the quadrupole shift and the intensity ratio confirm that the spin direction of Fe_2O_3 is in-plane and that TM is below room temperature, while the spin direction of Ir-Fe_2O_3 is perpendicular to the film and TM should be higher than room temperature. This work was partly funded by ALCA Program of JST and ImPACT Program of Council for Science, Technology and Innovation (Cabinet Office, Japan Government).

3. Center for Correlated Electron Systems, Institute for Basic Science, Seoul National University, Republic of Korea

Nanomagnets, due to reduced dimensionality, are characterized by a spatial variation of spin polarization and magnetic anisotropy [1,2] within an individual magnet, which often leads to a reduced magnetization stability [2]. Surface (or perimetric) engineering [3] has been employed to modify magnetic properties of nanomagnets. However, microscopic access to the local magnetic state in an individual nanomagnet [1,2] is called for to address the underlying mechanism. Here we report a tuning of the homogeneity of the spin-polarization in 10 - 20 nm size individual Co nanomagnets [1,2] by perimetrical contact with Fe [4,5]. Spin-polarized scanning tunneling spectroscopy resolves the spin-polarization of an individual island, with subnanometer spatial resolution. The study reveals uniform electronic states throughout the Co core with an atomically sharp interface at the Co-Fe border. We discuss the role of perimetrical contact for structural relaxation and for the local strain state, and we elucidate the impact on spin polarization and the magnetic anisotropy of single nanoislands.

Magnetic skyrmions are topologically protected particle-like spin structures, with a topology characterised by their Skyrmion number [1]. Numerical predictions suggest that they exhibit rich dynamical behaviour governed by their topology, such as the basic gyrotropic and breathing eigenmodes [1-3]. While recent advances have brought the static manipulation of skyrmions under control, their dynamical behaviour is largely unexplored experimentally. We provide here the first observation of the basic eigenmode dynamics of skyrmion bubbles. In particular, we present picosecond nanoscale imaging data i) of the gyrotropic mode of a single skyrmion bubble in the gigahertz regime [4] and ii) the breathing-like behaviour of a pair of skyrmionic configurations. The observed dynamical behaviour is used to confirm the skyrmion topology and show the existence of an unexpectedly large inertia that is key for accurately describing skyrmion dynamics [4]. These results demonstrate new ways for experimentally observing skyrmion dynamics and provide a framework for describing their behaviour. Furthermore, the results reveal a link between the dynamical behaviour of skyrmions and their distinct topology, with possible ramifications for Skyrmions research including recently proposed technological applications [5].

Fr.I.1_O2 - High-frequency dynamic modes of a magnetic antivortex

K. Buchanan [1], G. Riley [1], J. Liu [1], A. Haldar [1], M. Asmat-Uceda [1]

1. Colorado State University, Colorado, United States

Magnetic vortices have been studied extensively in recent years because of their rich physics as well as their potential for applications. Magnetic antivortices, the topological counterpart of the vortex state, have similar potential; however, comparatively few experimental investigations have been conducted because they are more difficult to create. This presentation will discuss experimental measurements of the high-frequency spin dynamics of a magnetic antivortex made using micro-focus Brillouin light scattering (micro-BLS). Permalloy nanostructures with a pound-key-like shape that promotes the reliable formation of AV's [1] were patterned on top of gold waveguides that were used to excite the structure. The pumping frequency was swept from 1-7 GHz and the BLS intensity from a ~250-nm spot focused at various locations on the patterned structure were recorded. BLS spectra corresponding to the three possible magnetic states were obtained: AV, saturated along the dynamic field, and saturated perpendicular to the dynamic field. Spatial scans reveal that the modes in the 5-6 GHz range occur primarily in the legs of the structure and the modes in this range are similar for all of the magnetic states. A mode observed at 3.4 GHz is, however, unique to the AV state and is associated primarily with dynamics within the AV (intersection) region. The experimental results will be compared with detailed micromagnetic simulations of the expected modes. This work was supported by DOE-BES ER46854.

The lateral arrays of magnetic dots with submicron in-plane sizes attract a considerable attention due to the presence of a vortex (half-skyrmion) magnetization configuration in their ground states. The vortex core excited by external magnetic field or electric current oscillates in 100 MHz - 1 GHz range providing a narrow frequency linewidth. The coupled vortex oscillators are promising candidates for spin-torque nano-oscillators emitting microwaves. One of unresolved problems is synchronization of several nano-oscillators that would allow increasing essentially the generated microwave power. The need of close packing of such magnetic dots to increase the interdot magnetostatic interactions leads to necessity to consider the collective vortex dynamics in dot clusters. In the present paper we develop an analytical approach to the dynamics of coupled vortex dot oscillators. The clusters consist of N=3 or N=4 laterally placed cylindrical dots on a substrate in the form of equilateral triangles or squares. The interdot magnetostatic interaction is accounted via multipole decomposition on the inverse the dot center-to-center distance. The gyrotropic eigenfrequencies/eigenmodes of collective vortex oscillations are calculated analytically [1] and compared with recent broadband ferromagnetic resonance and X-ray imaging experiments on interacting clusters of permalloy dots. The calculated fine structures of the excitation spectra of N=3 and 4 dot clusters are similar. The splitting of the degenerated gyrotropic frequency of isolated dots about of 10-30 MHz is determined by interdot coupling integrals, which are expressed explicitly in the form of multipole decomposition. The fine structure of the dot spectra can be tuned by changing the vortex core polarizations by an external magnetic field. The spread of the collective mode frequencies is approximately 3 times larger for the antiparallel vortex core polarizations than for the aligned case.

Fr.I.2_I1 - Nonlinear unidirectional spin Hall magnetoresistance

P. Gambardella[1]

1. Department of Materials, ETH Zurich, Switzerland

Magnetoresistive effects constitute a prominent manifestation of spin-orbit coupling and spin dependent conductivity in ferromagnets, with manyfold applications in sensor technology. Most such effects, including the anisotropic magnetoresistance (AMR), giant magnetoresistance (GMR), and spin Hall magnetoresistance (SMR), do not distinguish between opposite orientations of the magnetization. Indeed, all linear MR are even with respect to the inversion of either the current or magnetization owing to the time reversal symmetry embodied in the Onsager's reciprocity relations. In noncentrosymmetric conductors, however, nonlinear resistive terms can give rise to an MR that is linear in the magnetization. In this talk, we report on a new MR effect1 occurring in ferromagnet/normal metal bilayers with strong current-induced spin accumulation.2-4 The effect combines features that are typical of the current-in-plane GMR and spin Hall effect (SHE), whereby the spin accumulation induced by the SHE in the normal metal replaces one of the ferromagnetic polarizers of a typical GMR device. Differently from GMR, however, this effect introduces a nonlinear dependence of the resistance on the current, which gives it unique unidirectional properties: we show that the longitudinal resistance of Ta|Co and Pt|Co bilayers changes when reversing the polarity of the current or the sign of the magnetization. This unidirectional MR scales linearly with current density and has opposite sign in Ta and Pt, which we associate to the modulation of the FM/NM interface resistance due to the current-induced spin accumulation. We expect such a resistance to be a general feature of noncentrosymmetric magnetic systems with strong spin-orbit coupling, including magnetic semiconductors and topological insulators.

Fr.I.2_O2 - Influence of non-magnetic spacers on spin wave spectra in two-dimensional binary magnonic crystals

P. Malago [1], P.Gruszecki [2], L. Giovannini [1], M. Krawczyk [2]

1. Dipartimento di Fisica e Scienze della Terra, Universitá di Ferrara, Ferrara, Italy
2. Faculty of Physocs, Adam Mickiewicz University In Poznan, Poznan, Poland

We study theoretically the influence of a non-magnetic spacer between ferromagnetic dots and ferromagnetic matrix on the spectra of spin wave excitations in two-dimensional bi-component magnonic crystals. With the use of the dynamical matrix method supported by micromagnetic simulations we investigate structures that are inhomogeneous across the thickness, i.e., composed of square array of grooves in permalloy matrix partially filled with ferromagnetic dots. We show that the introduction of the non-magnetic spacers significantly modify the total magnetic field in magnonic crystals, especially at the edges of the grooves and dots. This allows effective manipulation of the magnonic band structure, especially of the spin waves localized at edges of the dots or in matrix's material, at the edges of grooves. These two types of edge modes can be identified in the same magnonic crystal with properly designed non-magnetic spacers. Moreover, we demonstrate that the frequencies of the spin waves in these structures are significantly influenced by the dot material. We show that, with a single ferromagnetic material, it is possible to design a two-dimensional magnonic crystal preserving simultaneously some properties of bi-component magnonic crystals and magnonic antidot lattice. Finally, the influence of the non-magnetic spacers on technologically relevant parameters, like group velocity and magnonic band width, is evaluated and its usefulness for applications discussed. The research has received funding from Polish National Science Centre project DEC-2-12/07/E/ST3/00538, from the European Union's Horizon 2020 programme under the Marie Sklodowska-Curie GA No 644348 (MagIC), and from MIUR-PRIN 2010-11 Project2010ECA8P3 'DyNanoMag'.

FR.I.2_O3 - Spin and orbital magnetic moment of reconstructed √2 ×√2R45° magnetite(001)

L. Aballe [1], L. Martín-García [2], R. Gargallo-Caballeroa [2], M. Monti [2], M. Foerster [1], J. F. Marco [2], J. de la Figuera [2]

Magnetite is a functional material with applications in a variety of fields ranging from catalysis to information storage or soil decontamination. It is ferrimagnetic with a high Curie temperature, a half-metal conductor, multiferroic at low temperatures and with a metal-insulator transition known for the last century. Despite its interest, many of its properties are still under discussion, from the origin of the metal-insulator transition to its half-metal character or even its magnetic moments. The experimental data scatter in this latter point, from vanishing orbital moments to giant ones, has been shown to strongly depend on the surface quality and preparation, since most studies make use of the surface-sensitive soft X-ray Magnetic Circular Dichroism (XMCD) technique[1]. We here present the magnetic properties of a well-characterized magnetite (001) surface, prepared by sputtering/annealing cycles providing the √2 ×√2R45° reconstruction. The distribution of magnetic domains on the surface, as well as the near-surface magnetic moments were measured by XMCD-Photoemission Electron Microscopy with different kinetic energies of the secondary electrons, in order to vary the depth sensitivity[2]. A reduced total moment of 3.3 m_B and a ratio of about 0.10 between orbital and spin moment was found, which we attribute to the $Fe2^+$-poor surface reconstruction[3].

The unique properties of non-trivial topological states, e.g. magnetic skyrmions, may path the way towards novel spintronic devices. However, these spin textures have only been observed in special class of materials possessing non-centrosymmetric crystal structure and at low temperatures, which limits their application potential. We offer an alternate route to design magnetic heterostructures that resemble swirls, vortices or skyrmions with distinct topological charge densities at room temperature [1]. We will present results on nanostructures consisting of soft-magnetic 40 nm thick $Ni_{80}Fe_{20}$ and 5 nm thick Co/Pd multilayers separated by a Pd spacer (1 to 30 nm) mediating an interlayer exchange coupling strength that ranges from 0.1 to 2 mJ/m2. Depending on the interlayer coupling either planar vortices or donut states are imprinted into the Co/Pd layers. Driving full or minor hysteresis loops allows to stabilize topologically distinct donut states with topological charges of about 1 and 0. Evidence for the stabilization of the predicted non-collinear spin textures in the Co/Pd layers is provided by direct imaging of the magnetization patterns utilizing X-ray magnetic circular dichroism (XMCD) with magnetic soft X-ray transmission microcopy (MTXM) and X-ray photoemission electron microscopy (XPEEM). Modifications in both core size and out-of-plane magnetization components with respect to vortices in nanopatterned soft-magnetic materials induce distinct magnetization dynamics with time dependent gyrofrequencies. Supported by DFG (MA 5144/2-1), ERC under EU FP7 program (FP7/2007-2013)/ERC n.306277 and FET programme under FET-Open grant number 618083. Dzyaloshinskii-Moriya interaction (DMI) in heavy metal/ferromagnetic thin film structures has recently drawn great attention [1-7]. Such interfacial DMI is known to be responsible for high domain-wall velocities [1-3] in perpendicularly magnetized layers and for the formation of a magnetic skyrmion state [5], which is expected to be promising for ultrafast and high-density storage devices. So far, several experimental methods to verify the interfacial DMI has been proposed [2,6,7]. However, since all those methods have been reliant upon the magnetization dynamics which requires specific measurement techniques and instruments including Brillouin light scattering, ferromagnetic resonance, and domain wall imaging, it is not trivial to experimentally address DMI, and therefore, the development of an easily accessible technique is still a challenge. Here, we present an asymmetric hysteresis loop in asymmetric nanostructures under an application of an in-plane bias field, which can be used for a static and macroscopic measurement of the interfacial DMI. The measured asymmetry is directly proportional to the strength of the in-plane field and the asymmetry created in the structure. Moreover, we show the dependence of the asymmetry on the adjacent top layer (X) in Pt/Co/X, which is expected to lead to different strengths of the DMI. With the help of analytical and numerical studies, we have also quantified the DMI in these systems, and those are generally in very good agreement with the previously reported values.

Recently, an atomic-scale two-dimensional magnetic skyrmion lattice at the Fe/Ir(111) interface has been discovered using spin-polarized scanning tunneling microscopy (SP-STM).[1] Skyrmions offer new exciting possibilities for spintronic applications, using them as digital information carriers. For these applications the mass production of devices using multilayer growth on large-scale substrates is indispensable. In 2009, the heteroepitaxial growth of single crystal Ir(111) films on Si(111) wafers with yttria-stabilized zirconia buffer layers has been demonstrated.[2] For our study we epitaxially grow one monolayer of Fe on top of this multilayer substrate. The SP-STM experiments reveal a magnetic skyrmion lattice, being fully equivalent to the magnetic ground state that has previously been observed on an Ir(111) bulk single crystal substrate. In addition, it is found to be robust against local atomic lattice distortions induced by multilayer preparation. Our work paves the way towards spintronic applications of nano-skyrmions in ultrathin films and multilayer systems.

Localized magnetic moments in a metal are coupled by indirect exchange interactions, which are mediated by the conduction electrons of the nonmagnetic host. For hosts with weak spin-orbit coupling, this exchange can be described by an isotropic Ruderman-Kittel-Kasuya-Yoshida (RKKY)-interaction. The damped oscillation of this interaction as a function of distance between ferromagnetic and antiferromagnetic coupling has already been observed [1]. However, for materials with strong spin-orbit coupling, such as platinum, an additional anisotropic Dzyaloshinskii-Moriya (DM) type term has to be considered [2,3]. In our work, we report for the first time a study of the distance dependency of this DM term in pairs of an Fe-H2 Kondo complex and an Fe atom adsorbed on Pt(111). To this end, we used a scanning tunneling microscope in an ultrahigh vacuum facility at a very low temperature of 0.3 K. We have built several pairs of various distances and performed inelastic scanning tunneling spectroscopy (ISTS) above each atom in such pairs. This reveals a splitting of the Kondo resonance and a shift of the Fe atom spin-excitation, dependent on the strength of the isotropic and DM components of the RKKY interaction for the specific distance. By using a model including the coupling to the substrate electrons in 3rd order perturbation theory [4], we were able to extract the strength of both components and find that in our system the DM term is of similar magnitude as the isotropic exchange. These results are confirmed by first-principles calculations using the KKR method

Systems consisting of single magnetic atoms adsorbed on solid surfaces represent the smallest possible realization of a magnet and have received much attention due to their potential applications in quantum computation. Moreover, they represent model systems for investigating the origin of the magnetic anisotropy energy (MAE) and fundamental magnetic interactions. The majority of the research so far has focused on transition metal (TM) atoms, and has resulted in the highest observed value of MAE, 58 meV, for Co on MgO[1]. Yet TMs have limited potential as single atom magnets due to their strong hybridization with the substrate which lowers their spin relaxation times. To overcome this problem, we propose to use rare earth (RE) elements. Their 4f electrons have much larger values of spin-orbit coupling than 3d electrons in TMs, and are highly localized. This should lead to less hybridization and therefore much larger values of MAE and longer spin relaxation times. Here we present x-ray absorption spectroscopy and magnetic circular dichroism measurements used to determine the electronic ground state and magnetic anisotropy of single Ho atoms adsorbed on platinum, copper and silver surfaces. In particular, for Ho on Pt(111) we reveal an intermediate Jz = ± 5.4 ground state with no hysteresis [2]. This is in disagreement with scanning tunneling microscopy study by T. Miyamachi et al. [3], where authors claim single ion magnetic behavior with the maximal Jz = ± 8 ground state. For Ho on the other two surfaces we find Jz = ± 6.7 ground states, with different 4f occupations: 4f10 on Cu(111) and 4f11 on Ag(111) surface.

The adsorption of molecules on metal surfaces presents a rich variety of physical phenomena. Depending on the interaction strength, these phenomena move from the creation of interface dipoles for physisorbed molecules to hybridization and charge-transfer through covalent metal-molecule bonds via strong chemisorption [1]. In some cases, a strong interaction can even lead to a surface rearrangement [2] triggered by kinetic and electrochemical processes, and eventually account for the formation of novel hybrid phases. In this work, we study the interaction of novel rare-earth quinoline molecules (Tb_3q_9) with non-magnetic metallic surfaces. The molecules preserve their structural, chemical and magnetic properties when deposited onto noble metal (Au) and passivated (SiO_2) surfaces. However, the adsorption on reactive metals such as Cu induces a magnetic phase at the interface involving molecular Tb-atoms, as determined via SQUID magnetometry and element-specfic X-ray magnetic circular dichroism (XMCD) [3]. Remarkably, the magnetic ordering persists up to room-temperature for the Tb3q9/Cu system and is linked to a chemically-triggered change in structure and stoichiometry of the interfacial species, as confirmed by infrared (IR), ultraviolet and X-ray photoemission spectroscopy (UPS/XPS). Cross-sectional transmission electron microscopy (TEM) and spectroscopy (EDX/EELS) investigations confirm the formation of a new phase involving both the high-spin metal atom present in the molecule (Tb) and the metallic surface atoms (Cu). The fact that these purpose-made molecules are able to trigger the creation of a new inorganic phase with robust magnetic properties at a non-magnetic metal surface underlines the importance and role of interfacial chemistry to crucially modify surface properties and thus design building blocks for spintronic applications.

Fr.J.1_I1 - Quantum criticality and emergence of the T /B scaling in strongly correlated metals

Shinji Watanabe [1], Kazumasa Miyake [2]

1. Kyushu Institute of Technology, Fukuoka*, Japan*
2. Toyota Physical and Chemical Research Institute Nagakute, Japan

Unconventional quantum critical phenomena observed in the heavy-electron metal beta-$YbAlB_4$ have attracted much attention [1]. The criticality is common to those observed in $YbRh_2Si_2$ [2] and even in the quasicrystal $Yb_{15}Al_{34}Au_{51}$ [3], which has been proposed to be explained theoretically by critical Yb-valence fluctuations [4,5]. By developing the theoretical framework of the quantum valence criticality under a magnetic field, we analyze the scaling behavior over four decades of the ratio of temperature T to magnetic field B observed in the magnetization in beta-$YbAlB_4$ [1]. We show that the T /B-scaling behavior can appear near the quantum critical point of the valence transition [6]. The emergence of the T /B scaling indicates the presence of the small characteristic energy scale of the critical Yb-valence fluctuations. The key origin is clarified to be due to the atomic origin of the Yb-valence fluctuations under the strong local electron correlation, giving rise to the spatially localized critical mode. In the presentation, we overview the quantum critical phenomena of valence fluctuations and discuss the mechanism of the emergence of the T /B scaling. The possibility of new universality class formed by critical valence fluctuations will be also discussed toward understanding the unconventional criticality commonly observed in the Yb-based periodic-crystal and quasicrystal systems.

Fr.J.1_O2 - Electronic correlations in Hund metals

E. Bascones [1], L. Fanfarillo [1]

1. Instituto de Ciencia de Materiales de Madrid (ICMM-CSIC), Madrid, Spain

A new concept has emerged in the last years in correlated electron systems: the Hund metal. This name was coined within the context of iron superconductors and refers to a strongly correlated metallic state found in multi-orbital systems with Hund's coupling playing a key role in setting the correlations [1]. Until very recently [2] the nature of correlations in Hund metals has been controversial and not well understood. When the atoms become spin polarized the overlap between the atomic and single particle states decreases suppressing the quasiparticle weight. Nevertheless the system seems to be far from a Mott transition as the transition is not found for moderate increase of interactions. On the other hand the strong increase of correlations as half-filling is approached has led to a description of Hund metals as doped Mott insulators. This has led to a discussion on the role of Mott physics in these systems. We have addressed the correlations in multi-orbital systems as a function of interactions, number of orbitals and electronic filling. We have clarified the nature of correlations in Hund metals and solved the controversy between Hund and Mott systems [2]. Our calculations clearly show that the suppression of coherence in Hund metals is directly connected to the Mott insulating state at half-filling. However correlations due to Hund's coupling are intrinsically different to those in Mott states. This is observed in the charge fluctuations, which are only weakly reduced or even enhanced in Hund metals as the quasiparticle weight is suppressed, contrary to what happens in Mott correlated systems. We have shown that the dependence of correlations, energy scales, charge and spin fluctuations can be understood by looking at the hopping processes which are suppressed or promoted by Hund's coupling.

Fr.J.1_O3 - Competition between Hund's coupling and Kondo effect in an extended one-dimensional periodic Anderson model

I. Hagymasi [1], J. Solyom [1], O. Legeza [1]

1. Wigner Research Centre For Physics, Budapest, Hungary

We study the ground-state properties of an extended periodic Anderson model with inter- and intraband interactions to understand the role of Hund's coupling between localized and itinerant electrons using the density-matrix renormalization group algorithm. By calculating the von Neumann entropies we show that two phase transitions occur as the hybridization is increased in the symmetric half-filled case due to the competition between hybridization and Hund's coupling. In the intermediate phase, which is bounded by two critical points, we found a dimerized ground state, while in the other two phases the ground state is spatially homogeneous (Haldane-like and Kondo-singlet-like). We also determine the entanglement diagram of the system by calculating the mutual information, which clarifies the structure of each phase.

Fr.J.1_I4 - Non-local correlations beyond DMFT and (quantum) criticality

K. Held [1]

1. Vienna University of Technology, Wien, Austria

Dynamical mean field theory (DMFT) has been a big step forward for our understanding of electronic correlations. A major part of the electronic correlations, the local ones, are included. The arguably most fascinating physical phenomena of solid state physics, however, such as (quantum) criticality and the physics of high-T superconductors are based on non-local correlations. To address these problems, recently diagrammatic extensions of DMFT have been developed: dynamical vertex approximation[1], dual fermion approach, 1PI and DMF2RG [2]. Among others, these approaches allow for describing spin-fluctuation-mediated pseudogaps and for calculating critical exponents of the 3D Hubbard model [3]. Most recently, it could be shown that long-range fluctuations are the fate of the Mott-Hubbard transition in 2D [3]. I will also present our current efforts to calculate the critical behavior at a 3D antiferromagnetic quantum critical point.

Fr.J.2_I1 - Controlled optical switching of ferromagnetic thin films and nanostructures

E. Fullerton[1]

1. Center of Magnetic Recording Research, University of California, San Diego, United States

The possibilities of manipulating magnetization without applied magnetic fields have attracted growing attention over the last fifteen years. The low-power manipulation of magnetization, preferably at ultra-short time scales, has become a fundamental challenge with implications for future magnetic information memory and storage technologies. I will discuss recent experiments on the optical manipulation of the magnetization of engineered materials and devices using 100 fs optical pulses. We demonstrate that all optical switching can be observed in a broad range of materials and not limited to selected rare-earth transition-metal alloy films as had been previously observed. We observe all optical switching in a variety of materials, including ferrimagnetic alloys, multilayers, heterostructures and rare-earth-free Co-Ir-based synthetic ferrimagnets [1] and most recently observe optical control of ferromagnetic films and granular recording media [2]. The latter discovery can enable breakthroughs for numerous applications since it exploits materials that are currently used in magnetic data storage, memories and logic technologies. In addition, this materials study of all-optical switching offers valuable insight into the underlying mechanisms involved in optical control of ferromagnetic materials. This work is supported, in part, by the ONR MURI program and is in collaboration with C.-H. Lambert, M. Gottwald, R. Tolley, V. Uhlir, and Y. Fainman at UCSD, S. Alebrand, D. Steil, M. Cinchetti and M. Aeschlimann at University of Kaiserslautern, and M. Hehn, D. Lacour and S. Mangin at Université de Lorraine.

Fr.J.2_I2 - Ultrafast thermally induced magnetization switching in structured systems

T. Ostler [1], C. Zhu [1,2], R. Evans [1], R. Chantrell [1]

1. Department of Physics, University of York, York, United Kingdom
2. College of Electric Engineering, South China Agricultural University, Guangzhou, Guangdong, PR China

The recently discovered phenomenon of ultrafast Thermally Induced Magnetization Switching (TIMS) in ferrimagnets is an intriguing physical phenomenon with significant potential for ultrafast magnetic and spintronic devices. Predicted theoretically and found experimentally [1] in amorphous GdFeCo, the phenomenon arises from the excitation of a 2-magnon bound state [2] by an ultrafast laser pulse. The essential requirements for TIMS are two antiferromagnetically coupled sublattices with different longitudinal relaxation times. Here we will firstly outline the underlying physics of TIMS and proceed to describe some recent predictions of TIMS in complex structures including Gd/Fe multilayers and Synthetic Ferrimagnets (SFIM). The behaviour of the Gd/Fe multilayers depends strongly on the layer structure in a way which is related to the effective exchange field at the interfaces. This also has a strong bearing on the lifetime of the transient ferromagnetic-like state which drives the magnetization reversal and the laser power required to initiate TIMS. SFIM consisting of Fe/FePt bilayers separated by a material such as Ir or Rh to enforce AF coupling between the layers are also shown theoretically to exhibit TIMS, suggesting that the phenomenon can be extended beyond its current observation in amorphous ferrimagnets, leading to the design of materials and structures with possible applications in data storage.

Fr.J.2_O3 - Magnetic switching dynamics due to ultrafast exchange scattering in a toy model of a ferrimagnetic alloy

H.C. Schneider [1], A. Baral [1]

1. University of Kaiserslautern, Kaiserslautern, Germany

We numerically analyze ultrafast magnetic switching dynamics in the framework a 'toy model' that captures several important characteristics of ferrimagnetic alloy. [1] While existing theories for magnetic switching treat these materials by Heisenberg models for classical localized spins on different sublattices, we use a band picture, and standard microscopic interaction Hamiltonians. Our model consists of two spin-dependent carrier species: localized electrons in a flat band and delocalized (itinerant) electrons in a parabolic band. These are designed to resemble localized 4f-electrons in gadolinium and itinerant 3d-electrons in iron, respectively. The two electronic species are antiferromagnetically coupled via a mean-field exchange interaction, and a Stoner contribution provides an additional ferromagnetic coupling among the itinerant carriers. A standard microscopic electron-phonon interaction allows for energy dissipation from the itinerant carrier system. We calculate the one-particle spin-density matrices of both electronic species, and describe the dynamical contributions of the exchange interaction and carrier-phonon interaction at the level of Boltzmann scattering integrals. We demonstrate [2] that the exchange scattering (described by microscopic Boltzmann scattering integrals) between localized and delocalized carriers leads to an ultrafast redistribution of angular momentum between the two carrier species after ultrafast excitation, which we model be an instantaneous heating of the itinerant carrier system. We show that a transient ferromagnetic-like state can always be achieved by a sufficiently strong excitation. We find that this transient ferromagnetic-like state only leads to a complete magnetization switching for model parameters that also yield a compensation point in the equilibrium M(T) curve.

Apart from conventional ferromagnetic and antiferromagnetic order, some materials display a more complex, non-collinear spin structure. These intriguing structures, ranging from completely disordered spin glass states to skyrmions, are formed due to competing magnetic interactions on a microscopic scale. Amorphous rare earth - transition metal (RE-TM) alloys are one class of materials which are known to have non-collinear magnetic structure. However, this special magnetic structure is rarely taken into account when investigating spin dynamics in these materials. We studied the amorphous light RE-TM alloys NdFeCo and PrFeCo using the time resolved magneto optical Kerr effect (TR-MOKE) and find that the spin-structure also undergoes dynamic changes that have severe consequences for the measured signal. From static MOKE measurements, we deduce that the TM sublattice of the NdFeCo and PrFeCo samples has a fan-like distribution of magnetic moments that closes upon increasing an external magnetic field. Investigating the magnetization dynamics, it is discovered that after excitation with a 100 fs laser pulse, two processes occur. The first process is well known and consists of an ultrafast demagnetization within 1 ps after the excitation and subsequent remagnetization of the longitudinal magnetization. The second process is the motion of the fan-structure itself. At first, the system reconstructs the magnetic order on a time-scale of 50-150 ps arriving at a state with a smaller opening angle of the fan. Subsequently, the original opening angle is restored on a time-scale of nanoseconds. Increasing the external magnetic field up to 0.6 T we can fully close the fan and thus suppress this second process.

$CeCoIn_5$ is one of the most interesting and most intensively studied heavy-fermion (HF) systems. In $CeCoIn_5$ an antiferromagnetic (AF) phase develops at very low temperatures and high magnetic fields deep inside the superconducting phase. This incommensurated amplitude-modulated phase with Q = (q, ±q, 0.5), with q = 0.45, was named Q-phase [1] This intriguing phase has been matter of wide discussions and only recently it has been further clarified indicating a coupling of magnetism and the superconducting phase [2] Substituting Nd for Ce in $CeCoIn_5$ results in a rich phase diagram involving different phases: (i) HF ground state for $CeCoIn_5$ (ii) superconductivity and (iii) local magnetic moment magnetism for $NdCoIn_5$ [3]. A magnetically ordered phase develops deep inside the superconducting phase of $Nd_{0.05}Ce_{0.95}CoIn_5$ Results from thermal property measurements revealed a Tc = 1.8 K and TN = 0.9 K at zero magnetic field [4]. Recently, Raymond et.al. found that the AF state $Nd_{0.05}Ce_{0.95}CoIn_5$ (at zero field) has the same propagation vector Q' = (q, ±q, 1/2), with q = 0.45, as the Q-phase in $CeCoIn_5$ [4] These unexpected results add interest to the discussion about the nature of the Q-phase.
Our latest muon and neutron measurements further confirmed a weak magnetic signal at Q'. Further investigations on $Nd_{0.05}Ce_{0.95}CoIn_5$ revealed the magnetic structure and phase diagram of the AF phase. However, while the propagation vector of the AF phase in $Nd_{0.05}Ce_{0.95}CoIn_5$ is similar to the Q-phase, we observe some drastic differences regarding the characteristic domain population (see Ref. [2]).

Mo.A-P04 - Pressure dependence of superconductivity on filled-skutterudite YOs4P12

Y. Kawamura[1], H. Mikage[1], Yu Qi Chen[1], J. Hayashi[1], C. Sekine[1]

1. Muroran Institute of Technology, Muroran, Japan

Ternary metal pnictides with a general formula LnT4X12 (Ln=Lanthanide, T=Transition metal, X=Pnictogen) crystallize with a filled skutterudite structure (space group Im-3). YOs4P12 is one of filled skutterudite compounds, which shows superconductivity at TSC ~ 3 K [1]. Among 19 filled-skutterudite compounds which have superconducting correlation, only two compounds show positive rate in pressure dependence of superconducting transition temperature (dTSC/dP). One of them is LaFe4P12 and the other is YFe4P12[2, 3]. When Fe is substituted by Ru or Os in LaFe4P12, dTSC/dP becomes negative[1]. These difference can be explained from the density of states of electrons at Fermi level[4]. On the other hand, dTSC/dP of YRu4P12 or YOs4P12 has not investigated and is intriguing. The purpose of this study is investigating the pressure dependence of TSC on YOs4P12 and revealing the origin of its dTSC/dP. We have succeeded in synthesizing YOs4P12 with high pressure and high temperature technique. Impurity is less than 2 %. We measured magnetization by incorporating opposed ceramic anvil pressure apparatus into MPMS. TSC of YOs4P12 monotonically decreases with pressure in a rate of -0.11 K/GPa. In comparison with dTSC/dP of YFe4P12 (0.5 ~ 1.0 K/GPa[3]), the sing of dTSC/dP of YOs4P12 is reversed and the magnitude of it is very small. Because dTSC/dP of LaFe4P12 is 0.72 K/GPa and that of LaOs4P12 is -0.095 K/GPa, the relation between YFe4P12 and YOs4P12 is the same as the relation between LaFe4P12 and LaOs4P12. Thus we propose the origin of dTSC/dP of these compounds is the same.

Mo.A-P05 - Raman response function assisted unveiling of the interplay of the coexistent CDW and PDW orders in hole doped cuprates

P. Goswami[1]

1. D.B. College,University of Delhi, Delhi, India

The Raman response function (RRF),dependent on temperature T and the doping level p, is related to the real part of the longitudinal optical conductivity of a system like electron-doped or hole-doped cuprate and provides valuable information on the evolution of the carrier dynamics with T and p. We have calculated here RRF in the under-doped scenario where the partial density wave (PDW) and the charge density wave (CDW) instabilities, present at the hot spots of the spin-fermion (SF) model of hole doped cuprates, are linked by the (approximate) particle-hole symmetry of the SF model. The link is similar to that in the homogeneous d-wave superconductivity and the charge bond order. The combination of the CDW and PDW orders leads to a larger (SO(4)) symmetry. The corresponding ground state scenario could either be æstripe' order dominating or a æchecker- board' state. In the latter case, a chiral superconducting (SC)phase emerges upon lowering the temperature: coexistent SC solution could be accessed at the hot spots of the SF model where CDW/PDW order is also stabilized. We have also calculated RRF in this SC phase.We find that the RRF density or spectral weight density available for pairing in the PDW + CDW +SC phase does not change remarkably compared to that in the PDW/CDW phase. The chiral SC order may, thus, be considered as a bi-product of the emergence of the CDW/PDW order.

Mo.A-P12 - Structural changes, transport and magnetic properties of Fe1.02TeySe1-y-xSx compounds with ternary mixture of chalcogens

N. Baranov[1,2], A. Abouhaswa[2], A. Merentsov [2], N. Selezneva[2]

1. Institute of Metal Physics, Ekaterinburg, Russia
2. Institute of Natural Sciences, Ural Federal University, Ekaterinburg, Russia

This work aims to study the anion mixing effect on the crystal structure, superconducting and magnetic properties of FeSe-based compounds. Four series of polycrystalline samples with nominal compositions Fe1.02TeySe1-y-xSx where (y = 0.3, 0.4, 0.5, 0.6) and (x = 0, 0.1, 0.2, 0.3, 0.4, 0.5) were prepared by a solid state reaction method. The synthesized samples have been studied by means of X-ray diffraction, electrical resistivity and magnetic susceptibility measurements. The substitution of S for Se keeping the constant tellurium concentrations in Fe1.02TySe1-y-xSx is found to expand the crystal lattice in all samples despite the lower ionic radius of sulfur in comparison with selenium [1]. Together with the lattice expansion the substitution is observed to reduce the critical temperature of superconductivity in all series. The results of the magnetization measurements show that the materials exhibit bulk superconductivity, and the shielding volume fractions for all the samples decreases with increasing sulfur content. The results obtained in the present work show that the lattice, superconducting and magnetic properties of iron-chalcogen based superconductors can be tuned by the variation of S, Se and Te concentrations in the ternary chalcogen mixture. This work was supported by the Ministry of Education and Science of Russia (project No 1362) and by the program of the Ural Branch of RAS (project No 15-17-2-22).

Large Hubbard U limit of the quantum spin Hall insulator in the form of the Kane-Mele model on a zigzag ribbon of honeycomb lattice near half filling is studied via a renormalized mean-field theory. The ground state exhibits time-reversal symmetry (TRS) breaking dx^2 + i dxy -wave superconductivity, expected to support chiral edge states. To our surprise, however, at large spin-orbit coupling, the Z_2 phase with non-trivial spin Chern number in the pure Kane-Mele model is persistent into the TRS broken state (called “spin-Chern phase”), and has two pairs of counter-propagating helical Majorana fermion modes (MFs) at the edges. As the spin-orbit coupling is reduced, the system undergoes a novel topological quantum phase transition from the spin-Chern to chiral superconducting states. Our results demonstrate for the first time the 2D spin-singlet Z_2 topological superconductors which support helical MFs. Relevance of our results to adatom-doped graphene and irridate compounds is discussed.

Mo.A-P14 - Enhancement of superconductivity in multi-band systems by odd-parity mixing

M. Continentino [1], F. Deus [1], H. Caldas [2]

1. Centro Brasileiro de Pesquisas Físicas, Rio de Janeiro, Brazil
2. Universidade Federal de São João Del Rei, São João del Rei, Brazil

Hybridization is a key element in multi-band superconductors, such as, heavy fermions or high Tc cuprates. In these systems electrons coexisting at the common Fermi surface can arise from orbitals whose angular momenta differ by an odd number, like d-f or p-d orbitals. In this case the mixing between the electronic wave functions in different atomic sites is anti-symmetric in space which implies a k-dependent hybridization with the property V(-k) = - V(k). This feature of hybridization has a profound effect in the properties of multi-band materials and in particular on their transport properties. We show that in two-band superconductors, anti-symmetric hybridization enhances superconductivity increasing its critical temperature. Since hybridization arises due to the overlap of atomic orbitals, it can be tuned by pressure acting as a control parameter in the exploration of the material's phase diagram. Our work also shows that tuning the mixing of anti-symmetric orbitals with pressure promotes a crossover from a weak type of superconductivity, associated with pairs of loosely coupled electrons, to one of tight pairs of strongly coupled quasi-particles forming a Bose-Einstein condensate. This occurs, even for a weak, fixed value of the interaction. As an additional feature of anti-symmetric mixing we discuss the possibility of generating Majorana fermions in a wire with superconductivity induced by the anti-symmetric mixing of its orbitals with those of a bulk superconductor.

Mo.A-P15 - Magnetically controlled long-range critical current suppression by ferromagnetic proximity effect

T. Wren [1,2], V. Petrashov [2], O. Kazakova [1]

1. National Physical Laboratory, Teddington, U.K.
2. Royal Holloway University of London, London, U.K.

When a ferromagnet is in contact with a superconductor, the diffusion of spin polarised electrons from the ferromagnet into the superconductor suppresses the superconducting properties. Similarly, the superconducting electrons will diffuse into the ferromagnet, forming a base for the well-known proximity effect. Recently, it has been observed that non-collinear localised magnetic structures in proximity with superconductors can induce novel triplet superconducting currents 1,2, opening a possibility of manipulation of mesoscopic hybrid structures through control of the magnetic state.
In this work we investigate how switching between remnant magnetic states of submicron ferromagnetic element can be used to control superconducting properties in a simple bilayer mesoscopic structure consisting of an Al wire on top of a Ni disk. We observe that the critical current (I_c) of the hybrid device is suppressed and possesses a unique temperature dependence. In particular, the device is exhibits SNS-like behaviour at temperatures $T \sim 0.5T_c$ - T_c. The I_c suppression is long range in respect to the position of the Ni disk, causing a reduction of Ic in the aluminium wire up to 10 µm away from the ferromagnet. The same effect is observed when larger magnetic structures are used as heat sinks, eliminating local heating as the source of the I_c suppression. Finally, we show that the temperature dependence of I_c is dependent on the disks magnetic history both in the vicinity of the ferromagnet and far away from it. We interpret the long range suppression of critical current in terms of spin imbalance produced by the hybrid structure, indicating generation of a quasiparticle spin current and consequent suppression of superconducting properties.

Mo.A-P16 - Asymmetric Andreev reflection

Z. Bak [1]

1. Institute of Physics, Jan Dlugosz University, Częstochowa, Poland

We present theoretical study of the skew scattering at the Josephson junction. The resulting from skew scattering spin Hall effect /SHE/ observed in pure materials is rather small (below 0.5%), however, by now composite materials with 80% SHE were observed and this gave new impact to search for its applications. Most of SHE studies are devoted to bulk systems. Very recently an effect of asymmetric scattering at Josephson junction has been observed too. However, till now no microscopical mechanism behind it has been postulated. In our paper we present the model of asymmetric Andreev reflection at the Josephson junction that creates the SHE effect. The basic finding of our study is the prediction of a new resonance at Josephson junction which should effect in fluctuations of SHE.
As the Josephson current fluctuates with the eigenfrequency Ω^J the asymmetric Andreev reflection converts Josephson current into a transverse spin current (or Bose condensate). In this way there arises a forced condensate nano-oscillator which can have another characteristic eigenfrequency. When the nano-oscillator and Josephson eigenfrequencies are close to each other (or to their multiples) there arises a novel type of resonance.
Furthermore, we show that properly shaped Josephson junction interface can produce a skew scattering even if there is no significant spin-orbit interaction.
This offers new potential applications in spintronics based on the morphology of Josephson interfaces.

Mo.A-P17 - Dual-fermion approach to superconductivities in the two-dimensional kondo lattice

J. Otsuki [1]

1. Tohoku Universit, Sendai , Japan

Heavy-fermion superconductivities in rare-earth and actinide materials appear near antiferromagnetic or ferromagnetic quantum critical point (QCP). Since this situation is similar to, e.g., cuprate superconductors, one might expect an unconventional superconductivity occurring in f-electron systems. However, since the origin of magnetism is different between d- and f-electron systems, superconductivities induced by those fluctuations can be different. We thus consider the following fundamental and explicit question: Provided that an f-electron system shows an antiferromagnetic ordering which has the same spin configuration as in cuprates, which types of superconductivities are favored around its QCP? We address this question using the two-dimensional Kondo lattice model, which exhibits a QCP between antiferromagnetism and heavy fermion states.
In order to address heavy-fermion superconductivities, we employ the dual-fermion approach and perform diagrammatic expansion around the dynamical mean-field theory (DMFT). With this formalism, we evaluate FLEX-type diagrams to incorporate low-energy spin excitations near antiferromagnetic QCP.
By numerical calculations using the continuous-time QMC, we found enhancement of superconducting fluctuations near antiferromagnetic QCP. However, unlike the Hubbard model, the d-wave pairing is not particularly favored, and other pairings such as p-wave and g-wave are almost degenerate. We discuss the origin of the competing superconductivities in view of the Fermi-surface structure, which varies according to formation of heavy quasiparticles.

Mo.A-P18 - Superconductivity in high entropy alloys

Z. Jaglicic[1], P. Ko×elj[2], S. Vrtnik[2], A. Jelen[2], S. Jazbec [2], J. Lu×nik[2], J. DolinÜek[2]

1. University of Ljubljana, FGG And IMFM, Ljubljana, Slovenia
2. Jožef Stefan Institute, Ljubljana, Slovenia

High entropy alloys (HEAs) are solid solution alloys that contain five or more principal elements in equal or near equal atomic percent [1]. High entropy of mixing can stabilize disordered solid solution phases with simple structures like a body-centred cubic or a face-centred cubic with small unit cells of the edge length about three angstroms only. Due to the problems in growing homogeneous samples of macroscopic size only few different HEAs have been studied so far. They show enhanced mechanical properties (e.g. hardness) while their physical properties remain mostly unexplored.
The HEA with the composition of $Ta_{34}Nb_{33}Hf_8Zr_{14}Ti_{11}$ (in at. %) has been synthesized and its physical properties determined. [2] The temperature dependent resistivity and susceptibility measurements show a transition to a superconducting state at a critical temperature of Tc = 7.3 K. A 100 % Meissner effect and temperature dependent specific heat measurements led us to the conclusion that the superconductivity is a bulk effect, where the entire specimen becomes superconducting below critical temperature. The magnetization curves between 2 K and 8 K show a typical type II superconductor behaviour with the first critical field of 32 mT at 2 K. The upper critical field extrapolated to T = 0 is approximately 8.3 T.
Very recently a superconductivity at even a little bit higher critical temperature of approx. 7.7 K has been detected in another HAE composed of transition metals Ta-Nb-Hf-Zn, showing superconductivity as a common feature of this type of HEAs.

Mo.A-P19 - Magnetic field dependence of the superconducting proximity effect in a two atomic layer thin metallic film

J. A. Fischer[1], M. Caminale[1], A. Alvaro Leon Vanegas[1], A Stepniak[1], H Oka[1], D Sander [1], Jürgen Kirschner [1]

1. Max-Planck-Institut für Mikrostrukturphysik, Halle, Germany

The intriguing possibility to induce superconductivity in a metal, in direct contact with a superconductor, is under renewed interest for applications and for fundamental aspects [1]. The underlying phenomenon is commonly known as proximity effect. In this work we exploit the high spatial resolution of scanning tunneling spectroscopy at sub-K temperatures and in magnetic fields. We probe the differential conductance along a line from a superconducting 9 ML high Pb nanoisland into the surrounding two layer thin Pb/Ag wetting layer on a Si(111) substrate. A gap in the differential conductance indicates superconductivity of the Pb island. We observe an induced gap in the wetting layer, which decays with increasing distance from the Pb island. This proximity length is 21 nm at 0.38 K and 0 T. We find a non-trivial dependence of the proximity length on magnetic field. Surprisingly, we find that the magnetic field does not affect the induced superconductivity up to 0.3 T. However, larger fields of 0.6 T suppress superconductivity in the wetting layer, where the Pb island still remains superconducting. We discuss the unexpected robustness of induced superconductivity in view of the high electronic diffusivity in the metallic wetting layer.

Mo.A-P20 - A calorimetric investigation of $RbFe_2As_2$ single crystals

S. Khim [1], S. Aswartham [1], V. Grinenko [1], Christan G. F. Blum [1], F. Steckel [1], D.l Gruner [1], Anja U. B. Wolter [1], C. He [1], Stefan-Ludwig Drechsler [1], S. Wurmehl [1,2], B. Büchner [1,2]

1. Leibniz-Institute for Solid State and Materials Research, Dresden, Germany
2. Institut für Festkörperphysik, TU Dresden,Dresden, Germany

We present physical properties of single crystals of the iron pnictide superconductor $RbFe_2As_2$. A bulk superconducting transition at T_c ~ 2.7 K was consistently observed in resistivity, magnetic susceptibility and specific heat measurements. While the normal state resistivity following a T^2 dependence at low T is that of a conventional metal, the magnetic susceptibility shows a deviation from a conventional Curie-Weiss behavior and an broad local maximum around 80 K. A large Sommerfeld coefficient, γ_0 = 127 mJ/mol K^2, was observed seemingly a common feature of heavily hole-doped '122' pnictides. We analyze the superconducting transition in the specific heat data by using the *s*-wave BCS two-gap model. The presence of a small gap is discussed as possible explanation to account for the large specific heat contribution far below T_c. The large H_{c2} anisotropy ratio, $\Gamma = H_{c2}^{ab}/H_{c2}^{c}$ ~ 7 near T_c is also discussed within this multiband nature of the Fermi surface.

Mo.A-P21 - Collective spin fluctuations in stripe ordered $La_{1.875}Ba_{0.125}CuO_4$ detected by 139La nuclear magnetic resonance

Seung-Ho Baek [1], M. Huecker[2], G. Gu[2], B. Buechner[1]

1. IFW Dresden, Dresden, Germany
2. Brookhaven National Laboratory, Upton, NY, United States

We report 139La nuclear magnetic resonance (NMR) studies performed on a $La_{1.875}Ba_{0.125}CuO_4$ single crystal. Right at the charge ordering temperature T_CO = 54 K, the 139La spin-lattice relaxation rate 1/T1 sharply upturns, indicating that charge order triggers the slowing-down of spin fluctuations (SFs). In addition to the intradomain SFs, detailed temperature and field dependences of both 1/T1 and NMR signal intensity demonstrate that collective SFs develop below the spin ordering temperature T_SO = 40 K, implying the persistence of strong charge fluctuations (CFs) in the spin ordered state. We find that the collective SFs are rapidly suppressed with increasing magnetic field along the CuO_2 plane, which is well understood in terms of the enhanced spin order.

Mo.A-P23 - Magnetic properties of new filled skutterudite compound $BaFe_4As_{12}$

C. Sekine[1], T. Ishizaka[1], K. Nishine[1], Y. Kawamura[1], H. Gotou [2]

1. Muroran Institute of Technology, Murora, Japan
2. Institute for Solid State Physics, University of Tokyo, Tokyo, Japan

The filled skutterudite compounds, particularly P- and Sb-based compounds, have attracted much attention of their wide variety of strongly correlated electron behaviors, such as unconventional superconductivity, non-Fermi liquid behavior, anomalous metal-insulator transition, and multipole ordering. As-based filled skutterudite compounds also should be important for systematically investigating skutterudite systems. In fact, several compounds exhibit exotic properties, including superconductivity in $LnRu_4As_{12}$ (Ln = La, Pr) [1], canted ferromagnetic or ferrimagnetic phase transition in $EuFe_4As_{12}$ [2]. However, only preliminary studies have been conducted on the properties of As-based compounds because the compounds are quite difficult to prepare. High-pressure synthesis is a powerful technique for preparing As-based skutterudite compounds. New As-based filled skutterudite compound $BaFe_4As_{12}$ prepared under high pressure has been reported recently [3]. The temperature dependence of the electrical resistivity for $BaFe_4As_{12}$ reveals a metallic behavior and any anomalies were not observed down to low temperature. In this presentation, we report the magnetic properties for $BaFe_4As_{12}$. The magnetization, magnetic susceptibility and specific heat of $BaFe_4As_{12}$ were measured. The temperature dependence of the magnetic susceptibility shows a broad peak around 50K. This peak could be due to a spin fluctuation of Fe ions and suggests that this compound is an itinerant-electron metamagnet.

Mo.A-P25 - X-ray photoelectron spectroscopy studies of the superconducting Mo_2B and Mo_2BC

R. Escamilla[1,2], E. Carvajal[2], L. Huerta[1], E. Verdín[3], M. Cruz[2]

1. Instituto de Investigaciones en Materiales-UNAM, Coyoacán, Mexico
2. ESIME-Culhuacán, Instituto Politécnico Nacional, Mexico, D. F., Mexico
3. Departamento de Física, Universidad de Sonora, Sonora, Mexico

Mo_2BC polycrystalline sample was synthesized by the arc-melting method using Mo_2B as precursor. Studies of X-ray diffraction (XRD) showed that the phases are mainly single phase. Magnetization measurements showed a superconducting transition temperature (Tc) of about 7.0 and 5.2 K for Mo_2BC and Mo_2B, respectively. By X-ray photoelectron spectroscopy (XPS) the Mo 3d, C1s and B 1s core-levels were identified.

Mo.A-P27 - Interplay of charge density wave and superconductivity in BaPt2As2

C. Guo[1], W. Jiang[1], Y. Chen[1], Z. Weng[1], Y. Wang[1], L. Che[1], G. Pang[1], F. Gao[1], X. Lu[1], H. Yuan[1]

1. Department of Physics And Center For Correlated Matter, Zhejiang University, Hangzhou, China

The newly discovered superconductor $BaPt_2As_2$ shows evidence for the coexistence of superconductivity (SC) and charge density wave (CDW) state [1]. In this presentation, we study the interplay of SC and CDW in this compound by measuring the electrical resistivity ρ (T) under pressure. Application of pressure suppresses the first-order CDW-like transition (T_1=272 K at p=0 kbar) and leads to a jump of T_c from $T_{c1}\approx$1.6 K to $T_{c2}\approx$2 K around p_{c1}=6.7 kbar. With further increasing pressure, a weak resistive anomaly retains around T2 200 K and T_c slightly increases. Around p_{c2}=17 kbar, the resistive anomaly at T_2 develops into two pronounced first-order transitions; the one at higher temperature increases and the one at low temperature is suppressed with further increasing pressure. On the other hand, Tc undergoes another sharp increase at $p=p_{c2}$, with a nearly unchanged value at higher pressures. The nature of the pressure-induced resistivity anomalies at high temperatures remain unknown; they might be caused by a change of the CDW modulations or a structural transition. Our results suggest that $BaPt_2As_2$ provides a promising system to study the interplay of SC and CDW.

Mo.A-P28 - The in- and out-of-plane magnetisation of highly underdoped YBa2Cu3O6+x single crystals

I. Kokanovic[1,2], J. Cooper[2]

1. Department of Physics, Faculty of Science, University of Zagreb, Zagreb, Croatia.
2. Cavendish Laboratory, University of Cambridge, Cambridge, Uinted Kingdom

Measurements of static magnetic susceptibility chi_c(T) of YBa2Cu3O6+x single crystals for magnetic field (H) applied along the c-axis, and chi_ab(T) for H in the ab-plane, can give useful information [1,2] about their thermodynamic properties which are still being hotly debated. We briefly review the main results of this work - the T-dependent anisotropy well above Tc arises from the pseudogap and the g-factor anisotropy, while at lower T there is evidence for Gaussian superconducting (s/c) fluctuations with a strong cut-off above 1.1 Tc. We then present new data for highly under-doped crystals with hole concentrations per CuO2 plane, p =0.058 to 0.073, the region where neutron scattering studies [3] show competition between incom-mensurate magnetic short-range order and superconductivity. As found previously for polycrystalline samples [4], ordering the Cu-O chains increases Tc and substantially reduces the Curie term. At low T there is significant non-linear H dependence up to 5 T. In contrast to the spin susceptibility from the CuO2 planes, the Curie terms are isotropic. Plots of chi_c(T) vs. chi_ab(T) show an unexpected result, the Curie terms disappear above a p-dependent onset temperature TCurie_onset of order 200 K. We compare TCurie_onset(p) with the pseudogap energy scale and the onset of charge density wave order (x>0.5) and short-range magnetic order (x<0.5).
For all six samples chi_D(T)=chi_c(T)-chi_ab(T) has a weakly T-dependent linear region at higher T where chi_D(0) is 1-2 x 10-4emu/mol. We analyse deviations from this linear behavior in terms of 2D or 3D Gaussian s/c fluctuations and the possibility of small superconducting regions with Tc ~ 60 K.

3. Physikalisches Institut, Karlsruhe Institute of Technology, Karlsruhe, Germany

Superconductivity in iron pnictides and chalcogenides occurs in close proximity to antiferromagnetic order, giving rise to the assumption that superconductivity originates from electron-electron interactions. So far, experimental and theoretical studies underpin this assumption but have failed to unravel the pairing mechanism. A central question is the role of electronic correlations. We investigated the thermal expansion and magnetostriction of the stoichiometric compounds AFe2As2 with A = K, Rb, and Cs. The magnetostriction measurements exhibit quantum oscillations beyond the upper critical fields which allow determining the electronic structure and the effective quasiparticle masses m*. With growing unit-cell volume along the AFe2As2 the strength of the electronic correlations exhibits a huge increase of m*. This behavior is in line with the pressure dependence of the Sommerfeld coefficient determined from the thermal expansion above the superconducting transition temperature. Our measurements provide valuable input to explore the relation between crystal structure, electronic correlations and superconductivity on a more quantitative basis.

Mo.A-P31 - Spin-wave dispersion and magnetic exchange in antiferromagnetic Ca2CuO2Cl2

5. Materials and Structures Laboratory, Tokyo Institute of Technology, Yokohama, Japan

We measured the spin-wave dispersion in antiferromagnetic Ca2CuO2Cl2 (CCOC) as a function of momentum transfer along the in-plane high symmetry directions in the Brillouin Zone using Cu L3-edge Resonant Inelastic X-Ray Scattering (RIXS) with the ADRESS spectrometer on the Swiss Light Source (SLS). Magnetic excitations in High Temperature Superconducting (HTS) cuprates have been widely studied in the last twenty years, as the possible boson exchanged in the Cooper pairing leading to superconductivity (see [1,2] and references therein). Using Inelastic Neutron Scattering (INS), many of the cuprates have been extensively investigated. However, several pieces of the puzzle are still open, largely because of the lack of a theoretical handling of correlated electronic systems beyond idealized, simplistic models. Recently RIXS [3], has emerged as an alternative probe of the same excitations. The new technique easily extends INS observation to higher energies [1], with the potential to also probe small volume crystals. However, the technique has mainly been used so far, in the case of HTS cuprates, to extend studies of compounds already measured by INS [2]. Here we study the parent compound of a HTS cuprate for which there are no available INS studies so far: Ca2CuO2Cl2 [4,5]. The specific advantage of CCOC with respect to the already well-studied, and isostructural, **La2-xSrxCuO4** compound is that it is the only superconducting cuprate composed of low Z ions alone, which make it far more suitable for theoretical calculations compared to other HTS based on CuO2 planes. In this study we refine the exchange parameters J of the spin Hamiltonian of CCOC based on the measured spin-wave dispersion. Future measurements will be done on the doped, superconducting compound, allowing a study of the paramagnon evolution under doping as done in more commonly studied '214' cuprates [2].

A breakthrough in understanding the magnetic interactions of the hole doped high temperature cuprate superconductors was made by discovery of a near identical hourglass shaped magnetic excitation spectrum in the non-superconducting charge ordered La5/3Sr1/3CoO4 [1]. The underlying charge ordered structure of La2-xSrxCoO4 is however under debate, charge-stripes or checkerboard charge order?[2] The magnetism of an ideal checkerboard charge ordered state is spin frustrated, and we have previously shown how this spin frustration is lifted by magnetic stripe interactions in La3/2Sr1/2NiO4[3]. In our present studies we wish to address how the magnetism of charge-stripe order develops in the charge-stripe ordered phase on doping towards the checkerboard charge order phase of La2-xSrxNiO4. We will present results on the magnetic ordering from ÁSR, and inelastic neutron scattering on charge ordered La2-xSrxNiO4, and discuss potential implication for understanding the magnetism of charge ordered La2-xSrxCoO4.

4. CCNH, Universidade Federal do ABC (UFABC), São Bernardo do Campo, Brazil
5. Instituto de F\'isica ``Gleb Wataghin,' Universidade Estadual de Campinas, Campinas, São Paulo, Brazil

In this work we report the magnetic and electronic properties investigated by synchrotron techniques on single crystals and powdered crystals of GdT2Zn20 (T = Fe, Co). These compounds belong to the complex cage-structure family RT2Zn20 (R - rare earth, T - transition metal) [1] in which several physical phenomena can be observed, such as superconductivity, magnetic ordering, nearly ferromagnetic Fermi-liquid and heavy fermion behavior [2-4], which are strongly affected by the replacement of Co by Fe ions into the polarizable medium of the cage structure. GdCo2Zn20 orders antiferromagnetically below TN = 5.72(6) K, whereas the GdFe2Zn20 orders ferromagnetically at a remarkably high temperature of TC = 86.5(3) K. High quality single crystals of GdCo2Zn20 were investigated by x-ray resonant magnetic scattering (XRMS) in which we observed a commensurate antiferromagnetic ordering with a magnetic propagation vector (¢¢¢) below TN. The distance between the Gd-Gd ions of around 6A weakens the exchange interaction and helps explain this representative low temperature transition. The magnetic structure solved by XRMS revealed that only the Gd ions carry moment and that the Gd spins are aligned following the magnetic representation \Gamma_5. In contrast, powdered crystals of GdFe2Zn20 investigated by x-ray absorption near-edge structure (XANES) and x-ray magnetic circular dichroism (XMCD) techniques performed below the Curie temperature displayed a strong magnetic signal around 12.5 % and 9.7 % for both Gd-L2,3 absorption edges, respectively. This magnetic signal arises from a splitting between the 5d states (up and down). The strong RKKY exchange interaction between the Gd-Gd ions, due to a high density of states at Fermi level, polarizes the medium and consequently an interesting and unusual magnetic signal of ~0.06 % is detected at the Zn K-edge. However, measurements at the Fe K-edge revealed an unexpected absence of magnetic contribution for the Fe ions.

Mo.A-P34 - Longitudinal spin excitations in iron-pnictide parent compounds

M. Fidrysiak [1]

1. Wrocław University of Technology, Wrocław, Poland

Recent observation [1] of sizable longitudinal spin excitations (LSEs) in the spin density wave (SDW) phase of Fe-pnictide parent compounds NaFeAs and $BaFe_2As_2$ has serious consequences. The suggested interpretation of the low energy LSEs as a bottom of particle-hole continuum implies a major role of itinerant electrons and calls into question relevance of local-moment approaches to these materials. I point out that the above mechanism is difficult to reconcile with optical spectroscopy and discuss the possibility that the LSEs originate from two-magnon (2M) processes which are free of this problem and do not sharply distinguish between localized and itinerant magnetism.

The 2M continuum obtained within the localized J_1-J_2 model, previously used to study spin waves in $BaFe_2As_2$, is shown to qualitatively reproduce observed LSEs, but predicted inelastic neutron scattering intensities are too low to explain the data. I discuss two mechanisms of 2M continuum enhancement, emphasizing either itinerant or localized electrons. The first relies on 2M continuum renormalization by virtual electronic excitations between magnetically split bands in the SDW phase of an itinerant antiferromagnet and is studied within a minimal two-band model with perfect nesting of hole- and electron-like Fermi surfaces (FSs). The second is based on proximity to a magnetic quantum phase transition, where the magnetic order is softened by quantum spin fluctuations, and is discussed within an effective non-linear sigma-model approach. The electronic mechanism enhances 2M contribution to LSEs in the regime of small FS taking part in the SDW instability, but is insufficient to account for reported intensities. The spin fluctuation mechanism, on the other hand, agrees qualitatively with observed LSEs and reproduces correct order of intensities for parameters relevant to $BaFe_2As_2$.

3. Key Laboratory of Applied Superconductivity, Institue of Electrical Engineering, Chineses Academy of Sciences, Beijing, China

In recent years 122-type iron-pnictides have become a perspective superconductor for high field applications. Although having low critical current densities Jc at low fields, they show extremely low field dependence at high magnetic fields (above 8 T). Due to improvements in preparation processes absolute values of 122-based tapes reach Jc values higher than 104 A/cm2 at 10 T , which is necessary for applications. In this work we report on a magnetic investigation of silver sheathed Sr0.6K0.4Fe2As2 tape. The sample was prepared by ex-situ powder-in-tube technique (PIT). Sintered powder (900°C for 35 h) was ground and mixed with 5 wt% Sn, filled into Ag tubes and cold worked into tapes by drawing and flat rolling [1]. Transition temperature Tc = 34.2 K was achieved. Dc magnetic measurements were performed in fields up to 14 T between 4.2 K and Tc. From hysteresis loops irreversibility lines and magnetic critical current densities - obtained by Beans critical state model - were determined. From the relaxation measurements mean effective activation energies U according to Andersons flux creep theory were determined. The obtained U values are similar (< 40 meV at 4.2 K and 1 T) as for Bi2212 tapes, but an order of magnitude smaller in comparison with MgB2 wires. U is practically field independent above 3 T in contrast to the other two superconductors, thus explaining the much higher Jc values at high fields. The obtained vortex matter phase diagram is compared to those obtained for ex-situ PIT prepared MgB2 wires and silver sheathed Bi2212 tapes.

Until recently, the Nd-based compounds belonging to the widely studied Ln-1111 family of superconducting iron-pnictides (with Ln a lanthanide), have not been explored in great detail due to considerable difficulties in their preparation. The recent availability of Nd-1111 samples, covering a wide range of fluorine doping, allowed us to address many open questions regarding the 1111 family, as e.g.: what is the role played by the different rare-earths, are the Ln-1111 compounds all alike at intermediate F-doping, can magnetic fluctuations appear in the intermediate-doping regime, etc.
With a focus on the magnetic-to-superconducting crossover region, our dc magnetometry and muon-spin spectroscopy (μSR) investigations could show that Nd compounds confirm well-known aspects of 1111's, while exhibiting also new physics [1]. In particular:
– The FeAs long-range AF order at low fluorine doping ($x < 0.06$) is progressively replaced at intermediate doping ($x = 0.08$) by a short-range magnetic order, which coexists with superconductivity on a nanometric length scale. This result, together with the absence of magnetic order in high-fluorine ($x = 0.25$) superconducting samples, indicates a common behaviour within the Ln1111 pnictides (Ln being La, Sm, Ce, and Nd lanthanides [2,3,4]).
– Contrary to other Ln1111 cases, we detect sizable magnetic fluctuations (on the μSR time scale) in the intermediate-doping range. Interestingly, this dynamic magnetic component persists down to low temperatures, until the short-range static magnetic order and the superconductivity develop over the whole sample volume. The nature of these fluctuations, as well as their possible relation with superconductivity, will be discussed.

The problems of development of large scale and superconducting magnets generate hard requirements to structure materials of their windings. Properties of these materials should combine an extremely high robustness and good enough thermal and electrical conductivity. Mechanical and electromagnetic perturbation can destroy the superconductivity. In recent years the possibilities of enhancing the mechanical properties of metallic alloys, namely the yield strength, are studied. The focused thermomechanical treatment can help to decrease the grain size and increase the mechanical properties. The superconductor wire material with the composition of Nb3Cu with the ultrafine grain structure was tested in uniaxial tension up to the failure in the temperature interval 4.2 - 300 K. It was observed that in the fine grained NbCu alloy the plastic nature of the deformation is saved up to the temperature of 4.2 K. The fractographic observations show that the failure is always ductile with developed shear zone. The void size respects the uniform structure with the low grain size. As the test temperature decreases, the yield strength increases more than the fracture stress. The small decrease in the plasticity at low temperatures is related to the total deformation changes from 6.1 to 3.5 %. This work was supported by the projects Nos. 26220120021 and 26110230097 provided in the frame of Structural funds of the European Union.

Mo.A-P39 - Effects of La doping on A-site ordered Cr perovskite oxides with Zhang-Rice state

M. Isobe[1], H. Sakurai[2], H. Takagi[1]

1. Max Planck Institute For Solid State Research, Stuttgart, Germany
2. National Institute for Materials Science, Tsukuba, Japan

A-site ordered perovskite CaCu3Cr4O12 is an attractive material that exhibits valence degeneracy [1] and also it can be a negative charge-transfer material. Besides, it has been observed an unusual Cu valence state (Zhang-Rice state) in the recent report [2]. It shows a metallic behavior without any phase transition above 2 K. We have therefore investigated the effects of La doping on this material. Ca1-xLaxCu3Cr4O12 (x=0.0, 0.2, 0.4, 0.6, 0.8, 1.0) have been synthesized by solid state reaction under high pressure and high temperature conditions. In LaCu3Cr4O12, we have observed a magnetic transition around 220K. Also the lattice constant shows a small discontinuity and the resistivity exhibits the some anomaly at the transition. Still the resistivity reveals the metallic behavior down to low temperature. The recent results of muon-spin rotation and relaxation measurements have suggested that the magnetic transition is an antiferromagnetic ordering [3]. The transition temperature decreases with decreasing the La content in Ca1-xLaxCu3Cr4O12. Simultaneously it seems to be smeared out. We have not observed any superconductive behavior above 2 K in this system. We suppose that the charge and spin states of the Cu in this system are similar to those of the high Tc cuprates. However the CuO4 planers are isolated in the crystal structure, then the CuO2 planes cannot be constructed. Consequently it is considered that the superconductivity transition is suppressed to very low temperature.

Mo.A-P40 - Elastic softening in the orthorhombic compound YbPdGe

I. Ishii[1], Y. Noguchi[1], H. Goto[1], X. Xi[1], S. Kamikawa[1], K. Araki[2], K. Katoh[2], T. Suzuki[1]

1. Hiroshima University, Hiroshima-shi, Japan
2. National Defense Academy, Yokosuka, Japan

The Yb-based compound YbPdGe with the orthorhombic YbAuSn-type structure shows a ferromagnetic phase transition at 11.4 K. At high temperatures, 4f-electrons of Yb3+ ions in YbPdGe have a localized character, and the crystal electric field (CEF) effect acts on its physical properties. On the other hand, the electronic specific heat coefficient estimated is 150 mJ/(mol K^2) at low temperatures, indicating a heavy-fermion state. To investigate the phase transition at 11.4 K and the CEF effect, we carried out ultrasonic measurements on a single-crystalline YbPdGe sample. Characteristic elastic softening below 170 K is observed at high temperatures in the transverse elastic modulus C66 in contrast to the longitudinal modulus C22 without the softening. In the orthorhombic compound YbIrGe, the transverse moduli exhibit a similar elastic softening originating from the CEF effect, suggesting that the softening of C66 in YbPdGe is also caused by the CEF effect. At the phase transition, C22 and C66 show abrupt elastic hardening and softening, respectively, due to the magnetostriction.

Mo.A-P41 - Excitonic condensation and superconductivity in Ta2NiSe5

Y. Ohta[1], T. Kaneko[1], K. Seki[1], T. Toriyama[1], T. Konishi[1]

1. Chiba Universit, Chiba, Japan

The electron-hole pair (or exciton) condensation in thermal equilibrium into the excitonic insulator (EI) state has attracted renewed interest in recent years. A layered transition-metal chalcogenide Ta2NiSe5 is one such material, where the observed orthorhombic-to-monoclinic structural phase transition at 328 K has been discussed in terms of EI [1-4]. Recently, superconductivity was discovered in this material under high pressures [5]. We carried out the band structure calculation on Ta2NiSe5 and derived the three-chain Hubbard model with phonon degrees of freedom. We then applied the BCS mean-field theory to this model and showed that the excitonic condensation cooperatively induces the instability of the phonon mode at momentum q = 0, resulting in the structural phase transition [3]. We also applied the finite-temperature variational cluster approximation to the extended Falicov-Kimball model for Ta2NiSe5 and found that the calculated single-particle spectral function below and above the transition temperature reproduces the deformation of the band structure observed in experiment very well [4]. We also calculated the band structure under high pressures using the observed structural parameters and found that the quasi-one-dimensional band dispersions overlap to make the system semimetallic [5]. We discuss a possibility that the observed superconductivity may be due to the strong attractive interaction between electrons mediated by the excitonic fluctuations in a system of very low carrier densities.

Mo.A-P42 - Novel electronic structures in ru-pnictides RuPn (Pn = P, As, Sb)

H. Goto[1], T. Toriyama[1], T. Konishi[1], Y. Ohta[1]

1. Chiba University, Chiba, Japan

Recently, superconductivity has been discovered in Ru-pnictides, RuP and RuAs, under Rh doping [1]. These compounds crystallize in a MnP-type orthorhombic structure (space group Pnma), in which the RuPn6 octahedra form a face-sharing chain along the a axis. The chains are connected by the edges and Ru ions form a distorted triangular lattice in the bc plane. The parent compounds RuP and RuAs show two sequential phase transitions: (i) a weak transition from a metal to a pseudogap phase at 330 K for RuP and at 280 K for RuAs, and (ii) a first-order transition to a nonmagnetic insulator at 270 K for RuP and at 200 K for RuAs. By Rh doping, these two phase transitions are suppressed and thus superconductivity occurs in the vicinity of the pseudogap phase.
In order to elucidate the microscopic origins of these phase transitions and consider the mechanism of superconductivity, we have carried out the first-principles electronic structure calculations using WIEN2k [2]. We found that there appear nearly degenerate flat bands just at the Fermi level in the metallic phase, which come mainly from the 4dxy orbitals of Ru ions. The splitting of these bands accompanied by the spin-singlet formation may then be responsible for the observed metal-insulator transition and occurrence of the nonmagnetic insulator phase at low temperatures. These results are compared with the band structure calculated for RuSb that shows superconductivity without doping.

Mo.A-P44 - Superconductivity under pressure in FeSe1-xTex studied by dc magnetic measurements

K. Miyoshi[1], M. Kondo[1], K. Morishita[1], E. Mutou[1], G. Motoyama[1], K. Fujiwara[1], J. Takeuchi[1]

1. Shimane University, Matsue, Japan.

FeSe1-xTex is an iron-pnictide superconductor with the simplest crystal structure, which is composed by layers of edge sharing Fe(Se, Te)4 tetrahedrons stacked along c-axis. In the end material FeSe (Tc=8 K), Tc has been found to be enhanced up to 34 K under hydrostatic pressure mainly due to the change of the crystal structure from orthorhombic to tetragonal one under pressure. On the other hand, superconductivity under pressure in FeSe1-xTex is not sufficiently clarified. In the present work, we have studied the superconductivity under pressure in FeSe1-xTex with x=0.7 (Tc=14 K) by the measurements of dc magnetization using high quality single crystal specimens, in which excess Fe included in the as-grown crystal was removed by annealing in Te vapor. It is found that Tc increases and makes a maximum of 15 K at 1 GPa but rapidly decreases above 1 GPa under hydrostatic pressure using liquid Ar as pressure transmitting media. In contrast, Tc is found to increase up to 18 K at 2.5 GPa then decrease gradually under nearly uniaxial pressure along c-axis using NaCl as pressure transmitting media. We have also found that Tc makes a maximum of 16 K at 1 GPa but is nearly pressure independent above 1 GPa under uniaxial pressure along a-axis using NaCl. These behaviors suggest that the superconductivity is suppressed by the isotropic stress but is enhanced (not changed) by the uniaxial stress along c-axis (a-axis).

Mo.A-P45 - Charge density wave and superconductivity in novel Pt-based superconductors : SrPt2As2 and LaPt2Si2

S. Kim[1], K. Kim[1], B.I. Min[1]

1. Postech, Pohang, Korea

The intriguing coexistence of the charge density wave (CDW) and superconductivity in SrPt2As2 and LaPt2Si2 has been investigated based on the ab initio density functional theory band structure and phonon calculations. We have found that the CDW instability for the both cases arises from the Fermi surface nesting. The local split distortions Pt atoms in the [As-Pt-As] layers play an essential role in driving the five-fold supercell CDW instability as well as the phonon softening instability in SrPt2As2. By contrast, the CDW and phonon softening instabilities in LaPt2Si2 occur without split distortions of Pt atoms. The phonon calculations, however, suggest that the CDW and the superconductivity coexist in [X-Pt-X] layers (X = As or Si) for both cases.

Mo.A-P47 - Quantum criticality at the lifshitz point in electron doped iron arsenides

S. Das[1], M. Laad[2], V. Tripathi[3], J. Gillett[4], S. Sebastian[4]

1. University of Bristol, Bristol, United Kingdom
2. Institute of Mathematical Sciences, Chennai, India
3. Tata Institute of Fundamental Research, Mumbai, India
4. University of Cambridge, Cambridge, United Kingdom

The twin issues regarding the nature of the normal state and the competing orders are crucial for the understanding of unconventional, high temperature superconductivity in the iron arsenide superconductors. Clear signatures of electronic anisotropy, in the temperature-doping phase diagram, has been observed from transport, STM, ARPES and neutron scattering measurements. Majority of the experimental evidence has been based on electron doped BaFe2As2 (Ba122) series. Over here we track the evolution of resistivity anisotropy in the sister SrFe¼2As2 (Sr122) series as a function of Co doping. Although there are differences in the phase diagrams of Ba122 and Sr122, in terms of splitting of the structural and magnetic transitions as well as the magnitude and position of the superconducting dome with respect to the magnetically ordered region, we find that the maximum magnitude of resistivity anisotropy in both the systems is very similar. The experimental finding is interpreted in terms of an underlying orbital selective Mott transition that gaps out the dxz states leading to a Lifshitz transition associated with the quantum critical point.

Mo.A-P48 - Cohabitating phasesin metaldoped BaFe2As2: a structural corroboration

M. E. Saleta[1,2], E. Granado[1], C. Adriano[1], D. Tobia[1], P. G. Pagliuso[1], R. R. Urbano[1]

The Fe-based superconductors involved great effort of the scientific community in the last few years. They present rich phase-diagrams and unusual superconducting paring mechanism. In particular, the nature of the spin density wave (SDW) magnetic order, which is usually preceded by a tetragonal-to-orthorhombic structural transition, raised many debates. Our group has successfully growngood quality single crystals of BaFe2As2 (Ba122) pure and doped with Co and Cu (x = 0.01) in the Fe-site. The crystals were obtained by In-flux growth method.[1] Resistivity measurements showed that both doped samples present a phase transition at a critical temperature (T0) closeto 128K. In addition, a cohabitationof two phases (tetragonal/paramagnetic and orthorhombic/antiferromagnetic) around T0 was suggested by our NMR measurements.[2] With the goal to corroborate with the existence of a region where the two phases cohabitate, in this work we present a structural study on Co and Cu doped Ba122. We performed high-resolution X-ray diffraction experiment employing synchrotron radiation at Brazilian Synchrotron Light Laboratory (LNLS). We studied in detail the evolution on temperature of some characteristic diffraction peaks. In particular, we followedthe reflections that split when the sample undergoes the transition from tetragonal (I4/mmm) to the orthorhombic (Fmmm) phase. Our experiment verifies that the phase transition occur at a similar temperature that was reported from resistivity and susceptibility measurements. Moreover, we undoubtedly confirm that the tetragonal (PM) phase is cohabitating with the orthorhombic (SDW) one within a finite range of temperature around T0 as previously reported by NMR.

Mo.A-P49 - Induced p-wave superfluidity in imbalanced fermi gases in a synthetic gauge field

H. Caldas[1,2], M. Continentino[2]

1. Departamento de Ciencias Naturais. Universidade Federal de São João del Rei, São João del-Rei, Brazil
2. Centro Brasileiro de Pesquisas Físicas, Rio de Janeiro, Brazil

We study pairing formation and the appearance of induced spin-triplet p-wave superfluidity in dilute three-dimensional imbalanced Fermi gases in the presence of a uniform non-Abelian gauge field. This gauge field generates a synthetic Rashba-type spin-orbit interaction which has remarkable consequences in the induced p-wave pairing gaps. Without the synthetic gauge field, the p-wave pairing occurs in one of the components due to the induced (second-order) interaction via an ex- change of density fluctuations in the other component. We show that this p-wave superfluid gap induced by density fluctuations is greatly enhanced due to the Rashba-type spin-orbit coupling.

Mo.A-P50 - structural, electronic and magnetic properties of 42214 fe-based superconductors

A. Continenza[1], F. Bucci[1,2], G. Profeta[1]

2. CNR, SPIN at Università degli Studi dell'Aquila, L'Aquila, Italy

We present an ab-initio study of the newly discovered L4Fe2As2Te1-xO4 superconductors, where L is a rare earth element (L= Pr, Sm, and Gd). This family represents a new entry on the Fe-based superconductor scenery, showing similar features to the other 1111 family and critical temperatures reaching the order of 40K. As the structure is layered with Fe-As planes intercalated by L-O and Te planes, there are new tools that could be adjusted to push the critical temperature towards higher values. To this end, we provide a detailed first principles study of the structural, electronic and magnetic properties of this 42214 family as a function of the L involved, Te-content and F-content. Our first-principles study is able to interpret the important role of the L element on the structure of these new compounds, especially acting on the As-atom height with respect to the Fe-planes, a parameter often considered to be strongly related to electronic correlation and to spin fluctuation strength. A careful comparison with experiments, shows that the ab-initio results give a reliable representation of these materials, even taking into account the non-perfect stoichiometry of the compounds. An antiferromagnetic-stripe low temperature phase is predicted, although not yet experimentally observed. Native Te-vacancies and fluorine substitution are shown to act as charge dopant, decreasing the nesting function and thus weakening the magnetic order. Finally, analysis of properties such as magnetic stability, As-height and electronic states at the Fermi level allows to draw a consistent picture of this compound family and to give predictions on how to improve the material properties and the critical temperature. We believe that our study will contribute to the understanding of this new compound family and of the all Fe-based superconducting material, where the interplay between structure, electronic and magnetic properties is very complex.

Mo.A-P52 - Isovalent substitution effect of P to As on magnetic characteristics of EuFe2As2-xPx single crystals.

T. Kashiwagi[1], Y. Arakawa[1], T. Ishikawa[1], K. Kadowaki[1]

1. University of Tsukuba, Tsukuba, Japan

EuFe2As2-xPx system known as a member of the 122-system in Fe based superconductors has been studied in order to understand the characteristic features of the coexistence of magnetism and superconductivity. The mother compound of this system with x = 0 shows the spin-density wave order of Fe spins at TSDW = 190 K and subsequently magnetic order of Eu2+ moment at TN = 19 K. The isovalent substitution of P to As induces the superconductivity in this system and the Tc value increases up to 28 K around x = 0.2. It is also known that the superconducting region of x is narrower than that of other 122-systems. In order to understand the substitution effect of x in this system we have studied magnetic and transport properties of the under doped region of EuFe2As2-xPx single crystals grown by the self-flux method. The magnetization curves and the transport characteristics in magnetic fields indicate the clear reduction of the exchange interaction and the uniaxial anisotropy of Eu ions with increasing x. In addition to that the in-plane anisotropy is also reduced with increasing the doping level of P according to the experimental results of the doping dependence of the in-plane fields transport measurements. The result of the increasing of the symmetry of the crystal fields is consistent with the X-ray experiments. We will discuss the substitution effect of P into As on the transport characteristic of this system comparing with the reported phase diagram of the 122-systems.

Mo.A-P53 - Elastic softening in $HoFe_2Al_{10}$

S. Kamikawa[1], I. Ishii[1], H. Goto[1], T. Fujita[1], F. Nakagawa[1], H. Tanida[1], M. Sera[1], T. SuZuki[1]

1. Hiroshima University, Hiroshima-shi, Japan

The ternary compound $HoFe_2Al_{10}$ has the orthorhombic $YbFe_2Al_{10\text{-type}}$ structure (space group Cmcm). The specific heat of $HoFe_2Al_{10}$ exhibits Schottky anomaly at around 1.5 K, suggesting energy gap of $\Delta \approx 3$ K under a crystalline electric field (CEF) . To investigate the CEF effect in $HoFe_2Al_{10}$, we carried out specific heat and ultrasonic measurements on single crystalline samples. We found two Shottky anomalies at around 1.5 K and 20 K in magnetic specific heat. The transverse elastic modulus C55 shows a characteristic elastic softening below 20 K, which is observed down to 2 K. We carried out the theoretical analysis. The two Shottky peaks and the softening of C55 are reproduced by the 4f energy level scheme.

Mo.A-P54 - Superconductivity in LaPd2Al(2-x)Gax compounds

P. Dolezal[1], M. Klicpera[1], J. Pasztorova[2], J. Prchal[1], P. Javorsky[1]

Tetragonal CeT2X2 compounds (T: d-element and X: p-element) reveal such physical properties as pressure-induced superconductivity, valence fluctuating phenomena or strong crystal field exciton-phonon coupling in CePd2Al2. The CeT2X2 compounds crystallize generally in centrosymmetric ThCr2Si2-type or CaBe2Ge2-type of crystal structure. Superconductivity in these compounds is almost exclusively connected to ThCr2Si2-type structure, where the inversion centre takes place at the atomic position of Ce. On the other hand, the compounds crystallizing in CaBe2Ge2-type structure (where the centre of inversion is out of any atomic position) reveal frequently the structure instability at low temperatures.
The non-magnetic LaPd2Al(2-x)Gax compounds crystallize in centrosymmetric CaBe2Ge2-type structure and undergo a phase transition from tetragonal to lower symmetrical structure at low temperature. Our recent study [1] revealed the superconducting state in these compounds, which deviates substantially from the behaviour described by BCS theory: the positive curvature of field dependence of the superconducting transition temperature $T_{SC}(H)$, non-exponential temperature dependence of the electronic specific heat in the superconducting state and significantly lower value of the weak-coupling BCS limit. The temperature of superconducting transition linearly increases with Ga content up to x = 1.6 and decreases again for LaPd2Ga2. Present study is focused on structural and superconducting transitions in LaPd2Al(2−*x*)Ga2 series investigated by means of electrical resistivity measurement under hydrostatic pressure and in external magnetic fields. The application of pressure leads to a decrease of Tsc and the dependence of the $T_{SC}(H)$ is changed to a linear decreasing. The temperature of structural phase transition rises with increasing external pressure and moreover, another type of low-temperature crystal structure is induced by pressures > 0.7 GPa.

4. Department of Quantum Matter Physics, University of Geneva, Geneva, Switzerland

The suppression of magnetic order with pressure concomitant with the appearance of pressure-induced superconductivity was recently discovered in CrAs. Here we present a neutron diffraction study of the pressure evolution of the helimagnetic ground state towards and in the vicinity of the superconducting phase. Neutron diffraction on polycrystalline CrAs was employed from zero pressure to 0.65 GPa and at various temperatures. The helimagnetic long-range order is sustained under pressure and the magnetic propagation vector does not show any considerable change. The average ordered magnetic moment is reduced from 1.73(2) μ_B at ambient pressure to 0.4(1) μ_B close to the critical pressure $P_c \approx 0.7$ GPa, at which magnetic order is completely suppressed. This indicates a reduction of the magnetic volume fraction and a large coexistence region of magnetic order and superconductivity. The width of the magnetic Bragg peaks strongly depends on temperature and pressure, showing a maximum in the region of the onset of superconductivity. We interpret this as associated with competing ground states in the vicinity of the superconducting phase.

Mo.A-P56 - Effective doping, pressure-induced metallization and magnetic phases in the BiS2 family of superconductors from first principles

C. Morice[1], E. Artacho[1,2,3], S. E. Dutton[1], D. Molnar[1], H.-Jin Kim[1], S. S. Saxena[1]

The large variety of phenomena arising in the BiS2 family of materials is making these increasingly fascinating. A recent study of Bi4O4S3 has shown it to be a mixture of two phases. Using density functional theory, we explore the electronic structure of both the phases and demonstrate that the S2 layers dope the bismuth-sulphur bands, and this causes metallisation. We find that some compounds in the family have magnetic tendencies, in particular we find that Ce(O,F)BiS2 becomes ferromagnetic at low temperature, which has been confirmed experimentally since. We report the calculation of some magnetic coupling factors. In the Ln(O,F)BiS2 (Ln = La, Ce, Pr, Nd) subfamily of compounds, we show that the change of rare earth does not affect the Fermi surface, and predict that CeOBiS2 should display a pressure induced phase transition to a metallic, if not superconducting, phase under pressure. We also explore the influence of spin-orbit coupling on the electronic structure. [1] Effects of stoichiometric doping in superconducting Bi-O-S compounds (Accepted in J. Phys. Cond. Mat.) [2] Electronic and magnetic properties of superconducting LnOxF1-xBiS2 (Ln = La, Ce, Pr, and Nd) from first principles, arXiv:1312.2615

Mo.A-P57 - Magnetic ground states of superconducting $Eu(Fe_{1-x}M_x)_2As_2$ (M = Co, Ru, Ir) as revealed by single-crystal neutron diffraction

W. Jin[1,2], S. Nandi[1,2,3], Y. Xiao[1], Y. Su[2], B. Thomas[1,2]

3. Indian Institute of Technology, New Delhi, India

Among various parent compounds of the Fe-based superconductors, $EuFe_2As_2$ is a unique member of the ternary "122" AFe_2As_2 (A = Ba, Sr, Ca, etc) family since it contains two magnetic sublattices and the *A* site is occupied by the S-state rare-earth Eu^{2+} ion possessing a $4f^7$ electronic configuration with an electron spin S = 7/2, corresponding to a theoretical effective magnetic moment of 7.94 μB [1]. Recently, we have investigated the magnetic ground states in superconducting $Eu(Fe_{1-x}M_x)2As2$ compounds with 3*d*, 4*d* and 5*d* transition metal doping (M = Co, Ru and Ir) by single-crystal neutron diffraction measurements, respectively. In all three systems, the Eu2+ moments were found to be ferromagnetically aligned along the crystallographic c direction in the ground state, coexisting with the superconductivity. In superconducting $Eu(Fe_{1-x}Co_x)_2As_2$ (x = 0.18) with superconducting transition temperature T_{SC} = 8 K, the antiferromagnetism (AFM) of the Fe^{2+} moments still survives, although the spin-density-wave (SDW) order temperature is significantly suppressed to T_N = 70 K [2]. However, the Fe-SDW order is completely suppressed in optimally doped $Eu(Fe_{1-x}Ru_x)_2As_2$ (x = 0.24, TSC = 23 K) and $Eu(Fe_{1-x}Ir_x)_2As_2$ (x = 0.12, TSC = 22 K), attributed to stronger hybridization and more expanded bandwidth induced by 4*d* or 5*d* doping, as revealed by first-principles electronic structure calculations [3, 4]. Although the effect of transition-metal dopants in suppressing the Fe-SDW is different to some extent, they tend to modify the indirect Ruderman-Kittel-Kasuya-Yosida (RKKY) interaction among the Eu^{2+} spins in a similar way, tuning the magnetic order of the Eu sublattice from A-type AFM in the nonsuperconducting parent compound to FM in the superconducting doped compound. The coexistence of ferromagnetism and superconductivity in $Eu(Fe_{1-x}M_x)_2As_2$ is intriguing and a possible spontaneous vortex state might be responsible for the compromise between such two antagonistic phenomena.

Mo.A-P58 - LaAlO3/SrTiO3 quantum wells: engineering 2D-superconductivity and rashba spin-orbit coupling by selective orbital occupancy

G. Herranz[1], G. Singh[2], N. Bergeal[2], A. Jouan[2], J. Lesueur [2], J. Gázquez[1], M. Scigaj[1], N. Dix[1], F. Sánchez[1], J. Fontcuberta[1]

2. LPEM-UMR8213/CNRS-ESPCI ParisTech-UPMC, Paris, France

The discovery of 2DEGs at the LaAlO3/SrTiO3 interface has been heralded as one of the most relevant topics in modern condensed matter. Unlike more conventional 2DEGs -based on III-V or II-VI semiconductors -, carriers at the LaAlO3/SrTiO3 interface populate narrow 3d-bands, where electronic correlations are strong. This gives way to complex electronic phases: 2D superconductivity, magnetism -and even the coexistence of both-. There is a growing consensus that the specific symmetry of the occupied t2g-bands (dxy, dxz, dyz) should play a vital role in the emergence of correlated states. Therefore, altering the orbital hierarchy of the electronic band structure of these 2DEGs is a way towards the understanding of the interrelationship between orbital symmetry and the 2DEG complex phases. With this in mind, our research has revealed the distinctive reconstructions of the electronic structure at the LaAlO3/STiO3 interface when the 2DEG quantum is confined either along [001] or [110]. We have seen that the degeneracy within the t2g and the eg subbands of the t2g-manifold is broken inversely depending on the crystal orientation, enabling selective orbital occupancy modulated by orientational tuning [1]. By carrying out electrostatic gating experiments in LaAlO3/SrTiO3 wells, we have shown that the 2DEG reconstruction driven by crystal orientation leads to remarkable changes in the 2DEG properties. In particular, the anisotropy of the 2D-superconductivity as well as the Rashba spin-orbit field strength can be largely modulated by controlling the 2DEG subband filling. Such an orientational tuning expands enormously the possibilities for electronic engineering of 2DEGs at LaAlO3/SrTiO3 interfaces and opens new research fields to extend our current understanding of the link between orbital symmetry and magnetism and superconductivity at LaAlO3/SrTiO3 quantum wells.

Mo.A-P59 - New Insights in the phase diagram of URhGe

A. Gourgout [1,2], A Pourret [1,2], D. Aoki [1,2,3], J. Flouquet [1,2]

1. CEA, INAC-SPSMS, Grenoble, France
2. Univ. Grenoble Alpes, INAC-SPSMS, Grenoble, France
3. Institute for Materials Research, Tohoku University, Oarai, Ibaraki, Japan

The exotic electronic properties near a ferromagnetic quantum critical point are not very well understood. In this study we focus on the superconducting ferromagnet URhGe. The remarkable feature in this compound presents the magnetic field induced superconducting phase associated to a spin re-orientation at HR 12T for H parallel to b-axis (hard magnetization axis). This spin re-orientation transition at HR is supposed to be associated with is a topological change of the Fermi surface (FS) known as a Lifshitz type transition. In order to probe Fermi surface changes, we chose to measure thermoelectric power and Nernst effects on samples with different orientations of the thermal gradient (along and perpendicular to the easy magnetization axis, J along c, a and b-axis, respecively) with H parallel to b-axis. It is well known that thermoelectric power is particularly sensitive to any change of the FS. At low field, thermoelectric power as function of magnetic field shows small anomalies below HR possibly due to FS changes and a strong peak at HR. At very high magnetic fields, we observed quantum oscillations in the thermopower a frequency of 580 T. In addition, we detected anomalies in the different thermoelectric coefficients corresponding to two new energy scales that collapse at Hr. These low energy scales could possibly mark the appearance of a Fermi Liquid state at low temperature and confirm the presence of ferromagnetic fluctuations close to the QCP.

Mo.A-P60 - Enhancement of Tc due to pressure application in LaFeAsO1-xHx studied by NMR

N. Fujiwara[1], N. Kawaguchi[1], S. Iimura[2], S. Matsuishi[2], H. Hosono[2]

1. Kyoto University, Kyoto, Japan
2. Tokyo Institute of Technology, Tokyo, Japan

The prototypical iron-based high-Tc pnictide LaFeAsO1-xHx undergoes successive antiferromagnetic (AF)-superconducting (SC)-AF phase transition upon H doping. The superconducting phase has double-domes structure in the electronic phase diagram. Pressure application merges the double domes into a single dome, and the Tc minimum of 26 K at x=0.2 goes up to 45 K, the Tc maximum, by applying a pressure of 3.0 GPa. To investigate the high-Tc mechanism, we performed 75As nuclear magnetic resonance at 3.0 GPa. The relaxation rate divided by temperature, 1/T1T for x=0.2 exhibited monotonous increase with the increase in temperature above Tc, implying that spin fluctuations hardly have an effect on 1/T1T at ambient pressure. By applying pressure, the T dependence above Tc was almost the same with that at ambient pressure, despite that the enhancement of Tc due to pressure application was confirmed from remarkable decrease in 1/T1T below Tc. These features are also seen for 14% F-doped LaFeAsO1-xFx [1], suggesting that spin fluctuations are not essential to achieve high Tc in the La1111 series.

Mo.A-P61 - The nature of the metamagnetic transition in ferromagnetic superconductor UGe2

C. Lithgow[1], K. Kamenev[1], A. Huxley[1]

1. The University of Edinburgh, Edinburgh, United Kingdom

The coexistence of ferromagnetism and superconductivity requires an unconventional electron-pairing mechanism, since the conventional theory of opposite-spin Cooper pairs is ruled out by the spin-alignment due to the ferromagnetic order. In ferromagnetic superconductor UGe2 the microscopic mechanism for superconductivity is as yet unknown, however the emergence of the superconducting state seems to be connected to the critical point where a metamagnetic transition between two different phases of ferromagnetism is supressed, by high pressure, to zero Kelvin.
Hall effect and magnetoresistance measurements crossing this transition in temperature, pressure and magnetic field adds to our understanding of the nature of the different phases of ferromagnetism either side of the critical point and ultimately the nature of superconductivity in UGe2. Here we report the significant changes in the ordinary and anomalous Hall coefficients crossing the metamagnetic transition.

Mo.A-P63 - Doping effect on Pd site of quasi-one-dimensional Nb2PdS5

Z.-An Xu[1], C. Shen[1], B. Si[1], H. Bai[1], X. Yang[1], Q. Tao[1]

1. Zhejiang University, Hangzhou, China

Polycrystalline Nb2Pd1-xRxS5 (R=Ir, Ag, Ni, Pt) were synthesized by a solid-state method and superconductivity was investigated by measuring resistivity, Hall effect and magnetic susceptibility. While Ni and Pt are both isovalent dopants at Pd site, Ag (Ir) has one more (less) d electron compared to Pd, which is supposed to change the charge carrier density in the system. It is found that superconducting transition temperature (Tc) can be slightly enhanced by partial substitution of Ir on Pd, but the system is quickly suppressed to a metallic ground state with 30% Ag doping. Hall effect measurements show that Ir doping induces extra electron-type charge carriers to the system and Ag doping instead decreases the charge carrier density. A close correlation between Tc and charge carrier density can be established. Meanwhile Tc reaches a maximum around x=0.2 and finally vanishes with a semiconducting ground state for isovalent Pt doping. Ni doping shows a similar behavior. It is proposed that Tc may be tuned by chemical pressure induced by Pt or Ni doping.

Mo.A-P64 - Superconducting and quadrupolar properties of a dilute praseodymium system Y1-xPrxIr2Zn20 for x < 0.1

Y. Yamane[1], K. Wakiya[1], K. Matsumoto[1], T. Onimaru[1], K. Umeo[2], T. Takabatake[1]

1. Advanced Sciences of Matter, Hiroshima University, Hiroshima-shi, Japan
2. Natural Science Center for Basic Research and Development, Hiroshima University, Hiroshima-shi, Japan

Praseodymium-based compounds with $4f^2$ configuration exhibit interesting phenomena arising from hybridization between $4f$ and conduction electrons. The Pr^{3+} ion in a caged compound $PrIr_2Zn_{20}$ has the Γ_3 doublet CEF ground state with quadrupolar degrees of freedom. This system exhibits an antiferro-quadrupolar (AFQ) ordering at T_Q= 0.11 K and a superconducting transition at T_C = 0.05 K [1, 2]. The coexistence of the AFQ and superconducting state indicates that the quadrupole fluctuations possibly stabilize the superconducting state. In the present work, we have focused on a dilute Pr system $Y_{1-x}Pr_xIr_2Zn_{20}$ for x< 0.1 expecting that another type of the ground state would emerge from the Γ_3 doublet once the long-range AFQ order collapses by the Y substitution. We report on the measurements of the electrical resistivity, specific heat, and ac/dc magnetic susceptibility for polycrystals of $Y_{1-x}Pr_xIr_2Zn_{20}$ for x<0.1.
We have found superconductivity in YIr_2Zn_{20} at T_C = 0.13 K from the Meissner diamagnetic signal in the AC magnetic susceptibility. The T_C does not change for x up to 0.026. The magnetic part of the specific heat C_m of $Y_{1-x}Pr_xIr_2Zn_{20}$ was estimated by subtracting the data for YIr_2Zn_{20} and $LaIr_2Zn_{20}$ mixed in an appropriate ratio.
For x = 0.026 and 0.085, $C_m(T)$ shows a broad peak at around 9 K, which could be reproduced by a doublet-triplet two-level model. It indicates that the CEF ground state of dilute Pr^{3+} ion is the Γ_3 doublet as in $PrIr_2Zn_{20}$. Below 3 K, $C_m(T)/T$ follows -ln$T$ dependence. These results will be discussed from the view point of the quadrupolar Kondo effect in the dilute system.

Spin triplet superconductivity does not only exist in the bulk like Sr_2RuO_4 [1] but can also be generated at an interface between a spin-singlet superconductor (S) and a ferromagnet (F) via magnetic inhomogeneity [2]. However, there is another approach to realize the spin-triplet proximity effects with junctions between F and a spin-triplet superconductor (T). Theoretically, it has been predicted that spin-triplet proximity effect can be controlled by magnetization direction of F relative to the spin direction of the spin-triplet Cooper pairs [3].
We developed F/T hybrids by growing epitaxial ferromagnetic $SrRuO_3$ thin films on the *ab*-surface of Sr_2RuO_4 single crystals. The films are under compressive strain (≈ 2%) and ferromagnetic order appears below 160 K [4]. Conductance vs voltage shows the superconducting transitions at a characteristic voltage of the order 5 μV at 300 mK. Field dependent characteristic voltage reveals the presence of spin-triplet proximity effect at $SrRuO_3/Sr_2RuO_4$ interface. Our work will help opening a new field of research which may be called “Superspintronics”.

Mo.A-P68 - Pressure effects on superconducting properties of fese0.5te0.5

E. L. Martinez[1], Roberto Escudero[1]

1. Iim, Unam, Coyoacán, México, D. F., Mexico

During the last years, the compound $FeSe_{1-x}Te_x$ has been strongly studied in order to understand the changes in crystalline structure and critical temperature under hydrostatic pressure [1-3]. However, the superconducting parameters have been barely studied [4], and this paper proposed compares these parameters at different pressures. In this work we studied a high oriented sample of $FeSe_{0.5}Te_{0.5}$ using a high cell for MPMS (Quantum Design), Pb as in-situ manometer and Daphne 7373 oil as pressure media. We found that the superconducting properties of $FeSe_{0.5}Te_{0.5}$ were modified when an external pressure was applied during magnetic measurements. When the samples were subjected to pressures between 0.1 to 0.8 GPa, the critical temperature changed from 14.5 to 20 K with a rate of $dTc/dP=7.37$ K GPa^{-1}. The lower and upper critical magnetic fields ($H_{c1}(0)$ and $H_{c2}(0)$) were calculated from the experimental data and a linear fit near the Tc using a Werthamer-Helfand-Hohenberg (WHH) approximation [5]. $H_{c1}(0)$ increased from 0.1 to 0.5 T and H_{c2} changed from 2 to 18 T with external pressure, while the Ginzburg-Landau parameters were estimated between K=3.37-10, $\xi(0)$= 11.74-4.4 nm and $\lambda(0)$=78-22 nm. In summary, the lower and upper critical fields increased, while the coherence length and penetration depth decreased. These facts indicated a gain in to the density of superconducting carriers.

Mo.A-P69 - A manifestation of latent superconductivity in ferromagnet via a proximity effect in FS structures

Y.i Proshin[1], M. Avdeev[1]

1. Kazan Federal University, Kazan, Russia

It is well known that a proximity effect - an interplay between superconducting order parameter in S layers and magnetic order parameter in F layers in the artificial layered ferromagnet-superconductor (FS) structures - can lead to several striking phenomena. However, in standard approach to the proximity effect theories for these systems, a superconducting order parameter and an interelectronic interaction constant were neglected for a ferromagnet. Actually, an electron-electron interaction in a ferromagnet is in existence, but it is suppressed by strong exchange field. The interaction can be reveal itself only if an exchange field would be removed. In this virtual case, a ferromagnet is transformed to normal metal and this latent interaction can lead to superconducting correlations and, therefore, to a superconductivity onset with critical temperature Tcf, estimated by the BCS expression. We analyze such situation for dirty case basing on solutions of the Usadel equations. Changing different parameters of asymmetrical trilayers F1SF2 and F1F2S (thicknesses of layers, boundary transparencies, angle between magnetizations, external magnetic field, Tcf, and so on), we show that an existence of the electron-electron interaction in a ferromagnet can essentially change the phase diagrams of the FS systems. Thus, an appearance of latent superconductivity of F layers can be manifest itself in the proximity effect conditions. It will be especially expressed if magnetizations in both F layers have opposite signs. A peculiar kind of method of superconducting probing spectroscopy to detect unknown electronic parameters of F metals is proposed. Possible conditions for experimental observation of solitary superconductivity predicted us are also investigated.

The work is partially supported by Russian Government Program of Competitive Growth of Kazan Federal University. MA is also thankful to the RFBR (13-02-01202) for partial support.

Mo.A-P70 - Pressure dependence of superconducting and normal state properties in YFe2Ge2

K. Semeniuk[1], J. Chen[1], G. Lampronti[2], Y. Zou [1], M. Grosche[1]

1. Cavendish Laboratory, University of Cambridge, Cambridge, United Kingdom
2. Dept. of Earth Sciences, University of Cambridge, Cambridge, United Kingdom

The paramagnetic d-electron system YFe_2Ge_2 displays an unusually high Sommerfeld ratio of the specific heat capacity $C/T \simeq 100$ mJ/molK^2 at low temperature and can be tuned to the border of spin density wave order by partial substitution of Y with isoelectronic Lu [1], suggesting that YFe_2Ge_2 is located close to a spin density wave quantum critical point. Our ambient pressure, low temperature measurements reveal a $T^{3/2}$ power law temperature dependence of the electrical resistivity above a superconducting transition at about $T_c \simeq 1.8$ K [2].
The similarity both in terms of crystal and electronic structure between YFe_2Ge_2 and the alkaline metal iron arsenide superconductors (K/Rb/Cs)Fe_2As_2 has motivated alternative proposals regarding the pairing mechanism [3]. We explore the role of the nearby spin density wave quantum critical point for superconductivity in YFe_2Ge_2 by high pressure measurements in high quality samples with residual resistivity ratios of up to 200.

Mo.A-P71 - Competition of spin and charge orders in a model cuprate

Y. Panov[1], A. Moskvin[1], A. Chikov[1], I. Avvakumov[1]

1. Ural Federal University, Sverdlovsk Oblast, Russia

The fascinating issue of an intertwining effect between bulk superconductivity and static magnetic order in cuprate superconductors has attracted a lot of attention for many years (see e.g.: [1]). Here we present an unified approach to the description of the variety of the local intra-unit-cell order parameters determining a low-energy physics in cuprates. We start with a minimal model with the on-site Hilbert space reduced to only three effective valence centers [CuO4]7-,6-,5- (nominally Cu1+;2+;3+). Central point of the model implies the occurrence of unconventional on-site quantum superpositions of the three valence states characterized by different hole occupation: nh=0,1,2 for Cu1+;2+;3+ centers, respectively, and different conventional spin: s=1/2 for Cu2+ center and s=0 for Cu1+;3+ centers. We develop an S=1 pseudospin model with a non-Heisenberg effective Hamiltonian that provides a physically clear description of 'the myriad of phases' from a bare parent antiferromagnetic insulating phase to a Fermi liquid in overdoped cuprates. Making use of a generalized mean-field approximation (MFA) and classical Monte-Carlo technique we demonstrate a competition of the spin and charge orders in terms of a simplified model Hamiltonian and the evolution of the phase diagram with the doping charge concentration n. The work was supported by the Government of the Russian Federation, Program 02.A03.21.0006 and by the Ministry of Education and Science of the Russian Federation, projects Nos. 1437 and 2725.

We present a time-of-flight neutron-spectroscopy study of the high-T_C cuprate superconductor La_{1.855}Sr{0.145}CuO_4 (LSCO). High instrumental energy-resolution allowed us to probe the low-energy incommensurate spin-excitations in the 0.2-2 meV range. In the normal state, we observe two resonance-like features in the excitation spectrum. Upon cooling into the superconducting phase, these resonances appear to be suppressed, while the spectral weight at the lowest accessible energy-transfers decreases only gradually. Our results are discussed in terms of competition between superconductivity and spin-density-wave order.

Mo.A-P73 - Electrostatic Doping under Pressure

D. McCann[1,2], K. Kamenev[1, 3], A. Huxley[1,2]

1. Centre for Science at Extreme Conditions, University of Edinburgh, Edinburgh
2. School of Physics and Astronomy, University of Edinburgh, Edinburgh
3. School of Engineering, University of Edinburgh, Edinburgh

Electrostatic doping allows continuous tuning through a materials phase diagram by application of high electric fields thus eliminating any potentially obscuring effects normally associated with chemical doping. Electric Double Layer devices make use of this effect to induce a 2D superconducting state at interfaces in a range of materials. One such device is the Electric Double Layer Capacitor which can detect the onset of superconductivity through AC susceptibility measurements. We make use of such a device in an attempt to electrostatically dope and tune the superconductivity in the cuprate compound La_{1.93}Sr_{0.07}CuO_{4} as well as investigating whether application of pressure improves its efficiency.

Mo.A-P74 - Impurity defects in iron-doped Bi2212

S. Baar[1], N. Momono[1 2], J. Suzuki[2], J. Soda[2], K. Kobayashi[2], H. Takano[1,2], Y Amakai[2], T. Kurosawa[3], M. Oda[3], M. Ido[3]

The origin of the pseudogap and its influence on the electronic state are believed to be the key factors in understanding the mechanism of the high temperature superconductivity in cuprates. The modulation structure of the Local Density of States (LDoS) distribution has been intensively studied as a possible origin of the pseudogap. Recently a charge order with a similar characteristic wave vector as the LDoS modulation in the pseudogap state has been reported by bulk-sensitive experiments. However the origin of the charge order and the LDoS modulation is not yet fully understood. In the present study, high-resolution and low-temperature Scanning Tunnelling Microscopy / Spectroscopy (STM/STS) measurements were used to obtain information about the Local Density of States (LDoS) distribution on the sample surface. The single crystal was grown using the Floating zone method. The transition temperature T_C of the sample was determined to be 82 K and 89 K. The STS measurements were made at 8.5 K. The processed samples were pure and iron-doped slabs of an overdoped $Bi_2Sr_2CaCu_2O_{8+\sigma}$ (Bi2212). The LDOS of the Fe-doped Bi2212 shows a suppressed superconducting gap with a shifted global minimum. The STM- and dIdV- maps show impurity defects, which are suspected to be caused by the iron dopand. The fluctuations of the global minimum were mapped and compared to the locations of the impurities. Surprisingly, there were no correlations between the locations of the impurity defects and the global minimum variations. The Fe-doped sample was analysed while applying an external magnetic field, to further investigate the behaviour of the superconducting gap and the impurity sites.

Mo.A-P75 - Two superconducting phases separated by a Lifshitz transition in LaFeAs1-xPxO

Z. -An Xu[1], Ch.Shen[1], B. Si[1], X. Yang[1], Y. Luo[1], C. Cao[2], Chunmu Feng[1], G. CaO[1]

1. Zhejiang University, Hangzhou, China
2. Hangzhou Normal University, Hangzhou, China

Two distinct superconducting phases have recently been discovered in the P-doped 1111-type iron pnictide superconductors LaFeAs1-xPxO (0 äT x äT 1). The first superconducting phase is centered around x = 0.3 and then superconductivity disappears as P content increases to x = 0.5. For x >0.5, a second superconducting phase appears and Tc reaches a maximum at x = 0.7. We found that the upper critical field Hc2 is significantly larger in the second superconducting phase although the maximum of Tc is close to each other. Hall effect and thermopower measurements reveal a distinct difference in the normal state transport properties between the two superconducting phases. Further study of Zn impurity effect implies that there could be a change in the superconducting pairing symmetry between the two superconducting states. First-principles band calculations suggest that there could be a Lifshitz transition around x =0.5.

Mo.A-P76 - Pseudogap and kinetic energy of unconventional superconductivity in the two-dimensional Hubbard model

3. Centro Brasileiro de Pesquisas Físicas, Rio de Janeiro, Brazil

In conventional superconductors described by the Bardeen-Cooper-Schrieffer (BCS) theory, the transition from the normal to the superconducting state is accompanied by a reduction in the potential energy and an increase in the kinetic energy. On the other hand, in high-temperature superconductors the potential and the kinetic energies present an unconventional behavior that may be strongly related to the pseudogap phenomena. In this work, we analyzed the kinetic and potential energies in the superconducting state of the two-dimensional Hubbard model. The model includes hopping to first (t) and second (t2) nearest neighbors and is investigated by the Green's function method within a n-pole approximation [1,2], which allows to consider superconductivity with d-wave pairing. In the present scenario, a pseudogap emerges near the anti-nodal points in the Fermi surface, when the strong coupling regime is reached. The obtained results show that in the low doping region, the system enters the strong coupling regime and the opening of a pseudogap is followed by a decreasing of the kinetic energy and an increasing of the potential energy. This result corroborate the scenario recently presented by Gull and Millis [3] that attributes the pseudogap to the strong correlations present in the underdoped regime. A phase diagram of Coulomb interaction U versus the occupation n is also presented. This phase diagram shows clearly that the pseudogap regime coincides with the strong coupling regime in which the kinetic and potential energies present an unconventional behavior. Finally, we show that the pseudogap and the unconventional behavior of the kinetic and potential energies are close related to strong antiferromagnetic correlations.

3. Quantum Matter Institute, University of British Columbia, Vancouver, Canada
4. Department of Physics, Oakland University, Rochester, United States

We study the properties of a superconducting phase in a diatomic chain with two different atoms in the unit cell. One of the atoms contains an s- and a p-orbital while the other has just a p-orbital. The kinetic energy of the model has a hopping term between orbitals p (tpp) and an antisymmetric hybridization (V) between the orbitals s and p of the two different atoms. We add by hand a superconducting term that is treated at the mean-field level. By using the Green's function method, we calculate the superconducting order parameter and analyze the effect of tpp and V over it. This model was then applied to understand the superconducting phase of LaOBiS2 [JPSJ 81, 114725 (2012)], whose electronic structure has been shown to be approximately one-dimensional [PRB 86, 220501 (2012)]. We model it as a chain of Bismuth (p-orbital) and Sulfur (s- and p-orbital) atoms. We were able to determine that, for tpp and V values consistent with those obtained from DFT calculations for LaOBiS2, there exist a superconducting phase which is strongly dependent on variations in these hopping parameters. This is consistent with experimental findings in LaOBiS2 showing a strong dependence of the superconducting phase with pressure [PRB 90, 220510 (2014)], which is well known to affect the value of hopping parameters and hybridization.

Mo.A-P78 - The transport measurement on KxFe2-ySe2 at high pressure

4. RIKEN, Wakō, Japan

The superconductor FeSe has simpler crystal structure, and its Tc can be raised by doping alkali metal from 8 K to over 30 K. In addition, the K-doped FeSe has two separated superconducting phases with pressure and the Tc of the superconducting phase at higher pressure (SC-2) is 48 K at 12 GPa [1]. KxFe2-ySe2, has Fe-vacancies and two states, the metallic state and the insulator state. The phases co-exist and are decided by the order of iron vacancies [2]. In this study, the sample dependence of KxFe2-ySe2 is researched with transport measurement at high pressure. Four samples, which have different heat-treatment, were used. The SC-2 didn't appear in some samples, and every sample showed different temperature dependence of electric resistance. We will report the relation between differences of samples and their superconductivity in poster presentation.

Mo.A-P79 - Magnetic measurements of superconducting KxFe2-ySe2 single crystals under high pressure

K. Miyoshi[1], M. Kondo[1], K. Morishita[1], G. Motoyama[1], K. Fujiwara[1], J. Takeuchi[1]

1. Shimane University, Matsue, Japan

KxFe2-ySe2 is an FeSe based superconductor with Tc=30 K, having a crystal structure composed by intercalating K atoms between the layers of edge sharing FeSe4 tetrahedrons, which is the unit layer in FeSe superconductor (Tc=8 K). In FeSe based superconductors, there is a general trend toward higher Tc as interlayer distance or length of c-axis increases, as expected from the fact that Tc of (NH3)yAxFe2Se2 (A=alkali metal) is ranging from 30 K to 44 K depending on the c-axis lattice parameter. The importance of interlayer distance for the superconductivity can be confirmed by the investigations on the superconductivity under physical pressure, which compresses the lattice volume. In the present work, we have performed the measurements of dc magnetization for KxFe2-ySe2 single crystal specimens both under hydrostatic and uniaxial pressure, using miniature diamond anvil cell. In the experiments, liquid Ar and NaCl were used as pressure transmitting media to generate hydrostatic and uniaxial pressure, respectively. It has been found that Tc is pressure independent below 2 GPa but decreases rapidly above 3 GPa, indicating that the superconductivity disappears at about 5 GPa, in case that liquid Ar is used as pressure transmitting media. On the other hand, Tc is found to decreases rapidly above 2 GPa and is extrapolated to 0 K at about 3 GPa, in case that the uniaxial pressure is applied along c-axis using NaCl as pressure transmitting media. These behaviors suggest that the c-axis lattice constant is one of the important factor to determine Tc, so that the lattice compression along c-axis destroys the superconductivity more effectively, showing consistency with the general trend mentioned above.

Mo.A-P80 - Improvement of high-pressure thermal expansion measurement using an active-dummy method with an application to the antiferromagnetic superconductor CeRhIn5

K. Imura[1], M. Takahashi[1], K. Deguchi[1], N. Sato[1]

1. Nagoya University, Nagoya, Japan

Near a quantum critical point (QCP), where an ordering temperature goes down to zero temperature, there emerges a novel quantum state such as unconventional superconductivity. At a magnetic QCP, the Gruneisen constant diverges and hence thermal expansion measurements may be useful for studying physics of the QCP. In heavy fermions, the QCP can be achieved by the application of easily accessible magnitude of pressure. For high-pressure thermal expansion measurements, an active-dummy method using a strain-gauge is usually adopted. It is a powerful tool, but is not straightforwardly applied to the study on the QCP: the active-dummy method requires us to use two strain gauges, which are put on a sample and a dummy, and a small difference in their resistivity particularly below 4 K causes a spurious voltage that results in an error in the quantitative determination. In this paper, we present that such the spurious voltage can be reduced by selecting an appropriate pair of strain gauges. We also report the application of the method to thermal expansion measurements of CeRhIn5. At ambient pressure, CeRhIn5 exhibits an antiferromagnetic and superconducting transition below TN = 3.8 K and Tsc = 90 mK, respectively [1]. Note that whether superconductivity at ambient pressure is of bulk origin remains to be under debate. With applying external pressure, TN initially increases and shows a peak at 0.7 GPa, and then vanishes at a critical pressure Pc ~ 2.1 GPa. Besides a lot of experimental studies, a pressure-temperature phase diagram in the vicinity of Pc remains to be cleared. We measured the thermal expansion of CeRhIn5 using an appropriate pair of strain gauges, and obtained the pressure dependence of the thermal expansion at a constant temperature. From this result, we determine a phase transition line between the low-pressure antiferromagnetic state and high-pressure superconducting state.

Ferromagnetism (FM) and superconductivity (SC) have been considered to be antagonistic because FM spontaneous magnetization seems to be incompatible with SC diamagnetism. However, this simple consideration was overthrown by the discovery of UGe2, URhGe, and UCoGe in which 5f electrons are responsible for both of itinerant FM and SC. This raises a question of that this unique feature may arise from some characteristic nature of 5f electrons. To clear this problem, we study Y9Co7, a candidate of ferromagnetic superconductor. Y9Co7 exhibits FM (TFM = 5 K) and SC (TSC = 2 K) at ambient pressure [1], although it is controversial if the FM is a long-range order. (According to our recent measurements, the 3rd harmonic magnetic susceptibility shows a negative broad peak as a function of temperature [2], indicative of cluster glass-like inhomogeneous state.) To further investigate the correlation of the long-range or short-range FM with SC, we measured the dc magnetization and the ac magnetic susceptibility at temperatures above and below TSC. We found that their magnetic field dependences are those in a conventional ferromagnet and a superconductor, in contrast to those of UCoGe in which the lower critical magnetic field (Hc1) is absent [3]. From these results, we suggest that Y9Co7 is a conventional type II superconductor and hence has no spontaneous vortex state. We also measured the ac magnetic susceptibility under pressure. As the pressure increases, TSC increases while the ac susceptibility just above TSC decreases, similarly observed in a previous report [4]. Then, we constructed a pressure vs. temperature phase diagram, in which TSC decreases while a paramagnetic Curie temperature decreases. From this result, we suggest that the ferromagnetism (ferromagnetic fluctuation) competes with SC.

$CeCu_2Si_2$ shows significant increase in T_C around the critical pressure P_C = 4.5 GPa. It is proposed that superconducting mechanism around P_C results from the valence fluctuation of Ce ions. Our previous study revealed that the ^{63}Cu-NQR frequency ($^{63}\nu_Q$) suddenly deviated from the linear pressure dependence of $^{63}\nu_Q$ above 4 GPa, suggesting that Ce valence rapidly increases around P_C. Since valence transitions are not observed in powdered XRD measurement, valence crossover occurs in the narrow pressure range around P_C. Recently, theory of valence mediated superconductivity proposed that the valence transition appears with applying high magnetic field. Therefore we started to measure Cu-NMR of single crystal $CeCu_2Si_2$ in order to elucidate the field and pressure dependence of NQR frequency (ν_Q), and to search field-induced valence transitions. Since NMR spectrum of polycrystalline powder sample shows broad powder pattern, it is impossible to investigate the valence state. Under the magnetic field (= 8 T) parallel to *a*-axis and *c*-axis at ambient pressure, Knight shift is consistent with previous data obtained by the low field NMR and ν_Q is also consistent with that of NQR at zero field. We will report *T*-dependence of ν_Q under pressure and discuss valence and spin state, estimated by applying the field parallel to a-axis and c-axis.

Mo.A-P84 - Drastic enhancement of superconducting transition temperature in 112-type Ca1-xRExFeAs2 (RE = La, Ce, Pr, Nd) induced by negative chemical pressure

K. Kudo[1], Y. Kitahama[1], K. Fujimura[1], T. Mizukami[1], M. Nohara[1]

1. Department of Physics, Okayama University, Okayama, Japan

The 112-type CaFeAs2 is a recently discovered iron-based superconductor [1,2]. The compound crystallizes in a monoclinic structure and consists of alternately stacked FeAs and arsenic zigzag bond layers. It has been recognized that the rare earth (RE) substitution is necessary for stabilizing the 112 [1,2]. La-doped compounds show bulk superconductivity at 35 K [3], while Pr-, Nd-, Sm-, Eu-, and Gd-doped compounds show superconductivity at 10-15 K with a small shielding volume fraction of 5-20% [2,4]. Ce-doped compounds rarely exhibit superconductivity [4]. In this paper, we report that a negative chemical pressure induced by Sb doping increases the Tc of Ca1-xLaxFe(As1-ySby)2 to 47 K [5], which is the second highest Tc after 1111-type iron-based superconductors. Moreover, we show that bulk superconductivity at 43, 43, and 43 K is induced by Sb doping of Ca1-xRExFeAs2 with RE = Ce, Pr, and Nd, respectively [5]. These results highly contrast with those of other iron-based superconductors, in which Tc is generally enhanced by a positive pressure. We found that an increase in the lattice parameter b, which modifies the As-Fe-As bond angle, is important for optimizing the superconductivity in the 112 phase [5]. The Tc might be increased above 50 K, if the b parameter can be increased to approximately equal a.

In superconductors $Zr_{1-x}Lu_xB_{12}$ and $Y_{1-x}La_xB_6$ (x<0.1) with a transition to cage-glass state at $T^*\approx$ 50-100 K [1] heat capacity *C(T)* and magnetization measurements have been carried out on high quality single crystals in magnetic fields up to 9 T in combination with point-contact spectroscopy studies of the superconducting energy gap. For these higher borides with critical temperatures in the range $T_C\approx$4.5-7.4 K we have estimated the thermodynamic and upper critical fields, electron density of states' renormalization effect, electron-phonon interaction λ, superconducting gap $\Delta(T)$ [2] and pseudogap Δ^*. Our experiments reveal strong changes in aforementioned characteristics with variation of content x in these compounds with BCS-type superconductivity mediated by quasi-local vibrations of the ions of transition and rare earth metals (Y^{3+}, La^{3+}, Zr^{4+} and Lu^{3+}). We analyze step-by-step the transformation of II-order superconductivity with a wide range variation of the Ginzburg–Landau parameter κ=0.7-7. We discuss also the development of the structural instability, the formation of two level systems, their role in the suppression of superconductivity and the nature of pseudogap in the RB_6 and RB_{12} higher borides.

The high-*T*c superconducting phase is obtained by an intercalation of alkali or alkali-earth metals between the FeSe layers. For the solution method, the solvent molecules are intercalated simultaneously between the FeSe layers, and expand the interlayer spacing effectively. It is suggested that the *T*c for this system increases with increasing the interlayer spacing [2]. Recently the *T*c-dome as a function of the interlayer spacing was reported [3]. On the contrary, multi-phase character was also observed in the ammoniated FeSe system due to the difference in an amount of intercalants; solvent molecules and/or metal ions [4]. Thus, to extract the key parameter for the superconductivity in ammoniated FeSe system, it is important to control the superconducting phase precisely. Here, we present our synthesis method, and show the superconducting properties including the magnetization and resistivity experiments for $A_x(NH_3)_yFe_{2-d}Se_2$ samples. For example, in Ba doped FeSe sample, the magnetization and the resistivity experiments indicate that the onset-*T*c is obtained to be 43 K, which is higher than the previous result (38 K). We will discuss the correlation between the structural parameters and superconducting transition of $A_x(NH_3)_yFe_{2-d}Se_2$ system in detail.

Mo.A-P88 - V substitution of Co In Nd(Co1-xVx)2Si2; A crossover from antiferro to ferromagnetism

R. Roy Chowdhury[1], S. Dhara[1], B. Bandyopadhyay[1]

1. Saha Institute of Nuclear Physics, Kolkata, India

RT_2X_2 intermetallic compounds (R = rare earth, T = transition metal and X = Si) crystallize in the body centered tetragonal $ThCr_2Si_2$ type structure. Previous works suggest the R^{3+} ions are responsible for magnetism in the RCo_2Si_2 compounds, whereas Co does not carry any magnetic moment. In the work, non-magnetic Co has been substituted by V, having a larger atomic volume and a fewer number of d-electrons than Co. $NdCo_2Si_2$ shows antiferromagnetic transition at 34 K. Temperature dependence of magnetic susceptibility, in $Nd(Co_{1-x}V_x)_2Si_2$ (x = 0 to 0.35) follow ferrimagnetic behavior in between 50-300 K. Below ~ 30 K, the field dependence of magnetization curves tend to saturate at ~ 2 tesla and also coercivity is exhibited in hysteresis loops, indicating dominance of ferromagnetic interaction. Saturation magnetization moment M_s, increases with V content and for x = 0.35, M_s reaches to ~0.35-0.40 Bohr-magneton /f.u., much smaller than that of the rare earths. Suceptibility consists of a strong ferromagnetic part and paramagnetic part. The R^{3+} ions contribute to the paramagnetic part confirming the observed ferromagnetism to be originating from 3d moments. Also, in V doped samples exchange bias is observed which increase markedly below ~ 12 K where there is also a sharp decrease in the resistivity. Specific heat measurements of the parent compound show three transitions at ~ 13, 23 and 32 K respectively which are consistent with the magnetization data. Doped compounds show two sharp transitions at 26 K and 45 K respectively. For $NdCo_2Si_2$, magnetic entropy (S_{mag}) at transition 32K is about 52% of the total magnetic entropy value for Nd^{3+}, and in the doped sample S_{mag} at transition temperature 45 K is about 69-70% of the total magnetic entropy. The measurements indicate that partial substitution of Co by V in $NdCo_2Si_2$ result in ferromagnetism coexisting with antiferromagnetism.

Mo.A-P89 - Anomalous ferromagnetic anomaly coexisting with superconductivity in layered superconductor CeO1-xFxBiS2

T. Asano[1], T. Nakashima[1], R. Higashinaka, T. D. Matsuda, Y. Aoki

1. Tokyo Metropolitan University, Tokyo, Japan

BiS2-based layered superconductors LnO1-xFxBiS2 (Ln: rare earth) have been attracting much attention [1,2]. Among them, the coexistence of superconductivity and ferromagnetism has been revealed in CeO1-xFxBiS2 by magnetic susceptibility measurements using polycrystalline samples [3]. To investigate this intriguing anomaly, we have studied the physical properties of CeO0.5F0.5BiS2 using single crystals with the onset superconducting transition temperature of 3.2 K. The observed easy ab-plane anisotropy in the magnetization can be explained by a model that 4f –electrons of Ce ions are well localized with the crystalline-electric-field ground state of Jz=±1/2 doublet as in undoped CeOBiS2 [4]. It has been found that a ferromagnetic anomaly develops below 7 K along the c axis, even though this is the hard magnetization axis. The absence of specific heat anomaly around 7 K indicates that this is not a bulk thermodynamic phase transition. Instead, specific heat shows a profound -logT divergence below 3 K in a similar manner as observed in CeOBiS2 [4]. This finding clearly demonstrates that the unprecedented type of quantum critical behavior found in CeOBiS2 in the Ce-ion magnetic system remains almost unchanged even in the carrier doped CeO0.5F0.5BiS2.

Mo.A-P90 - NMR studies on the in-plane anisotropy of the iron pnictide LiFeAs

M. Toyoda[1], Y. Kobayashi[1], M. Itoh[1], M. Sato[2]

1. Nagoya University, Nagoya, Japan
2. Research Center for Neutron Science & Technology, CROSS, Naka, Japan

Possibility of the orbital fluctuation has been discussed as a mechanism of the superconducting (SC) pair in the iron pnictides with multi-orbitals, and various kinds of phenomena has been reported to demonstrate the presence of the orbital fluctuation. Among these phenomena, we have focused on physical properties with lower symmetry (the C_2 symmetry) within the Fe plane than the C_4 symmetry of the crystal structure. Until now, we have studied an in-plane anisotropy of the electric field gradient (EFG) at the As sites in the Co-doped $BaFe_2As_2$ using the ^{75}As NMR probe, and concluded that the static in-plane anisotropy of the electronic state is induced by Co impurities or defects in the Fe plane, which is consistent with the model of impurity-induced orbital order [1]. In this study, we present the results of ^{75}As NMR measurements on the iron pnictide LiFeAs which exhibits the SC transition at 18 K without atomic substitution. We found that the anisotropic parameter of EFG, h, at the As sites in the Fe plain is not zero even at 280 K and gradually increases with decreasing temperature, which may not be explained only by the *yz*/*zx* band splitting owing to spin-orbit coupling. The h value at 20 K is one order of magnitude less than the values in the superconducting Co-doped $BaFe_2As_2$. These results indicate that an amount of the defects within the Fe plane in LiFeAs is less than in $BaFe_2As_2$. The EFG anisotropy should be compared with the in-plane anisotropy of the other physical properties to discuss the anisotropic electronic state in this system.

The rare-earth nitride series are especially attractive for fundamental studies in spintronics and magnetism. Many of the series are intrinsic ferromagnetic semiconductors, and they possess interesting magnetic states resulting from the interplay between the spin and orbital contributions to the magnetic moments. They thus exhibit such surprising properties as a magnetisation in direct opposition to the spin moments in light rare earth nitrides [1], magnetic moments with no net angular momentum in EuN [2], and ferromagnetically aligned spins with no net magnetisation in SmN [3]. The last is a result of near complete cancellation of the orbital and spin moments. Perhaps most remarkably we have very recently discovered superconductivity below 4 K in SmN. We have observed the superconductivity through both resistivity and magnetisation measurements in a series of SmN films. The superconductivity occurs deep within the ferromagnetic phase, suggesting spin-triplet electron pairing of superconducting electrons. We have developed a theoretical description of this novel superconducting phase based on pairing within a fully spin-polarised electron system.

A half-quantum vortex (HQV) is expected to be found in the so-called A-phase of ^{3}He and the chiral p-wave spin-triplet pairing superconducting state [1,2]. It is formed by a π-rotation of the superconducting phase and also a π-rotation of the *d*-vector around the vortex core. Thus the magnetic flux through a HQV is one-half of the flux quantum Φ_0. HQVs are topologically possible objects, however, the energetic stability is a subtler question. Indeed, it has been pointed out that HQVs is unstable unless a weak spin-orbit coupling exists, based on phenomenological Ginzburg-Landau theory [3,4]. For experimental search of HQVs in real superconductors, it is useful to study the effects of material dependent factors on the stability of HQVs, such as the strength of the spin-orbit coupling, the anisotropy of the pairing interaction, the Fermi surface structure, and also the effects of magnetic field via a Zeemann coupling based on microscopic theory.

In this paper, as a first step, we study the quasiparticle states around a HQV or an impurity in a chiral or helical p-wave superconducting states in a square lattice tight-binding model based on the Bogoliubov-de Gennes theory. We confirmed that the zero-energy bound state, the so-called Majorana state, appears within the HQV [5], whereas it does not around the impurity. We also show the effects of spin-orbit interaction and Fermi surface structure.

Mo.A-P96 – La_3Co - superconductivity on the edge of ferromagnetism

J.Strychalska[1], M. Roman[1], B. Wiendlocha[2], A. Kozub[1], T. Klimczuk[1]

1. Faculty of Applied Physics and Mathematics, Gdańsk University of Technology, Gdańsk, Poland
2. Faculty of Physics and Applied Computer Science, AGH Univeristy of Science and Technology, Kraków, Poland

A polycrystalline sample of La_(3)Co was synthesized by arc-melting of stoichiometric amount of lanthanum (purity 99.9%) and cobalt (purity 99.95%) and annealed at 500 degrees Celsius for three weeks. Physical properties were studied by measuring susceptibility, specific heat and resistivity. The temperature dependence of resistivity above transition temperature (T_(c)=6 K) discloses a metallic-like character (drho/dT>0). The residual resistivity ratio is rho_(300K)/rho_(8K)=6. Traces of unreacted lanthanum metal is detected by a sudden drop of resistivity below T_(c)=6 K. The second, sharp drop of rho(T) at 4.65 K is associated with the transition of La_(3)Co to the superconducting state. By plotting H_(c2) versus T and using the WHH expression we obtained upper critical field mu_(0)H_(c2)=3.5 T, that implies the superconducting coherence length xi_(0)=10 nm. A clear heat capacity anomaly is observed below a transition temperature T_(c) = 4.44 K and confirms bulk superconductivity of La_(3)Co. The results of measuring the specific heat in magnetic field 3 T determined Sommerfeld coefficient gamma=31.1 mJ mol^(-1) K^(-2) and Debye temperature theta_(D)=133 K. The electron-phonon coupling constant estimated from the inverted McMillan formula (where mu*=0.13) was lambda_ep=0.82. Using gamma and the specific-heat-jump value deltaC/T_(c) at the superconducting transition temperature, we estimated deltaC/gammaT_(c), suggesting intermediate-coupling superconductivity. Estimated value of zero-temperature lower critical field, complying the demagnetization factor mu_(0)H_(c1)(0)=17.6 mT. Using obtained values we calculated a Ginzburg-Landau superconducting penetration depth lambda_(GL)(0)=162 nm. The Ginzburg-Landau parameter is kappa=16.7, indicating that La_(3)Co is a II-type superconductor. We estimated the thermodynamic critical field mu_(0)H_(c)=148 mT.

Mo.A-P97 - K-doping effect in Ba1-xKxFe2As2 studied by x-ray emission and absorption spectroscopy

Since superconductivity was discovered in the layered iron arsenides $Ba_{1-x}K_xFe_2As_2$ by partial substitution of Ba^{2+} with K^+ [1] i.e., by hole doping in the $(FeAs)^-$ layers, these compounds have received a great deal of attention as they show a high transition temperature ($T_C \approx 38$ K for x = 0.4). Recently, a new scenario of selective Mott physics has been found to agree with and disentangle a wealth of experiments on mass enhancements in electron- and hole-doped $BaFe_2As_2$ [2]. Within this framework, Mott correlations increase with hole-doping and accordingly the fluctuating local moments in the paramagnetic phase are also expected to build up.
A direct method to probe the local magnetic moment is the core-to-core (CTC) Kβ x-ray emission spectroscopy (XES) technique, sensitive to the 3*d* spin due to the intra-atomic 3*p*-3*d* exchange interaction. We have then applied CTC Fe Kβ XES to obtain the evolution of the Fe local moment with K-doping in $Ba_{1-x}K_xFe_2As_2$. The experiment was carried out at beamline ID26 of the European Synchrotron Radiation Facility (ESRF) at room temperature on single crystals covering the range $0 \leq x \leq 1$. Besides, valence-to-core (VTC) Fe Kβ XES and high-energy resolution fluorescence-detected x-ray absorption near edge structure (HERFD-XANES) spectra at the Fe K-edge were also collected to characterize the Fe local electronic structure.
The CTC Kβ XES spectra indicate a monotonic increase of the Fe local spin moment upon K-doping which is, however, smaller than reported for other iron-based superconductors [3]. On the other hand, the VTC Kβ XES and HERFD-XANES spectra reflect an enhancement in the hybridization between As and Fe occupied and unoccupied states respectively with increasing K content. The observed small magnetic moment increase in hole-doped $BaFe_2As_2$ can thus be explained in terms of a spread of the Fe 3*d* orbitals due to the strong covalence.

3. HZDR, Dresden, Germnay

FeTe1-xSex system, abbreviated in the literature as “11” represents structurally the simplest iron based system. These materials are rather unusual exhibiting huge upper critical fields that can be well above the Bardeen-Cooper-Scrieffer (BCS) paramagnetic limit, above which the pair-breaking Zeeman energy exceeds the binding energy of the Cooper pair. Recently, it has been noticed that samples prepared in different ways (starting from the same nominal composition) show physical properties that vary significantly. In this contribution we concentrate on the x=0.40 system. The two single crystal types have been prepared with a different cooling protocol. The fast-cooled sample shows superconductivity (SC) below 18 K but is on a microscopic scale inhomogeneous consisting from a matrix and large precipitates. The slowly cooled sample is of better crystalline quality, homogeneous but does not show SC down to 2 K. Excess of the interstitial iron within the matrix of the inhomogeneous crystal and within the homogeneous one is around 3 %. We have performed a series of high-field magnetoresistance and magnetization measurements on both types of crystals. The inhomogeneous sample exhibits Hc2(0)=45 (2) T for both field orientations. Anomalies connected with the destruction of the SC state by magnetic field are more pronounced for the a-axis direction than for the c-axis direction. The critical field decreases with the increasing temperature and for 16 K no anomaly could be observed. No significant anisotropy has been detected. Also for the homogeneous sample we have observed some traces of SC behavior. However, in overall, magnetoresistance curves for this sample show much smaller field variations pointing to only traces of SC phase in this sample. Thus, a very surprising result is observed: crystallographically homogeneous FeTe0.6Se0.4 system appears to be non-superconducting in contrast to a multiphase system.

Mo.A-P100 - Superconducting properties and pseudogap from preformed Cooper pairs in the triclinic (CaFe(1-x)Pt(x)As)10Pt3As8

M. Surmach[1], Felix Brückner [1], S. Kamusella[1], R. Sarkar[1], P. Portnichenko[1], J. Park[2], G. Gambashidze[3], H. Luetkens[4], P. Biswas[4], W. J. Choi[5], Y.I. Seo[5], Y.S. Kwon[5], H. Klauss[1], D. Inosov[1]

Using μSR, INS and NMR, we investigated the novel Fe-based superconductor with a triclinic crystal structure $(CaFe_{1-x}Pt_xAs)_{10}Pt_3As_8$ (T_c = 13 K). The T-dependence of the superfluid density from the μSR measurements indicates the presence of two superconducting gaps. Our INS data revealed commensurate spin fluctuations at the (π, 0) wave vector. Their intensity remains unchanged across T_c, indicating the absence of a spin resonance typical for many Fe-pnictides. Instead, we observed a peak around ω_0 = 7 meV at the same wave vector, which persists above T_c and is characterized by the ratio $\omega_0/k_BT_c \approx 6.2$, i.e. significantly higher than typical values for the magnetic resonant modes in iron pnictides (∼ 4.3). The T-dependence of magnetic intensity at 7 meV revealed an anomaly around T^* = 45 K related to the disappearance of this new mode. A suppression of the spin-lattice relaxation rate, $1/T_1T$, observed by NMR immediately below T^* without any notable subsequent anomaly at T_c, indicates that T^* could mark the onset of a pseudogap in $(CaFe_{1-x}Pt_xAs)_{10}Pt_3As_8$, likely associated with the emergence of preformed Cooper pairs.

Mo.A-P101 - C-axis resistivity of superconducting FeSe single crystals: upper critical field and its angular behavior

T. Romanova[1], D. Knyazev[1], A. Sadakov[1], D. Chareev[2]

1. Lebedev Physical Institute of Russian Academy of Science, Moscow, Russia
2. Institute of Experimental Mineralogy, Russian Academy of Sciences, Chernogolovka, Moscow, Russia

FeSe is the simplest representative of iron-based superconducting family and can be considered as a model system to study mechanism of superconductivity in this class of materials. We report out-of-plane resistivity measurements for high quality superconducting FeSe single crystals in magnetic fields up to 9 Tesla. This superconductor proved to be slightly anisotropic in terms of upper critical field Hc2 measured by in-plane resistivity [1]. Our goal was to study temperature and angular behavior of upper critical field in the H||ab geometry by out-of- plane resistivity measurements. For careful studying of C-axis resistivity we used direct Rc measurement technique that doesn't demand any additional mathematical models [2]. Temperature dependence of Hc2||c is in consistency with literature [1]. Derivative dHc2/dT is -5.74 T/K and estimation of Hc2(0) (WHH theory [3]) is 35.9 T. We studied superconducting transitions R(B) in different in-plane field orientation (the measuring current is always perpendicular to magnetic field. Hc2 obtained from magnetoresistance data exhibits anisotropic behavior.

Parent compounds of many iron-based high-temperature superconductors are metallic and magnetic, with a spin density wave character. At first sight, the metallic ground state suggests that magnetism originates from the Fermi surface nesting of itinerant electrons, consistently with band structure calculations. However there are several indications that electron correlations could be important and local moments might play a significant role together with itinerant electrons for magnetic, transport and superconducting properties [1].
Here we discuss the evolution of the magnetic and structural phase diagram of $Ln Fe_{1-x}Ru_xAsO$ for *Ln* = La, Pr via diamagnetic Ru for Fe spin dilution. The substitution of Ru for Fe is isoelectronic [2,3], hence allowing for investigation of the underlying physics without the complication of extrinsic modifications of the Fermi surface.
Muon spin relaxation measurements show that the Ru/Fe spin dilution directly produces a gradual disruption of magnetism which eventually disappears at the dilution threshold x=0.6, significantly higher than plain square bond dilution, and coinciding with the threshold for the J1-J2 frustrated square-lattice, localized spin model [2]. Neutron diffraction measurements show that the structural tetragonal-to-orthorhombic transition is a close precursor of the magnetic transition up to $x \approx 0.4$, thus indicating a relevant magneto-elastic coupling within the FeAs layers [3,4]. These results can be described in the framework of the Ising-nematic scenario predicted for localized spins in the J1-J2 model, indicating that a model of localized degrees of freedom is a proper framework to describe the magnetic character of oxy-pnictides.

Mo.A-P104 - Phase diagrams for coexistence of localised magnetism and superconductivity from a microscopic model

N. Costa[1,2], J. Pimentel[2], M. ElMassalami[1], T. Paiva[1], R. Rocha dos Santos[1]

1. Instituto de Física, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil
2. Departamento de Física, Universidade Federal do Piauí, Teresina, Brazil

Coexistence between superconductivity and magnetism is a topic of current interest as a unifying link between heavy fermions, borocarbides, iron pnictides, and possibly the cuprates. In view of this, working models which can reproduce several aspects of this coexistence can certainly contribute to a better understanding of the mechanisms at play. Here we consider a model consisting of localised spins interacting with conduction electrons through an exchange (Kondo) coupling, while the conduction electrons themselves are subject to an on-site pairing interaction; the presence of localised moments renders this model especially suitable to describe the borocarbides. We use a Hartree-Fock approximation in which the local spins are treated semi-classically, in the sense that their average values are modulated by a three-dimensional magnetic wavevector Q while the coupling with the conduction electrons is described in terms of fermion operators. This approach led us to obtain spiral magnetic phases with modulation wavevector depending on the coupling constants as well as on the conduction electron density, and on the temperature. We have found that for a range of parameters these spiral phases can coexist with an s-wave superconducting phase. Our main results are summarised as slices of the phase diagram, showing temperature vs. pairing interaction, temperature vs. Kondo coupling, and temperature vs. doping. For suitable combinations of the Hamiltonian parameters, these diagrams are in good agreement with experimental results for the borocarbides, obtained for different rare-earth elements, keeping the same transition metal, as well as for alloying the transition metal, for a given rare-earth element; in the latter case, the sequence of magnetic modes is adequately described by our model.

Mo.A-P107 - Superconductivity in YPt2Si2

A. Pikul[1], G. Chajewski[1], P. *Wiâniewski*[1], M. Samsel-Czeka[1], D. Kaczorowski[1]

1. Institute of Low Temperature And Structure Research, Polish Academy of Sciences, Warsaw, Poland

The RT_2M_2 intermetallic phases (where R is a lanthanide or actinide, T – a transition or noble metal, and M – a *p*-electron element) are known to crystallize in two closely-related derivatives of the tetragonal $BaAl_4$-type structure: a non-centrosymmetric primitive one of the $CaBe_2Ge_2$-type (space group P4/nmm) and a body-centered one of the $ThCr_2Si_2$-type (space group I4/mmm). As shown by Shelton et al. [1], the primitive unit cell consistently favors superconductivity over the body-centered one (at least in experiments performed above 1.1 K). The main aim of our work was to examine this relationship between crystal structure and physical behavior in an extended series of Y-, La-, and Th-based RT_2M_2 phases. Here we present preliminary results obtained for YPt_2Si_2.

A polycrystalline button of YPt_2Si_2 was prepared by arc melting. Subsequently, half of it was annealed at 850ºC for one week. X-ray powder diffraction revealed that both the as-cast fragment and the annealed one crystallize with the $CaBe_2Ge_2$-type structure (the lattice parameters for the latter are: a = 4.1594(1) Å and c = 9.8039(3) Å). Magnetic susceptibility, electrical resistivity and specific heat measurements, performed down to 0.35 K, showed that the as-cast sample becomes superconducting below about 1.7 K, while the annealed one at about 1.6 K, in agreement with the previous report [1]. Quantitative analysis of the magnetic susceptibility and specific heat data showed that the superconductivity in YPt_2Si_2 has a bulk character. Experiments performed in magnetic fields revealed that the transition can be suppressed by applying about 0.1 T for the as-cast specimen, and about 0.05 T for the annealed one.

Mo.A-P108 - Field-dependence of charge order in the cuprate high-temperature superconductor La2-xSrxCuO4

B. Lake[1,2], E. Schierle[1], E. Weschke[1], K. Siemensmeyer[1]

1. Helmholtz Zentrum Berlin Für Materialien Und Energie, Berlin, Germany
2. Technical University Berlin, Berlin, Germany

In the cuprate high-Tc superconductors a number of competing and co-existing phases are present and their role in the mechanism of high-Tc superconductivity is still a matter of debate. The most important of these phases are spin and charge order whose origins have been related to stripe formation or Fermi surface nesting. While incommensurate spin fluctuations were observed in the optimally doped La2-xSrxCuO4, static spin order was observed in underdoped La2-xSrxCuO4. These features are altered by the onset of superconductivity e.g. the appearance of a spin gap in the fluctuations and the enhancement of static order. The effect of magnetic field on the magnetism has also been explored and found to enhance the fluctuations and spin order while partially suppressing the superconductivity. Charge order has also been found in a number of underdoped cuprates superconductors. The charge order is observed as incommensurate peaks around the nuclear Bragg positions with twice the incommensurate wavevector as for the magnetic peaks. They appears gradually at temperatures well above Tc and unlike the spin order, show a clear change at the superconducting transition temperature below which they become suppressed. We have investigated the charge order in underdoped La2-xSrxCuO4 (x=0.11, Tc=29K) using resonant soft X-ray diffraction. We find that charge peaks appear at ~60K and gradually increase with decreasing temperature down to Tc=29K below which they become partially suppressed. We have further investigated the effect of an applied magnetic field of 6T (parallel to the out-of-plane c direction) on the charge order. We show that the superconductivity-induced suppression is reversed by the field and that the charge peaks continue to increase below Tc for fields up to 6T. These results demonstrate the strong competition between charge order and superconductivity.

Mo.A-P109 - The high pressure - low temperature structural phase diagram of KxFe2-ySe2

T. Giles[1], J. Poulten[1], M. Gamza[1], D. Daisenberger[2], H. Wilhelm[2], X. Chen[3], P. Niklowitz[1]

There has been significant interest in Fe-based superconductors due to their high critical temperatures. Some iron-chalcogenide parent compounds display antiferromagnetic Mott insulating behaviour similar to the Cuprates. $K_xFe_{2-y}Se_2$ exhibits antiferromagnetism with T_N ~550K. The antiferromagnetic transition appears to be closely coupled to a structural transition which has been identified as the onset of an Fe-vacancy order. With careful tuning of the Fe-valence by varying *x* and *y* a superconducting phase can be reached [1]. High pressure measurements [2,3] show the Mott insulating state and superconductivity to be suppressed gradually before completely disappearing at a critical pressure of about 9 GPa. A second superconducting phase emerges on further increase of pressure, with a higher critical temperature.
In this work high pressure and low temperature x-ray powder diffraction was performed on insulating and superconducting samples of $K_xFe_{2-y}Se_2$ using a diamond anvil cell to investigate any correlation between the superconducting phase diagram and the structural properties. In particular we focused on the Fe-vacancy order transition, which was known to be located at about 9 GPa at room temperature [2]. Our measurements show that the Fe-vacancy order transition is pushed to slightly higher pressures at low temperatures and occurs near the onset of the second superconducting phase emphasizing the relevance of the Fe-vacancy order for the superconducting phase diagram of $K_xFe_{2-y}Se_2$.

2. National Defense Academy, Yokosuka, Japan

YbPtGe with the orthorhombic ε-TiNiSi-type structure is reported as a heavy-fermion ferromagnet with T_C =5.4 K. Recent researches suggested its magnetic anisotropy can be ascribed to the crystal electric field (CEF) effect which acts on the eight-hold multiplet of the Yb^{3+} ion. In order to clarify the CEF effect and investigate the magnetic phase transition in this compound, ultrasonic measurements of YbPtGe and related theoretical calculation have been preformed. The transverse elastic modulus C_{66} exhibits a softening characteristic with a peak of 180 K while the longitudinal modulus C_{33} mode shows a continuous hardening during all temperature range. According to the theoretical strain-susceptibility fitting of the transverse elastic modulus by the CEF parameter obtained from Katoh's research [1], we argue that the softening at higher temperature range (>50K) as the result of quadrupole interaction between the ground and excited Kramers doublets of CEF. With further decrease the temperature below T_C, C_{66} mode exhibits a step-like softening phenomenon which is quite different from that of C_{33} mode and the possible mechanism of this was discussed.

4. Hangzhou Normal University, Hangzhou, China

$TlNi_2Se_2$ is a recently discovered nickel-chalcogenide superconductor (T_c = 3.7K). Measurements of the electronic heat capacity have revealed a Sommerfeld coefficient of $\gamma \sim 40 mJ/mol K^2$, indicating an unusually large effective mass of 14 – 20 m_e [1]. Several important questions regarding this material, such as the pairing symmetry and its relations to the iron based superconductors and the cuprates are the subject of debate [1, 2]. Using the Shubnikov-de Haas technique, we report preliminary measurements of quantum oscillations in $TlNi_2Se_2$. We compare our results to the expected Fermi surface obtained using band structure calculations in the LDA approximation. Measurements of the effective mass of the cyclotron orbits shed light on the possibility of heavy Fermion behavior in this material.

Mo.B-P02 - Unusual magnetic ground states of novel S = 1/2 square-lattice antiferromagnets Sr2NiO3X (X = F, Cl)

Y. Tsujimoto[1], K. Yamaura[1], T. Uchikoshi[1], T. Haku[2], T. Masuda[2]

1. National Institute For Materials Science, Tsukuba, Japan
2. Institute of Solid State Physics, The University of Tokyo, Tokyo, Japan

We present unusual magnetic properties of new quantum-spin square-lattice antiferromagnets, Sr2NiO3X (X = F, Cl), synthesized by high-pressure technique. These compounds adopt K2NiF4-type structure, but the preferential occupation of the halide ions at the apical positions causes the Ni center to take a square pyramidal coordination with five oxygen atoms. The nickel cation has the tri-valence state with low-spin state of S = 1/2. Interestingly, although these present compounds have a positive Weiss temperature, an antiferromagnetic ordering at 11 K takes place for X = Cl, and a spin freezing transition at 11 K fpr X = F. We discuss the magnetic ground states on the basis of a J1-J2 model with AFM nearest neighbor (NN) interactions and FM 2nd NN interactions.

Mo.B-P03 - Valley-spin locked, tunable super-current transport in superconductor / normal silicene or germanene/ superconductor junction

P. Goswami[1]

1. D.B. College,University of Delhi, Delhi, India

We start with the reduced silicene/germanene single-particle Hamiltonian in buckled 2D hexagonal lattice expressed in terms of Pauli matrices associated with the pseudo-spin. In these systems, where the Hamiltonian comprises of the Dirac kinetic energy, the spin-orbit coupling, and a mass term, the latter breaks the sub-lattice symmetry of the system's honey-comb structure and generates spin-split band gap with the help of the spin-orbit coupling. The buckled lattice generates a staggered sub-lattice potential between silicon atoms at A sites and B sites for an applied electric field Ez perpendicular to its plane. The physics of the system in the normal state is determined by two Dirac-like cones at K and K' points. By tuning Ez , one attains a critical value at which the system at the topological insulating phase goes to a semi-metal state where the æspin down' upon the æspin-up' band gap ratio(r) << 1 for the valley K, and r >> 1 for the valley K'. This state is termed as the ævalley-spin-polarized-metal' (VSPM)due to the opposite spin-polarization of the K and K' valleys. The combination of a s-wave superconducting proximity effect with VSPM is the focal point of this communication due to the possibility of creating Majorana fermions in this manner. We briefly discuss the possibility of the majorana hosting in this scenario. We also focus on the signature of both local and crossed Andreev reflection process. We show that the super-current flowing in the superconductor /normal/ superconductor junction is in pure VSPM state and completely tunable by Ez . This finding, together with the fact that the Andreev reflection process is fully valley-spin polarized, show that silicene/germanene provide a remarkable platform for tunable super-current transport.

Mo.B-P04 - Nonlinear dielectric susceptibility in a multiferroic quantum magnet Sul-Cu2Cl4

K. Povarov[1], A. Reichert[1], E. Wulf[1], A. Zheludev[1]

1. Neutron Scattering And Magnetism, Laboratory For Solid State Physics, Zurich, Switzerland

A S=1/2 spin tube Sul-Cu2Cl4 is a material, belonging simultaneously to the domains of quantum magnetism and multiferroicity. Being a highly frustrated gapped spin-liquid, it enters a helimagnetically ordered multiferroic phase as a result of magnetic field-induced quantum phase transition [1,2]. Previous measurements have already verified the presence of dielectric anomaly at the high-temperature phase transition boundary [3]. Our investigation shows that contrary to expectations dielectric susceptibility exhibits no criticality in the low-temperature limit. This implies the electric polarization itself is not an ordering parameter of the transition. The dielectric anomaly is studied in a wide range of temperatures and magnetic fields, down to 50 mK and up to 14 T. We track the phase boundary with a high precision and determine a crossover exponent of the phase transition to be 3/2. This is consistent with the Bose-Einstein condensation universality class of the quantum phase transition, typical for the field-induced magnetic order in gapped quantum magnets. However, we observe an unexpected intrinsic nonlinearity in the dielectric susceptibility above the critical magnetic field. This nonlinearity manifests itself, for example, in generation of higher harmonics of the displacement current under applied radiofrequency voltage. Higher-order susceptibilities, appearing in the ordered phase, are determined from the displacement current harmonics. It is worth mentioning that in principle the anomaly in dielectric susceptibility of Sul-Cu2Cl4 is very small compared to most other multiferroic materials. This makes the highly pronounced nonlinear behavior even more surprising. Understanding this nonlinearity remains a challenge for the theory.

Frustrated spin chains provide grounds for studies of exotic quantum phases caused by combination of frustration and quantum fluctuation. We have paid our attention to Cu3Mo2O9. The spin system consists of antiferromagnetic (AF) uniform spin-1/2 chains and AF spin-1/2 dimers. Chains and dimers are connected and magnetic frustration appears. This cuprate exhibits both AF long-range order with tiny ferromagnetic components and electric polarization below the transition temperature TN = 7.9 K. The ferromagnetic components appear only in finite magnetic fields parallel to the a or c axis. The ferromagnetic behavior disappears by slight substitution of Zn (0.2 %) for Cu sites. Several phase transitions and 2/3 magnetization plateau appear in magnetic fields. To understand these results, we determined the magnetic structure of Cu3Mo2O9 in neutron powder diffraction experiments. Spins in chains are nearly disordered, whereas magnetic moments in dimers are ordered. Probably, magnetic frustration generates the partial disordered state. The space group at room temperature was considered to be orthorhombic Pnma (No. 62). From the previously reported electric polarization and the present observation of reflections forbidden in Pnma in X-ray powder diffraction experiments at room temperature, the exact space group must be monoclinic P2_1/m (No. 11) that is one of subgroups of Pnma. The ferromagnetic behavior in magnetic fields parallel to the a or c axis is possible in the magnetic structure..

Mo.B-P06 - Magnetic ground state of novel zigzag chain compounds, NaCr2O4 and Ca1-xNaxCr2O4, determined with muons and neutrons

J. Sugiyama[1], H. Nozaki[1], M. Harada[1], Y. Higuchi[1], H. Sakurai[2], E. Ansaldo[3], J. Brewer[4,5], L. Keller[6], V. Pomjakushin[6], M. Mansson[7]

One-dimensional (1D) systems offer an intriguing example as relatively simple systems that display interesting magnetic phenomena and complex phases. This is in large part due to the competition between nearest-neighbor (intra-chain) and next-nearest-neighbor (inter-chain) interactions. Recently, the field of geometrically frustrated materials has been driven by the synthesis and discovery of new compounds in which the frustration can be tuned, particularly due to the progress of a high-pressure synthesis technique. Here, we report the results of muon-spin rotation and relaxation (\muSR) and neutron diffraction (ND) experiments on 1D zigzag-chain compounds, Ca1-xNaxCr2O4 [1], which is a solid solution system between CaCr2O4 and NaCr2O4. Both compounds possess a CaFe2O4-type Pnma structure. In the Ca1-xNaxCr2O4 lattice, the Cr2O4 double-chains, which are formed by a network of edge-sharing CrO6 octahedra, align along the b-axis so as to make an irregular hexagonal one-dimensional (1D) channel. The end member compound, novel NaCr2O4 [1], is found to enter into an antiferromagnetic ordered state below T_N=124 K. The combined analyses both for the \muSR and ND data provides a unique spin structure including a canting angle of the Cr moments [2]. On the other hand, the other end member compound, CaCr2O4, muSR measurements reveal the formation of a complex magnetic order below T_N=21 K, being consistent with an incommensurate AF proposed by neutron [3]. Moreover, we have studied the x=0.5, 0.75, and 0.85 samples to determine the variation of internal magnetic fields with x.

Due to the topology of one-dimensional objects, impurities always play an important role in their physical properties. An interesting case is the S =1/2 Heisenberg antiferromagnetic spin chains with high exchange constant - SrCuO2 and Sr2CuO3 - which were recently shown to exhibit an energy pseudogap in spin excitation spectrum upon introduction of impurities [1,2]. In an earlier study, we used neutron spectroscopy to obtain quantitative information about the effect of the Ni-doping in a spin chain material SrCuO2 [2]. This material has a double-chain structure where the chains are arranged in pairs and coupled via weak and geometrically frustrated interactions. We suggested a model based on a theoretical study of broken chains [3] which explained the data very well and reproduced the universal scaling behavior.
In order to clarify the role of the double chain in the spin pseudogap physics, we performed a neutron scattering study on a Ni-doped single-chain material Sr2CuO3. The role of the double chain was found to be related to the number of effective chain breaks. The proposed model was found to explain the observations in both the single and double chain materials in a broad temperature range. An extended neutron scattering study of both materials will be presented.

Mo.B-P08 - Influence of sample quality on the physical properties of the S=1 antiferromagnetic spin-ladder CaV(2)O(4)

S. Hiller[1], S. Guitarra[1], A. Caneiro[2], M. Salamon[3], D. Niebieskikwiat[1]

1. Universidad San Francisco de Quito, Quito, Ecuador
2. Instituto Balseiro - Centro Atómico Bariloche, Bariloche, Argentina
3. University of Texas at Dallas, Richardson, United States

In this work we study the magnetic and transport properties of different CaV(2)O(4) samples. This compound presents quasi one-dimensional (1D) V chains, with an antiferromagnetic (AFM) S=1 spin-ladder ground state. Due to this 1D characteristic, it is expected that the physical properties of CaV(2)O(4) are very sensitive to impurities, defects, and disorder in general. Indeed, different previous works show dissimilar results about the magnetic response of this vanadium-oxide. Here, we present results on samples prepared by different methods and conditions (solid-state and wet-chemical routes), showing the influence of the sample quality and preparation protocol on the physical properties of this material. Not only the magnetic and electric properties depend on the sample quality, also one of the important findings is that the nitrate decomposition route produces samples with a higher order temperature.

Mo.B-P09 - Low dimensional magnetism induced by chalcogen ordering.

Today┤s solid state research focuses mostly on cations and treats anions as a homogenous matrix. Here, we follow a different approach. By designing the anionic lattice in materials, the ordering of two or more anions leads to the formation of anionic super-structures. The anionic order causes different environments, in which cations dwell. The position of a certain cation will now depend on its nature. A soft/hard cation will try to enter a site, neighboring as many soft/hard anions as possible, according to the HSAB rule. Moreover, if mixed valence is expected for the cation, a charge order might occur where a low/high oxidation states will choose soft/hard anions as next neighbors. Locally, the cations can be found with completely new coordination, often cancelling the local inversion symmetry and allowing for magneto-electric coupling. To exemplify this, spin-ladder compounds AEFe2Ch2O (AE = Sr, Ba, Ch = S, Se) were synthesized having iron magnetically coupled along the ladders via Ch and over the rungs via O, which is different from the pure selenide or an oxide spin-ladder. Further, the heteroleptic coordination of iron causes an unusual electric field gradient to appear. The spin-spin coupling strengths and transition temperatures on these ladders are dependent on AE and Ch. A second example is Ba3V2S4O3, which possesses a quasi-one-dimensional atomic lattice due to ordering of S and O, where also a charge disproportionation coincides with the coordination of vanadium. Hence, V3+ (S = 1) is found in columns of face sharing VS6 trigonal antiprisms, while O is found only next to V5+. Although no long ranged spin order is observed, broad magnetic features are visible at high temperatures, probably related to spin excitations in the one-dimensional spin system. The structural polarity, as induced by the non-centrosymmetric crystal structure might play a role.

Mo.B-P11 - Quasi one dimensional magnetism in Mn1-xFexNb2O6 compounds

M. Hneda[1,2,3], J. Cunha[3], M. Gusmão[3], O. Isnard[1,2]

1. Institut Néel du CNRS, Grenoble, France
2. Université Grenoble Alpes - Joseph Fourier, Grenoble, France
3. Instituto de Fisica, Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil

Physical properties of ANb2O6 have attracted much interest due to their quasi-one dimensional magnetic behavior. The structure can be viewed as a stacking of slightly tilted oxygen octahedra surrounding the ions, forming zigzag chains along the c axis. In this work, we concentrate on the Mn1-xFexNb2O6 compounds ($0 < x < 1$) that present orthorhombic Pbcn crystal symmetry and exhibit the presence of weakly coupled chains. Several samples are investigated by both X-ray and neutron powder diffraction, specific heat and magnetic measurements. The cation chains are Heisenberg type (weak anisotropy) for Mn and Ising like chains (strong anisotropy) for Fe. In addition opposite behavior occurs in the extreme compounds since for A=Mn it is observed a negative Curie-Weiss temperature indicating dominant antiferromagnetic interactions. On the contrary, A=Fe shows a positive Curie-Weiss temperature which suggests dominating ferromagnetism coupling. Due competing interactions between the magnetic ions different magnetic structures can be obtained. MnNb2O6 presents a magnetic structure characterized by a propagation vector k=(0,0,0) and FeNb2O6 by k=(0,1/2,0) and (1/2,±1/2,0). We thus use the substitution of magnetic cations to change the interatomic distances and modify the exchange interactions between the magnetic ions both intra and inter magnetic chains. Specific heat measurements are presented down to 1.8K and discussed in the light of magnetic measurements and compared to results of neutron diffraction data.

Mo.B-P12 - Magnetic properties of quasi one-dimensional antiferromagnet BaCo2Si2O7

M. Akaki[1], A. Okutani[1], D. Yoshizawa[1], H. Kuwahara[2], M. Hagiwara[1]

1. Center For Advanced High Magnetic Field Science, Graduate School of Science, Osaka University, Osaka, Japan
2. Department of Physics, Sophia University, Tokyo, Japan

One-dimensional antiferromagnetic spin systems are known to exhibit various exotic magnetic properties caused by quantum fluctuations. The compounds with Co2+ under an octahedral crystal field are sometimes regarded as a fictitious spin (S) 1/2 one-dimensional Ising-like antiferromagnet. In contrast, the compounds with Co2+ ions under a tetrahedral crystal field usually show a Heisenberg-type magnetism with S = 3/2. In this study, we have investigated magnetic properties of quasi one-dimensional antiferromagnet BaCo2Si2O7 single crystal in high magnetic fields. In BaCo2Si2O7, CoO4 tetrahedra are connected at their corners to form chains running along the c axis. BaCo2Si2O7 shows a weak ferromagnetism below the Néel temperature TN = 21 K [1, 2]. At 4.2 K, a large magnetic anisotropy was observed in the magnetization process measured in a pulsed high magnetic field. Below 13 T, the slope of the magnetization curve parallel to the c axis is smaller than that perpendicular to the c axis. This result suggests that the c axis is a magnetic easy axis. On applying magnetic fields further along the c axis, some magnetization jumps were observed around 14 T. These results suggest that BaCo2Si2O7 shows an easy-axis magnetic anisotropy, and thus can be regarded as a one-dimensional Ising-like antiferromagnet. We will also present the experimental results of magnetostriction and electron spin resonance measurements of BaCo2Si2O7 and discuss its magnetic properties.

3. Physikalisches Institut Universitõt Stuttgart, Stuttgart, Germany
4. Institut Neel, CNRS, Grenoble, France.

The coherence phenomenon of electron spin has attracted a great interest for the last decade due to its potential application for quantum information processing. Usually, electron spin qubits are made of paramagnetic impurities [1-4], which loose they coherence because of the environment interactions (spin bath, photon bathà). Hereby we will present a completely new concept in the domain of quantum information. In Heisenberg spin chains, a non magnetic defect polarizes the surrounding spins and creates a quantum trapped soliton of total spin S=1/2. Since the correlated defect belongs to the chain, the isotropic Heisenberg exchange protects the correlated defect from the environment and highly reduces the loss of quantum memory. Using electron paramagnetic resonance (EPR), we observed the signal coming from quantum defects in the organic Heisenberg spin S=1/2 chain (TMTTF)2X (X=PF6,AsF6 or SbF6). The signal contains two lines: a main line (ML) from the uniform spin chain and a very sharp line (SL) attributed to the correlated defects. The linewidth of SL, about 0.1G, is one of the smallest ever observed in correlated impurities. The anisotropy of the g-factor of SL is exactly the same that the one of ML and the intensity of SL doesn't follow the Currie behaviour of an isolated paramagnetic impurity. Using time domain EPR, we observed quantum coherence (Rabi oscillations) of strongly correlated defects in (TMTTF)2PF6 (preliminary results can be found here [5]). In this presentation, we will discuss the coherence properties of strongly correlated defects.

Mo.B-P14 - Magnetic properties of layered one dimensional γ-CoV_2O_6 and NiV_2O_6 magnetic oxides: a comparative study

M. Lenertz[1,2], A. Dinia[2], S. Colis[2]

1. Laboratoire Léon Brillouin – CEA, Gif-sur-Yvette, France
2. Institut de Physique et Chimie des Matériaux de Strasbourg - Université de Strasbourg, Strasbourg, France

Low-dimensional magnetic oxides show an increasing interest from the scientific community mainly due to their strong anisotropy, their magnetization variations showing plateaus corresponding to different magnetic configurations. In most cases, these properties result from magnetic frustrations. γ-CoV_2O_6 and NiV_2O_6 are such one dimensional magnetic oxides that exhibit an antiferromagnetic ground state and present a same triclinic crystal structure (P-1 space group). Recent studies have shown that the structural modulations in the γ-CoV_2O_6 chains' leads to more complex magnetic structures[1]. While the synthesis and structural properties are generally well known, the magnetic properties of NiV_2O_6 have never been reported. The aim of this work is to study the magnetic properties of NiV_2O_6 with respect to the ones of the well known γ-CoV_2O_6. Our results show that the lattice parameters of NiV_2O_6 are slightly smaller than those of γ-CoV_2O_6 which can be understood on the basis of the smaller ionic radius of Ni2+ (0.055 nm) with respect to that of high-spin Co2+ (0.058 nm). The magnetic measurements indicate that both compounds are antiferromagnetic in the ground state, with Néel temperatures of 7K (for γ-CoV_2O_6) and 16K (for NiV_2O_6), in agreement with the smaller lattice parameters of NVO. The magnetization curves recorded at 1.8K show a stepped variation with sharp field-induced magnetic transitions. A magnetization plateau at one third of the saturation magnetization is observed for γ-CoV_2O_6 while only the onset of this plateau is visible for NiV_2O_6. The stronger coupling in NiV_2O_6 is also reflected in the MH loops by i) the larger field needed for the ferro- / ferri- magnetic transition, ii) the smaller slope corresponding to the antiferromagnetic state, iii) the absence of any hysteresis at 1.8K for NiV_2O_6, and iv) the much larger (estimated) saturation field of NiV_2O_6.

Research in quantum magnetism depends strongly on the availability of prototypical model materials that serve as clean quantum simulators. One special low-dimensional spin geometry is the spin ladder, the study of which has recently become possible by the discovery of new model materials that are experimentally accessible in magnetic field, temperature and energy range. The possible realisation of controlled exchange randomness in such systems has become an exciting new direction. One such prototypical spin ladder material is the S = 1/2 Heisenberg antiferromagnetic 2-leg ladder $(C_5H_{12}N)_2CuX_4$ for X=Br, Cl (BPCB, BPCC) which has chemical flexibility on the halogen site X.
We present work on the effects of random Chlorine substitution on BPCB, focusing on the average ladder superexchange parameters as a function of composition from magnetic susceptibility and providing a case study on the elementary excitation spectrum of a system with weak bond disorder as measured by inelastic neutron scattering (INS).
We find a strong compositional dependence of both ladder rung and leg exchange. The dispersion in the weakly bond disordered case shows a renormalized singlet-triplet mode, with a line shape that is reminiscent of magnon-magnon interacation, and components that are better described by localized modes. In a microscopic description, the statistical case of substitution is considered and applied to a model, which is solved by exact diagonalization. Numerical results and experimental data are compared, showing remarkable agreement. Hence we demonstrate the effects of bond disorder on the excitation spectrum of a one-dimensional system, realised in the spin ladder Hamiltonian.

Mo.B-P16 - The spin structure on the ground state of the equilateral triangular spin tube CsCrF_4

K. Matsui[1], T. Goto[1], H. Manaka[2], Y. Miura[3]

3. Suzuka National College of Technology, Suzuka, Japan

CsCrF_4 is S = 3/2 three-leg Heisenberg spin tube system, in which magnetic Cr3+ ions form equilateral triangles stacked along the leg direction without rotation. Due to low dimensionality and to the geometrical frustration within an equilateral triangle, the system is expected to have an exotic ground state, and has been believed to have the ground state of the spin liquid. However, quite recently, the existence of a magnetic phase transition has been suggested by muSR and neutron scattering measurement. In order to investigate the magnetic structure at the low-temperatures, we have measured the temperature dependence of 19F/133Cs-NMR spectra down to 0.31 K. First, from the temperature dependence of Knight shift in high temperature paramagnetic region above 20 K, the hyperfine coupling constant for each F-sites 6j, 3f(3g), 3g(3f) was determined to be -0.146, 0.345 and -0.636 T/muB, respectively. Next, in low temperatures, both 19F and 133Cs-NMR spectra showed drastic broadening at 3 K, and at around 0.3 K, there appeared a wide plateau expanding at both the sides of the sharp central peak. The distance between the two edges at both sides tends to be 1.8 T. The observed abrupt broadening in spectra at 3 K indicates a long-range magnetic order of Cr3+ moments. Characteristic spectral profiles with sharp edges can be understood in terms of the contribution from each fluorine site as follows. 3g-sites are expected to contribute to the sharp central peak due to geometrical canceling between the two Cr sites above and below. For the hyperfine coupling constant of 6j is too small to carry the wide edge, its main contribution must be from 3f site, which indicate that the size of ordered moment of Cr3+ may be 2.6 or 1.42 muB, depending on the determination of the hyperfine coupling constant of 3f site to be 0.345 or -0.636T/muB, respectively.

Mo.B-P17 - NMR study on the Ru-dimer system with valence fluctuation

Y. Hosoya[1], T. Goto[1], A. Endo[1], T. Hashimoto[1], M. Masuko[1], T. Hayashita[1], S. Iguchi[2], T. Sasaki[2]

1. Sophia University, Tokyo, Japan

The ground state of S=1/2 spin dimer with the antiferromagnetic interaction is the singlet with a finite spin excitation gap. This nonmagnetic state shows the quantum phase transition to the magnetic state under high magnetic field, which is well known as the magnon-BEC reported in many spin dimer systems. The purpose of this study is to introduce a new method of valence fluctuation to cause a quantum phase transition in dimer systems.
The target compound is Ru-based binuclear complex [{$Ru^{III}(acac)_2$}$_2$(m-OEt)], in which Ru takes the trivalent state with S=1/2. The valence state of ruthenium can be fine-tuned by changing the methyl group on the bidentate ligand, acetylacetone to substituents with different electronegativity such as trifluoromethyl group.
We have investigated this substitution effect of CF_3 on their magnetic property by means of the magnetic susceptibility and the longitudinal nuclear spin relaxation rate T_1^{-1} of $^1H/^{19}F$-NMR. The prepared samples were [{$Ru^{III}(acac)_2$}$_2$(m-OEt)] and [{$Ru^{III}(fhma)_2$}$_2$(m-OMe)]. In the latter fhma system, half of methyl groups on bidentates are substituted with CF_3. The two stereoisomers, in each compound, that is, D L type called meso form and D D: L L type called racemi, were separated by column chromatography.
Both the meso and racemi forms of acac system showed extremely small magnetic susceptibility with nearly flat temperature dependence between 4 and 200K, indicating they are in the spin singlet state with a gap comparable to the room temperature. In the fhma systems, while the meso form sample showed a behavior similar to acac systems, the racemi form sample exhibited large magnetic response: both the susceptibility and T_1^{-1}, these two scaled each other, increased prominently with increasing temperature, and the ratio to the other three reached 30 at 100K. This unique behavior in the fhma system of the racemi form may be caused by the slight change in the Ru valence due to CF_3 substituion.

Mo.B-P18 - Cu-NMR study of the quasi-one-dimensional antiferromagnet $Cu_3Mo_2O_9$

T. Kawase[1], H. Kuroe[1], K. Misoka[1], T. Hamasaki[1], T. Sekine[1], T. Goto[1], T. Sasaki[2], M. Hase[3], K. Oka[4], T. Ito[4], H. Eisaki[4]

1. Department of Physics, Sophia University, Tokyo, Japan
2. Institute for Materials Research, Tohoku University, Sendai, Japan
3. National Institute for Materials Science (NIMS), Tsukuba, Japan
4. National Institute of Advanced Industrial Science and Technology (AIST), Japan

The target material of this research is a quasi-one-dimensional antiferromagnetic quantum spin system $Cu_3Mo_2O_9$, consisting of a spin-1/2 linear chain (Cu1) and spin-1/2 distorted dimer (Cu2 and Cu3) weakly interacting with each other. Existence of these three non-equivalent Cu sites and of the frustration effect routed in the tetrahedral structure formed by the nearest neighboring four Cu's suggested an unprecedented spin state. So far, the measurements of magnetization and specific heat by Hamasaki *et al*. have revealed that long range magnetic order occurs at T_N = 7.9 K. However the detailed magnetic structure in the ordered state is undissolved until now. In order to investigate the spin structure in the ordered state, we performed Cu-NMR measurements on a single crystal.

The single crystal with an approximate size of 2×4×10 mm^3 prepared by an infrared imaging furnace was set on the sample rotator in the cryo-cooled cryostat with a 12T superconducting magnet where $^{63/65}$Cu-NMR spectra were obtained by a conventional spin-echo method. The field direction was rotated within ac *ab*-plane. At 4.2K, we observed three sets of peak-groups, corresponding to the three inequivalent sites of Cu. Each peak group consists of many peaks corresponding to the eqq-splitting, the isotopes and the two chains in the unit cell connected with the glide symmetry.

From the detailed analysis of the temperature dependence and the field direction dependence of the resonance line shifts, the observed peaks have been successfully assigned to the three Cu sites. The internal magnetic fields of Cu1, Cu2 and Cu3 sites were determined to 0(±0.2)T, 4.7(±0.4)T and 9.6T(±0.9) in *H//c* respectively. One of the main conclusions of this study is that the Cu1 in the chain site has little magnetic moment and that Cu2 and Cu3 are magnetically asymmetric. These results are consistent with the recent neutron study by Hase *et al*.

Mo.B-P19 - Antiferromagnetic ground states and phase separation in doped AA-stacked bilayer graphene

A. Sboychakov[1,2], R. Akzyanov[3], A. Rozhkov[1,2,3], A. Rakhmanov[1,2,3], F. Nori[2,4]

4. Department of Physics, University of Michigan, Ann Arbor, United States

We study electronic properties of AA-stacked graphene bilayers. In the single-particle approximation such a system has one electron band and one hole band crossing the Fermi level. If the bilayer is undoped, the Fermi surfaces of these bands coincide. Such a band structure is unstable with respect to a set of spontaneous symmetry violations. Specifically, strong on-site Coulomb repulsion stabilizes antiferromagnetic order. At small doping and low temperatures, the homogeneous phase is unstable and experiences phase separation into an undoped antiferromagnetic insulator and a metal. The metallic phase can be either antiferromagnetic (commensurate or incommensurate) or paramagnetic depending on the system parameters. The incommensurate AFM phase is mathematically equivalent to the Fulde-Ferrel-Larkin-Ovchinnikov state in superconductors. We derive the phase diagram of the system on the doping-temperature plane and find that under certain conditions, the transition from the paramagnetic to the antiferromagnetic phase may demonstrate reentrance. When disorder is present, phase separation could manifest itself as a percolative insulator-metal transition driven by doping. The application of the transverse voltage induces the exciton order parameter on the antiferromagnetic background. The value of this second order parameter is proportional to the biased voltage and the value of the nearest- neighbor interplane Coulomb repulsion.

Mo.B-P20 - High field magnetization of single crystals of the *S*=1/2 quasi-1D Ising-like Antiferromagnet $SrCo_2V_2O_8$

A. Okutani[1], T. Kida[1], T. Usui[2], T. Kimura[2], M. Hagiwara[1]

1. Center For Advanced High Magnetic Field of Science, Graduate School of Science, Osaka University, Osaka, Japan
2. Graduate School of Engineering Science, Osaka University, Osaka, Japan

Quantum spin systems in high magnetic fields have attracted much interest, since they sometimes show very fascinating phenomena. $SrCo_2V_2O_8$ is a quasi one-dimentional (1D) Co^{2+} spin system, which crystallizes in the tetragonal $I4_1cd$ space group [1]. The temperature evolution of magnetic susceptibility for the magnetic field $H \parallel c$ (chain direction) exhibits broad maxima around 40 K and a rapid drop below 5 K. From the specific heat measurements, the Néel temperature is determined to be 4.8 K at H=0. With increasing magnetic fields for $H \parallel c$, the transition temperature shifts lower, and the field-induced Néel order to disorder transition occurs at about 4 T when at 2 K [2]. Such magnetic behavior is similar to $BaCo_2V_2O_8$ (tetragonal $I4_1/acd$), which is known as S=1/2 quasi-1D Ising-like antiferromagnet [3]. We report the results of the high field magnetization measurements at 1.4 K on single crystal samples of $SrCo_2V_2O_8$, which were grown by the floating-zone method, to investigate the difference between $SrCo_2V_2O_8$ and $BaCo_2V_2O_8$. For $H \parallel c$-axis, the magnetic transition from the ordered to disordered state and an anomaly on the magnetization curve were observed at 4.0 T and 25.1 T, respectively, and the saturation field is 29.5 T. On the other hand, the magnetization achieves saturation at 45.5 T for $H \parallel [110]$, but the magnetization gradually increases in magnetic fields of up to 50 T for $H \parallel a$-axis. We will report the similarities and differences in magnetization curves between $SrCo_2V_2O_8$ and $BaCo_2V_2O_8$ [4].

Mo.B-P21 - 1H-NMR study of spin-1/2 triple-chain magnet Cu3(OH)4MoO4

Y. Fujii[1], H. Kikuchi[2], K. Nakagawa[2], S. Takada[2], M. Fujisawa[3]

1. Research Center For Development of Far-Infrared Region, University of Fukui, Fukui, Japan
2. Department of Applied Physics, Faculty of Engineering, University of Fukui, Fukui, Japan
3. Technical Department, Tokyo Institute of Technology, Meguro, Tokyo, Japan

Geometrically frustrated magnets on low dimensional lattices with S=1/2 spins have been attracting much interest because quantum effects are expected to appear without long range ordering (LRO). In Cu3(OH)4MoO4 (mineral name: szenicsite), there exist a triple-chain structure of Cu2+ (S=1/2) which forms a ribbon of isosceles triangles. As is reported in our previous work [1], the magnetic susceptibility of Cu3(OH)4MoO4 shows a broad maximum around 80 K and the magnetization increases smoothly up to 48 T. Further, no LRO is observed down to 2 K in the specific heat measurements. These results are approximately explained with a naive model of three identical antiferromagnetic spin-1/2 chains without interchain interactions. However, due to a divergent behavior of the susceptibility below 20 K, which is attributed to the contribution from impurities, intrinsic susceptibility of the bulk sample is still unclear. In order to study the magnetic ground state of Cu3(OH)4MoO4 from a microscopic viewpoint, we have performed 1H-NMR measurements of Cu3(OH)4MoO4. The width of the spectrum increased with decreasing temperature, suggesting the inhomogeneous broadening due to impurities. The shift of the spectrum, in contrast, showed a maximum around 100 K and decreased down to the lowest temperature of 1.5 K. These results support the picture of the antiferromagnetic chain model for Cu3(OH)4MoO4. We will discuss our results comparing with magnetic properties of Cu3(OH)4SO4 (mineral name: antlerite) [3] whose crystal structure is very similar to that of Cu3(OH)4MoO4.

Mo.B-P22 - From order to randomness: an experimental investigation of disorder in a one-dimensional spin system

T. Shiroka[1,2], F. Eggenschwiler[1], M. Pikulski[1], M. Thede[1,2], A. Zheludev[1], H. Ott[1,2], J. Mesot[1,2]

2. Paul Scherrer Institut, Villigen PSI, Villigen, Switzerland

Quantum fluctuations dominate the low-temperature physical properties of low-dimensional systems, such as 1D or 2D arrays of spins. Ordinary long-range order is suppressed and unusual magnetic states emerge. By their nature, 1D systems are particularly sensitive to disorder, which can break the translational invariance, introduce random couplings between individual spins, and lead to a so-called random singlet (RS) phase [1,2], characterized by couplings of spins at arbitrary distances to form weakly-bound singlets. What exactly happens when a regular spin-chain is exposed to an increasing degree of disorder is not well known. To address this question we considered BaCu2Si2O7, a model material featuring weakly interacting S = 1/2 spin chains, and studied a series of this compound where, by systematically replacing Si with Ge, we achieve randomness in the Cu2+ exchange interactions. Since Heisenberg spin-1/2 chain materials are well recognized as strongly-interacting quantum systems, our series is perfectly well suited for clarifying the role of disorder in the 1D case [3,4]. Results of magnetometry measurements combined with those of local-probe 29Si NMR studies, including lineshape, relaxation-time, as well as stretching-exponent data, were used to monitor the evolution of the disorder-related properties from BaCu2Si2O7 to the maximally disordered BaCu2SiGeO7, with intermediate disorder steps. A low-degree of disorder suppresses the 3D ordering temperature quite effectively and, with maximum disorder, the system adopts the theoretically predicted RS phase. Our results are expected to trigger a more rigorous understanding of the role and significance of disorder in low-dimensional spin systems.

Mo.B-P23 - Spin-Oobit torques originated from topological surface states of Bi2Se3

Y. Wang[1], P. Deorani[1], K. Banerjee[1], N. Koirala[2], M. Brahlek[2], S. Oh[2], H. Yang[1]

1. Department of Electrical and Computer Engineering, National University of Singapore, Singapore

Recent progresses have demonstrated the manipulation of magnetization via spin-orbit coupling in heavy metal/ferromagnetic (FM) layer heterostructures. The search for new materials possessing a higher conversion efficiency between the charge currents and spin currents (i.e. higher spin-orbit torques) is crucial to realize next generation spintronic devices. The three dimensional topological insulators (TI) are a new class of quantum state of materials that have an insulating bulk and a topological surface state. They exhibit strong spin-orbit coupling and are expected to show a high charge to spin current conversion efficiency. In this work, we investigate the spin-orbit torques at different temperatures in Bi2Se3 (20 nm)/Co40Fe40B20 (CFB, 5 nm) heterostructures by spin torque ferromagnetic resonance (ST-FMR) measurements. We find in our Bi2Se3/CFB, the charge-spin conversion efficiency shows an abrupt and nonlinear increase as temperature decreases. In the context of spin Hall mechanism, the spin Hall angle has been reported to be almost independent of temperature or in some cases a gradual increase as the temperature decreases. This indicates that the spin Hall effect from the Bi2Se3 bulk is not the dominant mechanism for our observation of temperature dependent spin-orbit torque in Bi2Se3/CFB. In addition, we have confirmed that the direction of in-plane spin polarization to the electron momentum in our Bi2Se3/CFB is consistent with that expected from the topological surface state of TIs (spin-momentum locking). The out-of-plane spin-orbit torque also shows an increasing trend as temperature decreases. We conclude that our observations especially in the low temperature range (less than ~ 50 K) could be correlated with the topological surface state in our Bi2Se3/Co40Fe40B20 heterostructures.

Mo.B-P24 - off-diafgonal spin-spin correlations in noncollinear antifferomagnets or in applied magnetic fields

A. Kruchkov[1], H. Ronnow[1], M. Zhitomirsky[2]

1. Laboratory for Quantum Magnetism (LQM), École Polytechnique Fédérale de Lausanne (EPFL), Lausanne, Switzerland
2. Service de Physique Statistique, Magnétisme et Supraconductivité, UMR-E9001 CEA-INAC/UJF, Grenoble Cedex 9, France

We study semi-analytically and numerically the contributions of the off-diagonal spin-spin correlators to the total dynamical structure factor of the system. The study mainly considers the square lattice Heisenberg antiferromagnet in the moderate magnetic field and also can be generalized for noncollinear structures.

Mo.B-P27 - Symmetry-protected topological phases/transition in spin-1/2 zigzag chains and the relevance to Rb2Cu2Mo3O12

H. Ueda[1], S. Onoda[1,2]

1. Condensed Matter Theory Laboratory, RIKEN, Wako-shi, Japan
2. RIKEN Center for Emergent Matter Science (CEMS), Wako-shi, Japan

We study a ground-state phase diagram of frustrated spin-1/2 chains in the space of the nearest-neighbor ferromagnetic and second-neighbor antiferromagnetic exchange couplings J_1 and J_2, the relative amplitude δ of the nearest-neighbor bond alternation, and the easy-plane XXZ exchange anisotropy, by means of a density-matrix renormalization group method for infinite systems [1]. We numerically identify projective representations for four distinct time-reversal invariant symmetry-protected topological (SPT) phases; two parity-symmetric dimer phases near the Heisenberg and XX limits and two parity-broken vector-chiral (VC) dimer phases in between. A small nearest-neighbor bond alternation induces a direct SPT transition between the two distinct VC dimer phases. We also find numerically that two Berezinskii-Kosterlitz-Thouless transitions, which occur from the gapless to the two distinct gapped VC phases in the case of $\delta = 0$, meet each other in the case of $\delta > 0$ at a Gaussian criticality of the same Tomonaga-Luttinger parameter value as in the SU(2)-symmetric case.
Besides, we obtain the model parameters for a relevant material $Rb_2Cu_2Mo_3O_{12}$, which explain overall experimental findings on the temperature dependence of the magnetic susceptibility, the spin excitation gap from the non-magnetic ground state, and the dynamical spin structure factor [2]. A spin-gapped vector-chiral order induced by a staggered scalar-chiral ring-exchange interaction under the magnetic field is proposed as a possible scenario for a field-induced ferroelectricity in the absence of long-range cycloidal magnetic order [3].

Mo.B-P29 - Natural Mineral epidote in magnetic fields

K. Prokes[1], B. Klemke[1], J. Hoffmann[1]

1. Helmholtz-Zentrum Berlin, Berlin, Germany

In this contribution we report on the magnetic properties of a natural mineral epidote. Epidote, which crystallyzes in a monoclinic crystal structure with an approximate chemical formula Ca2(Fe,Al)Al2(SiO4)(Si2O7)O(OH), contains magnetically active Fe3+ ions that are in the high spin state. Iron atoms form weakly coupled linear chains extendet along the b axis. We have measured the specific heat and magnetic bulk properties of a small natural single crystal of this material down to 0.04 K. Static magnetic field of up to 14 T applied along the three principal axes was used. We show that at low temperatures the magnetic response is weakly anisotropic. The magnetic susceptibility and the specific heat shows a broad maximum around 6 K that is affected by the applied magnetic field. Also the low-T specific heat upturn that is strongly magnetic dependent and exhibits a non-trivial dependence. We also report on the neutron diffraction results obtained at low temperatures and in magnetic fields of up to 7 T applied along the b axis. While no signature of a long-range magnetic order is found in zero field, increase of diffracted signal in magnetic fields indicate an induced magnetic order.

Mo.B-P30 - Effects of the underlying geometry on the physical properties of topological insulators

T. Melo[1], D. Viana[1], Y. Gomes[2], W. Moura-Melo[1], J. Fonseca[1], A. Pereira[1]

1. Departamento de Física, Universidade Federal de Viçosa, Viçosa, Brazil
2. Centro Brasileiro de Pesquisas Físicas, Rio de Janeiro, Brazil

Three-dimensional topological insulators (3D TI's) come to be an exotic state of matter where non-trivial topology of the insulating bulk renders conducting electronic-type states at the borders. In addition, such mettalic-like states propagate in a such a way that their spin and linear momentum are orthogonal each other over the surface, the so-called spin-momentum locking. A number of additional special properties make them potential candidates for several applications ranging from spintronics to quantum computation. Here, we would like to call the attention to some facts regarding how the underlying geometry of a 3D TI render it additional interesting effects. Indeed, in a conical TI an peculiar electric polarization comes about so that narrower (apperture angle < 30 degrees) cones tend to polarize towards the apex while in wider ones (apperture angle > 30 degrees) the polarization is reversed. On the other hand, on the surface of a genus-1 toroidal 3D TI there appear two Berry phases associated to the geometrical periodic boundary conditions. In turn, this yields infinitely degenerate zero-modes and two independent bound-states along the confined dimensions. In addition, whenever a laser beam is shed onto a micro-sized spherical 3D TI the response is so that a net controllable force tends to drift the sphere center (in usual dieletric spheres net force vanishes at the focus of the beam). Such a drift may be useful for optical tweezer applications in biology, for instance, while distending a DNA strip or a membrane. Financial support: Capes, CNPq and Fapemig (Brazilian agencies).

Mo.B-P31 - Gennus one toroidal topological insulator

J. Fonseca[1], V. Carvalho-Santos[2], W. Moura-Melo[1], A. Pereira[1]

1. Universidade Federal de Viçosa, Viçosa, Brazil
2. Instituto Federal de Educação, Ciência e Tecnologia Baiano - Campus Senhor do Bonfim, Senhor do Bonfim, Brazil

We considerer the theoretical possibility of a toroidal topological insulator (TI). From a geometrical point of view the toroidal topological insulator is a good form to investigate the conection betwenn geometry and topological properties of the TI because it have a variable gaussian curvature, gennus 1 and the sphere can be recovered as a limit case. An effective Hamiltonian that describe the surface states of a toroidal topological insulator is obtained and the bulk and surface spectrum are investigated. The toroidal TI supports zero-modes energy in your surface. The boundary conditions on surface wavefunction are discussed and the connection with two types of Berry phase. The authors are grateful to CNPq, FAPEMIG and CAPES (Brazilian agencies) for financial support.

Mo.C-P01 - Field and temperature dependence of spin fluctuations in $ZrZn_2$

P. Reiss [1], G. Lonzarich [1], F. Malte Grosche [1]

1. Cavendish Laboratory, University of Cambridge, Cambridge, United Kingdom

ZrZn2 is a low temperature band ferromagnet (T_c ~ 28 K), which displays non-Fermi liquid transport properties over a wide temperature range: above T_FL ~ 1K and even beyond T_c, the electrical resistivity follows a power-law temperature dependence with an exponent 5/3, whereas the electronic contribution to the thermal resistivity is linear in temperature. This has been explained in terms of a magnetic fluctuation model, which includes a self-consistent renormalisation for the magnetic susceptibility [1, 2]. Applied magnetic fields up to 9 T have been observed to increase the cross-over temperature T_FL to ~ 7 K. Previous calculations did not include effects of magnetic fields. We will present the results of an extended calculation which accounts for the role of applied field, allowing a comparison between high field resistivity measurements and the predictions of a magnetic fluctuation model. Furthermore we will show that the magnetic transition is expected to be continuous in this model. However this transition is characterised by a strongly temperature dependent coefficient b(T) of the quartic term in a Landau-Ginzburg expansion. Moreover, b(T) changes sign at Tc, with b(T) < 0 in the ordered phase.

Mo.C-P02 - Effect of Ce Doping on Elastic and Thermal Properties of $SrCoO_3$

R. Thakur[1], R. K. Thakur[1], N.K. Gaur[1]

1. Barkatullah University, Bhopal, India
2. Barkatullah University, Bhopal, India
3. Barkatullah University, Bhopal, India

$SrCoO_3$ has a cubic perovskite crystallographic structure which adopts a long-range with Curie temperature of T_c=266K and is considered a candidate for realization of intermediate spin ground state. The elastic and thermodynamic properties for $Sr_{1-x}Ce_xCoO_3$ ($0.05 \leq x \leq 0.45$) with temperature have been investigated by using modified rigid ion model (MRIM). The computed results on the elastic constants (C_{11}, C_{12} and C_{44}) are the first report on them. Using these elastic constants we have computed other elastic properties such as elastic constants (C_{11}, C_{12}, C_{44}), Cauchy pressure, Internal strain parameter, tetragonal shear modulus, Shear modulus and B/G ratio, Young's modulus, Poisson's ratio, Lame's parameter, Anisotropy parameter, Transverse, Longitudinal and Average wave velocity.
The present values of Young moduli increases from $Sr_{0.95}Ce_{0.05}CoO_3$ to $Sr_{0.55}Ce_{0.45}CoO_3$ which indicates that $Sr_{0.55}Ce_{0.45}CoO_3$ is stiffer than $Sr_{0.95}Ce_{0.05}CoO_3$. The calculated anisotropy factors A for $Sr_{1-x}Ce_xCoO_3$ ($0.05 \leq x \leq 0.45$) are greater (or lesser) than 1 which indicates that these compounds have an elastically anisotropic character. Based on the calculated results, we conclude that these compounds belong to the class of metallically bonding material, i.e. they are ductile in behavior. Here, all C_{ij} constants for $Sr_{1-x}Ce_xCoO_3$ ($0.05 \leq x \leq 0.45$) compounds are positive and satisfy the generalized criteria for mechanically stable crystals: $(C_{11}-C_{12})>0$, $(C_{11}+2C_{12})>0$ and $C_{44}>0$. Therefore, we conclude that Ce doped $SrCoO_3$ should belong to metallically bonding materials by analyzing their elastic modulus. We have also reported the thermodynamic properties such as cohesive energy (φ), Molecular force constant (*f*), Reststrahlen frequency (u), Debye temperature (q_D) and Gruneisen parameter (g). On the basis of above discussion we have calculated the specific heat and thermal expansion coefficient for $Sr_{1-x}Ce_xCoO_3$ over the wide temperature range $1K \leq T \leq 300K$.

Mo.C-P03 - First principles study of strain induced phase diagram and spin-orbit coupling in (SrIrO3)m/(SrTiO3)1 superlattice

W. Fan[1], T. Shirakawa[1,2], S. Yunoki[1,2,3]

1. Computational Condensed Matter Physics Laboratory, RIKEN, Wako, Japan
2. Computational Materials Science Research Team-RIKEN Advanced Institute for Computational Science (AICS), Kobe, Japan
3. Computational Quantum Matter Research Team-RIKEN Center for Emergent Matter Science (CEMS), Wako, Japan

In order to understand the electronic and magnetic phase transitions under the condition of lattice distortion, strong spin-orbit coupling (SOC) and electron correlation in 5d iridates, especially to understand some recent experiments on thin films of iridates by strain engineering, we studied (SrIrO3)m/(SrTiO3)1 superlattice by using first principles methods. The band structures show sensitive dispersion behaviors. Under certain distortion (e.g. by means of IrO6 octahedra rotation and Ir-O bond length), metal-insulator transition (MIT) takes place. The magnetic ground state is confirmed as the in-plane non-collinear antiferromagnetic insulating state with a large anisotropic magnetic exchange interaction, such as Dzyaloshinski-Moriya (DM) interaction. This is the signature of large SOC.
We further studied the phase diagram of (SrIrO3)m/(SrTiO3)1 under epitaxial strain and adjustable correlation (U), which may be manageable from experimental point of view. It turns out that four phases can appear, which are paramagnetic metal (PM), magnetic metal (MM), non-collinear antiferromagnetic insulator (NCAFI) and collinear antiferromagnetic insulator (CAFI). On the other hand, the strain also influences the SOC. To explain this SOC change, I considered the competition or cooperation of two factors involved: the effective electric field and d-p hybridization. It shows that SOC saturates under compressive while drops monotonically under tensile strain. Our work may be a theoretical guidance for experiments to realize various novel magnetic phases in 5d transition metal oxides.

Mo.C-P04 - Onsite magnetic moment and magnetocrystalline anisotropy studies of Lu-/Y- substituted $NiFe_2O_4$

U. Kodam[1], R. Reddy V[2], Markandeyulu G[1]

1. Indian Institute of Technology Madras, Chennai, Tamil Nadu, India
2. UGC-DAE Consortium for Scientific Research, University Campus, Khandwa Road, India

The $NiFe_{2-x}R_xO_4$ (x = 0, 0.05, 0.075, R = Lu and Y) compounds are seen to form in cubic inverse spinel phase with $Fd\bar{3}m$ space group, from the XRD and Raman spectra results. The lattice constant value of $NiFe_2O_4$ is 8.3351(1) Å whereas, those of $NiFe_{1.95}Lu/Y_{0.05}O_4$ are 8.3459(3) Å and 8.3406(3) Å, respectively and those of $NiFe_{1.925}Lu/Y_{0.075}O_4$ are 8.3515(8) Å and 8.3411(1) Å respectively. The magnetic moments values of $NiFe_{1.95}Lu/Y_{0.05}O_4$ at 20 K are respectively 2.293 μ_B/fu and 2.347 μ_B/fu and those of $NiFe_{1.925}Lu/Y_{0.075}O_4$ are respectively 2.1 μ_B/fu and 2.173 μ_B/fu. These values are less than that of $NiFe_2O_4$ (2.364 μ_B/fu) the contraction is attributed to the substitution of Fe^{3+} by Lu^{3+}/Y^{3+} in the B-site. The value of K_1, the first order magnetocrystalline anisotropy constant was obtained by the law of saturation method. The values of K_1 at 20 K of $NiFe_2O_4$ and $NiFe_{1.95}Lu/Y_{0.05}O_4$ are 42.19 kJ/m^3, 36.29 kJ/m^3 and 54.17 kJ/m^3 respectively and those of $NiFe_{1.925}Lu/Y_{0.075}O_4$ are 74.6 kJ/m^3 and 55.76 kJ/m^3 respectively. The observed variation in the temperature dependent K_1 for all the compounds is explained on the basis of *single-ion* model. Mössbauer spectra recorded at 5 K, 300 K were fitted with two sextets corresponding to the Fe ions at the tetrahedral and octahedral sites. The effective magnetic moments of $NiFe_{1.925}Lu/Y_{0.075}O_4$ calculated from the Mössbauer spectra (at 5 K) are 2.49 μ_B/fu and 2.4 μ_B/fu respectively that are larger than the corresponding values from the magnetization measurements, probably due to the inversion parameter, which is less than 1.

Mo.C-P05 - Multiband spin-lattice relaxation in Gd^{3+}-doped YCo_2Zn_{20} probed by electron spin resonance

M. C. Baez[1], A. Naranjo-Uribe[2], J. M. Osorio-Guillén[1,2], C. Rettori[1,3], M. A. Avila[1]

1. CCNH, Universidade Federal do ABC (UFABC), Santo André, Brazil
2. Instituto de Física, Universidad de Antioquia UdeA, Medellín, Colombia
3. Instituto de Física ``Gleb Wataghin'', Universidade Estadual de Campinas (UNICAMP), Campinas, Brazi

The understanding of the physical properties of complex materials with cage-like structures, such as the family RT_2Zn_{20}, have attracted the attention of many researchers focused in condensed matter physics. In this work, we perform temperature dependent Electron Spin Resonance (ESR) experiments on Gd^{+3} doped YCo_2Zn_{20} intermetallic single crystals, ($Y_{1-x}Gd_xCo_2Zn_{20}$: $0.001 \leq x \leq 1.00$) showing a Korringa-like relaxation rate $b = \frac{d(\Delta H)}{dT}$ of b = 8.8(3) Oe/K and b = 1.9(1) Oe/K for the lowest and highest concentration respectively. These results indicate that this system features an *exchange bottleneck* effect, also revealed by the g-shift ($\Delta g = g - 1.993$) that crosses from positive, Δg = 0.026(10) for x = 0.001 (*unbottleneck* regime), to negative Δg = -0.014(3) for x = 1.00 (*bottleneck* regime). Consequently, in this case we are able to identify the spin-lattice relaxation mechanism of the excited Gd^{+3} electron, which is processed via different types of conduction electrons. First-principles Density Functional Theory band structure calculations combined with heat capacity, DC magnetic susceptibility and ESR results allows to extract the exchange interaction parameters between the localized magnetic moments of Gd^{3+} and the different types of electrons present at the Fermi level (J_{fs}, J_{fp} and J_{fd}). The combination of experimental data and band structure calculations can provide a better understanding of the *RKKY* mechanism responsible for the antiferromagnetic order in the $GdCo_2Zn_{20}$ intermetallic compound in terms of microscopic parameters. We thank the financial support of FAPESP, CAPES and CNPq.

Mo.C-P06 - Anisotropy of magnetic interactions in complex Ir oxides from band structure calculations

A. Yaresko[1]

1. Max Planck Institute For Solid State Research, Stuttgart, Germany

In complex Iridium oxides magnetic interactions become anisotropic due to strong spin-orbit interaction of Ir 5d electrons. In alpha-Li2IrO3 and alpha-Na2IrO3 Ir ions form a honeycomb lattice and their magnetic interaction are suggested to be strongly bond-dependent and to be described by a Kitaev model. Recently, another complex Ir oxide beta-Li2IrO3 has been synthesized which is expected to be close to forming a Kitaev spin liquid. Ir ions in this compound form a ``hyper-honeycomb'' lattice, a three-dimensional analogue of the honeycomb lattice of alpha-Na2IrO3. We present results of LSDA+U band structure calculations for alpha-Na2IrO3 and beta-Li2IrO3 with various magnetic configurations constrained by symmetry. It is shown that the change of the total energy cannot be described by an isotropic Heisenberg-like model and anisotropic interactions are at least as strong as the isotropic ones.

Mo.C-P07 - Asymmetric spinwave dispersion relations in the presence of interfacial Dzyaloshinskii-Moriya interaction using Brillouin light scattering

J. Cho[1], S. Ku Kang[1], C. You[1]

1. Inha University, Incheon, South Korea

The Dzyaloshinskii-Moriya interaction which is known the antisymmetric component of the exchange interaction originates from the combination of strong spin-orbit coupling and low structural symmetry. However, it is also existed at the interface between a magnetic layer and a high spin-orbit coupling adjacent layer, so-called the interfacial Dzyaloshinskii-Moriya interaction (iDMI), which has been proposed by Fert [1, 2]. The Brillouin light scattering (BLS) is able to detect propagating spin wave excitations with $\pm k$-wavevectors simultaneously. This non-contact inelastic light scattering method allows us to measure asymmetric spin wave dispersion relations due to the iDMI. In this study, we determine the iDMI energy on the heavy metal /ferromagnet/ Heavy metal structure by employing BLS. A series of 2-nm-thick CoFeB films with different heavy metal (Ta and Pt) are fabricated by dc magnetron sputtering. We find that symmetric dispersion relations (zero-iDM) on the symmetric Pt/CoFeB/Pt and Ta/CoFeB/Ta samples and clearly asymmetric dispersion relation (finite iDM) on the asymmetric Pt/CoFeB/Ta and Ta/CoFeB/Pt samples as the different chirality directions. In our result, different sign of asymmetry dispersion is arisen by different position of Pt/CoFeB interface. It means that Pt/CoFeB interface is leading the iDMI. Furthermore, it is revealed that the iDM energy density is +0.64 ± 0.05 mJ/m^2 and -0.50 ± 0.1 mJ/m^2 for Pt/CoFeB/Ta and Ta/CoFeB/Pt samples, respectively.

Mo.C-P08 - Rashba Spin-orbit torques in two-dimensional itinerant ferromagnets

A. Qaiumzadeh[1], R. Duine[2], M. Titov[1]

1. Radboud University, Nijmegen, Netherlands
2. Utrecht university, Utrecht, Netherlands

Magnetization dynamics in single ferromagnets can be triggered by charge current in the presence of spin-orbit coupling. We investigate Rashba spin-orbit torques in metallic two-dimensional ferro- magnets via functional Keldysh theory. A reactive, anti-damping-like spin-orbit torque, as well as a dissipative, eld-like term are calculated microscopically, to the leading order in spin-orbit strength. By calculating the rst vertex correction we show that the intrinsic anti-damping-like spin-orbit torque vanishes unless the scattering rate is spin-dependent.

Mo.C-P09 - High temperature magnetism of epsilon-Fe2O3 : the transition from hard to soft ferrimagnetism

M. Gich[1], J. Padilla[1], J. Nogués[2,3], J. Kreisel[4,5], A. Roig[1], J. L. Garcia-Muñoz[1]

5. University of Luxembourg, Walferdange, Luxemburg

Despite being the less studied ferrimagnetic iron oxide, epsilon-Fe2O3 displays appealing room temperature properties such as a huge coercivity (20 kOe)[1] and multiferroicity[2]. This rich physics stems from a complex structure with four Fe3+ sublattices and it is related to the existence of a substantial spin-orbit coupling [3]. However, the structural details that give rise to these properties are still not understood. We have studied the magnetic properties of epsilon-Fe2O3 between room temperature and 925 K by magnetic, Raman and neutron diffraction measurements. Upon heating, the saturation magnetization undergoes a monotonical decrease but the coercivity and remanence sharply drop and vanish at 480 K. Above 500 K and up to 870K epsilon-Fe2O3 is ferrimagnetic and presents a soft magnetic behaviour. Interestingly, this transition from superhard to soft ferrimagnetism involves changes in the magnetic state and magnetostructural effects that are relevant for a better understanding of the origin of spin-lattice coupling in epsilon-Fe2O3.

Mo.C-P10 - Orbital and spin structures in transition metal compounds with face-sharing octahedra

K. Kugel[1], D. Khomskii[2], A. Sboychakov[1], S. Streltsov[3,4]

1. Institute for Theoretical and Applied Electrodynamics, Russian Academy of Sciences, Moscow, Russia
2. II. Physikalisches Institut, Universität zu Koeln, Koeln, Germany
3. Institute of Metal Physics, Ural Branch, Russian Academy of Sciences, Ekaterinburg, Russia
4. Ural Federal University, Ekaterinburg, Russia

Specific features of orbital and spin structure of transition metal compounds in the case of the face-sharing MO_6 octahedra are analyzed. In this geometry, we consider the form of the spin−orbital Hamiltonian for transition metal ions with double (e_g^{σ}) or triple (t_{2g}) orbital degeneracy. Trigonal distortions typical of the structures with face-sharing octahedra lead to splitting of t_{2g} orbitals into an a_{1g} singlet and e_g^{π} doublet. For both doublets (e_g^{σ} and e_g^{π}), in the case of one electron or hole per site, we arrive at a symmetric model with the orbital and spin interaction of the Heisenberg type and the Hamiltonian of unexpectedly high symmetry: SU(4). Thus, many real materials with this geometry can serve as a testing ground for checking the prediction of this interesting theoretical model. We also compare general trends in spin−orbital exchange interaction for three typical situations: those of MO_6 octahedra with common corner, common edge, and the present case of common face, which has not been considered yet.

Mo.C-P11 - XAS and XMCD study on Co doped Ga0.6F1.4O3 films

D. Kim[2], J. Kim[1]

1. Pohang Accelerator Laboratory, POSTECH, Pohang, Korea
2. Department of Physics, POSTECH, Pohang, Korea

GaFeO3 is a well known piezoelectric ferrimagnet where electron and spin degree of freedoms are coupled. There are four different cationic sites, Ga1(Td), Ga2(Oh), Fe1(Oh), and Fe2(Oh) and Fe1 and Fe2 are antiferromagnetically coupled. But, in Ga2-xFexO3 including GaFeO3, there are site disorders depending on the x and the fabrication methods and resultantly they became ferrimagnets. In this work, we studied the electronic and magnetic structure of Co doped Ga0.6F1.4O3 films by measuring X-ray absorption spectroscopy and X-ray magnetic circular dichroism on the L edges of Fe and Co. The XAS of Co L edges clearly show that doped Co ions takes the Fe sites and the ground state of them are d7 high spin state(Co2+) under Oh symmetry or its subgroup. It is also interesting that a few percent doping of Co makes a noticeable change in the XMCD spectra of host Fe. It indicates Co doping induces a big change in the site disorder of host ions too. Through these experimental results, we clearly explain why the total magnetization decreases by factors and the electronic leakage decreases by orders just by doping a few percent of Co ions to Ga0.6F1.4O3 films.

Mo.C-P12 - Large anisotropic g-factor due to crystalline spin-orbit interaction in bismuth

Y. Fuseya[1], Z. Zhu[2], B. Fauque [3] N, W. Kang[4], B. Lenoir[5], K. Behnia[3]

1. University of Electro-Communications, Chofu, Japan
2. Wuhan National High Magnetic Field Center
3. Ecole Supérieure de Physique et de Chimie Industrielles, Paris, France
4. Ewha Womans University, Seoul, South Korea
5. Ecole Nationale Supérieure des Mines de Nancy, Nancy, France

The g-factor mirrors the effect of the crystalline spin-orbit interaction, which is a central issue in contemporary solid state physics. It is a crucial task for various fields, such as spintronics, multiferroics, and topological insulators, to understand and manipulate the g-factor of solids. However, on the other hand, it has been a hard task. For example, the origin of large anisotropic g-factor of holes in bismuth has been a mystery for more than a half century; their Zeeman energy is more than twice larger than their cyclotron energy when the magnetic field is along the trigonal axis, but becomes vanishingly small for the perpendicular orientation. Here, we report a theoretical solution to this longstanding puzzle based on a relativistic k.p theory of multiple band. Furthermore, we also present new experimental results that show the crystalline spin-orbit interaction can be actually manipulated according to our new understandings. Our new approach opens a new direction for the study and manipulation of spin-orbit interaction with possible applications, such as for spintronics, multiferroics, and topological insulators.

Mo.C-P13 - Diluting magnetism in Honeycomb lattice Iridates and understanding magnetic exchange

S. Manni[1,2], Y. Tokiwa[1], P. Gegenwart[1]

1. I Physikalisches Institut, Georg-August-Universtaet Goettingen, Goettingen, Germany
2. Ames Laboratory and Department of Physics and Astronomy, Iowa State University, Ames, Iowa, United States

Honeycomb lattice iridates A2IrO3 (A= Na, Li) has drawn immense interest in the correlated electron physics community due to its realization as a novel spin-orbit Mott insulator with very unusual magnetic structure and also due to controversial discussion in background of different models like localized Heisenberg-Kitaev(HK) model [1]. The cause of this controversy lying in deep of complicated interactions within honeycomb arrangement of Ir Seff=1/2 moments. In our lab we have synthesized A2IrO3 in single and poly-crystalline form and characterized structurally, magnetically and thermodynamically. We have identified both the system has long range antiferromagnetic (AF) ordering below TN = 15 K with strong AF interaction between Ir S=1/2 [2,3]. We have synthesized A2(Ir1-xTix)O3 single and poly-crystal for Na and Li system respectively to study systematic dilution of Ir magnetism by nonmagnetic Ti for better understanding of magnetic interactions. Upon dilution both Na and Li honeycomb system shows spin glass behavior but in Na system spin glass temperature (Tg) and AF Weiss temperature drops very sharply towards zero before percolation limit whereas for Li system these two parameters persist much above percolation limit. This signifies Na2IrO3 is fundamentally nearest neighbor interaction system and in Li2IrO3 further neighbor interactions are significantly important. We observe a smeared quantum phase transition for x=0.5 dilution in Li-system which is rear for a Seff=1/2 antiferromagnetic system.[4] The result is published in Ref. [4]. Work Supported by ERASMUS MUNDUS and DFG.

Mo.C-P14 - Neutron diffraction studies on the magnetic structure of a-RuCl3

C. Ritter[1], A. Jain[2], N. Sung[2], B. Kim[2]

1. Institut Laue Langevin
2. Max Planck Institute for Solid State Research, Stuttgart, Germany

The importance of the spin-orbit coupling (SOC) in determining the electronic ground state of transition metal oxides has recently been a focus of both theoretical and experimental efforts. On the theoretical side the Kitaev model, which describes the interactions of spins Jeff = ¢ on a honeycomb lattice by including bond dependent exchange interactions resulting from the SOC, is a rare example of exactly solvable models with highly nontrivial properties such as a quantum spin-liquid state and fractional statistics. However, being highly artificial, the model is difficult to realize in a real-world material. A number of promising candidates have been proposed in strongly spin-orbit coupled 5d transition-metal oxides (such as Na2IrO3 and Li2IrO3), which have the requisite bond-directional interactions of the form in the Kitaev model. The search for the Kitaev spin-liquid has recently been extended to 4d transition-metal oxides with a-RuCl3 as one of the possible candidates as it crystallizes in a layered structure where the Ru3+ ions sit on a honeycomb lattice and see a nearly perfect RuCl6 octahedral environment. Although magnetic susceptibility data had indicated a finite-temperature long-range magnetic order, the determination of its magnetic structure is of crucial importance in assessing the proximity to the Kitaev quantum spin liquid state. Here we present the results from the first neutron powder diffraction measurements which strongly support the presence of a zigzag type magnetic order, quite similar to that of Na2IrO3. In the low temperature neutron diffraction patterns, we have observed two magnetic Bragg peaks which could be indexed with a propagation vector k = (¢, 0, ¢). Using magnetic symmetry analysis, the refinement of these two peaks was possible with an allowed irreducible representation and confirmed the three-dimensional nature of the magnetic order despite the fact that neighboring Ru-Cl layers are weakly coupled by van der Waals forces.

Mo.C-P16 - Mechanism of the electron paramagnetic resonance line broadening in the hole doped manganites La_{1-x} Ca_xMnO_3

M. Auslender[1], E. Rozenberg[2], A. Shames

1. Ben Gurion University of the Negev, Department of Electrical and Computer Engineering, Beersheba, Israel
2. Ben Gurion University of the Negev, Department of Physics, Beersheba, Israel

Since the first experimental studies of electron paramagnetic resonance (EPR) in the hole doped manganites La_{1-x} Ca_xMnO_3 ($0<x<0.5$), it has been recognized that the EPR signal linewidth increases upon heating starting from some temperature above the Curie point, with no signs of saturation. In those and later publications on the base of measured temperature dependences of the EPR, different mechanisms of such a broadening, contradicting partially to each other even for the same manganites, were suggested such as: one-phonon spin-lattice relaxation of three- and four-valent Mn ions and small-polaron hopping. Most of those attributions, however, were made on the base of restricted data obtained on low-quality samples and/or in a narrow temperature range, and until nowadays, increasing the EPR linewidth has remained a puzzle. In this contribution, we address the mechanism of this phenomenon for both single- and polycrystalline samples in unprecedentedly wide range of Ca compositions and temperature. On the base of the temperature slope and absence of activation of the linewidth at $x > 0.2$, we substantiate ruling out both spin-phonon and polaron-hopping mechanisms, respectively. Moreover, the EPR g-factor data, allow us to argue that most of eg electrons of leave the formerly trivalent Mn sites to be more mobile bond-occupating ones, even at low x. This facilitates using the double exchange (DE) model for a theoretical description. Including the spin-orbital interaction of the charge carriers with the lattice and impurities, we calculate the contribution of the carriers to the EPR linewidth both for the case of weak and strong Hund exchange. The temperature dependences of the EPR linewidth obtained within our theory fit well the experimental data. A part of these results were communicated in JAP, 113, 17D705 (2013).

Mo.C-P17 - Magnetic order and Trigonal crystal field effects in Sr3NiIrO6

E. Lefrançois[1,2], L.C. Chapon[1], S. Virginie[2], P. Lejay[2], R. Ballou[2], D. Khalyavin[3], S. Rayaprol[4], E.V. Sampathkumaran[5], D.T. Adroja [3,6], A.M. Pradipto[7], S. Picozzi[7], M. Moretti Sala[8]

Oxides of the family A3MM'O6 (A = alkaline-earth metal, M, M' = transition metal) attracted a lot of attention because of their unconventional magnetic properties linked to the coexistence of low dimensionality, magnetic frustration and magnetocrystalline anisotropy. In these compounds, the M and M' ions form chains which are distributed on a triangular lattice. In consequence, the magnetism of the compounds with an easy-axis of anisotropy, which confines the magnetic moments along the chains direction, should be strongly frustrated. We studied the 5d-based compound Sr3NiIrO6, where the strong spin-orbit coupling on the Ir4+ ions might induce unexpected behaviors through spin-orbit entanglements. Single crystal magnetization, powder neutron diffraction and single crystal resonant inelastic scattering (RIXS) measurements were performed. The magnetization measurement revealed the existence of a large easy-axis anisotropy confining the Ni2+ and Ir4+ magnetic moments along the chains. Besides the zero-field cooled and field-cooled measurements show that there are two characteristic temperatures: T1 = 70 K and T2 = 17 K. The first temperature is associated with a deviation from a Curie-Weiss behavior and the appearance of magnetic order with propagation vector k=(0,0,1). At T2, the susceptibility reaches a maximum followed by a sudden drop. The magnetic structure can be determined from powder neutron diffraction only up to a global phase. However, symmetry arguments allowed determining the exact nature of the magnetic ground state below T2, thus clarifying the universal magnetic properties of this family of compounds [PRB 90 (014408) 2014]. RIXS measurements allowed probing the electronic and magnetic excitations inside the t2g triplet thus estimating the strength of the spin-orbit coupling as well as the amplitude of the trigonal distortion of the IrO6 octahedra. Besides the low-temperature measurements also show the emergence of a non-dispersive magnon around 90 meV.

Mo.C-P19 - X-ray Magnetic circular dichroism in the spinel-type vanadium oxides AV2O4 (A=Mn,Fe)

K. Matsuura[1], H. Sagayama[1], Y. Nii[1], N. Duy Khanh[2], N. Abe[1], T. Arima[1]

1. The University of Tokyo, Tokyo, Japan
2. Tohoku University, Sendai, Japan

Spinel-type vanadium oxides FeV2O4 and MnV2O4 are considered to exhibit different types of V3+ orbital order from each other. The orbital structure at V3+ in MnV2O4 has been reported as real-function type antiferroic orbital order and that in FeV2O4 as complex-function type ferro orbital order. In order to tackle this issue, temperature dependence of x-ray absorption spectrum (XAS) and x-ray magnetic circular dichroism (XMCD) spectrum are investigated in both the spinel compounds. XMCD spectroscopy is widely applied for estimating element-selective orbital and spin angular momenta in 3d transition metals and their compounds quantitatively by using simple formalisms of orbital and spin sum rules. The application of the sum rule to the obtained V edge XMCD spectra and the comparison with crystal field multiplet calculation suggest a real-function orbital ordered state with quenched orbital angular momenta in both FeV2O4 and MnV2O4. A dissimilarity in XAS spectra implies a quantitative difference of the effect of trigonal distortion on the electronic structure between FeV2O4 and MnV2O4.

Mo.C-P20 - Current induced switching in Transition-metal/Ferromagnetic multilayers

J. Kim[1], D. Kim[1], Y. Jang[1], B. Kim[1], K. Rhie[1]

1. Department of Display and Semiconductor Physics, Korea University, Sejong, South Korea

The spin orbit torque (SOT) may lead to a better conceptual basis for developing 3- terminal magnetic memory cells [1]. After the Miron's work [2], many results shown that SOT is a good mechanism to change a magnetization direction of ferromagnetic layers which include a transition-metal (TM)/ferromagnetic (FM) multilayers structure. [3, 4] In this study, we use Pt/Co, FeZr(amorphous paramagnetic)/CoFeB, and Ta/CoFeB multilayers to understand an effect of SOT in each structure. In Pt (t1)/Co/Pt (t2) case, the thickness of both upper (t2) and lower (t1) Pt layers are varied separately. The sign of SOT is changed when t2 is thicker than t1, which means injected spin currents from upper and lower Pt layers have different spin directions. Since the amount of injected spin current is proportional to thickness of TM, one is able to observe the competitions of spins injected from upper and lower paramagnetic layers. The critical current to switch magnetization decreases with the increase of in plane magnetic field strength. And the sign of Hall voltage is changed when the direction of applied filed is switched. We observed magnetic field dependence of switching current and thickness dependence of spin Hall sign

Mo.C-P21 - 51V NMR study on the orbital degenerated system Sr2VO4 with the K2NiF4 type structure

Y. Kato[1], Y. Shimizu[1], Y. Kobayashi[1], M. Itoh[1], H. Sakurai[2], T. Kao[2,3], H. Yang[3]

1. Department of Physics, Graduate School of Science, Nagoya University, Nagoya, Japan
2. National Institute for Materials Science, 1-1 Namiki, Tsukuba, Japan
3. Department of Physics, National Sun Yat-Sen University, Kaohsiung, Taiwan

Sr2VO4 with the K2NiF4 type structure has attracted much attention as a 3d1 system with the degenerated dxy/dyz orbital due to the tetragonal crystal field. Magnetic susceptibility shows a drop around 100 K where a structural transition takes place. Based on the first principle calculation combined with the path-integral renormalization group method, a stripe-type orbital and spin order, leading to the movement of the degeneracy, was proposed as a ground state. On the other hand, by taking account of the spin-orbit interaction for the degenerated orbital, the magnetic octupole transition was proposed to take place. However, the ground state and the mechanism of the phase transition have not been uncovered, although several experimental studies were performed. In this study we have made 51V NMR measurements on a powder sample to reveal local magnetic properties of Sr2VO4. We observed the 51V NMR spectrum with the negative Knight shift 51K having the hyperfine coupling constant due to the core polarization effect, A=-110 kOe/muB, above 120 K, whereas a weak NMR spectrum was observed to become nonmagnetic in the temperature range 100-120 K where the paramagnetic spectrum coexists. Below 100 K, only a weak nonmagnetic spectrum was observed with 51K=0, indicating that there is partly a nonmagnetic V site. This might be ascribed to the orbital order, although it is inconsistent with the tetragonal structure reported below 100 K.

Mo.C-P22 - Tuning the spectroscopic g-factor in permalloy

C. Gonzalez[1,2], Y. Yin[2], R. Dumas[2], C. Garcia[1]

1. Departamento de Fisica, Universidad Tecnica Federico Santa Maria, Valparaiso, Chile
2. Departament of Physics, University of Gothemburg, Gothemburg, Sweden

It is predicted that the spin-orbit coupling (SOC) has a significant role in quenching the electronic orbital angular momentum in ferromagnets [1], that results in a small deviation of the spectroscopic g-factor (g) from 2. In this work we apply a recently published methodology [2] to measure the value of g with very high precision in thin films of permalloy doped with different concentrations of metals which have significant SOC: Ag, Pt and Au. The results shows a positive correlation between the value of g, the dopant concentration and the dopant's SOC.

Spin-orbit interaction (SOI) in metallic surfaces can lead to a splitting of the spin degeneracy and the emergence of particular spin textures that are related to the entanglement between spin and orbital momentum. This can lead to interesting electron scattering phenomena where backscattering is forbidden by time reversal symmetry, as observed for topological surface states [1]. Here we study effect of the spin texture on electron scattering at surfaces characterized by strong Rahsba interaction. In the BiAg2 surface alloy, which is characterized by the strongest to date Rashba effect [2,3], we find that an SOI-driven spin-flip mechanism opens new backscattering channels. The alloy is formed on the surface after the deposition of monolayer of Bismuth, which induces a reconstruction. The scattering has been studied using Scanning Tunnelling Microscopy and Spectroscopy (STM/STS). In this way we have studied electron confinement by measuring the interference patterns formed by surface electrons scattered from monoatomic steps. We find that scattering is determined by i) an unconventional orbital/spin texture of the surface bands, which give rise to transitions with combined orbital and spin flips, and ii) by its chemical composition, which defines a heterogeneous electron localization and potential landscape. The negligible leakage we observe across some step structures indicate a strong confinement effect, comparable to that observed in metals with marginal SOI such as Ag(111) [4]. The results describe a scenario that is far more complex than the conventional Rashba-type two dimensional free-electron gas.

Mo.C-P25 - Current-induced spin polarization and spin-orbit torque in magnetized graphene with Rashba spin-orbit interaction

A. Dyrdal[1], J. Barnas

1. Faculty of Physics, Adam Mickiewicz University, Poznań, Poland

Electric current flowing in a system with spin-orbit interaction can induce spin polarization of conduction electrons. Such a nonequilibrium spin polarization in magnetic structures can generate a spin-orbit torque exerted on localized magnetic moments, and may lead to magnetization switching in the system.
Here, we consider theoretically current-induced spin polarization in graphene with Rashba spin-orbit interaction. To find the stationary nonequilibrium polarization in the linear response regime, we have used the Green's function formalism and derived analytical formulas for the induced spin polarization [A. Dyrdal, J. Barnas, and V. K. Dugaev, Phys. Rev. B 89, 075422 (2014)]. This polarization is oriented in the graphene plane and is normal to the current orientation. Furthermore, orientation of the spin polarization becomes reversed when the Fermi level (whose position can be controlled by an external gate voltage) crosses the Dirac points.
When graphene is deposited on a magnetic substrate, a nonzero equilibrium magnetization can be induced due to the proximity effect. In such a case, the other components of the current-induced spin polarization become nonzero, which in the lowest-order approximation depend linearly on the exchange field. We have derived analytical formulas for all components of the spin polarization. The spin-orbit torque exerted on the magnetization has also been determined.

Mo.D-P02 - Silicon-based current-controlled reconfigurable magnetoresistance logic device

X. Zhang[1], Z. Luo[1]

1. School of Materials Science and Engineering, Tsinghua University, Beijing, China

Silicon-based complementary metal-oxide-semiconductor (CMOS) transistors have achieved great success. However, the traditional development pathway is approaching its fundamental limits. Magnetoelectronics logic, especially magnetic-field-based logic, shows promise for surpassing the development limits of CMOS logic and arouses profound attentions. Existing proposals of magnetic-field-based logic are based on exotic semiconductors and difficult for further technological implementation. Here, a kind of diode-assisted geometry-enhanced low-magnetic-field magnetoresistance (MR) mechanism is proposed [1]. It couples p-n junctioní»s nonlinear transport characteristic and Lorentz force by geometry, and shows extremely large low-magnetic-field MR (>120% at 0.15 T). Further, it is applied to experimentally demonstrate current-controlled reconfigurable magnetoresistance logic on the silicon platform at room temperature. This logic device could perform all four basic Boolean logic including AND, OR, NAND and NOR in one device [2]. Combined with non-volatile magnetic memory, this logic architecture with unique magnetoelectric properties has the advantages of current-controlled reconfiguration, zero refresh consumption, instant-on performance and would bridge the processor-memory gap. Our findings would pave the way in silicon-based magnetoelectronics and offer a route to make a new kind of microprocessor with potential of high performance.

Mo.D-P03 - Magnetic tunnel junctions with semiconducting rare earth nitride electrodes

H. Warring[1], J. Trodahl[1], F. Natali[1], B. Ruck[1]

1. The MacDiarmid Institute For Advanced Materials And Nanotechnology, Wellington, New Zealand

Magnetic tunnel junctions (MTJs) are predominantly based on conventional transition metal-based electrodes where the electrodes are only partially spin polarised, and hence the tunnel magnetoresistance (TMR) is limited. The TMR can be maximised by increasing the spin polarisation of the electrodes, as evidenced by studies of MTJs with half-metallic electrodes. Another class of materials which can harbour large spin polarisations are the ferromagnetic semiconductors. These materials are especially interesting for use in MTJs because in principle properties such as the carrier concentration and Fermi level can be tuned. The rare earth nitride series contains several examples of intrinsic ferromagnetic semiconductors, i.e., they are both ferromagnetic and semiconducting without the need for addition of dopant atoms. This combination gives them clear potential for creating and understanding spintronics devices. Although their physical properties have been widely studied, the rare earth nitrides have yet only been used in a small number of proof-of-concept devices. This talk will present developments in producing magnetic tunnel junctions using rare earth nitrides as the electrodes. An insulating GaN barrier separates two magnetic GdN electrodes in which the tunnelling current is modulated by the magnetisation of these layers. We find that the transport properties are heavily influenced by the electronic structure of the GdN electrodes. The Fermi level of the GdN is found to lie slightly above the middle of the GaN gap at low temperatures, consistent with recent predictions. Our results show that GdN tunnel junctions are promising candidates for further investigation into the role novel electrode materials can play in tuning the properties of magnetic tunnel junctions.

Mo.D-P04 - Experimental demonstration of Elliott-Yafet spin relaxation mechanism and room-temperature spin transport in highly-doped n-type Ge epilayers.

S. Dushenko[1], M. Koike[1], Y. Ando[1,2], T. Shinjo[2], M. Myronov[3], M. Shiraishi[1,2]

2. Kyoto University, Kyoto, Japan.
3. The University of Warwick, Coventry, United Kingdom

Ge possesses much higher carrier mobility comparing to Si, thus it is possible for Ge-based spin transport devices to overcome scaling limits of the Si-based devices. However, in contrast to successful realization of spin transport in Si at room temperature (RT), spin transport in Ge is still limited to low temperatures. We report the first experimental realization of RT spin transport in n-Ge epilayers and temperature dependence of the spin relaxation time. Under ferromagnetic resonance conditions spins were injected from Py (Ni80Fe20) strip into 50 nm thick heavily n-type doped Ge epilayer with a phosphorous doping concentration of 1.0Î10^19 cm-3. After transport through the n-Ge channel spin current was absorbed into a metal strip with large spin-orbit interaction (Pt or Pd in our study) and converted into a charge current via inverse spin Hall effect (ISHE). Using theoretical model for our spin transport geometry we calculate generated ISHE voltage and extract spin diffusion length in the n-Ge channel, which is estimated to be 660▒200 nm at RT. Additionally using temperature dependence of the ISHE voltage and mobility in the n-Ge channel we determine spin relaxation mechanism in highly doped n-Ge. In the temperature range from 130 K to 297 K spin relaxation time decreased 2.2 times with increasing temperature [1]. Thus indicating dominance of the Elliott-Yafet spin relaxation mechanism in the highly doped n-Ge epilayers.

Mo.D-P05 - Large magnetoresistance in silicon

X. Zhang[1], Z. Luo[1]

1. Tsinghua University, Beijing, China

Large magnetoresistance in silicon Xiaozhong Zhang and Zhaochu Luo School of Materials Science and Engineering, Tsinghua University, Beijing 100084, China Magnetoresistance (MR) reported in some non-magnetic semiconductors particularly silicon has triggered considerable interest owing to the large magnitude of the effect. We showed that MR in lightly doped n-Si can be significantly enhanced by introducing diodes and proper design of the carrier path. We designed a four-terminal Si-based geometrical enhanced MR device whose room-temperature MR ratio reaching 30% at 0.065 T and 20000% at 1.2T, respectively, approaching the performance of commercial MR devices. The mechanism of this GEMR is: the diodes help to define a high resistive state (HRS) and a low resistive state (LRS) in device by their openness and closeness, respectively. The ratio of apparent resistance between HRS and LRS is determined by geometry of silicon wafer and electrodes. Magnetic field could induce a transition from LRS to HRS by reshaping potential and current distribution among silicon wafer, resulting in a giant enhancement of intrinsic MR [1,2]. We also propose a new nonlinear method to increase low-magnetic-field MR by forming a sharp resistance transition with high magnetic sensitivity in the S-shape negative differential conductance region [3]. This two-terminal Si-based micro-device with simple structure could work at low voltage (~4V) and a large low-magnetic-field MR could be achieved at room temperature (~1,000% at 0.05 T). These two performances approaching that of magnetic metal-based MR devices, would pave the way in silicon-based magnetoelectronics.

Mo.D-P07 - Scattering matrix approach to the anomalous hall effect: 2D network model

P. Streda[1]

1. Institute of Physics, ASCR, Prague, Czech Republic

The general theory of irreversible processes leads to the conclusion that the linear response to the dynamical force, represented by the electric field, has to be equivalent to that given by the statistical force, represented by the gradient of chemical potential. While the anomalous Hall current induced by the electric field has been intensively studied, nearly no attention has been devoted to the response of the chemical potential gradient, which is based on the scattering matrix approach. The nonzero magnetization of ferromagnetic materials is attributed to the existence of the spin-polarized bands. Within the tight-binding approach these bands originate in a network of overlapping atomic spin-polarized orbitals. The main attention is devoted to orbitals having nonzero orbital momentum. Considering the sample in the form of a hollow cylinder, the chemical potential difference between cylinder edges gives rise to a non-zero orbital momentum parallel with its axis. It is determined by the part of free currents forming loops around the cylinder axis, anomalous Hall current. Their general properties has been studied by using the simple two-dimensional network model. Point contact coupling between orbitals, characterized by the energy independent transition probability, has been considered. Longitudinal and Hall conductivity has been establish by the detail analysis of the scattering matrix structure for the cylindrical sample. It has been found that the network model on square lattice shows the topological phase transformation for transition probability just equal to one half. At this point the spin-orbit energy is changing its sign. Above this value the anomalous Hall conductivity approaches the quantized value within the energy gap regions. This quantization is connected with chiral edge states arising in samples having form of the strip as experimentally observed on magnetic topological insulators.

Mo.D-P08 - Hot electrons transport in devices combining tunnel and Schottky barriers

C. Vautrin[1], Y. Lu[1], S. L. Gall[2], G. Sala[1], S. Robert[1], O. Lenoble[1], F. Montaigne[1], M. Wu[3], D. Lacour[1], M. Hehn[1]

1. Institut Jean Lamour
2. LPEP
3. Hefei National Laboratory for Physical Sciences at Microscale

We have recently unveiled experimentally a new interfacial trapping phenomenon for hot electron injection in silicon[1]. The transport measurements indicate that an interfacial charge trapping and a backscattering-induced collector current limitation take place when the temperature is lower than 25K. This results in a rapid decrease of the magneto-current ratio. In this presentation we will demonstrate an electrical control of this trapping effect thanks to a magnetic tunnel transistor made on wafer bonded substrate [2]. A model taking into account the effects of both electric field and temperature will be presented. It closely reproduces the experimental results and allows extraction of the trapping binding energy (1.6 meV). Finally we will also discussed the difficulties encountered during realization of equivalent devices having out of plane magnetizations. Links between Schottky barriers preparation techniques and the existence of perpendicular magnetic anisotropy in a CoNi multilayer are established made. A solution to join in the same devices a Schotkky barrier and perpendicular anisotropy will be revealed.

Mo.D-P09 - Spin dynamics in three coherently coupled quantum dots

B. Bu|ka[1], J. úuczak[1]

1. Institute of Molecular Physics, Polish Academy of Sciences, Poznan, Poland

Di Vincenzo *et al.* [1] proposed a scheme for universal quantum computations which can be realized by a three spin system with exchange interactions in three quantum dots (TQD) where logical qubits are encoded in the doublet subspace. A main advantage of the TQD system is a purely electrical control of exchange interactions by gate potentials which act locally and provide much faster operations. Recently experimental efforts [2] were undertaken to get coherent spin manipulations in TQD according to Di Vincenzo's scheme.

Inspired by the experiments [2] we performed theoretical studies of spin dynamics activated by Landau-Zener passages between different charge states. The system is modeled by an extended Anderson Hamiltonian with time dependent positions of quantum dot levels. We show that due to spin Stark effect [3] one can activate the qubit states confining only to the doublet subspace (without the quadruplet state which was used in [2]). This new scheme operates within a decoherence-free subspace and is immune to decoherence processes. First spin dynamics is considered for a linear TQD system (corresponding to the experimental situation). However in this situation two doublet states are nonequivalent what restricts qubit operations. Therefore, we propose TQD in a triangular geometry as the qubit, where manipulations (preparation and single quibit operations) are performed by an electric field which breaks the symmetry of the system and changes spin entanglement.

Mo.D-P10 - Spin-glass behavior of Fe doped InAs prepared by ion implantation and pulsed laser annealing

Y. Yuan [1], H. Cai [1], M. Helm [1], S. Zhou [1]

1. Helmholtz - Zentrum Dresden – Rossendorf, Dresden, Germany

Dilute magnetic semiconductors (DMSs) attracted great interests in the last several decades because of their potential for spintronic device [1]. III-V compounds especially GaAs based DMS has recently emerged as the most popular material for this new technology. However, that the low mobility of holes in p-type DMS limits the potential application in semiconductor spintronic devices. Therefore, the searching for n-type DMS is of interest.
The doping of Fe in InAs is attracting research attentions due to the possibility to fabricate n-type diluted magnetic semiconductors [2, 3]. However, the low solubility of Fe in InAs is the most difficulty to achieve InFeAs DMS. In this work, we obtain Fe doped InAs layers by ion implantation and pulsed laser annealing. This approach has shown success for preparing other III-V based DMSs [4, 5]. The formed InFeAs layers are proved to be epitaxial-like on InAs substrates. The prepared InFeAs layers reveal similar magnetic properties independent of their conductivity types. While the samples are lacking of charactersistics of DMS, they appear to be spin-glass like, revealing such as time-dependent magnetiszation measurements reveal aging and memory effects.

Mo.D-P11 - Spin filtering in double quantum dots aharonov-bohm ring under cubic rashba spin orbit interaction

K. Kondo[1]

1. Laboratory of Quantum Electronics, Research Institute For Electronic Science, Hokkaido University, Sapporo, Japan

A spin current generation without ferromagnetic metals is a key issue for spintronics devices. The spin orbit interaction (SOI) is expected to be a promising ingredient for the purpose. Especially, it is confirmed that the strength of Rashba SOI can be easily controlled by an external electric field. The theory of devices using SOI such as a spin-filter is very important in the field of spintronics. The spin-filtering devices can be used to generate and detect spin polarized currents. Many researchers have reported about the spin-filters using linear Rashba SOI. However, the spin-filters using cubic Rashba SOI are not yet reported. In this study, we investigate the spin filtering in double quantum dots Aharonov-Bohm (AB) ring under linear or cubic Rashba SOI. This AB ring consists of elongated quantum dots and quasi-one dimensional quantum nanowires under magnetic field. The spin transport is investigated from left nanowire to right nanowire in the above structure within tight binding approximation. In particular, we focus on the difference of spin filtering between linear and cubic Rashba SOI. The calculation is performed for the spin transmission with changing the penetrating magnetic flux for the AB ring subject to linear and cubic Rashba SOI, respectively. It is found that the perfect spin filtering is achieved for both linear and cubic Rashba SOI. This result indicates that this AB ring under Rashba SOI can be a promising device for spin current generation. Moreover, they behave in totally different ways in response to penetrating magnetic flux, which is attributed to linear and cubic behaviors in the in-plane momentum. This result enables us to make a distinction between linear and cubic Rashba SOI according to the peak position of the perfect spin filtering.

Mo.D-P12 - Electronic structure and transport properties of Bi2Te3 and Bi2Se3 with magnetic dopants

K. Carva[1], J. Kudrnovsk[2], M. ValiÜka[1], V. Hol[2,1]

1. Charles University, Prague, Czech Republic
2. Institute of Physics, Prague, Czech Republic

The surface state in topological insulators is protected against perturbations that keep time-reversal symmetry. Magnetic impurities violate time-reversal symmetry and thus may affect largely transport properties of topological insulators connected with the forbidden backscattering. We concentrate on Bi2Te3 and Bi2Se3 doped with Mn and Cr. It is known that there are several locations for these dopants available in the host lattice. Ab initio calculations employing the tight-binding linear muffin tin orbital (TB-LMTO) method and the coherent potential approximation (CPA) have been performed for the case of Mn/Cr placed in an octahedral interstitial position or the substitution of one of Bi atoms by Mn/Cr. Big volume difference between Mn and Bi/Se atoms represents a challenge for this method. The dopant moment as well as its DOS is shown to vary significantly depending on its location in the lattice. The exchange interaction between magnetic dopants and its possible magnetic ordering has been studied. We also calculate the conductivity tensor by means of the linear response theory, a strong dependence on the type and location of defect is found here. Hence the defects can be used to control many of material properties. This information can also help in identification of the defect location in real samples.

Mo.D-P13 - Anomalous proportional dependence of spin RA product on tunnel RA product in CoFe/SiO2/Si tunnel contacts

J. Lee[1], S. He[1, 2], B. Kang[1], B. Cho[1]

1. School of Materials Science And Engineering, Gwangju Institute of Science And Technology (GIST), Gwangju, South Korea
2. Gruenberg Research Centre, Nanjing University of Posts and Telecommunications, Nanjing, China

Efficient spin injection into a semiconductor is one of the most essential requirements in the field of semiconductor spintronics to realize novel spin-based devices, which utilize both the spin and charge functionality of electrons. In the past few years, electrical spin injection using 3-terminal Hanle technology has been widely reported in a variety of ferromagnet/tunnel oxide/semiconductor heterojuntions, in which an oxide tunnel barrier is employed to solve the conductivity mismatch between the metallic ferromagnet and the semiconductor. However, it has been found that the spin accumulation signal is highly sensitive to the thickness of the oxide barrier layer and its interfacial states [1-2]. Here, we systemically investigate the influence of tunnel resistance on the Hanle spin signal in CoFe/Silicon oxide/n+-Si structure. CoFe/SiO2/Si samples with different levels of tunnel resistance were fabricated, in which silicon oxide tunnel barriers were formed by plasma oxidation of the heavily doped n-type Si and CoFe was deposited by magnetron sputtering without breaking vacuum. To our best knowledge, this is the first study of spin injection in ferromagnetic tunnel contact using silicon oxide tunnel barrier formed by plasma oxidation. Fig. 1(a) and (b) show the typical Hanle curves measured at different bias voltages at room temperature and Hanle and inverted Hanle curves measured at 90K, respectively. Anomalous proportional dependence of the spin RA product on tunnel RA product is observed, as shown in Fig. 1(c) and (d). This tendency is similar to that reported in NiFe/Al_2O_3/Si and Fe/MgO/Si junctions [2]. It is known that recently there has been intensive debate about both the origin of the Hanle signal and the role of the tunnel barrier in the tunneling process of spin polarized carriers [3]. Our work will provide more experimental evidence for the study of spin injection in ferromagnet/tunnel oxide/semiconductor heterojuntions.

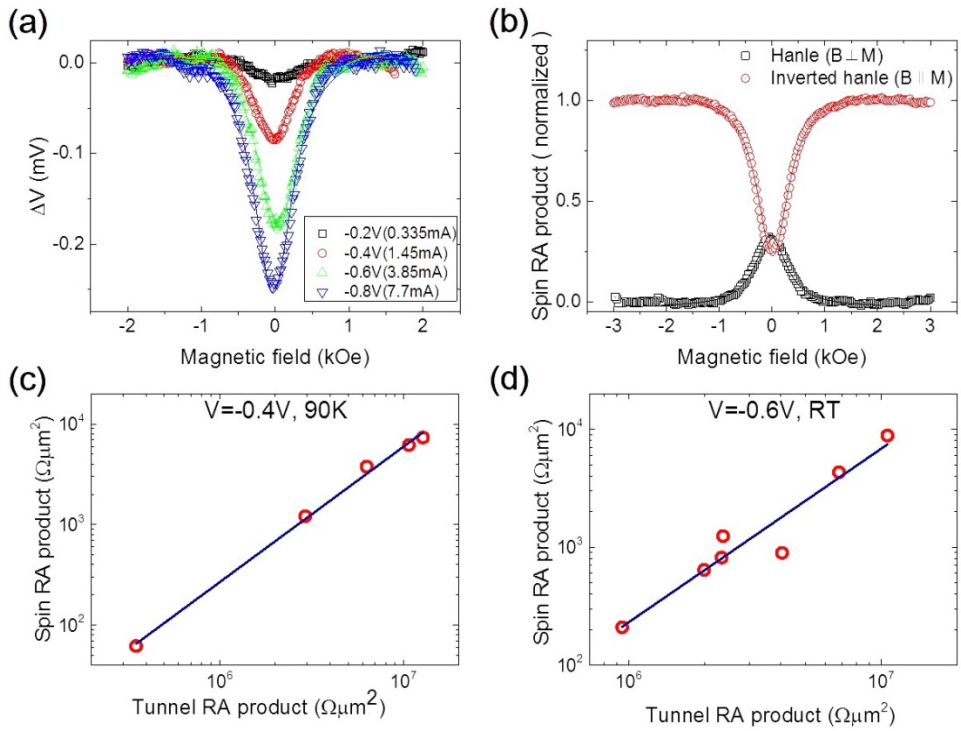

Fig. 1. Analysis of 3-terminal Hanle detection of CoFe/Silicon oxide/n-SOI junctions. (a) Hanle curves for spin injection measured at different bias voltages at room temperature. (b) Hanle and inverted Hanle curves measured at 90K. (c) and (d) Dependence of spin RA product on tunnel RA product.

Mo.D-P14 - Oxide diffusion barriers on GaAs(001)

A. Sarkar[1], S. Wang[1], R. Koch[1]

1. Johannes Kepler University Linz, Linz, Austria

Thin oxide layers functioning as tunnel contacts and/or diffusion barriers between a ferromagnetic electrode and a semiconductor template are expected to improve the spin injection efficiency by reducing the loss of the electrons' spin polarization at the interface. We present our recent results on the growth and properties of thin films of two transition metal oxides, MgO and MoO3, on GaAs(001)c(4Î4) substrates, with emphasis on their structure, morphology, stress, strain relaxation, and electrical properties. Furthermore, as an exemplary diffusing element in GaAs(001) we investigated the interdiffusion across the oxide barrier by means of Fe/(MgO,MoO3)/GaAs(001) heterostructures. The results on MoO3/GaAs(001) will be compared with that of MgO(001)/GaAs(001).

Mo.D-P16 - Electrical spin injection and detection in Si nanowire with CoFeB/MgO contacts

J. Chang[1], T. Park[1], B. Min[1], Y. Park[1,2], M. Jo[3], H. Choi[2]

Semiconductor spintronics deals with the manipulation of spin degree of freedom for electronic applications in semiconductors, and holds a great promise for overcoming the limit of conventional charge-based electronics. Silicon is one of promising materials for semiconductor spintronics because of the compatibility with complementary metal-oxide semiconductor and its long spin life time. In addition, the one-dimensional nanowires with single crystallinity and clean surfaces can provide an outstanding platform to study the role of the dimensionality and size effects in semiconductor spintronics. Here we show the electrical spin injection and detection in Si nanowires with an enhanced spin injection efficiency using MgO tunnel barrier, and discuss the effect of nanowire geometry on spin signals. Si nanowires used in the experiments are prepared by chemical vapor deposition (CVD) using phosphorus as a dopant. It is found that the Si nanowires (diameter of 50-80 nm) are highly n-type semiconductor with low resistivity (~13 mΩ·cm at room temperature). We employed the lateral spin-valve geometry with ferromagnetic CoFeB/MgO contacts for spin injection and detection. The non-local spin valve (NLSV) signal is as high as 380 ÑýV with the current of 100 nA at 1.8 K. A clear memory effect is also observed as a function of the magnetic field at low temperature. A unique feature of the NLSV observed in the Si nanowire is non-flat background voltage which can be understood to Hanle curve superimposed on the NLSV signal owing to the shape distortion of CoFeB right on top of a Si nanowire. The local magnetization of CoFeB affected by shape distortion determines the orientation of injected spins and governs relative magnetization of both CoFeB electrodes. The shape of the nanowire contributes to the observed spin signal, which has never been observed in thin film devices.

Mo.D-P17 - Spin accumulation and transport signals in Heusler Co2FeSi/MgO/n+-Si on insulator devices

Efficient spin injection and detection are essential for spintronics. For this purpose, spin transport has been intensively studied in various kinds of materials. We have been observing spin accumulation signals in Si with relatively long spin relaxation time by measuring three-terminal and four-terminal Hanle signals for CoFe/MgO/n^+-Si(100) devices [1], and observing local-MR and nonlocal (NL)-MR signals up to room temperature[2]. However, the estimated spin polarization was a small value of ~ 0.16 [2] and improving the spin polarization in Si is highly desired. On the other hand, spin devices with Co-based Heusler-compounds have been studied because of their enhancement in spin generation efficiency. In studies of spin polarization in semiconductors using Co_2FeSi, there have been some reports of efficient spin injection into Ge [3] and GaAs [4] channels. However, to our knowledge, there have been no reports for the case of Si channels.
In this study, we fabricated Heusler Co_2FeSi/MgO/Si on insulator (SOI) devices and examined spin accumulation and transport signals in n+-Si by NL four- and three-terminal Hanle measurements.
We prepared four-terminal devices with Co_2FeSi/MgO electrode on phosphorus-doped (~10^{19} cm^{-3}) (100)-textured SOI substrates. After the native oxide layer on the surface of the SOI layer was removed with hydrofluoric acid, the MgO layer was deposited by electron beam evaporation method under 200 degree C. Co_2FeSi and Ru capping layers were then sputtered in the same ultra-high vacuum deposition system. We produced a single-crystalline MgO layer on the SOI.
As a result, from the observation of NL four-terminal Hanle signals, we found that the spin polarization in n+-Si estimated from the signals is enhanced by using a Co_2FeSi compared to the case of a CoFe electrode. We will also discuss the local-MR and NL-MR signals in Co_2FeSi/MgO/SOI devices.

The electrical spin injection from a ferromagnetic metal (FM) into a semiconductor (SC) and the conversion of the spin polarization in a SC into an electrical signal are the essential requirements for spin controlled devices in semiconductor. The careful control of the interface between FM and SC is a key to successful spin injection and introduction of tunnel barrier between FM and SC is a well-known way to overcome the conductivity mismatch problem. The Fe/MgO layer can be epitaxially grown on GaAs layer and forms a basic building block for the magnetic tunnel junction which allows coherent tunneling of Δ_1 Bloch state of Fe. The spin polarized charge transfer through Fe/MgO/GaAs heterostructures was studied using spin dependent photocurrent, but fully electrical spin injection through the heterostructure has not yet been reported.
We have studied spin accumulation in n-doped GaAs electrically injected from Fe electrode via MgO tunneling barrier using three terminal (3T) Hanle measurement. The control of Schottky barrier height and the depletion width by means of the doping-modulation at the interface dramatically improve spin injection efficiency. The whole Fe/MgO/GaAs heterostructures were prepared *in-situ* process using cluster MBE system without vacuum breaking by which both clean interface and high-quality tunnel barrier were obtained. Large Hanle signal of ΔV = 6.3 mV at 10 K was detected and it is still sustained even at room temperature of 1.2 mV. The spin lifetime and spin diffusion length are measured to be 234 ps, and 0.97 μm respectively at 300 K. The bias dependence of the Hanle signal supports effective spin selectivity of injected electrons through epitaxial Fe/MgO/GaAs structure. Combination of in-situ grown MgO tunnel barrier and modulation doping technique appear to be very successful in spin injection to GaAs.

Mo.D-P19 - Spin transport through high-quality epitaxial Ge/Fe3Si heterostructures in Cu-based lateral spin valves

We have so far demonstrated the epitaxial growth of high-quality Ge epilayers on a ferromagnetic Heusler compound, Fe_3Si, by low-temperature molecular beam epitaxy (LT-MBE).[1] If spin injection and detection across the Ge/Fe_3Si interfaces are demonstrated, the vertically stacked Ge/Fe_3Si structure can be used for vertical semiconductor spintronic devices. Here, we report the first observation of spin transport across the vertically stacked Ge/Fe_3Si interfaces by using non-local voltage measurements in Cu-based lateral spin valves (LSVs).
Ge(~50 nm)/Fe_3Si(~25 nm) structures were grown on a non-doped Si(111) substrate (ρ = ~1000 Ωcm) by LT-MBE[1] and were processed into Ge/Fe_3Si electrodes with wire-shaped Cu channels in LSVs.[2] The junction size between Ge and Cu is about 150 x 150 nm^2, and the center-to-center distance between the electrodes is about 300 nm. Since the sidewalls of the Ge/Fe_3Si electrodes in the LSVs were covered by insulator films, spin-polarized carriers were injected vertically from Fe_3Si to Ge and pure spin currents were transported laterally from Ge to Cu. Clear non-local spin signals were seen at various temperatures although the signal obtained at room temperature was about one order of magnitude smaller than that in LSVs without Ge epilayers.[2] This work indicates that the vertically stacked Ge/Fe_3Si structure which we developed can be used for vertical semiconductor spintronic devices.
This work was partly supported by Grant-in-Aid for Scientific Research on Innovative Areas 'Nano Spin Conversion Science' (No. 26103003) from JSPS, and Grant-in-Aid for Scientific Research(A) (No. 25246020) from JSPS. M.K. and S.O. acknowledge JSPS Research Fellowships for Young Scientists.

Mo.D-P20 - MgO diffusion barriers for ferromagnetic electrodes on GaAs(001)

A. Sarkar[1], S. Wang[1], R. Koch[1]

1. Johannes Kepler University Linz, Linz, Austria

Intermixing at the interface between high-spin-polarization ferromagnetic layers and semiconductor templates is expected to significantly reduce the spin injection efficiency of spin and magnetoelectronics devices and recommends the use of appropriate diffusion barriers. We report on the investigation of ultrathin MgO(001) films serving as diffusion barrier between ferromagnetic Fe electrodes and GaAs(001) semiconductor templates. Epitaxial MgO/GaAs(001) heterostructures were prepared at different growth temperatures in a multichamber III/V-semiconductor-MBE system [1]. Investigations with reflection high energy electron diffraction, x-ray diffraction and high resolution cross-sectional transmission electron microscopy (HRTEM) reveal the growth of single-crystal cubic MgO(001) film at 200 °C with MgO(001)[100]||GaAs(001)[100] and a 4 : 3 lattice registry. The surface of the MgO films, characterized by atomic force microscopy, exhibits a root mean square roughness of only 0.5 nm. In situ stress measurements reveal tensile stress as low as 1.7 GPa for a growth temperature of 200 °C in good agreement with the calculated residual misfit strain [1]. Finally, the effectivity of MgO as a diffusion barrier was investigated by growing epitaxial Fe/MgO/GaAs(001) heterostructures. Structural characterization of the heterostructures reveal a well-ordered crystalline growth and an epitaxial relation of Fe(001)[110] || MgO(001)[100] || GaAs(001)[100] in good agreement with the literature [2]. Auger electron spectroscopy depth-profiling and HRTEM evidence diffusion of Fe into MgO and for to thin MgO barriers further into GaAs(001). Our results recommend a MgO barrier thickness larger than 2.6 nm for its application as a reliable diffusion barrier on GaAs(001) in spintronics devices.[3]

Mo.D-P21 - Manipulation of the magnetism in (Ga,Mn)As films by organic molecules

X. Wang[1], H. Wang[1], D. Pan[1], T. Keiper[2], L. Li[1], X. Yu[1], J. Lu[1], E. Lochner[2], S. Molnaýr[2], P. Xiong[2], J. Zhao[1]

As widely accepted a kind of magnetic semiconductor with an intrinsic ferromagnetism, (Ga,Mn)As has attracted much attention in the recent years.[1,2] However, the highest Curie temperature (Tc) of 200 K obtained by combining heavy Mn doping, post-growth nano-patterning and annealing,[3] is still well below room temperature and limits its application in spintronic devices. In (Ga,Mn)As, since the holes from Mn doping are known to mediate the ferromagnetic interaction among the Mn ions, Tc may be controlled via variation of its carrier density by electrical gating.[4] Unfortunately, the tunable temperature range is limited, usually only several Kelvin. In this work, we demonstrate a novel way for effective manipulation of Tc in (Ga,Mn)As by organic molecules.[5] Organic charge-transfer molecules were deposited on the surface of (Ga,Mn)As films by either solution-based self-assembly or vacuum thermal evaporation, which led to large carrier density modulation. Electron donor (acceptor) molecules were found to decrease (increase) TC. The maximum tunable value in TC is up to 36 K. The experimental results are qualitatively consistent with the p-d Zener model proposed by Dietl et al.[6]. Moreover, through proper preparation of the (Ga,Mn)As surface, self-assembled monolayer patterns of organic molecules with sub-75 nanometer line width were successfully created via dip-pen nanolithography. These results may open a new pathway to controlled nanoscale manipulation of magnetism in magnetic semiconductor, with potential applications in reconfigurable, non-volatile and hybrid molecular nano-spintronics.

Mo.D-P22 - Effect of Mn impurities on the 3-terminal Hanle signals in ferromagnet/oxide tunnel contacts on a semiconductor

A. Spiesser[1], H. Saito[1], S. Yuasa[1], R. Jansen[1]

1. National Institute of Advanced Industrial Science And Technology, Japan

In the last years, there have been lively discussions about the origin of the electrical spin signals observed in ferromagnet/insulator/semiconductor junctions. Many research groups have experimentally reported three-terminal Hanle signals that are orders of magnitude larger than what the standard theory predicts [1]. Nonetheless, the observed spin signals exhibit the typical features of precession of an induced non-equilibrium spin population, suggesting that intriguing physics is at play.
To explain the large spin voltage, two-step tunneling through localized states near the oxide/semiconductor interface or deep within the oxide was suggested [2,3]. However, this cannot explain the large spin accumulation signals that were recently observed in a direct Mn5Ge3 Schottky contact on Ge without an oxide tunnel barrier [4]. Nevertheless, one has to consider the possibility that some Mn atoms have diffused into the depletion region of the Ge and produced deep impurity levels in the Schottky tunnel barrier. Although previous studies have shown that the presence of impurities in magnetic tunnel junctions is detrimental for the spin transport [5], it is of interest to examine how impurities affect Hanle spin signals. Thus, we have intentionally inserted an amount of Mn impurities varying from 0.5 to 2 Å in the middle of a GeO2 oxide tunnel barrier and investigated the effect on the three-terminal Hanle signal in Fe/GeO2 junctions on p-type Ge(001) substrates. We have measured the Hanle and inverted Hanle effect and observed a strong decay of the spin signal with increasing amount of Mn. This shows that the presence of Mn impurities reduces the spin signal, rather than enhances it. The results, explained in terms of inelastic spin-exchange scattering of tunneling electrons by Mn ions, proves that enhanced Hanle spin signals are not due to tunneling via magnetic impurities.

Mo.D-P23 - Spin transport in an n-type 4H-SiC channel

E. Shigematsu[1], Y. Ando[1], G. Eguchi[1], T. Shinjo[1], T. Kimoto[1], M. Shiraishi[1]

1. Kyoto University, Kyoto, Japan

In a field of semiconductor spintronics, spin coherence is a crucial index for realization of spin transistors and quantum computation devices, and many attempts have been done to seek material with better spin coherence. Among Group-IV semiconductors, SiC, currently recognized as a potential wide-bandgap semiconductor for power device applications, is expected to have better spin coherence, because spin life time is proportional to the square of the bandgap in Elliott-Yafet mechanism [1]. In addition, 4H-SiC has spatial inversion symmetry, which exempts the Dresselhaus-type spin orbit interaction. Hence, an investigation of spin coherence in SiC can be an important research issue for further progress of group-IV spintronics. In this presentation, we show results on spin transport in n-type 4H-SiC by using dynamical spin pumping, which has been established in Si spintronics [2]. An n-type SiC epitaxial layer was grown on a semi-insulating SiC substrate. The patterns of NiFe (Permalloy, Py) and Pd were prepared by a lift-off method. In order to form an Ohmic contact, Ti was inserted beneath the Py and the Pd. Under the ferromagnetic resonance of the Py, an electromotive force (EMF) was observed from the Pd electrode. The sign of the EMF was inverted when the direction of the external magnetic field changes. Since the EMF of the self-induced inverse spin Hall effect (ISHE) in Py [3] and that of the ISHE in the Pd due to a spin current propagating through the SiC channel can be superimposed, we propose a procedure of separation of these two origins using an impedance matrix and discuss the spin-related properties of SiC.

1. Korea Institute of Science And Technology, Seoul, South Korea

The spin-field-effect transistor (spin FET) is one of the most attractive devices in the field of spintronics because gate-controlled spin orientation modulates the channel conductance. The basic mechanism of the spin FET is that the injected spins precess around the Rashba field and gate field controls the spin precession angle. In a quantum well system with a structural asymmetry along the growth direction (z-axis), the electrons flowing along the x-direction produce the Rashba effective magnetic field along the y-axis. Thus, to induce spin precession of an injected spin, the injected spin orientation should be x or z direction. The neighboring ferromagnetic electrode causes the interference noise, so the perpendicular magnetization material (z-direction) is very attractive for high-density spin FET. In this research, we utilized Tb20Fe62Co18/Co40Fe40B20/MgO electrodes as drain and source in an InAs quantum well channel. The top Tb20Fe62Co18 layer produces perpendicular magnetization and the Co40Fe40B20 layer enhances the spin polarization of the injection electrons. In our system, the electrons injected with spin polarization along the z-axis precess under the influence of the Rashba field (BRy). The magnitude of electric field, Ez, can be modulated by a gate voltage, and the magnitude of the Rashba field is proportional to the electric field. Thus, the precession rate therefore changes as a function of gate voltage. The detector is also a Tb20Fe62Co18/Co40Fe40B20/MgO electrode with perpendicular magnetization. The channel conductance is high (low) when a detected spin has orientation parallel (anti-parallel) with that of the detector. The channel conductance oscillates periodically as a function of gate voltage. A gate voltage change of 2 V makes it possible to operate spin FET using perpendicular spins. We clearly observed that the gate field controls the spin orientation and the channel conductance without an external magnetic field.

Mo.D-P26 - Electrical spin injection and detection in homoepitaxial GaAs(110) layers

H. Kim[1], H. S. Kim[1,2], J. Shin[1], H. Chul Koo[1,2], J. Chang[1]

1. Center for Spintronics, Korea Institute of Science & Technology, Seoul, South Korea
2. KU-KIST Graduate School of Converging Science and Technology, Korea University, Seoul, South Korea

GaAs quantum wells (QWs) on GaAs(110) substrates have attracted attentions for semiconductor spintronic device applications due to longer spin relaxation time compared to GaAs(001) channel. Furthermore, spin dephasing via the Dyakonov-Perel (DP) mechanism is strongly suppressed for growth-axis-oriented spins in the GaAs(110) QWs. As a result, much longer spin lifetime (of up to 10 ns) have been reported for GaAs(110) QWs compared to GaAs(001) QWs. For the realization of GaAs(110) channels of the longer spin relaxation time, the high quality epitaxial GaAs(110) growth is an essential ingredient. The homoepitaxial GaAs(110) growth, however, is more difficult than GaAs(001) growth because of the different arsenic incorporation due to the difference between nonpolar (110) and polar (001) surfaces. In this study, we carefully investigated the surface morphology evolutions and underlying pyramidal defects to implement the high quality GaAs(110) homoepitaxial growth by changing two key experimental parameters of layer thicknesses and growth temperatures. With the high quality of GaAs (110) channel excluding triangular-shaped surface defects and underlying stacking faults, we demonstrate spin transport from a ferromagnetic metal such as TbCoFe into the GaAs (110) channel to enhance the spin lifetime.

Mo.D-P27 - Spin injection in silicon and germanium: new elements for understanding

Electrical spin injection from ferromagnetic metals to silicon (Si) and germanium (Ge) is the first and basic requirement for the development of spintronic devices and their integration with mainstream semiconductor (SC) technology. The main solution to avoid conductivity mismatch is to use a tunnel barrier between the ferromagnetic metal and the SC. However, electrical spin injection is still a challenge and raises other important issues in the interpretation of electrical spin signals. In particular, the possible presence of localized states within the insulating barrier or at the interface between it and the SC may lead to wrong conclusions. To study the exact origin of spin signals, we managed to measure 3 and 4 contacts devices of silicon-on-insulator (SOI) and germanium-on-insulator (GeOI). These materials allow us to apply back gate voltages to the SC channel to vary its resistivity and carrier mobility. We have grown Ta/CoFeB/MgO/SOI and GeOI samples with n and p type doping using variable MgO thicknesses. Following the possible defects coming from tunnel barrier, the signal will be controlled by the tunnel barrier thickness. Moreover we have used three different techniques to grow the MgO tunnel barrier: by sputtering of MgO or Mg followed by a plasma oxidation and e-beam evaporation of MgO. By changing the growth method we also expect different kinds of interface with possible defects. We focused on tunnel junction grown using Mg and plasma oxidation for silicon and germanium with different doping. We obtained very different temperature dependencies as expected. We are able to see a transition in temperature from the spin accumulation into interface states to the spin accumulation into the conduction band of n-Ge. For this purpose, both electrical and dynamical spin injection measurements were carried out as a function of temperature and bias voltage for different MgO tunnel barriers.

Mo.D-P29 - Spin selective transport though quantum ring with magnetic impurities

P. Dahan[1]

1. School of Engineering At Ruppin Academic Center

A theory of magnetic impurities in quantum ring, QR, under magnetic field is formulated in terms of a resonance scattering model. We consider transition metal, substituting semiconductors QR and found that both short-range potential and resonance components of impurity scattering influence mainly the first QR energy level, near k≈0, k=m+ Φ/Φ_0, m and Φ/Φ_0 are respectively the angular moment and flux.
Since the resonance scattering potential has a strong energy dependence characteristic, the spin up and spin down of the QR are modified with different energy values, $\delta_{\uparrow}$ and $\delta_{\downarrow}$, respectively [1]. The zero-field spin splitting in the QR states involves various electronic effects. In particular, the polarized spin current can occur. The localized states in the QR serve as intermediate resonant states through which the tunneling takes place. Since the zero-field spin splitting of the first QR state is large, it can yield a very high spin polarization. This spin dependent transition property of the QR leads to enhanced transition probability for electrons populate a specific spin state, which results in polarization of the spin current. In principle, due to the above said effect such a system can be used as a spin filter and spin currents controller.

The integration of spintronics and photonics represents one of the most challenging tasks in modern optoelectronics. Among group-IV semiconductors, germanium plays a key role, owing to the large spin-orbit coupling, long electron spin lifetime and integrability with Si-based microelectronics. Although spin injection through optical orientation is a well-known technique, geometries that rely on optical excitation at normal light incidence provide a spin polarization vector perpendicular to the plane of the device, thus limiting their applicability in spintronic devices. However, it has recently been shown that two complementary in-plane spin populations can be optically generated in germanium by depositing a stripe-shaped platinum overlayer on top of the semiconductor. Spin generation can subsequently be electrically detected through the inverse spin-Hall effect (ISHE) measurements in the Pt layer or by using magnetic tunnel junctions (MTJs) in close proximity to the impinging light beam (at a distance less than the spin diffusion length Lsf). Here we will show our last results on optical generation and electrical detection of spin in Germanium using a confocal microscope setup and multi-terminal patterns comprising platinum stripes and CoFeB/MgO MTJs. In particular, MTJs are remarkably versatile probes since they can address different spin polarization components. This is possible either by fabricating MTJs with different well-defined remanence magnetization or by switching the magnetization with an external magnetic field. This combined electro-optical technique also allows to directly address the spin diffusion length and to quantify the spin current intensity injected into the ferromagnetic contact.

Mo.D-P31 - Suppression of spin decay in a laterally confined two-dimensional electron gas

P. Altmann[1], M. P. Walser[1], M. Kohda[1,2], C. Reichl[3], W. Wegscheider[3], G. Salis[1]

1. IBM Research, Zurich, Switzerland
2. Graduate School of Engineering, Tohoku University, Sendai, Japan
3. Solid State Physics Laboratory, ETH Zurich, Zurich, Switzerland

The decay of spin polarization in a two-dimensional electron gas is often dominated by the intrinsic spin-orbit interaction through the Dyakonov Perel mechanism. If the electron gas is laterally confined to a wire structure with a width smaller than the spin-orbit length, the corresponding spin decay rate is predicted to be suppressed quadratically with the confinement width. We experimentally investigate this effect of lateral confinement on the dynamics of electron spins in etched GaAs wire structures of 1–80 µm width. Using time-resolved Kerr rotation measurements, we spatially map the diffusive expansion of locally excited spin polarization in individual wires. The decay of spin polarization is separated into a contribution from the dilution caused by spin diffusion, and an exponential decay of the excited spin eigenmode. We observe a strong suppression of spin dilution at the transition to one-dimensional diffusion [1]. The exponential spin lifetime increases with decreasing wire width. This effect is small in samples with almost balanced Rashba and Dresselhaus spin-orbit interactions. We find that for narrow wire widths, the spin lifetime approaches the value for a two-dimensional electron gas with perfectly balanced spin-orbit interaction, suggesting that these rates are both limited by the cubic Dresselhaus interaction.

Mo.E-P02 - Tuning of magnetoresistance in organic-based devices by interface engineering

H. Jang[1,2], O. Jurchescu[2], C. Richter[1]

1. Semiconductor and Dimensional Metrology Division, National Institute of Standards and Technology, Gaithersburg, United States
2. Department of Physics, Wake Forest University, Winston-Salem, United States

Great efforts are underway to realize organic-based spintronics technologies including the exploration of the organic magnetoresistance (MR).[1] Organic MR is a unique magnetic field effect (MFE) on the electrical resistance of nonmagnetic organic semiconductor devices.[1] This unusual phenomenon has opened the door for developing novel applications such as organic spintronic devices and room temperature field sensors. While the underlying mechanisms for organic MR are still unsettled and debated,[1] it can be used as an experimental tool for improving the fundamental understanding of charge carrier transport mechanisms in organic semiconductors devices such as OLEDs.
In this presentation, we report a novel method of manipulating the organic MR in Alq_3 (tris-(8-hydroxyquinoline) aluminum) – based devices by simply adding a molecular self-assembled monolayer (SAM) at the interface between a metal electrode and an organic semiconductor.[2] SAMs have been known for their versatile use in various technological applications including their ability to alter the physical properties of an inorganic solid surface.[3] We show for the first time that the interfacial modification by simply inserting a fluorinated SAM (heptadecafluoro-1-decanethiol $[CF_3(CF_2)_7(CH_2)_2SH]$ or F-SAM) in organic-based devices changes the sign of organic MR due to the change in relative strength of different MFE mechanisms coexisting in organic-based devices.[2] In addition, we utilize different MFE mechanisms coexisting in organic-based devices by adding a thin TPD (N,N'-Bis(3-methylphenyl)-N,N'-diphenylbenzidine) layer to create a system whose organic MR can be tuned by an external bias voltage.[2]

Individual magnetic molecules embedded into electric circuits are envisaged as functional components in the emerging field of molecular spintronics. Single-molecule magnets (SMM), with high spin and high magnetic anisotropy are interesting candidates. We study three-terminal charge transport through individual Fe4 SMM. In these transistors, an Fe4 molecule is linked to two gold electrodes fabricated by self-breaking electromigration of a gold nanowire [1]. A third gate electrode is used to access different redox states of the molecule. The measurements reveal that the magnetic properties of the molecule are preserved and can be reversibly modified by adding a single electron into the molecule [2]. Interestingly, we observe that the current through the molecule can be significantly tuned by the presence of small transverse magnetic anisotropy perturbations [3] and individual vibrational modes of the molecule [4]. These two findings are of special relevance to use SMM as memory elements or qbits and opens the door to study quantum properties of the SMM such as quantum tunnelling and quantum interferences at the single molecule level. As a further step in the control of individual molecular spins, we work on ferromagnetic-functionalized graphene electrodes to inject spin-polarized currents into magnetic molecules.

Recent developments in spintronics involve the use of graphene layer because of its outstanding physico-chemical properties. In such hybrid devices their magnetic and transport properties will strongly depend on the contact with the ferromagnetic leads. [1] In order to understand the device properties it is therefore necessary to investigate the graphene/metal interfaces. Because of its sensitivity to the chemical environment of Cobalt, we have used Ferromagnetic Nuclear Resonance (FNR, i.e. Nuclear Magnetic Resonance for ferromagnets) to investigate the interface sates of Cobalt atoms at a Graphene/Cobalt single interface. FNR is a unique tool to study the interfaces of Cobalt films and multilayers and has been widely used for investigating the interfaces with metallic or semiconducting layers [2,3]. In this work we have studied Cu/Graphene/Cobalt/Fe artificial structures deposited by MBE on copper foils. This architecture allows probing by FNR a single Graphene/Co interface since the Graphene/Co and Co/Fe interfaces result in contributions in different frequency ranges. Our investigations show that FNR is able to provide information about the local magnetic properties of the interfacial Co atoms. The influence of graphene on the electronic structure of Co extends over several atomic planes into the bulk of the cobalt films. The results will be discussed at the light of recently published computation results predicting very strong hybridization for Cobalt atoms at the interface with graphene.

Controlling the spin of electrons in nanoscale electronic devices is one of the most promising topics toward devices with rapid and highly dense information storage. The interface magnetism or spinterface resulting from the interaction between a magnetic molecule and a metal surface, and vice versa, has become a key ingredient to engineering nanoscale molecular devices with novel functionalities. Here, we present a single-molecule wire displaying large (>10000%) magnetoresistance based on STM measurements. The molecular device is built by trapping individual spin crossover Fe(II) complexes between one Au and one ferromagnetic Ni electrode at room conditions. Large changes in the single-molecule conductance are measured when the electrons flow from the Au to either an alpha-up or a beta-down spin-polarized Ni electrode, the latter case being at least 100-fold more conductive than the former. The current flowing through such an interface appears to be strongly spin-polarized, thus resulting in the observed magnetoresistance effects depending upon the magnetic Ni polarization direction. The observation of strong magnetoresistance effects in a single-molecule device opens up a new door for the design and control of spin-polarized transport in nanoscale molecular devices at room temperature.

Mo.E-P07 - Magnetoresistance effect of magnetic tunnel junctions with an interface modified by [6]Cyclo-2,7-naphthylenes

Organic-magnetic materials hybrid structures attracted much attention from the viewpoint of spin injection into the organic molecules [1,2] and new interface effects [3,4,5]. However, there were only few reports on these effects observed at room temperature (RT), thus it is interesting to explore the new materials/molecules hybrid structure exhibiting remarkable spin-dependent transport at RT. Here, we reports the fabrication of magnetic tunnel junctions with an insertion layer of the [6]cyclo-2,7-naphthylenes (CNAP) at interface between ferromagnetic electrode and insulating barrier and the characterization of spin-dependent transport properties. The CNAP is a new molecule synthesized recently, which has a conjugated pi-electron system, cyclic molecular structure, and excellent thermal stability up to about 600oC [6]. The junction devices were prepared by an organic-inorganic hybrid multi-chamber deposition system being equipped with an in-situ shadow-mask exchange system. The stacking structure was glass substrate/Co(50 nm)/AlOx(2 nm)/CNAP(d = 0-20 nm)/NiFe (30nm) and the junction area was 1.5ü~1.8 mm2. The MR ratio at RT for the junction without CNAP was 2.2%, whereas it increased with increasing d and then exhibited the maximum value, 5.6%, at d = 3 nm. Temperature dependence of the junction resistance showed a tunneling-like transport below d = 5 nm. This result indicated that the CNAP-modified NiFe interface could have a high spin polarization even at RT [7]. This work was supported by JST-ERATO and Murata Science Foundation. We thank H. Kiso for his assistance of device fabrications.

Mo.E-P09 - Ferromagnet - organic semiconductor interface for molecular spin electronic devices

S. Majumdar[1]

1. Aalto University, Spoo, Finland

Organic or hybrid inorganic-organic spintronics is the newly developing branch of spintronics where the advantages of both the large spin polarization of the ferromagnetic metals and half metals and long spin de-coherence lengths of the organic semiconductors are explored. For improved spintronic components, it is important to investigate material properties at the hetero-interfaces. In the present work, we have done structural, magnetic and transport characterization of interfaces comprised of a half-metallic ferromagnet La0.67Sr0.33MnO3 (LSMO) and two different organic semiconductors namely Co-Pthalocyanine (CoPc) and rubrene. For the LSMO/CoPc interface, investigation of electronic, magnetic and magnetotransport properties indicate strong chemisorption of CoPc molecules on the LSMO surface improves the LSMO magnetic properties however at the same time the magnetoresistance (MR) of the CoPc coated LSMO increases which can be due to induce local trap states at the LSMO/CoPc interface where spin polarized charge carriers get trapped [1]. Similar increased MR of the LSMO-organic interface was observed for polymeric region-regular polyhexyl thiophene (RRP3HT) also [2]. For LSMO/rubrene interface, x-ray reflectivity measurements indicate a well-defined interface formation especially between vacuum-annealed LSMO and rubrene while x-ray photoemission measurements confirm a hybridization at the rubrene-LSMO interface. Magnetic measurements show due to this hybridization, ferromagnetic property of the LSMO improves whereas intentional disruption of this hybridization by insertion of AlOx layer results in a decreased ferromagnetism at the hybrid interface [3]. These results demonstrate that by modifying the interface formation between organic semiconductors and half-metallic oxides, it is possible to engineer interface spin polarization properties which could lead to the desired control of the molecular spintronic components.

Mo.E-P10 - Effect of molecular ordering on spin transport in Fe/MgO/CuPc/Co hybrid junctions

Y. Jeong Bae[1], N. Jong Lee[1], J. Wade[2], J. Kim[2], A. Pratt[3], T. Hee Kim[1]

1. Ewha Womans University, Seoul, Suth Korea
2. Imperial College London, London, United Kingdom

In the last decade, there has been remarkable advancement in the filed of organic spintronics. However, the realization of highly effective organic spintronic devices working at room temperature still remains a challenge. Understanding and controlling organic-inorganic interfaces are crucial for manipulating spin-dependent transport in organic magnetic tunnel junctions. Molecular ordering of the organic film between two ferromagnetic (FM) layers could also play a key role in spin transport properties of the hybrid FM metal/organic systems. In this work, we prepared Fe(001)/MgO(001)/Cu-phthalocyanine (CuPc)/Co hybrid structures for magnetic tunnel junctions (MTJs). Fe(001) and Co FM metals are utilized as a spin injector and detector. The CuPc films of various thickness from 1.6 nm to 5 nm were deposited on a 1.6 nm-thick MgO(001) oxide layer grown on Fe(001). This MgO(001)/CuPc hybrid barrier offers a possible solution for improving the performance of organic MTJs. As a result, we observed magnetoresistance (MR) behavior of ~ 200% at 77K and ~ 10% at room-temperature (RT) for the MTJ with the hybrid 1.6 nm MgO(001)/1.6 nm CuPc barrier, whereas no significant MR effect was seen in the MTJs with a single barrier CuPc. A systematic study to analyze the interface (surface) properties was carried out by using metastable He de-excitation spectroscopy (MDS) and Raman spectroscopy. The CuPc films grown on the MgO(001) reveals a herringbone-type molecular arrangement as the sample temperature drops below 250 K. This phase transition of CuPc beyond MgO(001) could be related to the abrupt change of the junction resistance below 250 K. Obviously, our results indicate the molecular ordering is an important key for spin transport in organic films. The results of spin-polarized MDS study highlight the spin polarization induced in CuPc molecular orbitals by the enhanced intermolecular interactions.

Mo.E-P11 - Tailoring spin-textured interfaces with organic molecules

M. Cinchetti[1], B. Stadtmüller[1], J. Seidel[1], N. Haag[1], C. Tusche[2], J. Kirschner[2], M. Aeschlimann[1]

The deposition of organic molecules on magnetic surfaces has revealed a very efficient and promising way to create interfaces with tailored spin properties [1]. The hybridization between the electronic bands at the surface of the magnet and the orbitals of the molecule can lead to a drastic change of the magnetic properties of the formed interface, like spin polarization, spin filtering [2] coercive field and exchange coupling strength. The versatility of organic molecules for spin applications is, however, not only limited to interfaces formed with magnetic materials, but extends to the much broader class of non-magnetic spin-textured materials, as recently demonstrated for magnetic skyrmions [3, 4]. Here, we have studied the electronic valence structure of the interface formed by PTCDA molecules adsorbed on a Pb/Ag(111) surface alloy by ARPES using a k-space microscope. The Pb/Ag(111) surface alloy shows a distinct spin-texture due to the Rashba-Bychkov effect [5]. We find that the band structure of the clean Pb/Ag(111) surface alloy is significantly modified by the adsorption of PTCDA, which we attribute to a change in the vertical relaxation of the positions of the Pb atoms in the surface alloy. This study indicates a new concept to tailor the spin texture of the Rashba system, namely by tuning the metal-organic interface “from the bottom”.

The magnetic field response of electroluminescence (EL) of organic light emitting devices (OLEDs) can be controlled by injecting spin-polarized carriers from ferromagnetic (FM) electrodes in principle. [1] However, in reality, the injection of fully spin-polarized carrier is difficult. [2] Also, the injected carriers can lose some of their spin information due to hyperfine interaction or spin-orbit interaction when moving through the organic materials before they emit light. In this work, we investigated a room-temperature (RT) spin-OLED with a magnetic anode such as bcc-Fe(001)\MgO(001) which is well known as a perfect spin filter. A semitransparent Al film was deposited on tris(8-hydroxyquinolinato)aluminum (Alq_3) film as a cathode. For the Si(001)\MgO(001)\Fe(001)\MgO(001)\Cu-Phthalocyanine (CuPc)\N,N'-Bis(naphthalen-1-yl)-N,N'-bis(phenyl)-2,2'-dimethylbenzidine (α-NPD)\Alq_3\LiF\Al structure, magnetoelectroluminescence (MEL) of ~ 6% was observed at RT in a low magnetic field of 1 kG for an applied voltage in excess of ~ 5 volts while these measurements showed less than 3% for not fully spin polarized FM anodes (Py, Fe(001) and poly-Fe) without the thin MgO(001) overlayer.
In order to get information of the OLED operating process, such as charge distribution, carrier mobility, current density and etc., numerical analysis was performed by using the MOLED simulation model [3] provided for a typical OLED architecture consisting of an organic multilayered structure between two parallel planar electrodes. In addition, our experimental results were analyzed in the framework of the electron-hole pair (e-h pair) model. All these results strongly support that enhancement of MEL could be attributed to the spin-polarized hole injection from the epitaxial Fe(001)\MgO(001) bilayer.

Mo.F-P01 - Massively parallel micromagnetic simulations of small-size nanoelements with applications to STT-MRAM devices

E. Semenova[1], D. Berkov[1]

1. General Numerics Research Lab, Jena, Germany

In this contribution we present a new numerical method which allows massively parallel micro¼magnetic simulations of the magnetization reversal in small-size nanoelements by fully exploiting the high acceleration factor available on GPU architecture only for large systems. The major target of our new methodology is the simulation of magne¼tization dynamics in nanoelements with the size of several tens of nanometers. These elements are at present of the primary interest as attractive candidates for a new generation of conventional and spin-torque-based magnetic random access memory (MRAM) cells.
We apply our method to the analysis of the ST-induced magnetization switching in elliptical nanoelements. Being able to compute simultaneously magnetization reversal of up to 1000 MRAM cells, we could obtain the dependence of the switching time on the element size and the current with a very small statistical error.
Comparison with the macrospin approximation has shown that full-scale micromagnetic simulations are essential starting from the nanoelement size as small as 40 x 50 nm2. Switching times obtained by full-scale simulations are larger than those predicted by the macrospin approach; this difference rapidly growths with the nanoelement size. Detailed analysis of the switching statistics and the nature of the switching process (available only from full-scale simulations) allowed deep understanding of the magnetization reversal in such nanostructures. In particular, we have shown that for moderate element sizes (short ellipse axis b = 40 nm, long axis a = 60 - 90 nm) magnetization switches via the nucleation of small 'reversed' regions and their further growth. For a > 90 nm the reversal occurs via the propagation of the domain wall across the nanoellipse.
We also compare the switching statistics in dependence on the element size for the two cases, where either the total current through the MRAM cell or the current density is kept constant.

Mo.F-P02 - Magnetization dynamics of a single-domain magnet under a spin-polarized current with a tilted polarization

Z. Sun [1], T. Wang[1], Z. Wang[1]

1. Soochow University, Suzhou, Jiangsu, China

Magnetization dynamics for a single-domain magnet under a spin-polarized current with any tilted polarization was investigated by solving the Landau-Lifshitz-Gilbert-Slonczewski equation. Taking into consideration the uniaxial magnetic anisotropy, the stationary-state solutions of the magnetization vectors can be analytically obtained by solving an algebraic cubic equation. It was found that one to three pairs of magnetization equilibrium states existed, depending on the current intensity and the direction of the spin polarization. The critical switching current threshold and reversal time for the magnetization reversal was also numerically found under different current polarization configurations with or without considering the spin polarized g-function. The work may be useful for designing in future spin transfer torque devices.

Mo.F-P03 - Temperature dependence of four terminal nonlocal spin signals with $Co_2FeAl_{0.5}Si_{0.5}$/n-GaAs Shottoky tunnel junctions

N. Tezuka [1], T. Saito [1], M. Matsuura [1], S, Sugimoto [1]

1. Department of Materials Science, Graduate School of Engineering, Tohoku University, Sendai, Japan

Semiconductor spintronics devices such as spin FETs and spin valve transistors have received much attention. In such applications, polarized spin electrons from ferromagnets must be injected into semiconductors at higher efficiency. Several groups have reported that spin injection/detection and spin transport in semiconductor, and have focused on using insulating barrier such as Al-oxide and MgO with a 3d transition ferromagnetic electrodes as spin injector/detector. We have reported spin signal for $Co_2FeAl_{0.5}Si_{0.5}$/n-GaAs junctions with Schottky tunnel barrier.[1)] In this presentation, we will show temperature dependence of four terminal nonlocal spin signals with $Co_2FeAl_{0.5}Si_{0.5}$/n-GaAs Schottoky tunnel junctions. $Co_2FeAl_{0.5}Si_{0.5}$(CFAS) Heusler alloy has high spin polarization which was estimated by tunnel magnetoresistance (TMR) effect.

Samples of n-GaAs 520 nm/n+GaAs 20nm/CFAS 10nm were deposited by molecular beam epitaxy on insulating GaAs substrates. CFAS were deposited with substrate temperature (T_{CFAS}) from room temperature to 400ºC. Lateral spin transport devices for four terminal measurement were fabricated using conventional electron beam lithography and Ar ion milling. The planar dimension of spin injector and detector were 1×20 μm^2 and 2.5×20 μm^2, respectively, and the distance between them was 2.25 µm.

Magnetoresistance curves were obtained measured temperature from 10 K to 290K. It is clearly shown the voltage change ($\Delta V_{nonlocal}$) corresponding to magnetization switching of both CFAS electrodes. The spin signal of $\Delta V_{nonlocal}$ decreased with increasing measurement temperature. This temperature dependency might follow the spin diffusion length and conductance change in semiconductor channel. That means the spin injection/detection efficiency slightly changed, which is consistent with the result of temperature dependence of spin polarization of CFAS measured by a TMR effect. We will also show the temperature dependence of spin signal for the junctions with various distance between two CFAS electrodes, and will discuss the spin transport properties.

This work was partly supported by Grant-in-Aid for Scientific Research, and Strategic Japanese-German Joint Research Program “ASPIMATT” from JST.

The synchronization of multiple nano-contact spin torque oscillators (NC-STOs) [1-3] is mediated by propagating spin waves (SWs) [4]. Additionally, it has been shown that the Oersted field generated in the vicinity of the NC can dramatically alter the emission pattern of SWs [5, 6], leading to highly anisotropic SW beams. In this work, we demonstrate that the Oersted field landscape of two nominally identical NCs, defined on top of an all metallic Co/Cu/NiFe pseudo-spin valve, can be dramatically different based on the geometry of the NCs. Synchronization is promoted (impeded) by the Oersted field landscape when the NCs are oriented vertically (horizontally) with respect to the in-plane magnetic field component. Additionally, the vertical positioning of the NCs gives rise to a unique Oersted field landscape that acts to localize, or trap, spin waves in a region just outside one of the NCs, as confirmed by micromagnetic simulations. Furthermore, it has been shown that in the vertical geometry, the frequency of the synchronized mode is driven by the frequency of the lower NC. This is made most evident in arrays where the NC diameters differ. Together, these phenomena establish a new kind of synchronization behavior. This work was supported by the European Commission FP7-ICT-2001-contract No 317950 “MOSAIC”,VR, SSF, and the Knut and Alice Wallenberg Foundation.

Mo.F-P05 - Reducing the switching current with a Gilbert damping constant in a nanomagnet with perpendicular anisotropy

Keisuke mada[1], K. Oomaru[1], S. Nakamura[1], T. Sato[1], Y. Nakatani[1]

1. University of Electro-Communications, Chofu, Tokyo

Magnetoresistive random access memory using Spin torque switching (Spin-RAM) is one of the candidates as the next generation of non-volatile memory [1-5]. To realize high-density Spin-RAMs, it is required to be a low switching current (I_{sw}). In order to reduce I_{sw}, one possibility is to use the perpendicular magnetization with small damping constant (α) value and/or with small saturation magnetization (M_s), because it is expected that I_{sw} is proportional to $\alpha \cdot M_s \cdot H_k$ [1,4], where H_k is the perpendicular magnetic anisotropy. In this work, we simulated spin-current-induced magnetization switching in a perpendicularly magnetized nanomagnet using the macrospin model, which is the simplest model available that is comparable with the analytical model. We investigated the effect of α on I_{sw} with varying t_p, M_s and magnetocrystalline anisotropy K_u ($K_u \propto H_k$).

The material parameters used for the simulation were similar to those of CoFeB. The parameters used in the simulation are M_s=600 emu/cm^3, K_u=1.76×10^6 erg/cm^3, spin polarization P=1.0, free layer volume V=11.2^3 nm^3, initial magnetization angle ϑ_0=0.129 rad and criteria angle ϑ'=p-0.129 rad. The results show that reduction of α below a certain threshold (α_c) is ineffective in reducing I_{sw} for short t_p. When t_p is short, it is necessary to reduce both α and M_s simultaneously until α_c is reached to reduce I_{sw}. The results presented here offer a promising route for the design of ultrafast information storage and logic devices using current-induced magnetization switching [6].

Mo.F-P06 - Point-Contact Spin Torque Oscillator with Highly Spin-Polarized Co_2(Fe, Mn)Si

T. Yamamoto[1], T. Seki [2], T. Kubota[1], H. Yako[1], K. Takanashi[1]

1. IMR, Tohoku Univ., Sendai, Japan
2. JST-PRESTO, Tokyo, Japan

Since the discovery of spin torque oscillation in a current-perpendicular-to-plane (CPP)-giant magnetoresistance (GMR) device, several types of spin torque oscillators (STOs) have been developed to achieve a large rf output power (P_{rf}) and a narrow spectral linewidth (Δf). Point-contact STOs have an advantage in narrow Δf, and rf oscillation has often been achieved at zero magnetic field. Generally, however, they show a smaller P_{rf} than those of CPP-GMR STOs. One promising material for high-P_{rf} STO is highly spin-polarized Co_2(Fe, Mn)Si (CFMS). Our group demonstrated a large P_{rf} in a CPP-GMR STO, and a micromagnetic simulation suggested the further enhancement of P_{rf} by improving the uniformity of the effective magnetic field in the CFMS layer. In this study, we fabricated point-contact STOs with CFMS, and investigated their oscillation characteristics.

CFMS (20) / Ag (5) / CFMS (5) (in nanometer) layered structures were prepared by an ultrahigh-vacuum magnetron sputtering system. The top CFMS layer was patterned into a mesa with an area of 20 × 40 μm^2, and a point-contact with a diameter of normally 140 nm was lithographically fabricated at the center of the CFMS mesa.

Fabricated STOs showed rf oscillations around 0.9 GHz with a narrow Δf of 3 MHz without external magnetic field. The low oscillation frequency is attributable to the gyration mode of magnetic vortex-like structure created in the CFMS layer, and the oscillation mode was changed by changing the applied current (I_{dc}). At I_{dc} = 7.3 mA, a large P_{rf} of 25.7 nW was obtained, which is the largest P_{rf} ever reported in all-metal STOs. The large P_{rf} and the narrow Δf are attributed to the high spin-polarization of CFMS and the advantage of point-contact geometry.

Mo.F-P07 - Magnetic phase transition and colossal magnetoresistive effect in Sm0.55Sr0.45-xAgxMnO3 (0 ≤ x ≤ 0.10) system

In the present noval work, we have investigated the Structural, transport, magneto-transport and magnetization properties on single phase polycrystalline samples of silver doped disordered Sm0.55Sr0.45MnO3 prepared via solid state reaction technology route. Rietveld refined x-ray diffraction results indicates an increase in lattice parameters and unit cell volume with Ag doping. The magnetization results show the presence of a first order paramagnetic to ferromagnetic transition; the transition temperature and amount of thermal hysteresis decreases on Ag doping. The transport, and magneto-transport results indicates decrease in metal to insulator transition, drastic increase in resistance and temperature coefficient of resistance (TCR %) with nearly unaffected colossal magnetoresistance effect. All these results indicate that at least a part of silver is incorporated in the lattice. SEM micrographs indicate that silver has also increased the grain growth sharpness and thus decrease the effect of grain boundary scattering. The significant value of TCR of ~43% of our samples indicates their applied nature for bolometric application. Keywords: Rietveld refinement, Metal - Insulator Transition Temperaure, Temperature Coefficient of Resistance, First Order Magnetism.

Mo.F-P08 - Spin torque ferromagnetic resonance in a nano-contact geometry

M. Fazlali[1], P. Dürrenfeld[1], E. Iacocca [1,2] N, M. Dvornik[1], M. Haidar[1], M. Ranjbar[1], J. Åkerman[1,2,3], R. Dumas[1,2]

Spin torque ferromagnetic resonance (ST-FMR) [1-4] is a widely used technique to probe the magnetodynamic response of individual sub-100 nm scale magnets. We present a quantitative experimental ST-FMR study of nanocontact spin toque oscillators (NC-STOs) over a wide range of frequencies, RF powers, and magnetic field angles. The material stack used is a fully metallic NiFe (free layer)/Cu (spacer)/Co (fixed layer) pseudo spin valve with a nominal NC diameter of 100 nm. The FMR resonances of both the Co and NiFe layers are observed and are well fit by the Kittel equation at all applied field angles. However, in contrast to conventional broadband FMR measurements on blanket films, our ST-FMR measurements reveal significantly more complex spectra consistent with not only the excitation of a uniform FMR mode, but additional higher order spin waves. Micromagnetic simulations highlight the importance role of not only ST, but also the RF current induced Oersted field in the vicinity of the NC, in generating the observed spectra.

We present a theoretical study of spin transfer torque (STT) [1,2] and tunnelling magnetoresistance (TMR) in antiferromagnets (AF) and ferrimagnet (FI) based tunnel junctions, where two magnetic metal electrodes, with at least one of them being FI or AF, are separated by a thin nonmagnetic insulating barrier. We found that electronic structure parameters such as the Fermi energy, band widths and the exchange splitting of the FI and AF electrodes strongly influence the STT and TMR properties including their bias dependence [3,4]. In particular, the STT spatial distribution within the leads shows nontrivial behavior, which can be explained in terms of interplay between exchange splittings of the two AF or FI sublattices. For example, for FI leads and due to their FI order, peculiar spin-modulated torque waves are observed. In addition, we identified the fundamental parameter for quantifying STT characteristic lengths in FI metals, which are also accessible to experiments for example by ferromagnetic resonance and spin pumping like in [5,6]. Such insights will be of importance for optimizing current induced magnetization reversal phenomena.

Mo.F-P10 - Effectiveness of negative index of surface anisotropy

C. Mitsumata[1], M. Mizuguchi[2]

1. National Institute For Materials Science, Tsukuba, Japan
2. Tohoku University, Sendai, Japan

In recent years, the control of the magnetization reversal by the electric field has become the major stream of spinstronics researches. The high frequency voltage control [1] showed hopeful potential for the low electric power consumption in there. The applied voltage also changed the surface anisotropy of metallic films [2], and it was possible to reduce the coercive force of magnetic films. [3] However, the magnitude change of a surface anisotropy restrictively reduced the coercive force. Contrastingly, the negative index of a surface anisotropy achieved the large reduction of a coercive force [4], even though mono atomic layer only became negative. On these techniques, the influence of the surface anisotropy in the spin torque oscillation (STO) system has been investigated in this paper. In the case of perpendicular magnetization system, it can be calculated that the magnetic torque due to the negative anisotropy enables to reduce the Gilbert damping torque in term of Landu-Lifshitz-Gilbert (LLG) equation. Namely, the gyro-magnetic precession term dominates the motion of spin in LLG equation. Also, in the high frequency voltage control, the increase of energy ratio of gyro-magnetic precession incrementally lowers the electric power consumption. Both reduction of coercive force and Gilbert damping assists to the low energy consumption in STO due to the spin transfer torque. Consequently, the negative index of a surface anisotropy is significantly effective for the continuous gyro magnetic precession in spinstronics devices.

Mo.F-P12 - Spin-torque generated equilibria in spin Hall systems and their role in magnetic switching

S. Yan[1], Ya. B. Bazaliy[1]

1. University of South Carolina, Columbia, United States

In a ferromagnet/heavy-metal bilayer device with strong spin Hall effect an in-plane current excites magnetic dynamics through spin torque. We analyze bilayers with perpendicular magnetization and calculate three-dimensional phase diagrams describing switching by external magnetic field at a fixed current. We then concentrate on the case of a field applied in the plane formed by the film normal and the current direction. Here we analytically study the evolution of both the conventional 'up''/'down'' magnetic equilibria and the additional equilibria created by the spin torque. Expressions for the stability regions of all equilibria are derived, and the nature of switching at each critical boundary is discussed. The qualitative picture obtained this way predicts complex hysteresis patterns that should occur in bilayers. By analyzing the phase portraits of the system we show that when the spin torque induced equilibrium exists, switching between 'up'' and 'down'' states proceeds through it as an intermediate state. Using numeric simulations we analyze the switching time and compare it to that of a conventional spin torque device with collinear magnetizations of the polarizer and the free layer.

Mo.F-P13 - Narrow linewidth spin-torque oscillator driven by localized current in ferromagnetic nano-contacts

M. Al-Mahdawi[1], Y. Toda[1], Y. Shiokawa[1], M. Sahashi[1]

1. Tohoku University, Sendai, Japan

Microwave nano-oscillators/detectors are sought after for applications like inter-/intra-chip comuunication, non-destructive testing, and lab-on-chip sensors. Spin-torque-driven oscillators of a ferromagnet by a spin-polarized current are a candidate for such a role á[1]. However, due to the large frequency non-linearity, oscillation linewidth increases compared to linear auto-oscillatorsá[2]. By device engineering, the non-linearity can be lowered and a smaller linewidth can be obtainedá[3]. Also, the expected presence of pin-holes and localized current in magnetic tunnel junctions was found to produce more coherent oscillations with different dynamics characteristics compared to more uniform junctionsá[4]. By combining both approaches, we were able to reach linewidths down to 2.3 MHz at 23-GHz oscillation frequency. The device stack was based on AlOx Nano-Oxide-Layer (NOL) with ferromagnetic Nano-Contacts (NCs) (thickness in nm): electrode layer/FeCo (5)/AlOx-NOL/FeCo (5)/Capping layerá[5]. The film was fabricated into elliptical pillars with 2-to-1 aspect ratio. Measurement of a 160 nm x 80 nm pillar under conditions of 2.8-mA applied current, and 185-Oe field applied 80deg away from long axis, oscillations were observed having 23-GHz freqeuncy and 2.27-MHz linewidth, resulting in a quality factor of more than 10000. Micromagnetic simulation showed the generation of propagating spin-waves (system's characteristic mode) from NCs. We will discuss the role of excitation from the NCs on the reduced non-linearity and linewidth, and the potential of NC-based spin-torque oscillators.

Mo.F-P14 - Experimental evidence of Rashba spin orbit torque in Py/β-Ta bilayer system

Ni Behera[1], Sujeet Chaudhary[2], Di. K. Pandya [3]

1. Indian Institute of Technology Delhi, Delhi, India

Rashba effect is an important phenomenon for generation of dissipation-less spin currents in ferromagnetic (FM) /paramagnetic (PM) hetero-structures. It is combination of both spin transfer torque (STT) and field like torque which originates from the interfacial spin Hall effect (SHE) phenomena. However at higher charge current the field like torque leads to Oersted field noise along with STT. In order to avoid such a problem we prefer to have dissipation less spin pumping mechanism with suitable choice of material system. So we explore the Py/β-Ta bilayer system in which β -Ta plays an important role for obtaining such a condition. For getting maximum spin pumping effect it is necessary to optimize thickness of β -Ta layer. Thus we report the thickness (t_{Ta}) dependence of ferromagnetic resonance (FMR) linewidth (ΔH) of Py(18 nm) bilayer samples grown on Si(100)/SiO_2 substrates at room temperature by pulsed dc magnetron sputtering. The ΔH is found to vary linearly with frequency for all thicknesses of Ta, indicating the intrinsic origin of damping. The Gilbert's damping constant (α) obtained from linewidth fitting data. The α values of Py/b -Ta bilayers are less than the bare Py layer and remain constant up to 6 nm Ta thickness. We ascribe this behavior to the effect of out of plane anti-damping spin orbit torque (SOT) also known as Rashba torque, which arises from Ta layer, acts on the in-plane magnetization of FM layer. Above the thickness 6 nm of Ta, there is slight increase in α values indicating that the decrease of anti-damping SOT beyond the $2\lambda_{SD}$, λ_{SD} being the spin diffusion length in Ta. We also determine the λ_{SD} and –ve value of interfacial spin mixing conductance ($g^{\uparrow\downarrow}$) from the fittings of the thickness dependent of change in α (Δα). The determined values are about λ_{SD} = 2.64 nm (close to literature reported value 2.74 nm) and $g^{\uparrow\downarrow}$= -1.5×10^{18} m^{-2} respectively.

Mo.F-P15 - Effects of Dzyaloshinskii-Moriya interaction on the spin transfer magnetization switching in magnetic tunnel junctions

Magnetic tunnel junctions (MTJ) are at the center of the magnetic random access memories (MRAM) technology. Nowadays, the research and development efforts are focusing on perpendicularly magnetized layers in the MTJ, taking advantage of the anisotropy provided by spin-orbit coupling at the interfaces with heavy metals such as Pt or Ta [1]. Recently, interfaces between ferromagnetic and heavy metals are also studied in a more fundamental context, because an antisymmetric interaction might appear at interfaces, namely an interfacial Dzyaloshinskii-Moriya interaction (DMI) [2]. We will present a micromagnetic study of the reversal of the free layer magnetization direction by spin transfer torque under different amplitudes of the DMI. In particular, we will evaluate the energy barrier or equivalently the thermal stability and the minimal current density necessary for switching as a function of the DMI amplitude. Our numerical simulations show that the DMI, even with small amplitude, is detrimental for the operation of MRAM devices, and must hence be minimized in the corresponding MTJ structures. The amplitude of the DMI can probably be tuned in some extent by interface engineering using materials with opposite DMI amplitude [3].

Mo.F-P16 - Spin torque oscillator under a quasiperiodic current

D. Laroze[0], A. Cabanas[2], P. Caranivi[2], J. Gallas[3]

1. University of Glasgow, Glasgow, Scotland
2. Universidad de Tarapaca, Arica, Chile
3. Universidade Federal da Paraíba, João Pessoa, Brazil

We study the deterministic spin dynamics of a spin valve oscillator in the presence of a time dependent electric current using the Landau-Lifshitz-Gilbert-Slonzewski equation. In particular, we study the case when the current consists in a constant and a quasiperiodic time dependence term. We numerically characterize the dynamical behavior of the system by monitoring the Lyapunov exponents, and by calculating Poincaremsections and Fourier spectra. In addition, we calculate analytically the corresponding Melnikov function, which gives us the bifurcations of the homoclinic orbits. We find a rather complicated landscape of sometimes closely intermingled chaotic and non-chaotic areas in parameters space. Finally, we show that the system exhibits strange nonchaotic attractors.

Mo.F-P17 - High frequency oscillation above 10GHz in zero applied field with Rh/FeCo perpendicular free layer Spin-Torque-Oscillator

Y. Shiokawa[1], K. Sakamoto[1], M. K.O Al-Mahdawi[1], J. Jung[1], M. Sahashi[1]

1. Department of Electronic Engineering, Tohoku University, Sendai, Japan

In order to realize the applicatiosn using Spin-Torque-Oscillator (STO), as the oscillator for wireless tip-to-tip communication, STO needs a high frequency above 10GHz in zero or low applied field. Some studies have reported the STOs with high frequency and high power realized by Out-of-Plane Precession (OPP) mode [1] [2], however, they must be applied a high perpendicular magnetic field. The Kittel's equation of OPP mode suggests that high frequency STO needs high applied field and/or uniaxial anisotropy field (H_a). In this study, we used the Rh/FeCo with high H_a [3] as free layer and we realized the high frequency oscillation with zero applied field.

We fabricated STO element with Sub./Rh 50/FeCo 2/AlOx NOL/FeCo 2.4/IrMn 7/Capping (nm). NOL (Nano-Oxide-Layer) as spacer layer was thin AlOx oxide layer with many Nano-Contacts (2 nm in diameter). The STO element size was 100 nm in diameter. The orientation of applied magnetic field was perpendicular to film plane.

We obtained the high effective internal field (H_a-$4\pi M_{eff}$) of 4.7 ± 0.5 kOe from R-H curve. It was higher internal field than Pt/Co of 0.7 kOe we fabricated. And the high frequency of 10.2 GHz at zero applied field with 24 mA (3.1×10^8 A/cm^2) was obtained. We analyzed the current dependence of frequency based on auto-oscillation model [4], and we obtained the threshold current I_{th} of 20 mA (2.6×10^8 A/cm^2). According to theory [5], this high I_{th} might be caused by high H_a.

Mo.F-P18 - Spin Hall magnetoresistance in cobalt ferrite thin films with different preferential axes

T. Tainosho[1], S. Sharmin[1], T. Niizeki[2], H. Yanagihara[1], E. Kita[1]

1. Inst. of Appl. Phys., Univ. of Tsukuba, Tsukuba, Japan
2. WPI-AIMR, Tohoku Univ., Sendai, Japan

The recently discovered spin Hall magnetoresistance (SMR) effect is an interesting phenomenon where the dependence of non-magnetic metal resistance on the magnetization of a ferromagnetic insulator may be attributed to the spin-mixing conductance at the interface. In this study, we report SMR at the interface between Pt/$Co_{0.75}Fe_{2.25}O_4$ (CFO) thin films with regards to magnetic anisotropy. Two CFO(001) films were epitaxially grown on MgO and $MgAl_2O_4$ (MAO) by the reactive magnetron sputtering technique. Pt Hall bars were then deposited on the CFO by the DC sputtering technique. Taking into consideration the lattice constants of the different substrates, the CFO(001) films were found to undergo either tensile (on MgO) or compressive (on MAO) stress and exhibit a magnetically preferential axis either out-of-plane (on MgO) or in-plane (on MAO). Moreover, the perpendicular saturation magnetization ($M_{s\perp}$) differs from that of in-plane ($M_{s\parallel}$) due to additional orbital angular momentum of Co^{2+} along [001] direction. From α-scans, i.e., angle dependent MR measurements (ADMR) with the rotation axis normal to the plane, the SMR ratios were found to be 0.074 and 0.073% for the bilayers on MgO and MAO, respectively, while the estimated spin mixing conductance (G_r) was 20.8 and 21.1 $\times 10^{14}$ ($\Omega^{-1}\cdot m^{-2}$), respectively. From β-scan, where the rotation axis along to the current, we obtained almost the same value of Gr for Pt/CFO/MgO as that from the α-scan despite $M_{s\perp}$ differing from $M_{s\parallel}$. Here, we assumed the value of spin Hall angle and spin diffusion length as 0.056 and 3.4 nm, respectively [1]. The G_r values are an order of magnitude larger than reported previously. We conclude that magnetic anisotropy or the existence of orbital moment does not have a significant effect on the SMR phenomenon. [1] Phys. Rev. Lett. 112, 106602 (2014)

Mo.F-P19 - Time-domain study of injection locked signal from a magnetic tunnel junction based spin torque oscillators

R. Sharma[1], P. Dürrenfeld[2], J. Åkerman [2,3], P.K Muduli[1,3]

1. Department of Physics, Indian Institute of Technology, Hauz Khas, New Delhi, India
2. Department of Physics, University of Gothenburg,, Gothenburg, Sweden
3. Materials Physics, School of ICT, KTH-Royal Institute of Technology, Kista, Sweden

Spin torque nano-oscillators (STNOs) are nano-sized microwave devices where signals in the GHz range can be generated by steady magnetization precession of the free layer.[1-2] STNOs are promising for wireless communication.[3] However, practical applications of these devices are yet to be realized due to their large linewidth and low output power. A solution for these limitations is injection locking or parametric excitation.[4-5] It produces a drastic reduction in linewidth and significant increase in power. Here, we report on a time domain study of injection locked STNO signals. The device under study shows a strong single mode at a frequency of 3.75 GHz at the field of 250 Oe near the threshold current of 6 mA and φ =196^0, where φ is the angle between the free and the reference layer .An external signal of power 0 dBm is applied over the frequency range of f_{ext} = 7-8 GHz. A strong enhancement of the signal near twice of the frequency of the STNO (*i.e.*, f_{ext} = 7.5 ± 0.10 GHz) is observed .The linewidth is found to significantly decrease from 115 to 13 MHz while the peak power shows an increase from 740 nV^2/Hz to 3750 nV^2/Hz. The frequency noise analysis of the locked signals shows a reduction of both white noise as well as 1/*f* noise observed in these devices.[6] However, the instantaneous frequency calculated for 50 ns segments shows that the locking phenomenon is not perfect and the instantaneous frequency is within the locking range of (f_{ext}/2 ± 0.04*)* GHz for 60 % of time.

Mo.F-P20 - Spin wave eigenmodes excited by spin transfer torque in circular nanopillars: influence of lateral size and Oersted field studied by micromagnetic simulations

M. Pauselli[1,2], G. Carlotti[1]

1. Dipartimento Di Fisica E Geologia UniversitÓ Degli Studi Di Perugia, Perugia, Italy
2. Istituto officina dei Materiali del Consiglio Nazionale delle Ricerche (IOM-CNR), Sede di Perugia, c/o Dipartimento di Fisica, Perugia, Italy

It is well known that a spin-polarized current can excite persistent dynamics in nano-pillars once it overcomes a critical threshold, thanks to the energy balance between the Spin Transfer Torque (STT) and intrinsic damping. Under the application of a sufficiently strong external field, the precession occurs around the local energy minimum defined by the magnetic field direction. In this paper we present the results of a micromagnetic study of the low-amplitude, linear, eigenmodes excited by STT in circular Permalloy nanopillars, 5 nm thick, having a diameter of either 100 nm or 300 nm. Both in-plane and out-of-plane externally applied fields are considered, with emphasis given to the effect of the Oersted field (OeF) on the frequency and spatial symmetry of the excitations. In the case of an in-plane applied field, the main excited mode is localized at the dot edges, where it oscillates out-of-phase (in-phase) if the OeF is considered (neglected). The out-of-phase mode is at slightly larger frequency than the in-phase one, due to the exchange energy contribution. For the out-of-plane case, instead, the main mode excited taking into account the OeF is an orthoradial mode with zero amplitude in the center of the dot. This is completely different from the fundamental mode with maximum amplitude in the dot center that the current would excite, at lower frequency, neglecting the presence of the OeF. Therefore, it turns out that inclusion of the OeF has a major impact on the output of simulations, because it modifies the symmetry of the excitation and the specific subset of eigenmodes activated by the injected current. This findings make it clear that simplistic models where the OeF contribution is ignored are not suitable to reproduce the main features of the low-amplitude eigenmodes and this is relevant in view of a detailed understanding of experiments.

Mo.F-P21 - Shape anisotropy dependence for Large Power Coherent Microwave MgO/CoFeB based Spin Transfer Nano-oscillators close to the in-plane/out -of-plane anisotropy transition

M. Tarequzzaman[1], Santiago Serrano-Guisan[1], J. D. Costa[1], Borme[1], Elvira Paz[1], R. Ferreira[1], P. Freitas[1]

1. INL - International Iberian Nanotechnology Laboratory, Braga, Portugal

Spin transfer nano-oscillators (STNOs) rely on the transfer of spin angular momentum from a spin-polarized current to a ferromagnet enabling to induce magnetic excitations like coherent magnetization precession. In order to implement such a technology several requirements like high emitted power (P_{out} ~ 1μW), narrow spectral linewidth (L < 1 MHz), high frequency operation (above GHz) and large tuneability are required. Very recently large power coherent microwave emission up to 300 nW and L ~ 40 MHz were observed in such MgO based magnetic tunnel junction (MTJ) nanopillar structures under out-of-plane magnetic fields [1, 2]. However, the operation frequency was still below the GHz regime.
Here we present spin transfer torque (STT) induced magnetization dynamic measurements in CoFeB/MgO/CoFeB based magnetic tunnel junction (MTJ) nanopillars with RA of ~ 3 Ω-μm^2 and a free layer thickness of 1.4 nm. At such conditions, the free layer magnetization is still in plane, but very close to the transition at which the interfacial perpendicular magnetic anisotropy becomes dominant, driving the magnetization out-of-plane. This delicate equilibrium allows the free layer magnetization to move easily under the influence of a spin polarized current resulting in large emitted power. At the same time, the free layer still experiences an effective field which is strong enough to result in oscillations above 2GHz. Large emitted power up to 300 nW with narrow linewidths up to L~ 30 MHz and operation frequency between 2.4 – 2.8 GHz is observed in such structures, showing a tuneability of 300 MHz/mA for current controlled coherent microwave emission larger than 30 nW. Shape anisotropy also plays a crucial role and different MTJ nanopillars shapes (circular, elliptical) and dimensions were characterized.

Mo.F-P22 - Experiment on spin current assisted magnetization reversal using spin pumping effect.

M. Takahashi[1], Y. Nozaki[1]

1. Keio University, Tokyo, Japan

In ferromagnetic / nonmagnetic bilayers, a spin current can be produced by spin pumping effect which is owing to the transfer of spin angular momentum from the magnetization precession in the ferromagnetic layer. The spin current generated by spin pumping effect is generally measured using spin Hall effect. In this study, we tried to alternatively measure the spin current from the change in a coercive field of spin-valve (SV) films. If the spin current generated in one of the ferromagnetic layer is absorbed in another one, the coercive field will change due to the spin transfer torque (STT) from the spin current.
SV consisting of NiFe100 nm/Cu10 nm/NiFe10 nm was shaped into a rectangle with lateral size of $1\times100\ \mu m^2$ using a conventional liftoff process. Underneath the SV, 4-μm-wide coplanar strip line was fabricated to apply microwave fields to the SV. From the giant-magnetoresistance measurement, the coercive fields of 10- and 100-nm-thick NiFe layers were found to be 62.4 and 91.4 Oe, respectively. By means of network analyzer ferromagnetic resonance (FMR) spectroscopy, we also measured FMR frequencies of the 10- and 100-nm-thick NiFe layers at remanent state (3.5 and 6 GHz, respectively). The dependence of coercive field in 10-nm-thick NiFe layer on the frequency of microwave field was measured. In the frequency range from 2 to 4 GHz, a decrease in coercive field caused by a microwave-assisted magnetization reversal was clearly observed. Further increase in the frequency up to 7 GHz causes an additional reduction in coercive field. This is attributed to the STT caused by the spin current from the harder NiFe layer in which FMR is excited by the microwave field. In the SV with parallel alignment of magnetization, spin current opposed to the magnetization that leads to the decrease in coercive field is considered to be generated.

Mo.F-P23 - Spin-Torque Oscillators: Energy Space Dynamics

Da. Pinn[1], D. Stei[2,3], A. Kent[3]

The excitation of large-angle steady-state out-of-plane (OOP) magnetization precession in spin valves and magnetic tunnel junctions using a spin-polarized dc current has recently attracted much interest due to its technological implications for the development of robust wide-band tunable RF oscillators. In this presentation, the dynamics of a macrospin subject to both in-plane (IP) and out-of-plane spin-torques is explored analytically by constructing an effective energy-space evolution equation. We find that the magnetic free layer can be thought as being torqued by a spin-current polarized along an axis that is tilted with respect to the IP direction. Our theory predicts a surprisingly simple relationship among material parameters capable of discriminating between switching and IP/OOP oscillatory behavior. We conclude by emphasizing the importance of including an additional angular dependence to the torque on top of the usual phenomenological sinusoidal dependence. Our results agree with recent experiments involving in-plane magnetized spin-valve devices that incorporate both an OOP magnetized spin polarizing layer and an IP magnetized reference layer.

Mo.F-P24 - NON-LINEAR MODE INTERACTION BETWEEN SPIN TORQUE DRIVEN AND DAMPED MODES IN SPINTORQUE NANO-OSCILLATORS

Spin torque nano-oscillators (STNOs) have attracted much interest in recent years due to their potential use as a new type of nanoscale microwave generator or microwave detector. A standard STNO configuration contains an in-plane magnetized synthetic antiferromagnet (SyF) as a polarizer and an in-plane magnetized free layer. Most experimental observations on the excitations of such STNOs have been analyzed theoretically or numerically in the frame of a single layer model, where the free layer is considered independent with respect to the SyF whose magnetization is supposed to be fixed. However, experiments on spin valve nanopillars reveal non-continuous features such as kinks in the frequency-field dependence that cannot be explained within in an independent free layer picture. Numerical macrospin simulations show that such kinks are due to a non-linear interaction between the spin torque driven mode and a damped mode. This interaction arises from the dipolar coupling between the free layer and the SyF and is mediated via the third harmonics of the STT driven mode. The kinks only occur at large applied currents and thus at large excitation amplitudes of the STT driven mode. Under these conditions, a new hybridized mode appears, characterized by a strong reduction of the linewidth. The reduced linewidth can be explained by a reduction of the non-linear contribution to the linewidth via an enhanced effective damping. Interestingly the effect depends also on the exchange interaction within the SyF. Upon reducing the exchange interaction strength by 30%, the current range of reduced linewidth is enhanced by a factor of two and the minimum linewidth is reduced by a factor of two. These results open strategies to optimize the design of STNOs in order to take advantage of the coupling mechanisms to improve microwave performances.

Mo.F-P25 - High frequency characterization of nanocontact spin torque oscillators with respect to altitude and azimuth angles of applied field

5. NanOsc AB, Kista, Sweden

The Nano-Contact Spin Torque Oscillator (NC-STO) is a nano-scale electrical device with the capability of generating microwave signals over a wide range of GHz frequencies and with a wide, and rapid, current and field tunability [J. C. Slonczewski, J. Magn. Magn. Mater. 159, L1 (1996)]. NC-STOs are based on the phenomenon of spin momentum transfer and exhibit a very rich magnetodynamics dependent on device geometry, material properties, and experimental conditions. [F. J. Albert, et al., Phys. Rev. Lett. 89, 226802 (2002)]. In addition, to reach admirable spin transfer torque, it is consequential to investigate STO behavior in different conditions.
We have experimentally studied variation in spin-torque-driven oscillations of NiFe free-layer of NC-STOs as a function of field direction. We measured the oscillation behavior of identically fabricated circular NC-STOs with 2 degrees of freedom for applied field angles. The samples in this study are single NC-STOs with these layer structures: Pd8-Cu50-Co8-Cu7-NiFe4.5-Cu3-Pd3, and nominal NC diameter: 100 nm. Based on high capability and accuracy of our measurement set-up, we applied fixed magnetic field of 0.95 Tesla and dc current of 20 mA to our samples, then we characterized our NC-STOs with full altitude angle Θ scan from 0 to 360 degrees for 3 different azimuth angles of ϕ= -15, 0 and 15 degrees.
Our results show totally inconsistent output with the geometrical symmetry of the device for different group of 12 symmetrically identical angles of the applied field (For example, 4 symmetric altitude angles Θ = 70, 110, 250 and 290 degrees with 3 different azimuthal angels of ϕ= -15, 0 and 15). The frequency of oscillation, microwave power and linewidth vary with field direction and polarity by hundreds of MHz, numbers of pW/GHz and hundreds of MHz, respectively. These results suggest some form of inhomogeneity in material and domain structures and also broken symmetry in geometry which cause a strong Θ and ϕ dependence of the oscillation behavior. From the point of view of potential reasons of the anisotropic frequency variations in these oscillators lead to obtain a deeper understanding and optimization of film growth and fabrication process.

Mo.F-P26 - Analytical model of a synthetic ferrimagnet spin torque oscillator: comparison of the self-polarized with the external polarizer case

B. Lacoste[1], M. Romera[2,3,4], U. Ebels[2,3,4], L. Prejbeanu-Buda[0]

3. CEA, INAC-SPINTEC, Grenoble, France
4. CNRS, SPINTEC, Grenoble, France

Spin-Torque Oscillators (STOs) are promising candidates for nanoscale radiofrequency devices. The most accepted theoretical model to describe the self-sustained oscillations of the magnetization in a STO, called here KTS model [1,2], describes well the dynamics of a single-layer (SL) free layer. We propose an extension of this model to two coupled layers. In real devices, coupling between the layers affects the magnetization dynamics, for example the coupling of the free layer with the reference layer via dipolar coupling [3]. Moreover, spin-transfer torque (STT) driven self-sustained oscillations can also be induced in a synthetic ferrimagnetic (SyF) that consists of two layers coupled via RKKY interaction and mutual STT. This can be achieved either by an external fixed polarizer [3,4] or in a self-polarized manner [5]. To describe such STT driven SyF excitations, the two coupled Landau-Lifschitz-Gilbert-Slonzcewski equations (one for each layer) are transformed to coupled complex equations. Assuming that the energy is almost constant along the STT-driven trajectories, the two equations are expressed in the coordinates of the linear (acoustic and optic) eigenmodes of the SyF. The final equations can be decomposed into conservative terms, describing the phase evolution, and dissipative terms, describing the amplitude evolution. The two equations are coupled to each other via the non-linear terms. The analytical results are validated by numerical simulations and only the important terms, mainly the diagonal terms, are kept. A major result is that the transition from the red-shift to blue-shift in the frequency-current dependence in a SyF with external polarizer can be explained by a vanishing of the non-linear coefficient. This is associated with a decrease in linewidth, interesting for applications. In the self-polarized SyF, the excited mode is optical-like, and the red-shift to blue-shift transition is found to be more complicated and to involve mode-mixing terms.

Mo.F-P28 - Mechanical analogy for spin currents and torques in diffusive systems

Y. B. Bazaliy[1]

1. University of South Carolina, Columbia, United States

We map the problem of spin-transfer torques in nanostructures with diffusive spin currents on a mechanical problem involving elastic strings connecting points of attachment that slide along the fixed straight rails. The obtained mechanical analogy provides a qualitative understanding of the effects of spin relaxation on spin torques and of the phenomenon of sign-changing angular dependence [1-3] of the spin torque efficiency factor g(theta).

Nanosized magnetic films contain an outstanding rich physics, technological applications and more potential for novel scientific purposes. Thus researchers put lots of effort for understanding the nature of these films and constructing functional nano-scale materials. Spin wave phenomena is one of the attractive topic due to improve in magnetic recording and giving opportunity for investigating the dynamics of magnetic parameters. In this study behavior of spin waves was investigated in patterned Á-metal thin film both theoretically and experimentally. The Á-metal (111) thinfilms with 7 Ám thickness were grown by thermal evaporation technique. Crystal structure and temperature dependence of static magnetic properties of the thinfilm were determined by XRD and VSM measurements. There was a small signal from (200) plane excepting (111) plane. Saturation magnetization and coercive field values of sample obtained from vibrating sample magnetometer are around 500 emu/cm3 and 10 Oe respectively. Dynamic and spin wave properties were investigated by FMR measurements for both continuous thinfilms and patterned structures. The patterns were square shaped, however size of squares were changed between 40-80 Ám. Main mode and magnetostatic spin wave modes in patterned Á-metal thin films were observed. Theoretical model and computer program were developed for evaluation of the FMR spectra. Different dimensioned squares showed different spin wave modes and magnetic parameters.

Mo.G-P04 - Structural control of standing spin wave properties in exchange-coupled multilayer strips.

X. Ya [1], k. Imamura [1], t. Tanaka [1], K. Matsuyama [1]

1. ISEE Kyushu University Japan, Fukuoka, Japan

Geometrically confined standing spin wave (SSW) has attracting intense research interests for practical application to power efficient SW based devices. The interlayer exchange coupling is promising to tune the magnetic properties for SW devices operated in a broad frequency range. In the present study, dynamics of the SSW in exchange-coupled multilayer strips with various layer structures has been systematically investigated by micromagnetic simulations. A multilayer strip (1 um width) and overlaid conductors (100 nm width) along the long axis of the strip were supposed as a model structure for the SSW excitation and its inductive detection. The following material parameter set were assumed for the soft (s) and hard (h) layers; perpendicular anisotropy Hk=13 kOe (s), 14~23 kOe (h),amping constant a = 0.01(s,h), Ms = 1000 emu/cc (s,h). The SSWs of magnetostatic forward volume wave mode with the wave vector along the strip width direction were generated with conductor fields.Systematic simulations were carried out for strips with various total thicknesses tt, the layer thickness ratio th/tt(th, hard layer thickness), and the repetition number of unit structure N (ex. N=2, [s/h/s/h]).

Simulation results reveal that the SSW resonance frequency fres can be continuously tuned from 4 GHz (th/tt = 0, tt=30 nm) to 23 GHz (th/tt = 1). The fres linearly increases with the increase of th/tt for N=3, while the dependence becomes nonlinear for N=1, 2. The nonlinear dependence can be associated with non uniform magnetization precession along the film thickness direction in the relatively thick unit layer (N=1, 2). The coherent precession in the sublayers was found to be failed at the weak interlayer exchange coupling smaller than a threshold value, where the magnetization dynamics of each layer obey the individual shape and crystalline anisotropy.

Mo.G-P05 - Spin-wave frequency non-reciprocity in permalloy thin films

O. Gladii [1], M. Haidar[1,2], Henry1, M. Kostylev[3], M. Bailleul[1]

Propagating spin-waves can now be used as a powerful spectroscopic probe of magnetic interactions in ferromagnetic thin films. They have been used to measure the adiabatic and non-adiabatic spin-transfer torques, and very recently the Dzyaloshinskii-Moriya interaction. For such studies, it is essential to measure and interpret the frequency non-reciprocity, i.e. changes of frequency occurring when the spin-wave propagation direction is reversed. Since the early days of spin wave studies, frequency non-reciprocity is known to occur naturally in the so-called Magnetostatic Surface Wave configuration (when the magnetization direction and spin-wave wave-vector lie in the film plane and perpendicular to each other), as soon as the top-bottom symmetry of the magnetic film is broken. This had been observed in thick yttrium iron garnet films. In this work, we revisit this problem both experimentally and theoretically in the technologically more relevant case of thin ferromagnetic metal films. Propagating spin-wave spectroscopy measurements were performed for a set of permalloy films with different thicknesses (t=6-40 nm) and at different wave vectors (k=1.55-7.8 rad/Ám). The frequency non-reciprocity is seen to depend strongly on film thickness and wave-vector, with values ranging from 2 to 50 MHz. This behaviour was reproduced using both micromagnetic simulations and an approximate analytical model based on the Kalinikos-Slavin theory of dipole-exchange spin-wave. We found that the measured values could be correctly accounted for assuming the top and bottom film surfaces have different surface anisotropies with a difference of 0.19 mJ/m^2. This work shows that propagating spin wave measurements give access to ferromagnetic film asymmetries with high accuracy, which opens new perspectives for advanced magnetic characterization.

Mo.G-P06 - Spin waves in planar quasicrystals of Penrose tiling

The investigated two-dimensional (2D) magnonic structures are the counterparts of the photonic quasicrystals [1] forming Penrose lattice. The considered magnonic systems possess however much richer physics due to magnetization pattern and inhomogeneous internal magnetic field influenced wave dynamics, additionally to the material structure which is common with photonic quasicrystals. Therefore, the studies of magnonic systems are challenging. We studied planar 2D quasicrystal in the form of thin slab composed of ferromagnetic inclusions (Co) embedded in ferromagnetic matrix (Py). The inclusions have a cylindrical shape and are located in the nodes of the Penrose lattice. We applied strong external magnetic field to saturate the system along specific in plane directions. The calculations were performed using plane wave method. We defined the supercell [2] which is a small fragment of the Penrose lattice. The periodic repetition of the supercell allows to cover the whole 2D plane without gaps and use the plane wave method. By extension of the size of the supercell we were able to approach the limit of quasiperiodic structure. We calculated the frequency spectra (density of states) of spin waves and the spatial profiles of dynamical components of the magnetization in dependence on direction of the magnetic field. We also traced the impact of the geometrical factors (filling fraction of inclusions, thickness of the structure) on the spectrum of spin waves.

Mo.G-P07 - Spin wave propagation in Permalloy films under tangentially magnetic fields with an arbitrary direction

M. Nakayama[1], M. Tashima[1], S. Kasai[2], S. Mitani[2], T. Manago[1]

1. Fukuoka University, Fukuoka, Japan
2. National Institute for Materials Science, Tsukuba, Japan

Spin wave propagation in ferromagnetic metals has attracted attention for novel spintronic devices such as signal transfer and signal processing.1-2) Spin wave propagation in ferromagnetic film has been investigated mainly on magnetostatic surface wave (MSSW), and there is a few papers for magnetostatic backward volume wave (MSBVW) and magnetostatic forward volume wave (MSFVW). These depend on the relationship between the magnetic field direction and propagation direction of spin waves. In order to design spin wave devices, the degree of freedom of a field direction is useful. In this paper, we investigated spin wave propagation in Permalloy (Py) films under tangentially fields with an arbitrary direction. The variations from MSSW to MSBVW are discussed. Py films with a thickness of 300 nm was prepared on a Si/SiO2 substrate. After isolating with SiO2 film, a pair of anntenas for excitation and detection was formed. The ditance between antennas were 5, 10, 20 um. Spin wave transmission measurements were performed by a microprobe station with a electromagnet for applying in-plane magnetic field and a vector network analyzer. We defined the field angles to the antenna direction; üE = 0 deg for the MSSW configuration, and üE = 90 deg for the MSBVW configuration. As increasing field angles up to 45 deg, the spin wave resonant frequency decreased with almost same spectra shape. At more than 60 deg, the shapes have different characteristics. The signal intensity decreased with increasing the angle. The intensity becomes about half at 45 deg, and about 1/20~1/30 at 90 deg. We observed the MSBVW characteristics only in shortest antenna distance of 5 um, which is reasonable because the attenuation length of MSBVW is very short. Thus, we successfully observed spin wave propagation from MSSW to MSBVW configurations.

Mo.G-P08 - High group velocity and large attenuation length of spin-waves in thick permalloy films

M. Ota[1], K. Yamanoi[2], S. Kasai[3], S. Mitani[3], T. Manago[1]

1. Fukuoka University, Fukuoka, Japan
2. Kyushu University, Fukuoka, Japan
3. National Institute for Materials Science, Tsukuba, Japan

Spin waves have attracted much attention as a new transfer tool of the spin current. The advantage of the spin wave is its long-range propagation over a 10 um-scale in a ferromagnetic metal such as Permalloy (Py), which is much larger than the spin diffusion length of the charge spin current. Spin wave devices using metal films, such as information transfer and logic operations using interference of spin-waves, expected to be suitable for integration with a Si process. In order to demonstrate these interference experiments, longer propagation length is favorable. In this paper, we investigated Py thickness dependence of the group velocity and attenuation length of spin waves. Py films with a thickness of 25 - 300 nm were prepared on a Si/SiO2 substrate. After isolating with SiO2 film, a pair of coplanar waveguides (CPWs) for excitation and detection antennas was formed, and the distance between two CPWs was varied from 10 - 300 um. Spin-wave (magnetostatic surface spin-wave: MSSW) transmission measurements were performed using a sampling oscilloscope with a time domain reflection/transmission (TDR/TDT) unit. The group velocity of the MSSW increases in almost proportion to the Py thickness. It reaches to 67 um/ns for 300-nm-thick film. The MSSW spectra were clearly observed even in 200 um of the antenna distance, although we previously reported that it was about 40~50 um for Py thickness of 25 nm. However, for over 100 nm in Py thickness, the attenuation length hardly changes despite group velocity is faster. This suggests that damping for spin wave is enhanced in thick Py film. Further investigation is necessary to solve this issue. Thus, high group velocity and long range propagation of MSSW is realized by using thick Py films.

Mo.G-P09 - Graded-index magnonics with local electrical currents

C. Davies[1], V.Kruglyak[1]

1. University of Exeter, Exeter, United Kingdom

It was recently reported [1] that a spin wave multiplexor could be realized using a network of Y-shaped Permalloy waveguides, mounted on a similar network of Y-shaped current-carrying wires. By switching the direction of the current, so that it flows under either arm of the structure, a local bias magnetic field can be introduced. This allows spin waves to be directed through either arm, with the direction toggled by the current. We demonstrate that the concept of graded-index magnonics can be used to explain the results of Vogt et al fully, by mapping the local spin wave group velocity distribution within the structure. First, we use finite element modelling to quantitatively solve Maxwell's equations to calculate the spatially-resolved non-uniform bias field across the network. Then, we use the Object-Orientated Micro-Magnetic Framework (OOMMF) to calculate the static magnetisation and effective field distribution in each simulation cell. We then use the dipole-exchange dispersion relation [2] to calculate the distribution of spin wave group velocity vectors across the Y-shaped structure. This enable us not only to explain the experimental results of Vogt et al but also to predict the optimal multiplexor geometry.

Mo.G-P10 - Spin wave excitations in artificial mutiferroic yttrium iron garnet - zinc oxide layered structures

Y. Khivintsev[1,2], A. Kozhevnikov[1], S. Vysotsky[1,2], V. Sakharov[1], O. Kiryasova[1], A. Veselov[1], Y. Filimonov[1,2]

1. Saratov Branch of Kotelnikov Institute of Radio-engineering and Electronics of Russian Academy of Sciences, Saratov, Russia
2. Chernyshevsky Saratov State University, Saratov, Russia

Combination of piezoelectric and ferromagnetic materials allows to tune magnetic properties through electrical control due to magnetostriction. In this work we experimentally studied spin wave (SW) excitations in such an artificial multiferroic in the form of yttrium iron garnet (YIG) - zinc oxide (ZnO) layered structure. Epitaxial YIG films on gadolinium gallium garnet (GGG) substrates were used in the experiment. ZnO films were grown on top of YIG by magnetron sputtering. Two types of samples were fabricated and tested. The first was coplanar waveguide (CPW) based on ZnO/YIG/GGG (structures #1) and in the second the microantennas for generation and detection of SW were fabricated on top of ZnO/YIG/GGG (structures #2). Also, in the second case YIG film was preliminary patterned in order to form 1D magnonic crystal and reduce YIG thickness between microantennas in order to realize wavelength conversation effect and examine shorter SW. Microwave measurements were done using a vector network analyzer along with a probe station with tangential magnetic bias field. For the structures #1 we observed absorption peak in the transmission characteristic corresponding to the ferromagnetic resonance (FMR). Position of the FMR peak was tunable not only by magnetic field but by voltage applied between the CPW signal line and ground planes as well (about 10 MHz at 1 kV). For the structures #2 we observed SW transmission band with stop bands corresponding to Bragg resonances. In this case voltage applied to electrodes fabricated on the sides of the SW beam for generation of tangential electric field in ZnO film caused oscillating changes in SW transmission characteristic. These changes were more pronounced (up to 7 dB/mm for electric field of 0.7 kV/mm) in the short wave part of the SW transmission band. This work was supported by RFBR (grants # 13-07-00941, 13-07-12421 and 14-07-00896).

Mo.G-P11 - Excitation of the spin wave beams with coplanar waveguide transducer

P. Gruszecki[1], A. E. Serebryannikov[1], W. Smigaj[1], M. Krawczyk[1]

1. Faculty of Physics, Adam Mickiewicz University in Poznañ, Poznañ, Poland

In this paper, we propose a microwave transducer in non-uniform coplanar waveguide (CPW) geometry for excitation of spin wave (SW) beams in thin homogeneous ferromagnetic films. Traditional CPWs consist of three parallel wires made of a good conductor and generate a weak radio-frequency (RF) magnetic field when carrying microwave current. The magnetic field component that oscillates in the plane perpendicular to the CPW axis exerts a torque on the magnetization, which in turn induces coherent magnetization precession around the equilibrium direction. This disturbance can propagate in the form of a SW. The RF magnetic field distribution in the ferromagnetic film plane is inhomogeneous and determines the SW excitation efficiency, its wavelength and direction of propagation. Here, we exploit these properties to show how by varying the profile of the CPW along its axis we can mold the envelope of the generated SW. In particular, this enables excitation of SW beams with a customizable waist width, rather than SWs with a nearly planar front, as in standard CPWs.

We provide a qualitative description of our idea and validate it in numerical simulations. An electromagnetic solver is used to obtain the RF magnetic field generated by a microwave current flowing through the CPW; this field distribution is then input to micromagnetic simulations to find the profile of the excited SW beam. Finally, we propose an extension of the SW beam generator that allows excitation of two (or multiple) beams with a single CPW in the same ferromagnetic film. Other technologically relevant applications are discussed as well.

The research has received funding from Polish National Science Centre project DEC-2-12/07/E/ST3/00538 and from European Union's Horizon 2020 research and innovation programme under the Marie Sklodowska-Curie GA No 644348 (MagIC).

Mo.G-P12 - Microwave radiation from parametrically excited magnons

M. Mino[1], H. Kawahara[1]

1. Okayama University, Okayana, Japan

Einstein condensation of nonequilibrium magnons at room temperature have been reported by many researchers. We study Microwave radiation from parametrically excited magnons in YIG. Measurements were performed with perpendicular and parallel pumping configurations. The radiation spectra are dependence on a pumping power, a shape of a sample and a pumping configuration. As the pumping power is increased, multi-frequency components of microwave radiation are observed simultaneously. For a spherical sample, microwave radiation from some magnetostatic modes, which are coupled on parametrically excited magnons, is observed. For a disk sample, radiation of a double frequency of a bottom mode and a frequency of a uniform mode are observed.

Mo.G-P13 - Stimulated thermalization of a parametrically driven magnon gas as a prerequisite for bose-einstein magnon condensation

D. A. Bozhko[1,2], P. Clausen[1], V. I. Vasyuchka[1], B. Hillebrands[1], G. A. Melkov[3], A. A. Serga[1]

1. Fachbereich Physik and Landesforschungszentrum OPTIMAS, Technische Universitõt Kaiserslautern, Kaiserslautern, Germany
2. Graduate School Materials Science in Mainz, Kaiserslautern, Germany
3. Faculty of Radiophysics, Taras Shevchenko National University of Kyiv, Kyiv, Ukraine

The realization of a Bose-Einstein condensation (BEC) of magnons is one of the great achievements in the area of quasi-particle gases, when the parametrically pumped magnon gas undergoes a phase transition leading to the spontaneous formation of a coherent state at the bottom of a spin-wave spectrum. Since the moment of this discovery, the physics of the parametrically driven magnon gases is under active theoretical and experimental investigation. Here, we report on the experimental insight into the evolution of a magnon gas determined by four-magnon scattering in the presence of the external pumping field. The experiment is performed using an in-plane magnetized single-crystal yttrium-iron-garnet film (YIG). In order to manipulate the magnon gas density, magnons were injected into YIG film using parallel parametric pumping. The temporal evolution of the magnon gas density was detected by the time- and wavevector-resolved Brillouin light scattering spectroscopy. We show that the magnons initially pumped to the transversal branch of the spin-wave spectrum do not scatter directly to the lowest energy states located at the longitudinal branch. Such a scattering is associated with the parametric excitation of the second group of short-wavelength magnons propagating at angles $< 90^\circ$ relative to the magnetization direction. Simultaneously, the initially excited transversal magnon group is suppressed by a mutual action of the second magnon group and the external pumping field. In conclusion, we suggest distinctly different phases of the thermalization process of a parametrically driven magnon gas: First, energy degenerated, parametric magnons are generated, which, secondly, scatter in a multistage magnon transfer process to the bottom of the magnon spectrum. The parametrically stimulated magnon thermalization is assumed as the essential precondition for the formation of the magnon Bose-Einstein condensate.

Mo.G-P14 - Spin-wave modes in magnonic crystal waveguides and inverted waveguides.

M. Mansurova[1], J. Panke[1], M. Münzenberg[2]

1. I. Physikalisches Institut, Georg-August-Universität Göttingen, Göttingen, Germany
2. Institut für Physik, Ernst-Moritz-Arndt-Universität Greifswald, Greifswald, Germany

This work contributes to the understanding of spin waves behavior excited on periodically structured magnetic thin films (magnonic crystals). The examined sample consist of 50 nm CoFeB continuous film, where a square lattice of 1 Ám antidots (3.5 Ám lattice constant) has been produced using Focused Ion Beam (FIB). In addition to a uniform precession mode and perpendicular standing spin wave (PSSW) that are detected on continuous film, a Damon-Eshbach (DE) mode is supported by the magnonic crystal [1]. The excited DE mode wavevector is parallel to the lattice vector of the magnonic crystal, and its frequency is strongly dependent on magnonic crystal┤s lattice constant and its relative orientation to the applied magnetic field. In this work, we determine the spin-wave spectra of two kind of different structures on the magnonic crystal. First, a magnonic waveguide is realized by introducing 3-5 defect lines in the crystal structure. Second, a set of inverted waveguides consisting of n by 40 unit cells, where n=2, 4..,20 was produced. Spin-wave modes have been excited and observed optically by a double-modulated pump-probe technique using a pulsed (40 fs) 800nm laser. Magnetization oscillations are detected using time resolved magneto-optical Kerr effect (TRMOKE) and the fundamental frequencies are determined performing fast Fourier transform of the measured signal. We observe that a Damon-Eshbach mode is supported only on inverted waveguides of more than n=6 rows. On the other hand, this mode can also be detected on defect lines (waveguides) of as large as 5 rows of antidots. This sets a limit on the number of unit cell that are required to produce a collective behaviour of spin waves in a magnonic crystal. Support by DFG MU 1780/ 6-1 Photo-Magnonics project is acknowledged.

By defining a periodic magnetic structure it iss possible to excite magnonic modes other than standard uniform magnetodynamic modes. However, a traditional top-down approach to define structures at length scales <100 nm is often challenging. Here we present a bottom up approach to such magnonic lattices. In order to achieve this we rely on epitaxial thin films of a prototypical perovskite, La0.7Sr0.3MnO3, on top of SrTiO3(001), with an intended structural twinned domain geometry, acting as a periodic perturbation for the magnonic lattice. Variable temperature ferromagnetic resonance spectroscopy provides evidence for additional magnonic modes. We will show that the origin of these modes can be related to a spatial modulation of the Curie temperature induced by the twin domain formation. This yields a temperature dependent magnetic variation in the saturation magnetization that forms the magnonic structure. We will discuss how film thickness and structural domain periodicity affects the excited modes. In particular the temperature dependence of the magnetic structure will be discussed and used in a model description of the system that accounts for the major features of FMR spectra.

Mo.G-P16 - Indirect vs direct magnonic band gap in two types of magnonic crystals: array of metallic stripes and array of grooves in YIG film

The magnonic band gaps in two types of the planar one-dimensional magnonic crystals comprised of the periodic array of the metallic stripes on yttrium iron garnet (YIG) film and YIG film with an array of grooves were analyzed experimentally and theoretically. In such periodic magnetic structures the propagating magnetostatic surface spin waves were excited and detected by microstripe transducers with vector network analyzer and by space resolved Brillouin light scattering spectroscopy. Properties of the magnonic band gaps were explained with the help of the finite element calculations in the frequency domain. The analysis of the imaginary component of the wavenumber of spin waves was found to be useful. The important influence of the nonreciprocal properties of spin wave dispersion induced by metallic stripes on the magnonic band gap width and the band gap width dependence on the external magnetic field has been shown. Indirect band gap and higher group velocity of spin waves in metallic magnonic crystal were identified as main cause of the wider band gap and steeper decrease of its width with increased external magnetic field as compared to the grooved magnonic crystal. The usefulness of both types of the magnonic crystals for potential applications and possibility for miniaturization are critically discussed.

The dynamical property of the spin wave and exploring their precise manipulation techniques have attracted much attention owing to its fast time scale in GHz range and high compatibility with a Si-based semiconductor integrated circuits Especially, understanding the thermal stability and the non-linear response induced by the large amplitude RF magnetic field are indispensable for the practical application. Impedance transmission measurements based on the vector network analyzer is one of the representative method for investigating the spin wave. However, the detectable spin waves are limited by the electrode design because the interlinkage magnetic flux is canceled out. In this paper, we demonstrate a sensitive detection method for the spin wave excited by the patterned electrodes. The standing spin waves for various wavelengths are effectively detected through the anisotropic magnetoresistance. Our device consists of a ferromagnetic film and the ladder-type nonmagnetic Cu electrode, which are electrically separated each other by a SiO2 film. An external magnetic field is applied along the Cu wire direction, and RF current flowing the ladder-type Cu wires generates the standing spin wave, which can be detected by the resistance of the Py film through AMR.
We clearly observed the resonant features consisting of the multiple peaks in the induced voltage.
From the analysis, the resonant magnetic fields are well explained by the ferromagnetic resonance and the standing spin wave with the half wave length given by the fraction of the integer number of the electrode spacing. Nonlinear resonant feature was observed only in the ferromagnetic resonance when the large RF power for the ac current above 15 dBm is applied. The origin for the nonlinear behavior can be understood by the effective demagnetizing field due to the nonuniform precession with large cone angle.

Mo.G-P18 - Evaluation of the thermal spin injection driven by ferromagnetic resonance

K. Yamanoi[1], Y. Yokotani[1], S. Yakata[2], T. Kimura[1]

1. Department of Physics, Kyushu University, Fukuoka, Japan
2. FIT

Thermal spin injection originating from the spin-dependent Seebeck effect is an attractive method for creating spin current without the use of the electricity. Recently, we have found that CoFeAl has a relatively large spin-dependent Seebeck coefficient because of its unique band structure.[1] In this method, producing the temperature gradient, which is the driving force for the thermal spin injection, is a key for the large spin-current generation and the seamless device integration. So far, the temperature gradient is produced by the Joule heating. On the other hand, since the ferromagnetic metal is known to be heated by ferromagnetic resonance (FMR), the thermal spin injection may be driven by the FMR. In addition, this can be another mechanism for the dynamical spin injection a. In the present study, we focus on the thermal spin injection due to FMR heating.
First, we evaluate the temperature increase due to the FMR for several ferromagnetic thin film. The temperature change due to the FMR heating seems to increase with the damping constant of the ferromagnetic metal. Then, the efficiency of the thermal spin injection due to the FMR heating is evaluated by measuring the frequency dispersion of the FMR spectra in ferromagnetic metal/Cu bilayer system. A significant reduction of the frequency dispersion was clearly observed in CoFeAl/Cu system. This result strongly supports the large spin-dependent Seebeck coefficient for CoFeAl.

Mo.G-P19 - Propagation of Volume Mode Spin Waves

L. Van Tilburg[1], F. Buijnsters[1], A. Fasolino[1], M. Katsnelson[1]

1. Radboud University, Nijmegen, Netherlands

Spin waves are collective spin oscillations that play a role in many dynamical processes, and understanding their dynamics may lead to innovative ideas for new applications. In this poster we present preliminary results of a new numerical package for performing micromagnetic simulations of spin waves. Spin wave propagation and interactions are studied by solving the Landau-Lifshitz-Gilbert equation. As a benchmark simulation we reproduce the spin wave pattern found in recent experiments, with very good agreement. The properties of the spin wave dispersion for the Backwards Volume Magnetostatic Spin Waves (BVMSW) are investigated and we present results on modes with a group velocity of zero at nonzero k.

Mo.G-P20 - Division and multiplication of a ferromagnetic resonance frequency on the basis of the nonlinear microwave magnetoelastic transducer

V. Vlasov[1], L. Kotov[2], V. Shavrov[3], V. Shcheglov[3]

3. IRE Russian Academy of Sciences, Moscow, Russia

The coupled oscillations of magnetization and elastic displacements in normally magnetized ferrite plate excited by the alternating magnetic field which frequency coincides with the frequency of a ferromagnetic resonance of a magnetic subsystem [1] are considered. When the resonant frequency of an elastic subsystem makes multiple part of resonant frequency of a magnetic subsystem, the excitation of elastic oscillations at the elastic resonance frequency represents process of division of initial frequency in the multiple relation is possible. When the resonant frequency of an elastic subsystem in multiple number of times exceeds frequency magnetic the multiplication of initial frequency in the multiple relation is possible. Processes of the division and multiplication of frequency are possible only in strongly nonlinear mode, and polarization of an exciting field has to be linear for the multiplication. Phase portraits of the excited elastic oscillations are constructed at division and multiplication cases. It is shown that the division and multiplication are observed only in that case when time of a relaxation of elastic oscillations not less than much exceeds time of a relaxation of the magnetic oscillations. The work was supported by RFBR (grant # 13-02-01401-a)

The system of ordinary differential equations described in the paper [1], is dealing with the electromagnetic excitation of nonlinear magnetoelastic oscillations in the normally magnetized ferrite plate when the parametric excitation of spin waves was blocked and is introduced in the given paper. The present paper deals with investigation of features of the magnetization vector nonlinear precession and the elastic displacement close to ferromagnetic resonance condition by two methods, the first one - by the eigenfunction expansion method and the second one - by the method of lines. The research was made for one-layer and two-layer ferrite plates. The case of the first elastic mode excitation is the only one that is considered in the research. The alternating circular polarized magnetic field was oriented in the plane of the plate. The systems of ordinary differential equations in nodes of the spatial grid were solved numerically by the Runge-Kutta 7-8 orders method with control of the integration at every step length. The time evolution of magnetic and elastic oscillations caused by the alternating field was analyzed. Dependences of magnetoelastic oscillation relaxation time on magnitudes of dc and alternating magnetic fields, saturation magnetization, the magnetoelasticity constant, magnetic and elastic relaxation parameters were determined. Magnetoelastic coupling efficiency in particular is determined by the ratio of the relaxation times of magnetic and elastic subsystems was revealed. Several regimes of precession changing each other by increase of the alternating field amplitude were identified. It was found that the magnetoelastic interaction changed the character of the observed precession regimes especially under the condition of the elastic resonance. In case of detuning the eigenfrequency of magnetic and elastic resonances, chaotic oscillation modes took place. The boundaries between regular and chaotic oscillations depending on the magnetic dissipation parameter, frequency and amplitude of the alternating field were determined.

Magnetic nanostructures containing flux closure and vortex domain configurations have potential applications ranging from information storage technologies to spin torque oscillators. The magnetisation dynamics of confined magnetic structures can be complex and consist of standing wave modes in regions with uniform magnetisation, oscillations of the domain wall structure[1] and gyration of the vortex core[2]. In our recent work we demonstrated how voltage induced strain can be used to significantly modify the configuration of magnetic flux closure domains in structures fabricated using Fe81Ga19[2]. Here we present investigations of the effects of a strain-induced uniaxial magnetic anisotropy on the magnetisation dynamics of Fe81Ga19 square structures in the flux closure configuration. Using time-resolved XMCD PEEM and micromagnetic simulations we find that an induced anisotropy energy of 10 to 40 KJ modifies the precession frequency of the uniform magnetic regions, the oscillations of the domain wall structure by up to 0.8GHz, and the gyration of the vortex cores by up to 150MHz in square objects between 500nm and 2000nm. This shift in frequency of oscillation is also accompanied by a reduction in the number of frequency modes present in the system from 3 to only one dominant mode. Our investigations show that inverse magnetostriction provides a promising route for tuning significantly the complex magnetisation dynamics of magnetic nanostructures.

In the emerging field of magnon-spintronics, spin waves are exploited to carry and process information in materials with periodic modulation of their magnetic properties, named magnonic crystals (MCs). Here, one finds the appearance of allowed and forbidden frequency bands which can be exploited to tailor the spin wave dispersion as well as to design micro-devices operating in the GHz frequency range. In this paper, we present the results of advanced micromagnetic simulations performed using the open source GPU-accelerated code MuMax3. We consider two-dimensional MCs consisting of Permalloy (Ni80Fe20) square antidot lattices with a fixed periodicity p=200 nm and different hole sizes, namely 25 nm, 50 nm, and 100 nm. For each case, the band structure is analyzed in the Damon-Ehsbach (DE) configuration (wavevector perpendicular to the applied magnetic field) within the first three artificial Brillouin zones, with emphasis given to the dispersive character and spatial profile of the most prominent modes. It is shown that in the case of the smaller holes several modes have a finite group velocity, comparable to that of the DE mode of the unpatterned film. Instead, in the case of the larger holes, the eigenmodes are less dispersive and resemble stationary waves, localized within the minima of the highly-inhomogeneous internal field. To reduce the effect of such inhomogeneity of the internal field, arising at the hole edges, we studied bi-component MCs where the antidots are filled with a second magnetic material (e.g. Cobalt). In this case, one recovers the dispersive character of the modes even in presence of relatively large holes. Finally, we propose the realization of tunable magnonic filters based on the exploitation of the above antidot lattices.

Ferromagnetic nanostructures have recently attracted much interest for the wide potential applications in high density magnetic recording media, logic devices and various spin orbit torque phenomena [1,2,3]. In many kinds of next generation nano spin devices, the damping process plays an important role in the devices performance. Therefore, more deep studies are needed to understand the damping processes in the nano devices structures including nanowires. In this study, we simulated the ferromagnetic resonance using micromagnetic with the different shape anisotropies in xy plane at zero temperature. In order to remove the finite size effect, we incorporated two-dimensional periodic boundary condition (PBC). The resonance frequencies are obtained by the fast Fourier transformation of time dependent Mx (transverse) and My (longitudinal). As the result, the demagnetization factor for longitudinal conditions, Nz (Ny) is increasing (decreasing) as decreasing the periodicity of PBC from 50 to 150 nm. In the transverse condition, Nz (Ny) is increasing (decreasing) as increasing the periodicity of PBC. In the macro-spin model, they must be identical, but micromagnetic simulation reveals the demagnetization factors different for two different magnetization states. The Gilbert damping constant for transverse case is increasing from 0.018 to 0.051 as the increasing periodicity of PBC, longitudinal case is almost constant as 0.021. Our finding can be explained by the wavevector dependent damping processes, which has been reported by K. Gilmoreí»s theoretical work [4]. He claimed that the damping constant dramatically decrease from 0.2 to 0.05 as the wavevector decrease from zero to 1% of Brillouin zone edge at the low temperature.

Members of the family Re2V2O7 (Re = Yb, Tm, Lu) are quantum ferromagnetic insulators with pyrochlore structure that have been recently found to exhibit numerous exceptional properties including the magnon Hall effect, which is driven by the antisymmetric Dzyaloshinskii-Moryia interaction (DMI). Lu2V2O7 has been identified as a potential dispersionless magnon medium and, as such, a prime candidate for magnonics and possibly the first magnon topological insulator [1,2,3]. We present the results of an inelastic neutron scattering study on the time-of-flight spectrometer MERLIN (ISIS, UK) to probe the spin dynamics of Lu2V2O7. We observe well-defined spin waves and determine the spin Hamiltonian including its exchange parameters. The data is in agreement with a minimal model used to explain the magnon Hall effect, and allows to extract directly the ratio between the ferromagnetic exchange and the DMI, which is the driving parameter of the effect.

We present investigation of the one-dimensional (1D) magnonic quasicrystals (MQs) made from infinitely long permalloy (Py) stripes separated by air. 30 nm thick, 700 nm (A) and 350 nm (B) wide Py stripes with 100 nm air gap are quasiperiodic ordered according to Fibonacci inflation rule. The number of stripes and total width of the structure are expressed by Fibonacci number Fn. The structure is saturated by external magnetic field applied along the stripes. In focus of our study are ferromagnetic resonance (FMR) and spin wave excitation spectra. Results obtained for MQs are compared with results for magnonic crystals (MCs) composed of periodic array of the same Py stripes and separations. We have proposed and realized quasiperiodic (and periodic) structures suitable for investigation of fractal properties of the spin wave spectra in nanoscale magnonics. We show, that dipole coupling existing in MQ is sufficient for formation of the collective spin wave excitations. Investigation of the MQ consisting of different number Fn of stripes provides the mechanism to explore the fractal nature of the spin wave spectra in MQs. We have found that for large MQs, multilevel structure of magnonic gaps exhibits property of self-similarity and FMR spectra with many absorption peaks. The magnonic gaps in MQs have been found also in frequency range below the first magnonic band gap in respective MC. Obtained results are promising for further experimental investigation and applications in magnonics, including its reprogrammable property. The research has received funding from Polish National Science Centre project DEC-2-12/07/E/ST3/00538, project SYMPHONY (program TEAM/2011-8/4) of the Foundation for Polish Science and from the EU's Horizon2020 research and innovation programme under the Marie Sklodowska-Curie GA No644348.

Mo.G-P27 - Spin-wave scattering by domain walls in ultrathin ferromagnetic films

F.Buijnsters[1], A. Fasolino[1], M. I. Katsnelson[1]

1. Institute For Molecules And Materials, Radboud University Nijmegen, Nijmegen, Netherlands

There is an increasing focus on the essential role of the Dzyaloshinskii-Moriya (DM) interaction in the dynamics of magnetic structures in (ultra)thin films. For example, there are now strong indications that the DM interaction can greatly enhance the maximal propagation speed of a domain wall by stabilizing its internal structure [1]. At the same time, it has been claimed that the DM interaction does not influence the effect a domain wall has on spin waves that pass it [2]. Our calculations indicate that this conclusion is not general and that, in fact, the DM interaction can modify the interaction of spin waves with a domain wall in an essential way. We provide explicit analytical and numerical predictions on the magnitude of this effect. Our results show how the internal structure of the domain wall could be used as a novel switching element in the construction of magnonic devices beyond what was proposed in [3].

Mo.G-P29 - Broadband GHz magnetic susceptibility tensor of a synthetic antiferromagnet: experiment and semi¡analytical approach

D. E. Gonzalez-Chavez[1], E. Monteblanco[1], R. Dutra[1], R. L. Sommer[1]

1. Brazilian Center For Research In Physics, Rio de Janeiro, Brazil

A synthetic antiferromagnet (SAF) is one of the most basic magnetic coupled layered systems. It is composed by two ferromagnetic layers coupled antiferromagneticaly through a thin metallic layer via the Ruderman-Kittel-Kasuya-Yosida interaction. Since the development of the spin valve structure, the SAF has been used as the replacement of the single, pinned or free, layers in read heads, magnetic random access memories and spin transfer torque oscillators (STOs). In particular, it is possible to enhance the output power of STOs by using appropriate SAF configurations. In this work we provide further insight on the effect of the SAF configuration by analyzing the ferromagnetic resonance response of a NiFe(20nm)/Ru(1nm)/NiFe(20nm)/IrMn(20nm) sample with SAF behavior by using vector network analyzer ferromagnetic resonance measurements with in-plane exciting RF field in, both, parallel and perpendicular directions relative to the applied static field direction. For both configurations we observe spectra with similar dispersion relations, with two resonant modes, but with absorption amplitudes on the resonant branches depending on the RF field direction. These amplitudes are related to the susceptibility tensor component probed by the RF field. We use the model explained in a previous work [1] to fully describe and reproduce the experimental results. From our model we calculate the susceptibility tensor and extract the magnetic moment oscillation amplitude and phases for each layer as a response to the RF field. A detailed analysis on the evolution of the oscillation amplitudes and phases with the applied field, on both resonant modes, is performed.

Mo.G-P30 - Ferromagnetic resonance measurements of CoFeCrB alloys films for in-plane spin transfer torque devices

C. Lacroix[1], K Oguz[2], J. M. David Coey[2], D. Ménard[1]

1. Polytechnique Montreal, Montreal, Canada
2. Trinity College Dublin, Dublin, Ireland

Decreasing the magnetization of the CoFeB free layer in MgO based magnetic tunnel junctions is desirable for reducing the critical current density Jc for spin transfer torque switching. While it has been reported that substituting Fe ions with Cr decreases the magnetization of the CoFeB layer and allows for reducing Jc by a factor of four*, the effect of Cr substitution on the damping mechanisms involved in the magnetization dynamics have yet to be clarified. Multilayers stacks of SiO2(500 nm)/MgO(5 nm)/Co40Fe40-xCrxB20(30 nm)/Ta(5 nm) were grown on a Si(001) substrate using a Shamrock sputtering system for x = 0, 4, 8 and 18. The damping properties of the CoFeCrB films were investigated using angle-dependent and frequency dependent ferromagnetic resonance (FMR) in a resonant cavity (9.6 GHz) and in a shorted waveguide configuration (26 to 75 GHz). The magnetization Ms of the CoFeCrB films, determined from the fit of the resonance fields, show that Ms diminishes as the content of Cr increases, in agreement with SQUID magnetometry measurements. The g-factor, an indicator of spin-orbit coupling, equals 2.15 for x = 0, and diminishes as x increases, tending towards a value of 2 when Ms approaches zero. The linewidth of the FMR peaks increases with the content of Cr. The angular and frequency dependencies of the measured linewidth are fitted for all films (x =0, 4, 8 and 18) assuming three different contributions: 1) an intrinsic damping modeled by a phenomenological Gilbert parameter, 2) an inhomogeneous broadening and 3) a two-magnon damping. Our results show that the Gilbert damping parameter decreases from 145 to 107 MHz as x increases. Furthermore, when x = 0 or 4, the two-magnon damping is negligible in comparison to both the Gilbert damping and the inhomogeneous broadening. However, when x = 8 or 18, a two-magnon damping is required to properly model the linewidth.

Mo.G-P31 - Spinwave dynamics in elliptical dots: experiment and simulations

R. Pinto[1], D. E. Gonzalez-Chavez[1], R. Sommer[1]

1. Centro Brasileiro de Pesquisas Físicas, Rio de Janeiro, Brazil

The dynamical properties of patterned magnetic sub-micrometric elements have attracted an increasing interest in the last decade because of the observation of new effects induced by the lateral confinement on the spin excitation spectrum.
In this work we explore the magnetization dynamics of periodic arrays of $Ni_{80}Fe_{20}$ patterned elements using the vector network analyzer ferromagnetic resonance technique (VNA-FMR).
Two examples are presented: an array of disks with diameter of 1µm and array of ellipses with dimensions of 2.4 µm x 1.4 µm, both with 50 nm thickness.
Our arrays were produced, onto a Si wafer, by combining e-beam lithography, magnetron sputtering and lift-off techniques. We were able to control the magnetostatic interaction in the arrays by varying the the spacing between the elements.
The samples were characterized by alternating gradient force magnetometry and magnetic force microscopy. The obtained M vs. H curves showed the typical behavior inherent to vortex states. From the broadband measurements we obtained the dispersion relations for fields up to ± 800 Oe, for two radio frequency field configurations (h_{rf} ^ H_{dc}) and (h_{rf} // H_{dc}).
In the saturated states, were the magnetization of each element of the array is aligned to the external field, we observed the uniform Kittel and localized spin wave modes. On the other hand for the vortex states a rich structure of spin-wave modes was observed, such as modes with integral numbers, m and n, which represent the azimuthal and radial modes. Micromagnetic simulations were performed in order to have a further insight of the experimental results. With them we obtained the details of the excited spin eigenmodes in the frequency domain at a given bias field.

Mo.H-P01 - Influence of demagnetization field direction on domain structure and size of ultra-thin CoPt perpendicular anisotropy films

R. Hara[1], K. Hayakawa[1], H. Kawamura[1], R. Sugita[1]

1. Department of Media And Telecommunications Engineering, Ibaraki University, Hitachi, Japan

CoPt based perpendicular anisotropy films have been studied for magnetic devices such as magnetic recording media, but there has been little discussion on the relationship between domain structure and the applied field direction for ultra-thin films. In this study, we clarify the influence of demagnetization field direction on domain structure and size of ultra-thin CoPt perpendicular anisotropy films. Samples whose structure was Pt(2 nm) / Co70Pt30(3-10 nm) / Ru(20 nm) / Pt(100 nm) / Glass substrate were prepared using an RF magnetron sputtering system, and were AC demagnetized with perpendicular or in-plane field. From MFM observations, it was found that the 3 nm thick CoPt film had irregular domain whose size was about 400 nm in the case of the perpendicular demagnetization, while it had mixed structure of irregular and maze domains whose size was about 200 nm in the case of the in-plane demagnetization. For the perpendicularly demagnetized 3 nm thick film, nuclei of reversed domain hardly emerge due to high perpendicular anisotropy, while for the in-plane demagnetized one, magnetization in in-plane direction easily rotates upward or downward because of being unstable. Therefore the domain size of the former is larger than that of the latter. The domain size monotonically decreased with increase of film thickness for both demagnetization directions, and the difference of the size between both demagnetization directions disappeared for the 10 nm thick film. For the 10 nm thick film, in both demagnetization directions the maze domain whose domain width was about 70 nm was observed. In conclusion, the domain size of perpendicularly demagnetized CoPt films was larger than that of in-plane demagnetized films for the thickness less than 10 nm, and for the 3 nm thick film the former was twice as large as the latter.

Mo.H-P02 - Stress-engineering of CoFe2O4 thin films

The inverse spinel oxide CoFe2O4 (CFO) is an interesting and complicated material that has been object of intense research due to its interesting properties. The interest lies on the fact that this spinel is an attractive high magnetostrictive insulating material with large Curie temperature Tc and proved spin-filter efficiency [1-3]. The complication comes from the difficulty selecting the adequate substrate and deposition conditions to obtain the desired properties of CFO. Depending on the strain induced by the substrate and on the deposition conditions, the inversion degree of the spinel can be modified [4,5] affecting both magnetic and electric properties of CFO. In order to study the effect of ionic reorganization in the lattice under very different growth conditions, we have compared CFO thin films prepared by Pulsed Laser Deposition (PLD) and a chemical solution deposition method (Polymer Assisted Deposition, PAD). Samples of different thickness were deposited on MgAl2O4 (001) and MgO (001) substrates under different heat treatments, oxygen pressures and deposition rates to study the degree of ionic inversion and also to study the relaxation mechanisms of CFO on both substrates. All the samples have been structurally, magnetically and electrically characterized. The cation and defect distribution have been analyzed by Scanning Transmission Electron Microscopy (STEM), High Angle Annular Dark Field (HAADF) imaging and Electron Energy Loss Spectroscopy (EELS). Our study provides a guide to prepare thin films of these samples with the desired magnetic and electrical properties.

3. Dipartimento di Fisica ed Astronomia, UniversitÓ di Bologna, Bologna, Italy

Brillouin light scattering (BLS) was exploited to study the effect of the exchange coupling (EC) at the interface between antiferromagnetic (AF) and ferromagnetic layers on spin-wave properties in spin-valves (SVs). The stacking of the samples was Cu(5 nm)/IrMn(tu)/NiFe(5nm)/Cu(5nm)/NiFe(5nm)/IrMn(to); tu and to are the thicknesses of the AF IrMn (Ir25Mn75) underlayer and overlayer, respectively. Three different samples were studied: SVA (tu = 10 nm, to = 0 nm), SVB (tu = 10 nm, to = 6 nm), and a reference sample, SVR (tu = to = 0 nm). The samples were deposited by DC magnetron sputtering in a magnetic field of 400 Oe. The EC strongly affects the SV magnetization process by inducing a bias field (HB) on the pinned NiFe layer, that results in a shift of the NiFe loop along the measurement axis. BLS spectra were acquired by sweeping the applied field (H) over the upper branch of the hysteresis loop (from positive to negative saturation) and encompassing both the parallel (P) and antiparallel (AP) alignment of the NiFe layers. In the saturated state, in SVA and SVB the frequencies of the two measured modes increase with respect to the ones in SVR, and their frequency difference depends on H orientation with respect to HB direction. At the transition from the P to the AP alignment, the mode frequencies undergo an abrupt variation and the frequency dependence remarkably changes. The experimental frequencies are compared with those calculated by a theoretical model that includes in a phenomenological way the effects of the EC at the IrMn/NiFe interface[1]. For both the SVA and SVB samples, the accordance between experimental and theoretical frequencies is good in the P state, larger differences are present in the AP state.

With multiferroic materials integrated into the spintronics, spins might be manipulated by an electric field, leading to the development of the next generation of low power consumption, magnetic memory storage, and high speed information technologies. Multiferroic BiFeO3 (BFO) shows coexistence of ferroelectric (FE) and magnetic orders at room temperature with FE Curie temperature, TC-FE ~ 1100K and antiferromagnetic (AFM) Neel temperature, TN ~ 640K. In fact, the AFM order parameter in the multiferroic acts as a medium that indirectly couples the ferromagnetic (FM) ordering of a FM thin film and the FE ordering of the multiferroic. To study the AFM/FM coupling mechanics, we propose as strong FM candidate, half metallic manganite perovskite La2/3Sr1/3MnO3 (LSMO) has been widely used as a spin source in spintronics, with Curie temperature (TC ~350K). We have grown BFO/LSMO bilayers on (100) SrTiO3 substrates by using DC and rf sputtering technique at pure oxygen pressures. Samples were structurally characterized by X-ray diffractrometry; morphologically by statistical analysis of atomic force microscopy. Polarization curves in samples indicates the ferroelectric property of the BFO at room temperature. Magnetic characterization have been carried out by thermal demagnetization curves at zero field and at applied field cooling, as well as ZFC and FC isothermal magnetization curves.

Mo.H-P06 - Co80Pt20 films with columnar grains and perpendicular magnetic properties produced by epitaxial deposition on Ru/Cu bilayers

S. Chen[1], C. Wen[1], C. Wang[1], T. Sun[2], C. Wang[3], P. Kuo[3]

Ordered Co3Pt film is a promising material for high density recording media, due to its magnetocrystalline anisotropy constant being higher than that of current CoCrPt recording materials by a factor of around 10 times. Furthermore, the manufacturing temperature of Co3Pt used for obtaining high perpendicular magnetic properties is similar to that used in current hard disk manufacture. However, single-layered Co3Pt films incline towards in-plane magnetic anisotropy or random orientation, which cannot be utilized in perpendicular magnetic recording application. It has been reported that Co-rich Co-Pt films with high perpendicular magnetic properties can be achieved by introducing a Pt underlayer or Ru/Pt bilayer. However, the expensive Pt layer in the films would result in excessively high cost. In this study, the magnetic anisotropy of single-layered Co80Pt20 film with thickness of 50 nm deposited directly on glass substrates at ambient temperature inclines towards random orientation. It tends to an in-plane magnetic anisotropy by the introduction of a (10 1) texture of 30 nm Ru layer under the Co80Pt20 film. The perpendicular magnetic anisotropy would be increased slightly by inserting a 100 nm thick Cu layer between the Co80Pt20 and Ru layers. However, when the Cu layer is introduced under the Co80Pt20/Ru bilayer films, the magnetic anisotropy becomes perpendicular. This is because a fcc Cu (111) underlayer can promote hcp Ru (0002) seed layer to induce (0002) texture well in hcp Co80Pt20 magnetic layer, leading to a good perpendicular magnetic anisotropy of Co80Pt20 films. It is found that a columnar Co-rich Co-Pt nano-grains with perpendicular coercivity of 4580 Oe and perpendicular squareness of 0.77 can be achieved by depositing Co80Pt20(50 nm) film onto Ru(30 nm)/Cu(100 nm) bilayer films at ambient temperature. This Co80Pt20 film is a promising candidate for perpendicular magnetic recording media applications.

Mo.H-P07 - Tuning the magnetoimpedance response in NiFe/Cu/Co films through the magnetic interaction between ferromagnetic layers

Magnetic materials exhibiting asymmetric magnetoimpedance effect are of large interest due to their potential for application in sensor devices. Asymmetric effects are obtained by inducing an asymmetric static magnetic configuration, usually done by magnetostatic interactions or exchange bias. In the present work, we investigate the quasi-static and dynamical magnetic behavior in ferromagnetic NiFe/Cu/Co films. We produce $Ni_{81}Fe_{19}$ (25 nm)/Cu(t_{Cu})/Co(50 nm) films, with t_{Cu}=0, 1.5, 3, 5, 7, and 10 nm, grown by magnetron sputtering. The quasi-static magnetic properties are investigated through magnetization and magnetoresistance measurements. Both are dependent on the thickness of the non-magnetic Cu spacer, and indicate a biphase magnetic behavior for the films with Cu thicknesses above 3 nm. Magnetization dynamics is investigated through magnetoimpedance measurements obtained using a RF-impedance analyzer, in a frequency range between 0.1 and 3.0 GHz. The results present asymmetric magnetoimpedance in films with biphase magnetic behavior. Besides, the magnetoimpedance response can be tailored by changing the thickness of the non-magnetic Cu spacer material and probe electrical current frequency. By considering this set of films, we verify the competition between two kinds of magnetic interactions between ferromagnetic layers: ferromagnetic exchange coupling and magnetostatic coupling. They are strongly dependent on the spacer thickness and affect in different ways the magnetic behavior. We show that the strength of the bias field increases with the thickness of the spacer and that the field value H=30 Oe corresponds to the magnitude of the effective coupling strength between the soft NiFe and hard Co layers, for films with t_{Cu}>3 nm. The results place films with biphase magnetic behavior exhibiting magnetoresistence and asymmetric magnetoimpedance effect as very attractive candidates for application as probe element in the development of auto-biased linear magnetic field sensors.

Mo.H-P08 - Optical and magneto-optical interactions in permalloy thin and ultrathin films on Si substrates

Permalloy is a well-known magnetic alloy with high magnetic permeability, low coercivity and a very small magneotstriction which makes it promising material for various practical applications. Recently, novel spintronics concepts have been proposed, such as magnetic logic circuits, spin valves or MRAMs [1] employing permalloy layers. Although the functionality of these new spintronic devices is widely investigated by magneto-optical methods, only the spectral dependence of complex refractive index of permalloy is reported [2]. One could hardly find a precise spectral examination of its complete permittivity tensor, which describes both optical and magneto-optical interactions in this material. However, knowing it is necessary for theoretical predictions of the complex magneto-optical response of novel spintronic nanostructures. In this work, we present a systematic study of optical and magneto-optical properties of permalloy films in the photon energy range from 1.2 to 5.5 eV. The samples with nominal thicknesses of 10 nm and 150 nm were deposited onto Si substrates. They were examined by x-ray diffraction and atomic force microscopy to get information about their crystallinity, thickness and surface morphology. Spectroscopic ellipsometry and magneto-optical spectroscopy were performed at room temperature and the spectra of polar Kerr rotation and ellipticity were recorded in the magnetic field of 1.2 T, sufficient to magnetically saturate the samples. The spectral dependence of the diagonal and off-diagonal elements of permittivity tensor were deduced from ellipsometric and magneto-optical measurements using a Yeh's matrix formalism extended to absorbing media [3]. The spectra of both diagonal and off-diagonal elements of the permittivity tensor showed metallic behavior with notable differences, indicating a change of physical properties in ultrathin permalloy layers.

The magnetization dynamics of systems with reduced dimensions have been extensively studied due to their technological relevance in a variety of devices. Spintronic devices use to operate with magnetization reversal times comparable to the natural ferromagnetic resonance (FMR) precession period, a behavior dependent on the intensity of the radio frequency field, shape of pulsed excitations, as well as on the structural properties and magnetic uniformity of the sample/device. Although FMR is useful to obtain the intrinsic magnetic properties of the material in saturated state, the properties of nonsaturated samples are rarely investigated due to the complexity of the magnetic configuration. In this work, we present an experimental investigation of the static and dynamic magnetic properties of ferromagnetic Ni81Fe19 films with thicknesses between 50 and 1000 nm. The quasi-static magnetic characterization is performed through magnetization curves. The dynamical magnetic behavior is studied through the traditional FMR experiment (at 9.4 GHz), FMR dispersion relations obtained with a vector network analyzer by measuring the reflection coefficient of a microstrip transmission line with the sample (from 50 MHz to 7 GHz), and magnetoimpedance measurements (from 100 MHz to 3 GHz). Considering the results, films thinner than 150 nm exhibit well-defined in-plane uniaxial magnetic anisotropy and one absorption peak in the FMR experiment, as well as just one ferromagnetic resonance mode in the FMR dispersion relations and magnetoimpedance curves. For films thicker than 200 nm, magnetization curves indicate isotropic in-plane magnetic properties with out-of-plane anisotropy contribution, a behavior related to the stress stored in the film, and to the columnar microstructure. FMR experiment presents more than one absorption peak, both suggesting the excitation of non-uniform modes. FMR dispersion relations and magnetoimpedance curves present complex magnetic behavior, depicted by several ferromagnetic resonance modes detected at relatively low fields. We discuss the results in terms of the mechanisms governing the dynamics at distinct frequency ranges, excitation modes, and quasi-static magnetic properties.

Mo.H-P12 - Experimental setup for investigation on magnetic thin layers by in-situ neutron reflectometry

5. Max Planck Institut für Festkörperforschung, Stuttgart, Germany

Thin magnetic layers are used in many magneto-electronic devices. A thorough understanding of their texture and the coupling between them is, therefore, essential to improve functionality. In order to avoid the incorporation of impurities and surface contamination, these layers have to be grown under ultra-high-vacuum (UHV) conditions. An excellent method to analyze their structural and magnetic properties is polarized neutron reflectometry (PNR). Up to now, the sample growth and analysis have been performed in separate steps. The grown samples had to be removed from the vacuum after the growth process and put into the neutron beam line for analysis. This procedure is time consuming and leads to the sample being exposed to the environment which could alter their properties. In this contribution, a compact in-situ vacuum sputtering chamber with integrated DC and RF sputtering equipment for performing in-situ neutron reflectometry experiments will be presented. It can be easily transported and installed at neutron beam lines and combines both, deposition and measurement, into one single setup. This allows magnetic properties of thin films as a function of their thickness and composition to be investigated, both, quickly and on one single sample, at different evolutionary deposition steps. Despite the compactness of the device, no compromises regarding conditions for growth and measurement were made: A coil allows field dependent measurements and a cryostat with integrated heater can set the sample temperature in a range from 10K to 1000K. We constructed our device to be fully compatible to the REFSANS (FRM II) and the AMOR (PSI) ToF neutron reflectometers. At the later, we can perform PNR measurements using the state-of-the-art SELENE neutron optical setup which reduces measurement times from hours to several minutes.
The results of very promising measurements on Fe/Pd and Fe/Cr layers are shown in contributions by Sina Mayr and Wolfgang Kreuzpaintner.

Mo.H-P15 - Giant magnetoresistance and Magnetic properties of epilayers-perovskite LBMTO

5. Laboratory of Nanoscale Condensed Matter Physics, National Institute of Materials Physics, Magurele, Romania

An epitaxial thin film of La0.67Ba0.33Ti0.02Mn0.98O3 (LBMTO) was synthesized using pulsed laser deposition technique (PLD) with a desirable thickness of 95 nm. The film grown on SrTiO3 (0 0 1) substrates exhibited a paramagnetic-to-ferromagnetic second order phase transition at 291 K. The as-grown film displays a giant magnetoresisitance (GMR) up to 150% at room temperature under 5T applied magnetic field.

Mo.H-P16 - Dependence of Curie temperature on the thickness of Pt layer in Co/Pt system

T. Koyama[1], A. Obinata[1], Y. Hibino[1], A. Hirohata[2,3], B. Kuerbanjiang[3], V. Lazarov[3], D. Chiba[1]

1. The University of Tokyo, Tokyo, Japan

3. University of York, Heslington, England, United Kingdom

A Co ultra-thin film on Pt underlayer has attracted attention in the research field of spintronics because it brought new findings such as the realization of ferromagnetic phase transition by electric field in metal*1. If the thickness of Co layer is below the characteristic length of the exchange interaction, the Curie temperature of the system becomes smaller than that of bulk Co. In this work, we show that not only the thickness of the Co layer*2 but also that of the adjacent Pt layer determines TC and the saturation magnetic moment of the system. We studied dependence of Curie temperature on thickness of ultra-thin Co and Pt layers in several series of perpendicularly magnetized (Pt/)Co/Pt samples. The Curie temperature and the saturation magnetic moment increased with the Co layer thickness and even with the theickness of the Pt layer, which is normally non-magnetic material. The Curie temperature was found to depend linearly on the total magnetic moment of the system and the coefficient of the linear fittings were the almost same, regardless of whether the thickness of the ferromagnetic Co layer or the Pt layer was varied. The Curie temperature increases also with the magnetic anisotropy, but no systematic dependence was observed on it. These results suggest that the magnetic moment induced in the Pt layer due the ferromagnetic proximity effect*3 plays a significant role in determining the Curie temperatures of such two-dimensional ferromagnetic systems. This work was partly supported by the PRESTO program of JST, Grants-in-aid for Scientific Research (S) from JSPS.

Mo.H-P17 - Sputtered thin films of Ti substituted barium hexaferrite for miniaturized components of electronic devices in the microwave range

N. Gutzeit[1], Bernd Halbedel[2], H. Romanus[3], J. Müller[1,3]

1. Technische Universität Ilmenau, Institute for Microelectronics and Nanoelectronics, Group of Electronics Technology, Ilmenau, Germany
2. Technische Universität Ilmenau, Institute of Materials Engineering, Group of Inorganic-Nonmetallic Materials, Ilmenau, Germany
3. Technische Universität Ilmenau, Center of Micro- and Nanotechnologies, Ilmenau, Germany

M-type barium hexaferrite thin films can be used for miniaturized components of electronic devices at microwave frequencies. Through the partial substitution of the iron ions by titanium ions the magnetic resonance frequency can be shifted to lower values. This paper will present the challenging manufacturing process by RF magnetron sputtering with the use of a self-made barium hexaferrite target at the Center of Micro and Nanotechnologies of the Technische Universitõt Ilmenau, Germany, as well as the characterization of the sputtered thin films. Barium ferrite thin films are sputtered on polycrystalline alumina substrates. The deposited, X-ray amorphous barium ferrite thin films are annealed after the sputtering process. The chemical composition is measured by EDX and ICP-OES. The influence of the titanium ion amount on the crystallization temperature is shown by X-ray diffraction and SEM images. The hexagonal barium hexaferrite phase is clearly proven by the measured diffractograms using the GID X-ray measurement method. The crystallites have a hexagonal, typical plate-like shape with dimensions at the nanometer scale. Results of static magnetic field measurements show the influences of the chemical composition and the peak temperature of the tempering process on the coercivity and the hysteresis loop.

Mo.H-P18 - Magnetic properties of irradiated Co_2MnSi Heusler alloys

I. ABDALLAH[1], N. BIZIERE[1], B. PECASSOU[1], G. BENASSAYAG[1], J. BOBO[1], E. SNOECK[1]

1. CEMES, CNRS, Toulouse cedex 4, France

The Heusler alloys Co_2MnSi are ferromagnetic materials known for their high spin polarization and low magnetic damping parameter (α), making this material of particular interest for spintronic and radiofrequency devices. In this study, we demonstrate that the atomic disorder induced by He^+ irradiation modifies the dynamic parameters of CMS in different ways as a function of the irradiation dose.

40 nm CMS films were prepared on MgO substrates using magnetron sputtering technique with a deposition temperature of 600° C and post annealed at 800°C. Irradiation with 150 KeV light He^+ ions is then performed at doses between 10^{14} and 10^{17} ions/cm². Angular ferromagnetic resonance experiments were carried out in stripline geometry to extract the static (saturation magnetization $\mu_0 Ms$, the magneto-crystalline anisotropy field $\mu_0 Hk$) and dynamic (Gilbert coefficient α and extrinsic losses) magnetic parameters. Structural properties were investigated using X-Ray diffraction and Transmission Electron Microscopy (TEM).

We observed two different magnetic behaviors as a function of the irradiation dose. Below 10^{15} ions/cm^2, the extrinsic dynamic losses increase, while the static magnetic parameters and the gilbert constant remain constant. For higher doses, we observe a splitting of the FMR absorption peak appears, corresponding to a decrease of $\mu_0 Ms$ from 1.25 to 1.1 T while the anisotropy field increases by about 20%. Moreover, the damping coefficient can be multiplied by 2. These effects are shown to correspond to a crystallographic phase transition (L21/B2 or B2/A2) which goes along with an additional mechanical strain between the MgO and the CMS of the order of 0.2%. This is demonstrated by a shift in X-Ray diffraction peaks and by geometrical phase analysis from STEM-HAADF experiments.

Mo.H-P19 - Thickness dependent properties of Sr2FeMoO6 thin films grown on SrTiO3 and (LaAlO3)0.3(Sr2AlTaO6)0.7 substrates

M. Saloaro [1], Il. Angervo[1], H. Huhtinen[1], P. Paturi[1]

1. Wihuri Physical Laboratory, Department of Physics and Astronomy, University of Turku, Turku, Finland

The magnetoresistive Sr2FeMoO6 (SFMO) has high spin polarization and large intrinsic magnetoresistance at room temperature due to exceptionally high Curie temperature. Therefore, it has proven to be extremely promising material for novel spintronic applications. The applications require high quality thin films and therefore the the role of the substrate material and the film thickness is investigated. Two series of SFMO films with different pulse numbers from 250 to 10000 were made using pulsed laser deposition. The series were made on SrTiO3 (STO-series) and (LaAlO3)0.3(Sr2AlTaO6)0.7 (LSAT-series) substrates, which have different lattice mismatch with SFMO (-1.05% and -1.88%, respectively). The characterization by X-ray diffraction shows that all the films were phase pure and fully textured. The in-plane strain in the LSAT-series was almost independent of the pulse number having an opposite sign to the lattice mismatch. In the STO-series the in-plane strain was compressive as expected from the mismatch and it decreased with increasing pulse number. The magnetic and resistivity behaviour had same tendency with both series. The Curie temperature and the saturation magnetization increased with pulse number up to 2000 pulses after which they were nearly constant. In the temperature dependence of the resistivity, a clear low temperature upturn indicating semiconductive spinchannel was observed in both series and it was notably larger in the films grown with lower pulse numbers. Considering the applications, the best properties are achieved when the pulse number is at least 2000. Major changes in magnetic properties were not observed between the series, but the structural properties suggest that the STO substrate with lower lattice mismatch should be used.

Mo.H-P20 - Defect induced enhanced low field magnetoresistance in Pr 0.6 Ca 0.4 MnO 3 thin films

T. Elovaara[1], S. Majumdar[1,2], H. Huhtinen[1], P. Paturi[1]

1. Department of Physics and Astronomy, University of Turku, Turku, Finland
2. Department of Applied Physics, Aalto University School of Science, Espoo, Finland

We have investigated the effect of grain boundaries on the electronic transport properties of thecolossal magnetoresistive low bandwidth manganite Pr 0.6 Ca 0.4 MnO 3 (PCMO) thin films. A series of PCMO films were prepared by pulsed laser deposition method on MgO substrate with varying deposition temperature. Characterizations of the structural, magnetic and magneto-transport properties show that the films prepared at lower ablation temperature contain higher amount of structural defects and an increasing amount of crystal orientations as the level of texturing decreases. According to the low field magnetoresistance (MR) measurements the poorly textured samples display an increased low field MR due to a grain boundary tunneling effect at low temperatures compared to the fully textured PCMO film on STO substrate. In the high field MR measurements, the samples also showed a colossal magnetoresistive insulator to metal (IMT) switching of almost eight orders of magnitude at low temperatures, and the IMT transition field could be reduced over 2 T by illuminating the sample.

Mo.H-P21 - Laterally confined magnonic waveguide with ferroelectric load

A. Sadovnikov[1], E. Beginin[1], S. Sheshukova[1], Y. Sharaevski[1], S. Nikitov[1,2]

2. Kotel'nikov Institute of Radio Engineering and Electronics of Russian Academy of Science, Moscow, Russia

We report the experimental and numerical investigations of spin-electromagnetic waves propagating in laterally coupled finite-width multiferroic waveguide. We demonstrate the symmetric and asymmetric modes transformation when the coupled magnetic waveguide are loaded with the ferroelectric layer. Experimental study of eigenmodes of laterally confined multiferroic was performed by using microwave measurements techniques and space-resolved Brillouin light scattering spectroscopy. Numerical simulation was provided by the developped finite-element method (FEM) of electromagnetic eigenspectrum calculation. We show that the spatial distribution of magnetization of the width-modes in laterally confined multiferroic structure changes due to the electrodynamic coupling between the spin waves localized mainly in the finite-width ferrite layer and the electromagnetic waves propagating in the ferroelectric layer. Moreover the effectiveness of coupling depends on the mode number, propagating in the layered structure. This work was partially supported by scholarship of the President of the RF (SP-1551.2013.5), Grant from Russian Science Foundation (Project # 14-19-00760), by the Russian Foundation for Basic Research (Grant # 13-07-12409, 14-02-00976).

Mo.H-P22 - Magnetic waveguide arrays studied by brillouin light scattering

A. Sadovnikov[1], Evgeny

1. Saratov State University, Nonlinear Processes Department, Saratov, Russia

We report the results of experimental investigation of the spin waves propagation in the laterally coupled planar YIG waveguide array by Brillouin light scattering (BLS) spectroscopy. Decomposition of eigenmodes reveals the width modes interference in the waveguide arrays. Due to the the symmetry breaking of the taper structure the spatial distribution of the magnetization corresponds to the superposition of the lowest odd modes (m = 1,3) in the input waveguide and the odd (m = 1) and even (m = 2) modes in central waveguide with a number n=0. Experimental studies of the frequency transmission coefficients, spatio-temporal dynamics of MSSW propagation and power transmission between waveguides in array were performed. The different levels of input RF power, different pulse-modulated and continuous microwave signals of different frequencies were considered. To explain the obtained experimantal result we performed the numerical simulation with FDTD method (LLG equation). We demonstrate that in the coupled magnetic waveguides the phenomena of the spin wave coupling and discrete diffraction can be observed. Nonlinear propagation, interactions between waves and generation of discrete solitons are interesting field for further studies. This work was partially supported by scholarship of the President of the RF (SP-1551.2013.5), Grant from Russian Science Foundation (Project # 14-19-00760), by the Russian Foundation for Basic Research (Grant #15-07-05901, # 13-07-12409).

Mo.H-P23 - Ion Irradiation Induced Relaxation of Tensile Strain and Change in Directionality of Magnetic Domains in $BaFeO_{3-\delta}$ Thin Films

F. Aziz[1], M. Chandra[1], S. Das[2], M. Prajapat[2], K. Asokan[3], K. R. Mavani[1]

1. Discipline of Physics, Indian Institute of Technology Indore, Madhya Pradesh, India
2. Department of Physics, Indian Institute of Science Education and Research Bhopal, Bhopal, India
3. Inter-University Accelerator Centre (IUAC), Aruna Asaf Ali Marg, New Delhi, India

Perovskite $BaFeO_{3-\delta}$ (BFO) thin films (~ 250 nm), deposited on MgO (001) single-crystal wafers, were irradiated by ion beams of: (*i)* 200 MeV Ag^{+15} and *(ii)* 100 MeV O^{+7} (Series-1 and Series-2, respectively). These two series of films are investigated for structural and magnetic properties of BFO films at room temperature. There is a systematic variation in structure of the BFO films with increasing Ag^{+15} beam fluence, causing a relaxation of the tensile strain in the films. The Magnetic Force Microscopy (MFM) images show clear patterns of stripe-like magnetic domains of remanent magnetization, which were analyzed and studied by Fast Fourier Transformations. With increasing ion fluence, the formation of stripe-domains gradually changes the direction from 'one' crystallographic plane to 'two'. In contrast to Series-1, there are no systematic changes in the structure of Series-2 films. MFM patterns of Series-2 show gradually diffusing directionality of magnetic domains with increasing ion fluence. The simultaneous and systematic changes in strain and magnetic properties indicate correlated properties of BFO thin films at room temperature.

Mo.H-P25 - Strain induced magnetic anisotropy variation of $CoFe_2O_4$ films[§]

S. Park[1] . Lee[1], C. Cho[1], J. Ba , J. Kim

1. Pusan National University, Busan, South Korea
2. Korea Basic Science Institute, Daejeon, South Korea

Co-based ferrite ($CoFe_2O_4$) is useful for high-density magnetic recording and magneto-optical media application due to its large magnetic anisotropy (K_1 ~ 2.01 x 10^6 erg/cm^3 in <100> orientation), magnetic elastic constant (λ_s^p ~ -110 x 10^{-6}), high Curie temperature and excellent chemical stability. In order to fulfill the desired application, higher coercivity, smaller grain size, low surface roughness and low sample preparation temperature are required.
In this presentation, we showed magnetic anisotropy variation of $CoFe_2O_4$ films grown on MgO(001) and Al_2O_3(0001). Depending on the substrates and deposition temperature, the films exhibited different crystallinity and magnetic easy axis. These variations could be associated with the different strain state of films. With higher deposition temperature, films became isotropic. In the case of films grown on Al_2O_3(0001), strain state of the film changed from compressive to tensile with deposition temperature [1]. On the other hand, films grown on MgO(001) exhibited out-of-plane tensile state at lower deposition temperature and became less tensile state with increased deposition temperature. The room temperature in-plane and out-of-plane magnetic hysteresis loops showed a decreased out-of-plane anisotropy when the deposition temperature was increased. Simple uniaxial magnetic anisotropy energy calculation based on the experimental data showed a direct correlation between the uniaxial magnetic anisotropy direction and stress of the films. Furthermore, the deposition temperature-dependent cation distributions from X-ray photoelectron spectroscopy measurement revealed the possible microscopic origin of the magnetic anisotropy variation.

Mo.H-P26 - Interlayer thickness dependence of the magnetic coupling in FePt multilayered dots

Hirokazu[1], H. Iwama[1], M. Doi[1], T. Shima[1]

1. Tohoku Gakuin University, Sendai, Japan

In order to apply to a next generation ultra high-density magnetic storage media, a lot of studies about the $L1_0$ ordered FePt thin film has been performed, because of its huge uniaxial magnetic anisotropy. It has been found that the coercivity of FePt thin film is increased by reducing the particle size. Besides, independent magnetization reversal of the top and bottom FePt layers have been observed in FePt multilayered film. In this study, $L1_0$ ordered FePt (001) circular dot arrays with FePt/MgO/FePt structure have been prepared and the relationship between the magnetic properties and the size of the dots and the interlayer thickness have also been investigated in order to obtain a design guideline for a high-density multi-level magnetic recording media. The FePt/MgO/FePt films were prepared by using a magnetron sputtering system. The thickness of the top and bottom FePt layers was fixed at 5 nm and 10 nm, respectively. While the thickness of MgO interlayer was 5 nm. The dots arrays were microfabricated from the continuous films through electron beam lithography method and Ar ion milling. The remarkable steps in the s the magnetization curves for the continuous multilayered films and the dots are clearly observed that indicate an independent magnetization reversal of the top and bottom FePt layers. These steps can be observed for the dots with D = 0.8 ~ 3 μm^{ϕ}, however, they disappeared for the dots with D = 0.3 ~ 0.7 μm^{ϕ}. The magnetic coupling behavior as a function of the size of the FePt/MgO/FePt dots and the thickness of the interlayer will be discussed in detail.

Mo.H-P28 - Unusual anisotropic magnetoresistance in single crystalline Fe films and Pt/Fe bilayers

J. Li[1], M. Jia[1], L. Sun[1], Z. Ding[1], H. Ding[2], Y. Wu[1]

1. Fudan University, Shanghai, China
2. Nanjing uniersity, Nanjing, China

Magnetoresistance (MR) is a fundamental transport property of magnetic thin films. Recently, a new MR effect named spin-Hall magnetoresistance (SMR) has been observed in Pt/YIG system [1] with the behavior of , which is distinctly different from the conventional anisotropic magnetoresistance (AMR) in polycrystalline magnetic films with [2]. It still remains an open question whether this MR behavior can be observed in single ferromagnetic film without the Pt layer. In this contribution, we report on a novel interfacial AMR effect in epitaxial Fe(001) films and an AMR enhancement in single crystal Pt/Fe(001) bilayers. For Fe/MgO(001) films, the resistivities show the behavior of up to 400nm, very similar to SMR in in Pt/YIG system. The anisotropic resistivities , i.e. , , and , show an apparent linear 1/tFe dependence. We also observed an enhancement of AMR [3] when capping a thin Pt layer on the Fe(001) thin films, and such enhancement of AMR can be attributed to the Pt magnetic moment in the conduction band induced by the spin dependent exchange scattering at Pt-Fe interface. Using a semi-classical model, we extracted the spin-diffusion length in Pt layer, which is 1.7-2.6 nm from 300K to 6K.

Mo.H-P30 - Effects of the Layer Thickness on the Magnetic and Magneto-optical Properties of Sputtered and Annealed La0.66Sr0.34MnO3 Thin Films on Silicon

M. Monecke[1], O. Ciubotariu[1], P. Richter[1], P. Thoma[1], G. Salvan[1], D. R.T. Zahn[1]

1. Semiconductor Physics, Technische Universitõt Chemnitz, Chemnitz, Germany

La1-xSrxMnO3 is a conductive oxide which is crystallizing in a perovskite structure. The magnetic and electronic properties change with the concentration of strontium [1]. Moreover, the high spin polarization make this material an ideal electrode for spintronic applications. In particular, the composition La0.66Sr0.34MnO3 (LSMO) was used in spintronic devices due to the nearly 100 % spin polarization at the Fermi level [2]. The electrodes are typically deposited by pulsed laser deposition on single crystalline substrates with similar lattice constants, e.g. SrTiO3 [3], to obtain single crystalline layers. Here LSMO films with varying film thicknesses between 10 nm and 300 nm were deposited by magnetron sputtering at room temperature on silicon (111) substrates covered with a native oxide. The films were annealed in ambient atmosphere at 775 °C for 20 min, 1 h, 3 h, and 9 h. Afterwards the layers were investigated by Variable Angle Spectroscopic Ellipsometry (VASE), Magneto-Optical Kerr Effect (MOKE) spectroscopy, and Superconducting Quantum Interference Device (SQUID) Vibrating Sample Magnetometry (VSM). The main goal of this work is to understand how the magnetic properties, the dielectric function, and the magneto-optical response of post deposition annealed LSMO are influenced by the layer thickness and annealing time. The results show that the magnitude of the off-diagonal elements of the dielectric tensor decreases drastically when the layer thickness is smaller than 20 nm. Furthermore, the magnetic properties like remanence, coercive field, and Curie temperature increase with longer annealing times for films which are thicker than 20 nm.

Mo.H-P31 - Spin wave eigenmodes of Dzyaloshinskii domain walls

P. Borys[1], Felipe G. Sanchez[2], J. Von Kim[2], R. Stamps[1]

1. University of Glasgow, Glasgow, Scotland
2. Institut d'Electronique Fondamentale, Univ. Paris-Sud, Orsay, France

The Dzyaloshinskii-Moriya interaction (DMI) is an antisymmetric exchange interaction that arises in systems lacking inversion symmetry and possessing strong spin orbit coupling, such as ultrathin ferromagnetic films with heavy metal underlayers. It has been shown that the DMI stabilizes different kinds of chiral spin textures, such as Néel-type walls called Dzyaloshinskii domain walls that are favoured over Bloch-type walls. Here, we will present a theory for the spin wave eigenmodes of a Dzyaloshinskii domain wall. The mode frequencies for spin waves propagating parallel and perpendicular to the domain wall are computed using a continuum approximation. In contrast to Bloch-type walls, it is found that the spin wave potential associated with Dzyaloshinskii domain walls is not reflectionless, which leads to a finite scattering cross-section for interactions between spin waves and domain walls. Consequences for spin wave driven domain wall motion and band structures arising from periodic wall arrays are discussed.

Mo.H-P33 - Anomalous Hall Effect in antiferromagnetic Mn5Si3 films

C. Sürgers[1], G. Fischer[1], H. v. Löhneysen[1]

1. Karlsruhe Institute of Technology, Karlsruhe, Germany

The anomalous Hall effect (AHE) in ferromagnets is usually assumed proportional to the magnetization. However, an AHE has been proposed to appear even in an antiferromagnet with a highly noncollinear and non-coplanar spin structure. Particularly interesting is a material which has collinear and non-collinear phases at different temperatures. This unusual situation arises in non-cubic antiferromagnetic Mn5Si3 with atoms Mn1 and Mn2 at two inequivalent lattice sites. In the long-range ordered antiferromagnetic AF2 phase between the Neél temperature TN2= 99K and TN1 = 66 K, two third of the Mn2 atoms have moments oriented in a collinear fashion. In the AF1 phase below TN1, the Mn1 atoms acquire a moment in addition to realigned Mn2 moments. The moments point into different directions forming a highly non-collinear magnetic structure attributed to topological frustration. The magnetic structure in the AF1 phase can be modified by a magnetic field thereby strengthening the AF2 arrangement. Here we show that a large AHE contribution develops in Mn5Si3 thin films well below the Neél temperature as soon as the spin arrangement changes from collinear (AF2) to non-collinear (AF1) with decreasing temperature [1]. The magnetic-field dependence of the AF1/AF2 phase boundary is in good agreement with earlier neutron scattering experiments. Furthermore, we demonstrate that the large AHE arising from collinearity is not observed when the material is turned ferromagnetic by carbon doping without changing its crystal structure. The results motivate future experimental work on the Hall effect in non-collinear antiferromagnets.

Mo.H-P34 - Proximity effects in Fe/Cr/Gd multilayers

V.V. Ustinov[1], M.V. Ryabukhina[1], E.A. Kravtsov[1], Y. Choi[2], D. Haskel[2], Y. Khaidukov[3]

1. Institute of Metal Physics, Ekaterinburg, Russia
2. Advanced Photon Source, Argonne National Laboratory, Argonne, United States
3. Max Plank Institute for Solid State Research, Stuttgart, Germany

Ferromagnetic 4f rare-earth/3d transition metal multilayers are popular model systems displaying a rich variety of magnetic phases in applied fields. Fe/Cr/Gd multilayers where Fe-Gd exchange coupling is mediated by antiferromagnetic Cr are promising systems where one may govern Fe-Gd interlayer exchange coupling by playing with Cr layer thickness and temperature. In our presentation we report on depth-resolved and element-specific magnetization density profiles in Fe(35 A)/Cr(t A)/Gd(50 A), t = 0-8 A multilayers determined by complementary application of SQUID-magnetometry, polarized neutron and resonant x-ray magnetic reflectometry. We show that the insertion of antiferromagnetic Cr spacer changes magnetic structure of multilayers as compared with Fe/Gd multilayers. First, it shifts the compensation point to lower temperatures. Second, it switches otherwise antiferromagnetic Fe-Gd interlayer magnetic ordering to noncollinear one - the thicker Cr spacer the more significant is the deviation from antiferromagnetic Fe-Gd interlayer ordering. Third, it leads to an enhancement of Gd magnetic moments in the interfacial regions near Fe. The effect is similar to that observed in Fe/Gd multilayers but the value of induced Gd magnetic moment is lower. Forth, it causes to reduction of magnetic moments in the core of Gd layers even at very low temperatures.

Mo.H-P35 - Formation of ordered antiferromagnetic phase NiFeMn under thermo-magnetic treatment of manganese-permalloy bilayers

I.V. Blinov [1], T.P. Krinitsina[1], M.A. Milyaev[1], V.V. Popov[1], V.V. Proglyado[1], V.V. Ustinov[1]

1. Institute of Metal Physics, Ekaterinburg, Russia

A method of formation of an ordered antiferromagnetic (AF) phase NiFeMn under thermo-magnetic treatment of manganese-permalloy bilayers has been suggested. A possibility of application of an AF alloy [NiFe](1-x)Mn(x) as a pinning layer in spin valves is studied. The results obtained can be used for fabrication of nanostructures with enhanced functional characteristics.

Samples including a disordered AF alloy [Ni80Fe20](1-x)Mn(x) were fabricated by magnetron sputtering on MPS-4000-C6 (Ulvac) device. For the formation of unidirectional anisotropy a permanent magnetic field of 110 Oe was applied under sputtering.

The as-prepared samples are characterized with a hysteresis loop shifted relative to the magnetic field axis. The surface density of energy of the exchange interaction at a FM/AF interface is found to be equal to 0.05 erg/cm2, whereas the measured blocking temperature of the [Ni80Fe20](20nm)/[[Ni80Fe20](1-x)Mn(x)](50nm) system is about 150 Celsius degrees.

A higher blocking temperature 270 Celsius degrees has been obtained for the system Al2O3/[Ni77Fe23](5nm)/Mn(50nm)/[Ni77Fe23](30nm)/Ta(5nm) fabricated by electron-beam evaporation on Varian device and subjected to the thermo-magnetic treatment at 260 Celsius degrees for 4 hours. In this case the ordered AF phase NiFeMn is formed. The surface density of energy of the exchange interaction at a FM/AF interface in this case is 0.27 erg/cm2. These values of blocking temperature and surface density of exchange energy are noticeably higher than those for the system [Ni80Fe20]/[Ni80Fe20](1-x)Mn(x), and are comparable with blocking temperature and surface density of exchange energy for the system with AF layer of IrMn.

The magnetoresistance of a spin valve including the AF alloy [NiFe](1-x)Mn(x) is 7.15 %.

Mo.H-P36 - $CoFe_2O_4/Fe_3O_4$ superlattices; MBE growth and magnetic properties

Q. Nguyen Van[1], Y. Shin[2], Rhim S. H.[1], A. Tuan Duong[1], M. Nguyen Thi[1], S. Cho[1], M. Christian[2]

1. Department of Physics, and Energy Harvest Storage Research Center, University of Ulsan, Ulsan, South Korea
2. Institute of Physics and Chemistry for Materials of Strasbourg, Strasbourg, France

Magnetite, Fe_3O_4 , is a ferrimagnet with a cubic inverse spinel structure and exhibits a metal-insulator, Verwey, transition at about 120 K.[1] It is predicted to possess as half-metallic nature, 100% spin polarization, and high Curie temperature (850 K). Cobalt ferrite is one of the most important members of the ferrite family, which is characterized by its high coercivity, moderate magnetization and very high magnetocrystalline anisotropy. It has been reported that the $CoFe_2O_4/Fe_3O_4$ bilayers represent an unusual exchange-coupled system whose properties are due to the nature of the oxide-oxide super-exchange interactions at the interface[2]. In order to evaluate the effect of interface interactions on magnetic and transport properties of ferrite and cobalt ferrite, the $CoFe_2O_4/Fe_3O_4$ superlattices on MgO (100) substrate have been fabricated by molecular beam epitaxy (MBE) with the wave lengths of 50, and 200 Å, called 25(Å)/25(Å) and 100(Å)/100(Å), respectively. Streaky RHEED patterns in sample 25(Å)/25(Å) indicate a very smooth surface and interface between layers. High-magnification HAADF image and selected area electron diffraction (SAED) pattern in TEM cross section measurement indicated the successful growth of superlattices. Interestingly, magnetization curves showed a strong antiferromagnetic behavior, which was formed at the interfaces.

Mo.H-P37 - Modification of Interfacial Magnetism in Weakly Strained Manganite films

N. Bingham [1,2], A. Suszka[1,2], C. Fernandes Vaz[3], V. Franco[4], L. Heyderman[1,2]

1. Laboratory for Micro- and Nanotechnology, Paul Scherrer Institute, Villigen, Switzerland
2. Laboratory for Mesoscopic Systems, Department of Materials, ETH Zurich, Zurich, Switzerland
3. Swiss Light Source, Paul Scherrer Institut, Villigen, Switzerland
4. Departamento de Física de la Materia Condensada, ICMSE-CSIC, Universidad de Sevilla, Sevilla, Spain

Interfaces of thin film manganite heterostructures are of particular interest and are well-documented sites for fundamentally altered magnetism. Generally, much of the work in interfacial studies involves substrate-induced strain on the magnetic film. This results in changes of the film properties with the film adopting the in-plane symmetry of the substrate [1]. However, it is predicted that weakly strained films can induce the formation of nano/micro-scale phase separation in manganites leading to an enhancement of colossal magnetoresistance effects. We explored this modification of the magnetic structures in thin film manganites by investigating a strain-relaxed (50 nm) La0.66Ca0.33MnO3 (LCMO) film capped with (5 nm) BaTiO3 (BTO) and compared the results with those of an LCMO film without the addition of BTO. The films were deposited on MgO substrates via pulsed laser deposition. Temperature and field dependence of magnetization were measured in the temperature range of 5-300K and in magnetic fields up to 5 T. A paramagnetic to ferromagnetic transition of LCMO occurs at Tc ~250 K in both cases. However, for the LCMO/BTO sample there is a second transition at 150 K, which is attributed to the macroscopic modification in the magnetic behavior in the LCMO film at the rhombohedral to orthorhombic BTO structure transition. Magnetocaloric effect (MCE) measurements confirm this modification. X-ray absorption and x-ray magnetic circular dichroism data taken at the Mn L3,2 and Ti L3,2 edges at the SIM beamline, Swiss Light Source, show an electronic modification of the LCMO layer at the interface with the BTO film and identify primarily Mn2+ ions. These measurements also reveal sub-microscopic magnetic correlations above Tc on both the Mn and Ti edges, which could be attributed to local magnetization modification at the interface between LCMO and BTO layers above Tc.

Mo.H-P38 - Ferromagnetic and spin-wave resonances in multilayer nanogranular films [(Co40Fe40B20)X(SiO2)100-X/α -Si:H]n and [(Co40Fe40B20)X(SiO2)100-X/SiO2]n

E. Denisova[1], L. Chekanova [1], R. Iskhakov[1], Y. Kalinin[2] , A. Sitnikov[2]

1. Kirensky Institute of Physics SB RA, Krasnoyarsk, Russia
2. Voronezh State Technical University, Voronezh, Russia

Multilayer films, consisting of granular $(Co_{40}Fe_{40}B_{20})_X(SiO_2)_{100-X}$ layers as thin as magnetic granule diameter alternating the a-Si:H or SiO_2 layers and the single layer films $(Co_{40}Fe_{40}B_{20})_X(SiO_2)_{100-X}$ (30< X <80) with the thickness much larger than the magnetic granule diameter have been investigated by means of ferromagnetic resonance (FMR) at 9.2 GHz.
The FMR spectrum for H applied parallel to the film plane consists of a single absorption line for all types of samples. It is found that the value of the resonance fields H_r is independent of metal layer thickness t (2.5 < t < 5 nm). The H_r magnitudes for multilayer $[(Co_{40}Fe_{40}B_{20})_X(SiO_2)_{100-X}/a\text{-}Si:H]_n$ films (for all thickness of the silicon layer) are larger than for single layer films with the same composition. From resonance fields we evaluated an effective shape anisotropy field of magnetic phase. The FMR linewidth of multilayer films is much less than for $Co_{40}Fe_{40}B_{20}$-SiO_2 films. When the external field is applied perpendicular to the film plane it is possible to observe multipeaked spectra, due to resonance absorption by standing spin-wave resonance modes. There are up to 11 peaks in SWR spectrum of the $Co_{40}Fe_{40}B_{20}$-SiO_2 films. The separation of granular layers with a-Si:H or SiO_2 layer leads to a reduction in the number of SWR peaks. A surface resonance mode is observed for all samples. The surface anisotropy field is evaluated as a function of X ($0.9 < K_s < 0.5$ erg/sm^2). It is found that the $H_r(n^2)$ (where n is the mode number) dependencies are non-linear. Such behavior is probably caused by the fluctuations of magnetic parameters (the magnetization and the ferromagnetic exchange coupling) in nanocomposite films. The magnetic properties of the films are discussed in relation with the microstructure of the multilayer systems.

Mo.H-P39 - Asymmetry in the Activity of Nucleation Centers in Ultrathin Pd/Co/Pd Trilayers

R. Shull [1], Y.L. Iunin[2], P.J. Chen[1], V.I. Nikitenko[2]

1. National Institute of Standards and Technology, Gaithersburg, United States
2. Russian Academy of Science, Chernogolovka, Russia

Normally, when a ferromagnet undergoes a magnetization reversal, the nucleation of domains with the opposite magnetization occurs at the same locations for opposite magnetic field directions. Recently, however, a new phenomenon of asymmetry in the activity of nucleation centers was revealed in Co/Pt films and multilayers [1]. In these cases, many nucleation sites for reversal domains were found to depend upon the direction of the reversal field. In order to determine if this new phenomenon is universal, we used Kerr microscopy to study in detail the domain nucleation and growth processes in Pd(10)/Co(0.2)/Pd(10 nm) trilayers sputtered on a MgO substrate at 300 K. As ultrathin Co/Pt and Co/Pd films and multilayers with perpendicular magnetic anisotropy have played an important role in magnetic data storage and advanced spintronic devices in recent years, this study is particularly timely. The experiments were performed as follows. First the sample was saturated by applying a magnetic field greater than the coercivity (HC) of the sample, followed by a gradual reduction and then reversal of the external field. During the field reduction and reversal, the nucleation and evolution of reversal domains was studied. Interestingly, just like in the Co/Pt system, asymmetrical magnetic domain nucleation centers were also observed in the Co/Pd trilayers of this study, where the reversal begins for one direction of magnetic field only. Thus, the asymmetry in the activity of nucleation centers is not specific to the Co/Pt system, but is a rather general phenomenon. It was also found here that applying a large enough perpendicular magnetic field (much greater than HC) suppresses the asymmetrical nucleation.

Potential applications in spintronic devices such as non-volatile memories make tunnel junctions (MTJ) object of great interest. One of the main challenges in the field is finding materials showing high magnetoelectric effect, in which electric and/or magnetic field can control their magnetic and electric state. On this purpose, magnetic and electric properties of certain oxides may be engineered on demand by epitaxial growth on a substrate. In this work, epitaxial bilayers of La2/3Sr1/3MnO3 (≈23 nm) / SrMnO3 (≈2.7 nm) were grown by pulsed laser deposition (PLD) on two different substrates: SrTiO3 (STO) and (LaAlO3)0.3(SrAl0.5Ta0.5O3)0.7 (LSAT), aiming at observing the impact of epitaxial strain on the tunnel transport properties. Recent theoretical calculations have proposed that SrMnO3 becomes multiferroic under epitaxial strain [1]. Both samples were structurally characterized by reciprocal space maps as well as by scanning transmission electron microscopy, showing a lattice parameter deformation for SMO of in-plane +1.66% and out-of-plane ù1.36% in the samples grown on LSAT, and in-plane +2.63% and out-of-plane ù2.81% when substrate was STO. However, final volumes of the unit cell considering these deformations are very similar (~2% bigger than in bulk) for both samples within the experimental error. Tunnel transport properties were locally characterized by conductive atomic force microscopy (CAFM), using nanostencil lithography to deposit Au contacts on the sample. I(V) characteristic curves show that the thin SMO barriers retain the insulating behavior. I(V) curves were fitted to Simmons and Brinkman models [2,3], obtaining the characteristic parameters of the barriers. No difference was found between the average barrier heights, suggesting than the cell volume controls the characteristics of the barrier.

Mo.H-P42 - Magnetization boundary conditions at a ferromagnetic interface of finite thickness

V. Kruglyak[1], O. Gorobets[2], Y. Gorobets[3], A. Kuchko [3,4]

We have developed a systematic approach by which to derive boundary conditions at an interface between two ferromagnetic materials in the continuous medium approximation [1]. The approach treats the interface as a two-sublattice material, although the final equations connect magnetizations outside of the interface and therefore do not explicitly depend on its structure. Instead, the boundary conditions are defined in terms of some average properties of the interface, which may also have a finite thickness. In addition to the interface anisotropy and symmetric exchange coupling, this approach allows us to take into account coupling resulting from inversion symmetry breaking in the vicinity of the interface, such as the Dzyaloshinskii-Moriya antisymmetric exchange interaction. In the case of negligible interface anisotropy and Dzyaloshinskii-Moriya exchange parameters, the derived boundary conditions represent a generalization of those proposed earlier by Barna┼ø and Mills and are therefore named “generalized Barna┼ø-Mills boundary conditions”. We demonstrate how one could use the boundary conditions to extract parameters of the interface via fitting of appropriate experimental data. The developed theory could be applied to modeling of both linear and non-linear spin waves, including exchange, dipole-exchange, magnetostatic and retarded modes, as well as to calculations of non-uniform equilibrium micromagnetic configurations near the interface, with a direct impact on the research in magnonics and micromagnetism.

Mo.H-P43 - Thickness dependence of Gilbert damping of (Ru,MgO)/CoFeB/Ru trilayers

S. Bunyaev[1], A. García-García[1,2], A. Vieira Silva [2], J. M. Teixeira[1], J. Ventura[1], S. Cardoso[2], P. Freitas[2], G. Kakazei[1]

Gilbert damping α is a crucial parameter of magnetic materials that determines operating speed and energy effectiveness of spintronic and magnonic devises. CoFeB is suggested to be the most promising material for electrodes in magnetic tunnel junctions (MTJ) with MgO barriers, since it possess low damping values and can exhibit perpendicular magnetic anisotropy. However, available data of α dependence on CoFeB alloys thickness and buffer material remain incomplete and sometimes controversial. Two series of the samples (Ru,MgO)/(Co70Fe30)80B20/Ru were probed by broadband ferromagnetic resonance (FMR) in a frequency range from 1 to 20 GHz at room temperature. The thickness of CoFeB layer grown at room temperature via ion-beam sputtering was varied from 1.5 nm up to 40 nm. The method described in [1] was applied to obtain the FMR linewidth from complex magnetic permeability function. The approach proposed by Bilzer [2] was used then to extract α from the linewidth. As expected, increase of α with the CoFeB thickness decrease has been observed for both series. For the samples thinner than 20 nm the annealing at 330ºC during one hour leads to α decrease for MgO buffer and to its increase for Ru one. The obtained results are important for the design of CoFeB based ultra-thin MTJs stacks that layers with different buffers. It is necessary to take into account the dependence of α on buffer material and annealing parameters.

Co/Ni multilayers can exhibit an effective anisotropy with in-plane and/or out-of-plane components. The balance between these two orthogonal anisotropies depends on the growth conditions and the structural parameters of the multilayer, but it can be altered by subsequent thermal treatments. In this work we analyze the annealing effects on the magnetization reversal curves of “as grown” samples and post-annealed multilayers. In-plane and out-of-plane hysteresis loops were obtained at room temperature for three sets of measurements; (i) Co/Ni multilayers deposited at room temperature, (ii) Co/Ni multilayers deposited at high temperature, and (iii) post-annealing of Co/Ni multilayers deposited at room temperature. A significant change was observed in samples exposed to high temperatures, either during deposition or post-annealing. Remanent magnetization becomes null in both cases. X-ray diffractograms and surface roughness characterization by atomic force microscopy show that the microstructure is significantly affected by deposition or annealing temperatures. Surface roughness increases with temperature, which has a strong effect on the Co-Ni interface and consequently on the magnetic properties of the multilayers.

Mo.H-P45 - Transverse Kerr effect transformation of by normal metal film atop ferromagnetic metal surface

V. Skidanov [1]

1. Institute For Design Problems In Microelectronics RAS

Recent years observation of magnetooptical signal from additional ferromagnetic layer is considered as a promising way to enhance sensitivity of biochips based on plasmonic properties of noble metals.
The present report is devoted to experimental investigation of possibility to enhance magnetooptical signal by additional normal transition metal layer with nanoscale thickness. It is shown that the presence of normal transition metal layer with thickness up to 100 nm atop or/and under ferromagnetic metal significantly modifies magnetooptical reply of the film structure.
Inversion of the transverse Kerr effect is seen clearly when white light falls on the Cr layer side. Value and sign dependence of magnetooptical signal upon thickness of normal layer was found so that the inversed signal amplitude can exceed signal amplitude from pure Py film.
Up to three-fold enhancement of the magnetooptical signal was observed in configuration when light falls on the thin Py layer (≤ 10 nm) atop normal metal layer with thickness more than 20-30 nm. Thin normal metal underlayer (< 20 nm) leads to signal reduction.
Investigations were made with a wide number of normal transition metals with different filling of atomic shells 3d, 4d and 5d (Ti, Cr, Mo, Ta, Re, Pt, W). It was shown that the influence of normal metal layer rigorously depends upon filling of atomic d-shell of the metal. Inversed signal amplitude gradually reduced with d-shell filling. The most amplitude of inversed signal was observed for Ti and Ta coatings. No signal inversion was observed for Cu and Au coatings with filled 3d and 5d atomic shells. But two-fold enhancement of magnetooptical signal from Py film was found with Cu or Au layers underneath.

Mo.H-P46 - Domain wall propagation in Co/Pt-wedge/Co film with perpendicular anisotropy

M. Matczak[1,2], R. Schõfer[3,4], M. Urbaniak[1], B. Szymañski[1], P. Kuwik[1], F. Stobiecki[1,2]

Domain wall (DW) propagation in layers with perpendicular anisotropy, that is controlled by a uniform magnetic field, has the potential to be used for the transport of magnetic beads by the moving stray-field trap of a moving DW [1] or in sensors registering the maximum values of varying magnetic fields [2].
A magnetic multilayer of the structure substrate//Pt(15nm)/Co(0.8nm)/Pt-wedge(0-7nm)/Co(0.6nm)/Pt(2nm) was deposited by magnetron sputtering in a UHV system. The thickness of the Pt-spacer (tPt) changed from 0 to 7nm over a length of 18 mm. For tPt <2.6 nm, the magnetization reversal of the Co-layers occurs cooperatively, and for larger tPt sequentially. The Co-layer with 0.6 nm thickness (CoS) has a lower switching field and is magnetically softer then the tCo = 0.8 nm layer (CoH). In the 2.6 <tPt <3.0 nm range there are significant changes of the switching field due to a strong gradient of an interaction field Hmls (the field defines the position of the center of the minor hysteresis loop). For tPt>3.0 nm, Hmls is about zero and the switching fields of the Co-layers are equal to their respective coercive fields. Interestingly, in a region of the sample with strong interaction gradient, the magnetization reversal in the CoS layer takes place reversibly by the propagation of a single straight DW. To explain this specific nature of magnetization reversal in the CoS layer, DW propagation velocity measurements were performed in an area characterized by a negligible interaction (Hmls~0) and in a region with the gradient of the ferromagnetic interaction |dHmls/dx|>0. In the x-range with no interaction, the distance travelled by the DW, (dx), in a given magnetic field H, is proportional to the duration of the field pulse (dt), and the v(H) dependence is typical for creep propagation [3]. However, in the area with an interaction gradient Hmls, dx/ dt is a decreasing function of the pulse duration. Thus, in the presence of the ferromagnetic interaction gradient. a strong suppression of the thermally activated DW propagation of is observed.

In this work, we analyze the magnetic anisotropy field of amorphous alloy as-cast and thin film with composition Co67Fe4Mo1Si17B11 (Vitrovac6030). The amorphous alloy was obtained from VACUUMSCHMELZE GmbH & Co. KG, where this alloy was used as a target to grow thin films, being deposited by means of dc magnetron sputtering on a glass substrate; with a 3x10-2 mbar Argon pressure and sputtering power of 0.834 Watts. X-ray Diffraction patterns show similar amorphous structures between Vitrovac6030 as-cast and Vitrovac6030 thin film. Magnetic measurements confirm that the amorphous alloy has ultra-soft ferromagnetic properties with a coercive field of 0.035 G; while the thin film has a coercive field of 17 G, indicating a partial loss of ultra-soft ferromagnetic properties, and it is due to magneto-elastic contributions promoted by deposition method and the interface between substrate and the thin film. Magnetic anisotropy was analyzed by means of ferromagnetic resonance (FMR) and low-field microwave absorption (LFMA) measurements. FMR measurements of Vitrovac6030 as-cast shows a typical spectrum of Cobalt-based alloys, with transversal magnetic anisotropy; while the thin film has a broad FMR line, associated with a wide distribution relaxation times due to magneto-elastic contributions, originating by deposit method. LFMA measurements show a similar behavior that FMR and this suggests an increment in magnetic anisotropy field by magneto-elastic effects.

Cobalt ferrite (CoFe2O4) is a magnetic oxide with an inverse spinel type structure, and that it gives origin to their magnetic properties, also had been proposed as a component in magnetoelectric multilayer for technological applications development. In this work, thin films of cobalt ferrite were obtained by means of pulsed laser deposition (PLD); at vacuum pressure of ~10-6 Torr, with a constant oxygen pressure of 15 mTorr. The thin films were grown on a substrate of amorphous quartz and silicon <100>. The X-ray diffraction shows a preferential growth of crystallites in the direction <400> for both types of substrates. Atomic force microscopy shows a wide distribution of particle size. Magnetometry measurements show a high coercive field around of 2000 Oe in both substrates, and it is associated to an increment of magnetic anisotropy of particles due to preferential growth. Ferromagnetic resonance (FMR) spectra show two resonant absorptions associated with different magnetic phases, one phase corresponding to superparamagnetic particles and the other resonant absorption is associated with monodomain particles.
The authors acknowledge the financial support of DGAPA-UNAM, through the grants PAPIIT IG100314. Everardo Lopez M. is grateful to PAEP-UNAM and CONACYT-Mexico, through financial support and scholarship.

Mo.H-P49 - Electronic properties and magnetic moment distribution on perovskite type slabs

J. Pilo Gonzalez[1], J. Rosas Huerta[1], E. Carvajal Quiroz[1], M. Cruz-Irisson[1], O. Navarro Chávez[2]

1. Instituto Politécnico Nacional, ESIME-Cul, Coyoacan, México D. F., Mexico

Perovskite type slabs were excised from the Sr_2FeMoO_6, $SrFeO_3$ and $SrMoO_3$ bulk double perovskites (SFMO, SFO and SMO, respectively), leaving (001) free surfaces. Supercells were built up for each slab, keeping a 10Å initial free space, to optimize the geometry. Once the minimum energy state was identified, the electronic and magnetic properties of the [001] oriented slabs have been calculated within the Density Functional Theory (DFT) scheme, with the Hubbard-corrected Local Density Approximation (LDA+U) and using the CA-PZ functional [1]. Magnetic moment for each atom in the systems was calculated; spin values for the Mo atoms are 0.25ħ, 0.27ħ and 0.26ħ for the $SrMoO_3$ slab system case and they are aligned ferromagnetically. Contrarily, Mo magnetic moments in the Sr_2FeMoO_3 slab system align antiferromagnetically to the corresponding Fe atoms. The Densities of States (DOS) and band structures were calculated also to study the electronic behaviors. The vacuum region change, decreasing as geometry stabilizes (10Å to 9.743Å for the $SrMoO_3$ case) and the t_{2g} and e_g states roles were discussed contrasting with what is found to bulk materials [2].

This work was partially supported by COFAA-IPN, the multidisciplinary projects 2014-1640 and 2014-1641 from SIP-Instituto Politécnico Nacional, PAPIIT-IN100313 from Universidad Nacional Autónoma de México. J. Pilo and J. L. Rosas want to acknowledge the graduate fellowship from Consejo Nacional de Ciencia y Tecnología.

Mo.H-P50 - Preparation and magnetic properties of $NiFe_2O_4$ / $ZnFe_2O_4$ bilayers

Mahender C [1], Prabhu R.[2], Sahu B.N[2], S. Prasad[2], Venkataramani[1]

1. Department of Metallurgical Engineering and Materials Science, Indian Institute of Technology Bombay, Bombay, India
2. Department of Physics, Indian Institute of Technology Bombay, bombay, India

NiZnferrite (NZF), a versatile material used in various applications, requires high temperature processing and stoichiometric target to get proper magnetic properties, when deposited in thin film form. In this paper, we have deposited $NiFe_2O_4$ (NiF) and $ZnFe_2O_4$ (ZnF) bilayer of different thicknesses from two binary ferrite targets (NiF and ZnF). By annealing the bilayer at different temperatures we could obtain a good control on the magnetic properties. We first deposited NiF film (170 nm) on fused quartz substrate. The ZnF films with different thicknesses (20 to 350 nm) were deposited on top of this film to form a set of bilayers. These samples were deposited at room temperature and annealed in air at various temperatures for 2 hrs. The $4\pi M_S$ values of the as deposited bilayers continuously decreased from 0.45 kG to 0.2 kG with increase in ZnF layer thickness. But the $4\pi M_S$ values of bilayers annealed at 650 ˚C initially increased from 3.1 kG with the ZnF film thickness and reached a maximum of 6.5 kG for total film thickness 330 nm. It then drops to 3kG when ZnF thickness exceeds the thickness of NiF layer. The maximum spontaneous magnetization value of bilayers is near to bulk value 6.6 kG of $Ni_{0.7}Zn_{0.3}Fe_2O_4$ at 10 K. The variation in $4\pi M_S$ of bilayers with increasing ZnF layer thickness nearly follows the trend of magnetization curve of bulk $Ni_{1-x}Zn_xFe_2O_4$ with Zn concentration (x). A cross sectional TEM image of NZF bilayers with thickness 370 nm shows that there is inter diffusion between the two layers. In these set of experiments we are in a position to control the Zn substitution in NiF through diffusion across the bilayers and see the effect of Zn composition of nano crystalline grain sizes in NZF thin films.

Mo.H-P51 - Ferromagnetic-antiferromagnetic transition in [001]-oriented L10 FeMnPt films

T. Hasegawa[1], S. Kimura[1], K. Ito[1], S. Ishio[1], A. S. Kamzin[2], A. A. Valiullin[2], C. Barton[3], T. Thomson[3]

1. Department of Materials Science and Engineering, Akita University, Akita, Japan

3. School of Computer Science, University of Manchester, Manchester, England, United Kingdom

The [001]-oriented $L1_0$ (CuAu I type) FePt thin films have attracted much interest because the perpendicular magnetization is expected to have applications for storage media and spintronic devices due to a high magnetization (M_s ~ 1100 emu/cm^3) and a high magnetocrystalline anisotropy (K_u ~ 7.0 × 10^7 erg/cm^3) caused by the atomic arrangement having alternating Fe and Pt layers along the *c* axis. By replacing Fe with Mn in the equiatomic FePt bulk alloy, significant antiferromagnetic (AF) ordering is stabilized [1]. However, there are very few reports on the magnetic phase diagram of films. In this work, [001]-oriented $L1_0$ $(Fe_{1-x}Mn_x)_{60}Pt_{40}$ films (6.12 nm thick) were prepared. The films were deposited on (100) MgO substrates by magnetron spattering method, and those were subsequently annealed at 973 K for 10 minutes. The degree of order parameters was approximately 0.89 in all of the films. The lattice constant *c* decreased with x, and the gradients abruptly changed at around x ~ 0.54, while the gradient of the films with x > 0.60 increases in the bulk system [1]. The magnetic phase diagram is determined. At room temperature, the films with $0 \le x \le 0.52$ were in a ferromagnetic (FM) phase with a coercivity of several kilo-oersteds. The films with $0 \le x \le 0.54$ shows FM-paramagnetic (PM) transition at Curie temperature, and the films with $0.52 \le x \le 0.60$ show AF-FM-PM or AF-PM transition. At x = 0.52, which is close to the critical composition of the FM-AF phase change at room temperature, the K_u was about 1.3 × 10^7 erg/cm^3 which is sufficient for the high-density magnetic storage media over 6 Tbit/in^2.

Mo.H-P52 - Epitaxially Textured PCMO Thin Films Under Considerably Low Substrate Temperature

M. Nyman[1], T. Elovaara[1], J. Tikkanen[1], S. Majumdar[2], H. Huhtinen[1], P. Paturi[1]

1. University of Turku, Turku, Finland
2. Aalto University, Espoo,Finland

Among the perovskite manganites, a small-bandwidth compound of Pr{1-x}Ca{x}MnO{3} (PCMO), with fascinating electronical and magnetic properties like colossal magnetoresistance (CMR), coexistence of phase-separated regions, first order irreversible metamagnetic transition, large magnetocaloric effect and enormous resistive switching under optical or electrical excitation, has received a lot of technological and scientific interests and these phenomena have led to huge potential in the photovoltaic, magnetic data storage and memory applications. However, the applications are usually based on nearly atomically flat structures requiring high quality thin films of individual layer materials. Therefore, the optimization of the pulsed laser deposition (PLD) process, where the influence of the substrate temperature plays a significant role, is one of the main focus when developing novel multi-purpose thin films for wide-ranging future emerging-energy technologies. In this paper, we report the growth of well-crystallized and epitaxially textured PCMO thin films on SrTiO{3} substrates by pulsed laser deposition at a considerably low substrate temperature of as low as 450 C without high-temperature post-annealing treatments. Although a strong ferromagnetic interaction as well as large irreversible metamagnetic transition with a training effect have been observed for films grown at 450 C, the in-plane and out-of-plane lattice ordering is slightly improved with increasing substrate temperature. Therefore, the lowest magnetic field of 2 T for melting the insulating charge-ordering state at 70 K has been observed for films grown with substrate temperature between 550 and 600 C. The nucleation and growth of PCMO substrate at exceptionally low substrate temperature is qualitatively modelled by the combination of the kinetic energies and redox potential of the components of the ablation plasma, while the heat flow from the substrate is assumed to be less important. The results are of extreme importance for the future generation of energy-efficient oxide thin film fabrication routes for novel technology solutions.

Mo.H-P53 - Electrical, structural and morphological properties of epitaxially-grown Cr100-x Cox alloy films

C. Sheppard[1], A. Prinsloo[1], M. Kadam[1], E. Fullerton[2], D. Dekadjevi[3], P. Elies[3], J.Richy[3]

1. University of Johannesburg, Johannesburg, South Africa
2. University of California San Diego, La Jolla, United States
3. Université de Bretagne Occidentale, Brest, France

Comparison between Cr in bulk and thin film forms revealed that dimensionality plays an important role in modifying the spin-density-wave (SDW) structure [1]. The present study extends these investigations to include epitaxially-grown Cr100-xCox thin films, with $0 < x < 8$ and thickness 200 nm. These samples were prepared on MgO(100) substrates using DC magnetron co-sputtering. Hall coefficients for these films, determined on cooling from 350K to 2K in a constant magnetic field, exhibit a change in majority charge carriers with variation in temperature and concentration. The Néel temperatures (TN) of the films were determined from anomalies observed at TN in electrical resistance measurements as a function of temperature. The TN-x phase diagram obtained for these samples indicates a decrease in TN values up to x = 2.6, where after the TN values increase and peak at about 5 at.% Co. This TN-x behavior is reminiscent of that seen for bulk Cr-Co, where a triple point (L) is observed for a concentration xL = 1.3 at a temperature TL = 280 K [2]. However, in the case of epitaxial Cr-Co thin films, L is shifted to xL = 2.6 and TL is decreased to 220 K. Interestingly, XRD analyses on the Cr100-xCox thin films indicate that for samples with x approximately equal to xL the crystal coherence length in growth direction (100) is a maximum, while the mosaicity is a minimum. In addition, AFM studies indicate that the film roughness is also a minimum at xL, where well defined cubical structures are observed. For films with $x < xL$, small elongated angular structures are seen, while for films with $x > xL$ large tilted cubic structures are formed. Thus, the behavior of the TN-x curve seems to reflect both the intrinsic magnetic properties and growth changes with increasing Co content.

Mo.H-P54 - Tunneling anisotropic magnetoresistance in oxide heterostructures

L. Balcells[1], R. Galceran[1], C. Frontera[1], B. Bozzo[1], A. Pomar[1], J. Cisneros[1], Z. Konstantinovic[1], B. Martinez[1]

1. Instituto de Ciencia de Materiales de Barcelona – CSIC, Spain

Magnetic tunneling junctions (MTJ) are solid candidates for the development of a new generation of magnetic random access memories (MRAM). However, in spite of the intense work already done, some technical challenges, such as the uniformity of the magnetic properties of the electrodes, the insulating barrier uniformity or the thermal stability, are still not fully resolved. It has been recently shown that magnetoresistance in magnetic tunneling junctions may also depend on the orientation of the magnetization with respect to the crystallographic axes or to the direction of the current flow, in what is called tunneling anisotropic magnetoresistance (TAMR). The use of TAMR response would drastically simplify the technological implementation of MTJ since much of the above mentioned technical challenges will be suppressed. In this work we report on measurements of TAMR response as a function of temperature and magnetic field in different oxide heterostructures such as La2/3Sr1/3 MnO3/AlLaO3/Pt and La2/3Sr1/3 MnO3/MgO/Pt in which TAMR responses of about 4% at low temperature have been measured.

Mo.H-P55 - Magnetotransport properties and morphology of epitaxial Fe/MgO granular multilayers

Discontinuous metal-insulator multilayers (DMIMs) are a particular kind of granular cermets containing a continuous insulating and a discontinuous (granular) metal layer. They exhibit moderate tunneling magnetoresistance (TMR) ratio but an enhanced low-field sensitivity [1], which makes them promising candidates for magnetic sensors.
Recently [2] our Fe(0.6 nm)/MgO (3.0 nm) DMIMs show increase in TMR ratio by a factor of ~4.5 with deposition temperature (T_S) for samples deposited on MgO single-crystal, remaining constant for samples deposited on glass. This was explained by enhanced degree of (001) texturing of MgO layers with T_S.
In this work we discuss the role of T_S on Fe island growth mode onto MgO layers tacking into account previous researches by Boubeta *et al.* [3]. While low T_S yields flat surfaces, high temperature results in a 3D Fe growth. Magnetization measurements above blocking temperature exhibit sizeable deviation from common Langevin behavior. The experimental data were fitted using an extended model that accounts the island shape anisotropy and dipolar interactions between islands. It allows to determine and to elucidate the oblate spheroidal shape and size of Fe islands. Calculated values and can be used to estimate correlations between magnetic moments of Fe neighboring islands. Results are compared with transport and magnetotransport measurements.

Thin magnetic layers and heterostructures thereof are the basic building blocks of a large number of magneto-electronic devices. Their performance strongly relies on the magnetic properties of the layers, which are functions of their morphology, and on the coupling between them. Since these parameters can change during the process of growth, it is important for the understanding and optimization of magnetoelectronic devices to not only accurately monitor the structural but also the magnetic properties during the process of growth. While the structural characterization of thin films during growth by various techniques is common practice (as e.g. commonly done by RHEED/LEED, STM or synchrotron radiation), the in-situ measurement of the magnetic properties of films using (polarised) neutron reflectometry is a challenging task. Within a collaboration of TU München, University Augsburg and MPI Stuttgart, we operate a mobile sputtering facility for the growth and in-situ monitoring of magnetic multilayers, which can be installed at suitable neutron beamlines. In this contribution, first proof of principle (unpolarised and polarised) in-situ neutron reflectivity measurements carried out at the ToF reflectometer REFSANS at the FRM II neutron source and at the AMOR beamline at PSI will be presented. At the latter, use of the SELENE neutron optical concept allows very fast polarised neutron reflectivity measurements to be performed.

Mo.H-P57 - Influence of strain on the magnetic properties of LaMnO3 thin films

A. Pomar[1], J. Roqueta[2], J. Santiso[2], L. Balcells[1], C. Frontera[1], B. Bozzo[1], Z. Konstantinovic[1], N. BaguÞs[1,2], F. Sandiumenge[1], B. Martínez[1]

We present a detailed investigation of the epitaxial growth of LaMnO3 thin films on single crystalline SrTiO3 substrates by Pulsed laser deposition. A progressive evolution of the magnetic and transport properties as a function of oxygen pressure during deposition has been found. A concomitant modification of the film structure has been studied by high-resolution x-ray diffraction. Our results show that films grown at low PO2 are partially relaxed and they exhibit an antiferromagnetic/insulating behavior similar to their bulk counterpart. On the contrary, films grown under highly oxidizing atmospheres are fully strained and they present a strong ferromagnetic character while still electrically insulating. We interpret these findings in terms of different strain-induced orbital orderings. We will also discuss the possibility of tuning the functional properties of LaMnO3 by modifying the residual stress imposed by the substrate.

Mo.H-P58 - Probing short range order mediated tunable spontaneous magnetization in Zn0.95Co0.05O epitaxial films by x-ray absorption

Over the past decades, a fairly large number of studies have explored spin dependent magnetization in Zn1-xMxO (M=transition metal) based diluted magnetic semiconductors by putting special emphasis on the variation of transition metal concentration and co-doping of additional element [1, 2]. However, origin of spontaneous magnetization is still debated to originate either from substitution and/or segregation of transition metal [1, 2] or solely from defects [3]. To address these aforementioned issues, we have investigated tunable spontaneous magnetization triggered in paramagnetic Zn0.95Co0.05O films (Co=5% only) using non magnetic 500 KeV xenon ion irradiation for their potential application in next generation spintronics. The origin of spontaneous magnetization is understood from different degree of bound magnetic polaron stabilization [4] underlined through alteration in short range ordering near the Zn and Co cations in extended x-ray absorption fine structure analysis at Zn and Co K edges. Temperature and magnetic field dependent x-ray circular dichroism measurements at Co L2,3 edge consistently provide purely paramagnetic contribution of Co sublattice in as deposited Zn0.95Co0.05O film. However, coexistence of paramagnetic and ferromagnetic contribution persists in post irradiated Zn0.95Co0.05O films.

Mo.H-P61 - Study of dynamic and static magnetic properties of inverse opal-like structures based on Co and Ni

I. Shishkin[1], A. Mistonov[1,2], N. Grigoryeva[1], S. Grigoriev[1,2], D.Menzel[3]

1. Faculty of Physics, Saint Petersburg State University, Saint Petersburg, Russia
2. Petersburg Nuclear Physics Institute, Gatchina, Russia
3. Institut für Physik der Kondensierten Materie Technische Universität,Braunschweig, Germany

Inverse opal-like structures (IOLS) can be synthesized by filling the voids of opal templates with suitable structure-forming precursors and subsequent removal of the initial microspheres to leave three-dimensionally ordered porous materials. The inverse opals based on the ferromagnetic metals (Ni, Co, etc) represent a new class of the 3-dimensional nanoscale ferromagnetic structures, which are geometrically frustrated at room temperature. Method of ultra small-angle diffraction of synchrotron radiation has shown that the synthesized samples have presumably face-centered cubic ordering of the spherical voids with a period of 760 ± 10 nm. By small-angle neutron diffraction intensities of magnetic scattering as a function of external magnetic field for crystallographic planes of 202-family were obtained. It is assumed that the magnetic structure of inverse opals is a system of 4 magnetic subsystems, directed along four different 111 axes of the fcc structure. Different subsystems are magnetizing in different critical fields, so the magnetic scattering function has a stepped look. One can distinguish critical values of the magnetic field – coercivity; inflection field point; field point, where two branches come together; saturation field. By SQUID-magnetometry were obtained remagnetization curves for Co and Ni IOLS of the thickness in the range from 0.25 mkm to 13 mkm. This measurements were taken at temperatures of 5, 20, 45, 75, 180, 250, 300 K. For all the dependencies the critical fields were determined. They increase with IOLS thickness increasing that indicates presence of a magnetic connection between the layers. It was found also that magnetic hardness of material and developed porous surface affect on the temperature behavior of the film.

Mo.H-P62 - Comparison of FORC Results Obtained on L10 FeCuPt Measured by Three Different Methods

V. Provenzano[1], J. W. Lau[1], D. A. Gilbert[1,2], P. Silwal[1], K. B. Stritch[1], J. Liao[3], C. Lai[3], K. Liu[2]

3. National Tsing Hua University, Dept. of Materials Science and Engineering, Taiwan

The first-order reversal curve (FORC) method is a simple, yet versatile "magnetic fingerprinting" technique for revealing extremely detailed information about a magnetic material, from which magnetic properties-structure correlations can be inferred. So far the technique has been often used for qualitative studies of magnetic phases and magnetization reversal mechanisms [1]. It also has the potential to become a fully quantitative technique for determining key magnetic characteristics such as magnetic interactions and distributions [2]. The default option for FORC measurements has been the vibrating sample magnetometry (VSM) or the alternating gradient magnetometry. An essential component needed to transform the FORC technique to a widely applicable and fully quantitative method, is the ability to yield reliable and reproducible FORC data and distributions acquired by different instruments, analogous to comparing crystal structures probed by X-ray diffraction vs. neutron scattering. To this end, FORC measurements were performed using the anomalous Hall effect (AHE) and magneto-optical Kerr effect (MOKE) methods, which are complementary to magnetometry techniques for acquiring FORC data. In this paper we present the FORC results obtained on a series of FeCuPt films that had undergone rapid thermal annealing between 300 °C to 400 °C (in this range, FePt transforms from a predominantly disordered A1 phase to a L10 phase). The FORC results measured by the three methods, show both basic similarities and key differences. The differences are mainly because the VSM-FORC is sensitive to the magnetization across the entire sample, so is the AHE transport-based FORC, but conduction-path dependent; while the MOKE-based FORC is magneto-optical dependent on the sample local structure. These results demonstrate the validity of AHE-FORC and MOKE-FORC in probing essential magnetic characteristics of the samples, while providing additional and complementary capabilities to magnetometry-based FORC that are very useful for developing the best practice protocol for FORC data acquisition.

Fe-Co is proposed as a possible candidate alloy for permanent magnet applications due to its high magnetic moment. Apart from this, high magnetocrystalline anisotropy and coercivity is required for permanent magnets. In this work we present sputtered thin Fe-Co/ Au-Cu multilayer films doped with Carbon, in order to stabilize metastable tetragonal phases, by straining the unit cell and thus inducing magnetocrystalline anisotropy in the system [1]. By adding Carbon we can stabilize the strain and increase the magnetocrystalline anisotropy of the system [2]. In order to maintain the strain in the magnetic Fe-Co thin films, preventing the partial strain relaxation which we have observed as film thickness increases [3], we followed a multilayer (up to 24 layers) Fe-Co / Au-Cu approach, where variable thickness Fe-Co (1-3nm) and Au-Cu(1-3nm) layers were deposited on MgO (100) substrate at 300^{o}C. By employing this structure, strain is induced from both sides.
X-ray, SQUID and FMR measurements were performed. An intense Fe-Co (002) peak also indicates an epitaxial growth on Au-Cu buffer. There is also a peak shift of almost 0.5° compared to the theoretical value of *2Theta* = 65.31° which indicates a tetragonal distortion in the Fe-Co-C layers. In all multilayer samples, the easy axis of magnetization is in plane. A Magnetocrystalline Anisotropy Energy of about 0.4 MJ/m^3 is found in [$Fe_{45}Co_{55}$(3 nm)/$Au_{30}Cu_{70}$ (1 nm)]$_{12}$ system. Thus, our multilayer approach supports significantly the thickness scaling up of Fe-Co films preserving large perpendicular magnetocrystalline anisotropy. Furthermore a coercivity of about 900Oe was observed, which is a step forward towards permanent magnets applications.

Mo.H-P64 - Anomalous change and development of anisotropic residual stress at the initial stage of FeCo film growth

S. Nakagawa[1], H. Hayashibara[1], Y. Takamura[1]

1. Tokyo Institute of Technology, Tokyo, Japan

An anisotropic residual stress induced by sputter-deposition process is one of the method to cause uniaxial in-plane magnetic anisotropy in FeCo(B) thin films[1]. We developed the in-situ stress observation system of the anisotropic internal stress at the initial stage of the film growth by detecting displacement of cantilever substrate during the film deposition process to clarify initiation and accumulation of the internal stress σ. Since the thickness of the cantilever substrates is as thin as 30 micron, the deviation of the cantilever caused by the film stress can be detected by the laser displacement sensor during the initial stage of the film growth.
It is well known that low and high Ar gas pressure cause compressive and tensile internal stress, respectively, to the films prepared by sputter-deposition. However, the σ of all the films prepared at various Ar gas pressure shows tensile stress at the initial stage of the film growth. The tensile stress at the early stage is caused by the formation of island structure and their agglomeration on the substrate. The critical thickness of the film t_p where the stress changes from tensile to compressive is around 1.5 to 8 nm depending on the surface energies of the film materials and that of the substrate. FeCo films prepared at low Ar gas pressure shows the anomalous change of the internal stress which indicates two critical thickness t_p around t = 3.3 and 7.8 nm. The critical thickness would be t_{P1} considering surface energy. The origins of t_{P2} may be related to magnetic interaction during the island growth or structural transition of alloys. Development of anisotropic residual stress can be also detected during the film formation after the continuous layer developed..

Mo.H-P65 - Electrical control of magnetism in Heusler alloy $Co_2FeAl_{0.5}Si_{0.5}$ at room temperature

H. Wang[1], Y. Wu[2], H. Yu[2], Y. Jiang[2], J. Zhao[1]

2. School of Materials Science and Engineering, University of Science and Technology Beijing, Beijing, China

Magnetic materials with perpendicular magnetic anisotropy have received much attention due to its advantages in the application of spintronics devices, such as high integration density and low damping constant . For the aim of low-power operation, electrical manipulation of the magnetism is in urgent need, and much progress has been achieved such as the electrical switching of FeCo and CoFeB ultrathin magnetic films. Here, we show the electric field effects on the magnetism of Heusler alloy $Co_2FeAl_{0.5}Si_{0.5}$ ultrathin films with perpendicular magnetic anisotropy. The $Co_2FeAl_{0.5}Si_{0.5}$ samples were prepared by magnetron sputtering, in which the Pt buffer layer and the MgO cap layer make the $Co_2FeAl_{0.5}Si_{0.5}$ film perpendicularly magnetized. The samples were then fabricated into field-effect devices consisting of a top gate electrode, a dielectric insulator and a 10 to 30 μm wide channel. High-k dielectric HfO_2 with the thickness of 50 nm was deposited by atomic layer deposition (ALD), and the anomalous Hall effect was used to detect the local magnetization in the vicinity of the Hall probes. The Hall resistance Rxy, which is proportional to the perpendicular component of the magnetization, was recorded under different gate electric fields. An obvious dependence of the coercive field on gating voltage was observed from a 0.8 nm thick film, while a clear change of the magnetic anisotropy was obtained from a 1.1 nm thick one. $Co_2FeAl_{0.5}Si_{0.5}$ films thinner than 0.5 nm tend to show superparamagnetic behaviors at room temperature, and those films thicker than 2.0 nm show indistinguishable change under various gating voltages. It has been shown that the changing in the number of electrons plays a central role in enhancing or reducing the overall magnetic coupling in magnetic films, which is even strong enough and leads to the variation of Curie temperature. Here, the modulation of the coercive field and magnetic anisotropy with the gating voltage is certainly related to the carrier density variation near the interface between the magnetic film and the insulator. However, its dependence on the sample thickness is still an open question and needs to be further investigated.

Mo.H-P66 - Anisotropic magnetoresistance of Heusler-type half-metal ferromagnet and antiferromagnet bilayer thin films

T. Hajiri[1], M. Matsushita[1], M. Nishiwaki[1], H. Tanaka[1], K. Ueda[1], H. Asano[1]

1. Department of Crystalline Materials Science, Nagoya University, Nagoya, Japan

Recently, a magnetization switching using a spin-polarized current is attracting interest because a spin-polarized current can alter the magnetic orientation of an antiferromagnetic layer [1,2]. The critical current for magnetization switching on antiferromagnet is 10^-2 times smaller than that of ferromagnet [1]. A magnetization switching can be observed by an anisotropic magnetoresistance effect on antiferromagnet/ferromagnet exchange-coupled bilayer [3]. Besides, the sign of an anisotropic magnetoresistance effect includes the information about ferromagnetic half-metallicity [4]. We thus studied an anisotropic magnetoresistance effect on half-metallic ferromagnet (HMFM) Fe2CrSi thin films and HMFM-Fe2CrSi /antiferromagnet Ru2MnGe bilayer thin films. Anisotropic magnetoresistance ratio -0.17 % was observed on Fe2CrSi, suggesting that Fe2CrSi can be half-metallic. On the other hand, we succeeded in fabricating Ru2MnGe with Neel temperature TN = 381 K, which is higher than that of previous report (TN = 353 K) [5]. Using these compounds, we fabricated Ru2MnGe/Fe2CrSi exchange-coupled bilayer. Large anisotropic magnetoresistance ratio more than -1.0 % was observed on Fe2CrSi/Ru2MnGe exchange-coupled bilayer. Besides, the shift of anisotropic magnetoresistance curve due to exchange bias was observed along field-cool direction. We would like to discuss the anisotropic magnetoresistance ratio for thickness dependent bilayers.

4. CROCUS Technology Grenoble, France

Because thermal treatments are required to functionalize magnetic multilayers, chemical species diffusion can occur, which may lead to magnetic properties deterioration. This is the case for field cooling and post-deposition annealing treatments.
Atom Probe Tomography (APT) analysis being a very useful tool for the investigation of diffusion effects during thermal processes, we have investigated atomic diffusion in Cu/Co/IrMn/Pt exchange biased structures with various Pt cap, by APT. Three dimensional spatial distributions of atoms were obtained via analysis of Cu/Co/IrMn/Pt multilayers annealed at different temperatures (375, 475 and 525°C). The reconstructions obtained at different steps revealed gradual Mn diffusion in Co and Pt grains at Co/IrMn and IrMn/Pt interfaces respectively. Mn diffusion is revealed, first along Pt grain boundaries, and then laterally from the grain boundaries toward the inner parts of the Pt grains.
We estimated the diffusion lengths of Mn and Pt, through grain boundaries (d_{GB}) and within grains (d_L) for various annealing temperatures and for our typical experimental annealing time (1h). At both 375 and 475°C, the diffusion lengths are such that $d_{GB} >> d_L$, meaning that grain boundaries indeed act as short diffusion circuits at such temperatures. An important increase of the lattice diffusion length d_L of Mn occurs between 375 and 475°C, implying that Mn diffusion through the grains interfaces is activated between 375 and 475°C, leading to the formation of Pt-Mn mixed regions at the IrMn/Pt interface for annealing temperatures higher than about 400°C, in agreement with previous investigations. These results are consistent with the larger affinity between Mn and Pt atoms than between Mn and Ir.
These structural data were correlated to the films exchange bias properties. The influence of the topmost Pt capping layer thickness, i.e. the effect of the Pt atoms reservoir pumping Mn out of the IrMn layer, turned out to be crucial.

Mo.H-P69 - The resistive switching and magnetic properties of CuO and Cu2O films deposited by magnetron sputtering CuO target

Y. Hu[1], Z. Li[1]

1. Department of Applied Physics, National University of Kaohsiung, Kaohsiung, Taiwan

It is known that oxygen flux is one of the key parameters to obtain Cu2O films by magnetron sputtering metallic Cu target. More (less) oxygen flux would result in CuO (Cu2O) phase preferentially and it is difficult to obtain pure Cu2O or CuO phases by merely adjusting the oxygen flux. This work aims to prepare Cu2O or CuO thin films by magnetron sputtering CuO (99.995%) target with different ambient gases. All of the samples were deposited on silicon substrates at 250oC. X-ray diffraction and Raman spectroscopy results show that the samples grown in Ar and O2 ambient gases display the characteristic peaks of CuO, while those deposited in Ar and N2 exhibit instead the characteristic peaks of Cu2O. The results confirm that Cu2O and CuO films were successfully prepared by sputtering a ceramic CuO target under proper ambient gases. Scanning electron microscopy and atomic force microscopy images reveal that both the grain size and surface roughness of Cu2O film are larger than those of CuO film. Besides, both Cu2O and CuO films displayed bipolar resistive switching properties, which are thought relevant to point defects. We measured the M-H curves of both Cu2O and CuO films in low and high resistance states. Interestingly, the CuO film displays paramagnetic only, while the Cu2O film display paramagnetic and paramagnetic + ferromagnetic in low and high resistance states, respectively. For the Cu2O film in high resistance state, we confirmed that the electric conduction is Schottky emission, and suggested that oxygen vacancies near the interface between electrode and Cu2O film are responsible for the observed weak ferromagnetism.

Mo.H-P70 - Probing uncommensurated magnetic structures in thin films with GISANS

B. Wiedemann[1], S. Zhang[2], Y. Khaydukov[3,4], T. Hesjedal[2], O. Softwedel[3,4], T. Keller[3,4], S. Mühlbauer[5], A. Chacon[1], C. Pfleiderer[1], P. Böni[1]

3. Max-Planck-Institut für Festkörperforschung, Stuttgart, Germany
4. Max-Planck-Society, Outstation at FRM II, München, Germany
5. Forschungsneutronenquelle Heinz Maier Leibnitz, Technische Universität München, München, Germany

The discovery of a regular arrangement of magnetic whirls in bulk samples of MnSi has drawn big interest in the scientific community and inspired new techniques for the study of uncommensurated magnetic structures. Due to their non-trivial topology these so called skyrmions may not be destroyed by smooth changes of the local magnetization and are great candidates for future magnetic storage technologies. Lately many experiments have been performed on thin samples of chiral crystals in the search of the skyrmion lattice, but the results have been inconclusive. New methods of probing thin samples for uncommensurated magnetic structures are needed. In this study we present the results of Grazing-incidence small-angle neutron scattering (GISANS) experiments on epitaxial thin films of MnSi and discuss the magnetic structure in our samples consisting of an out of plane helix in the context of the effects of uniaxial anisotropies and dimensionality.

Mo.H-P71 - Magnetic and dielectric properties of hexagonal $ErFeO_3$ thin film

H. Yokota[1], T. Nozue[1], M. Fukunaga[2], S. Nakamura[3,4], A. Fuwa[5]

1. Dept. of Phys., Chiba Univ., Chiba, Japan
2. Dept. of Phys., Okayama Univ., Okayama, Japan
3. Dept. of Science and Engineering, Teikyo Univ., Itabashi, Tokyo, Japan
4. Advance Research Center of Science and Engineering, Waseda Univ., Tokyo, Japan
5. Dept. of Science and Engineering, Waseda Univ., Tokyo, Japan

Hexagonal $ErFeO_3$ thin film was fabricated by using pulsed laser deposition method. X-ray diffraction measurement (XRD) confirmed that *c*-axis oriented $ErFeO_3$ thin film was obtained without impurity or secondary phases. Temperature dependences of lattice constant were measured by XRD and no structural phase transition was detected between 20K and 900K. Additionally, super lattice reflections were observed by XRD. This result indicated that the crystal structure is determined as non-centrosymmetric $P6_3cm$ which suggests $ErFeO_3$ thin film is ferroelectric at room temperature. The double wave method also confirmed the ferroelectricity and the obtained spontaneous polarization is $90nC/cm^2$ at room temperature. Static magnetic measurements were carried out by a magnetic property measurement system (MPMS). When the weak magnetic field was applied along the *c* axis of the thin film, temperature dependence of the magnetization showed thermal history blow 120K. Weak ferromagnetism was observed in this temperature range and the spontaneous magnetization was $0.14m_B$/f.u. at 30K. Mossbauer spectroscopy was carried out with ^{57}Fe-enriched $ErFeO_3$ thin film deposited on Al_2O_3 (0001) substrate. The measurements were performed in transmission geometry using ^{57}Co-in Rh as the g-ray source. The Doppler velocity was calibrated with an Fe metal foil measured at room temperature. The paramagnetic spectrum at room temperature consists of an asymmetric doublet. The isomer shift and the quadrupole splitting are 0.299 and 2.12mm/s, respectively, indicating that the Fe ions are in high spin Fe^{3+} state and located in the distorted pentahedral oxygen coordination. Below 120 K, the magnetically ordered spectra were observed. It suggests that the Fe^{3+} spin is inclined toward *c* axis from the *c* plane and it induces weak ferromagnetism.

Mo.H-P72 - Electronic and magnetic structures of vanadium phthalocyanine monolayer and multilayer films prepared on Ag(111)

K. Eguchi[1], T. Nakagawa[2], Y. Takagi[2], T. Yokoyama[2]

1. Nagoya University, Nagoya, Japan
2. Institute for Molecular Science, Okazaki, Japan

Up to the present, many kinds of metal phthalocyanines (MPcs) have been synthesized after the discovery of CuPc in 1927. In the 3d-transition-metal series, 3d-MPcs composed of a phthalocyanine ligand and a metal center have been synthesized for M = Ti, Cr-Zn, while the synthesis of ScPc and VPc have not been successful, because they are unstable under the atmospheric condition. To systematically understand the electronic states of the central metal, the synthesis of the whole series of the 3d-MPcs is strongly required. In this study, VPc was synthesized on a Ag substrate surface under an ultra-high vacuum (UHV) condition and the electronic and magnetic properties of VPc was investigated by x-ray photoelectron spectroscopy (XPS), x-ray absorption spectroscopy (XAS), and x-ray magnetic circular dichroism(XMCD). The VPc monolayer was fabricated by directly depositing the V atoms on an H2Pc monolayer under UHV conditions. The VPc multilayer was synthesized by repeated VPc monolayer deposition and subsequent sample annealing at approximately 450 K. The N 1s XPS of these samples showed a remarkable reduction in the peak assigned to H-bonded N atoms concomitant with the appearance of a new peak attributed to V-bonded N atoms close to the peak of iminic N. Additionally, the oxidation state of V estimated from the V 2p XPS peak position corresponded to 1.6 and 2.4 in the monolayer and multilayer samples, respectively. These results clearly imply that the VPc monolayer and multilayer were successfully obtained. The main ground state electronic configuration of the V center was found to be 2Eg by angle-dependent V L-edge XAS. The results of XMCD suggested that VPc shows a paramagnetic state on the Ag surface but an antiferromagnetic state in the multilayer.

Mo.H-P74 - Formation of $L1_0$ phase by rapid thermal annealing for sputtered FeNi thin films

M. Mizuguchi[1], T. Tashiro[1], K. Sato[1], T. Konno[1], K. Takanashi[1]

1. Tohoku University, Sendai, Japan

Large uniaxial magnetic anisotropy materials are extremely promising for the application to high-density magnetic storage devices or permanent magnets. In particular, an $L1_0$–ordered FePt alloy reveals extremely large magnetic anisotropy, therefore numerous studies on the fabrication of FePt films have been reported. However, it is an essential problem that Pt is a noble metal, thus development of a material revealing large magnetic anisotropy without any noble elements is strongly needed. In this paper, we successfully formed $L1_0$–ordered FeNi phase, which is also known to show large magnetic anisotropy, by rapid thermal annealing (RTA) for sputtered films. Sputtering and RTA conditions were varied, and crystallographic and magnetic properties were precisely investigated. FeNi films with various thicknesses were prepared by co-deposition using magnetron sputtering on MgO(001) substrates at room temperature. After deposition, FeNi films were annealed in vacuum by using an RTA system with an infrared lamp. Crystallographic properties of films were investigated by x-ray diffraction (XRD) and transmission electron microscopy (TEM). Magnetic properties were characterized by a superconducting quantum interference device. Superlattice peaks indicating the $L1_0$–ordered FeNi phase were observed in XRD patterns only for films with the RTA treatment. TEM observations in FeNi films with the RTA treatment also revealed the clear superlattice spots in transmission electron diffraction patterns. It was also found that $L1_0$-formed areas were dispersed in FeNi layers. Magnetization curves also changed with the annealing temperature and the annealing time, which implied the successful formation of $L1_0$–ordered FeNi. In addition, the enhancement of coercivity and remanent magnetization was observed associated with the appearance of $L1_0$ phase.

Mo.H-P75 - Strain-induced spin reorientation of bcc-like iron films grown on Cu(001)

E.C. Corredor[1,2,3], M. Ciria[1,2], J. I. Arnaudas[2,3], F. Lofink[4], S. Rössler[4], R. Frömter[4], H. Oepen[4]

4. Institut für Angewandte Physik, Universität Hamburg, Hamburg, Germany

Magnetic properties are strongly influenced by the structure and the strain state of the material as is observed in Fe/Cu(001) epitaxial ultrathin films [1]. We address, using a microscopic approach, the question for the magnetization orientation within the transition regime from the onset of in-plane magnetization to the almost isotropic behavior with an effective magnetic easy axis parallel to the Cu <100> directions [2]. The in-plane orientation of the magnetization vector M in bcc-like Fe(110) films grown on Cu(001) by e-beam evaporation is determined, in situ, by means of scanning electron microscopy with polarization analysis (SEMPA)[3]. For thicknesses of 2 nm, slightly above the fcc/bcc phase transition, it is found that M is oriented along the <110> directions of the Cu(001) substrate. Following the Pitsch orientational relationship these correspond to magnetically hard <1-11> axes of bulk iron. This finding is in strong contrast to the behavior reported for thicker films (above 3 nm) of bcc Fe/Cu(001), where the <100> directions of the substrate are preferred. The magnetoelastic (ME) contribution to the magnetic anisotropy energy is discussed, inferring that the presence of a shear strain is mandatory to explain the spin reorientation. The shear strain in the Fe (110) plane is calculated utilizing results of previous He scattering experiments [4]. Using bulk ME constants, it is found that in each crystallite M deviates by 10 degrees from the bcc Fe <1-11> directions, which are collinear with the fcc Cu <110> axes. Hence, with four different structural variants, a fourfold effective magnetic anisotropy has to be expected.

Mo.H-P76 - Influence of elastically pinned domain walls on magnetization reversal in multiferroic heterostructures

A. Casiraghi[1], T. Rincón Domínguez[1], S. Rößler[2], K. Franke[1], S. Hämäläinen[1], D. López González[1], R. Frömter[2], H. Peter Oepen[2], S. Van Dijken[1]

Recent years have witnessed an increased interest in the study of magnetoelectric multiferroic systems [1], which represent a possible route towards electric-field control of magnetism. A promising approach exploits one-to-one domain correlations in elastically coupled ferroelectric and ferromagnetic systems [2]. In these multiferroic heterostructures, magnetic domain walls are firmly pinned on top of ferroelectric domain boundaries [2]. Here, we investigate the influence of pinned magnetic domain walls on the magnetization reversal process in a Co40Fe40B20 wedge film (thickness up to 150 nm) that is elastically coupled to a ferroelectric BaTiO3 substrate. We use magneto-optical Kerr microscopy to show that the magnetic field direction can be used for versatile switching between two distinctive magnetization reversal mechanisms, namely (1) double switching events involving every second stripe domain at a time or (2) synchronized switching of all domains. Furthermore, scaling of the switching fields with domain width and film thickness are also found to depend on field orientation. These results are explained by considering the dissimilar energies of the two types of pinned magnetic domain walls, magnetically charged or uncharged, that are formed in the system depending on whether the magnetic field is applied perpendicular or parallel to the stripe domains, respectively [3]. The local tunability of magnetic switching processes that can be attained in these fully correlated multiferroic heterostructures could be exploited as a platform to explore novel magnetic device concepts.

Mo.H-P77 - Temperature dependence of magnon contribution to resistivity in permalloy thin films

V. Mohanan Parakkat [1], A. Roy [1], A. P.S. Kumar [1]

1. IISc, Bengaluru, India

We investigate the contribution of thermally generated magnons towards the electrical resistivity of permalloy(Py) films by high field magnetoresistance(MR) measurements. In ferromagnets, the electrical resistivity contribution by the electron magnon scattering can be suppressed by application of high enough magnetic field. The temperature dependence of magnon contribution of resistivity in Py has not been previously reported in literature. Thin films of Py were grown by PLD (of thickness17nm) and sputtering (of thickness 20nm) on thermally oxidized silicon. MR measurements on films were carried out by applying field in the direction of current i.e. in longitudinal geometry. The application of field in the plane of the films and along current direction minimizes the effect of anisotropic magnetoresistance; also it is easier to saturate these films in the plane than out of plane. A linear decrement of resistance at high field above the technical saturation (in plane saturation field of Py < 0.01T) of the ferromagnetic films, points towards the suppression of the resistivity arising from the spin flip scattering interaction mediated by thermal magnons. The high field (above 1Tesla) slope in the MR is measured as a function of temperature. This quantifies the contribution of magnonic part of resistivity in these films. Higher the temperature, larger is the contribution of magnons to resistivity,hence greater will be the slope. The high field MR measurement is a sensitive tool for probing the behavior of the ferromagnetic systems after its saturation when other direct magnetometric techniques fail to detect minute changes in magnetization. The value of the slope of MR at room temperature for both films are comparable to the value reported for Ni film grown by molecular beam epitaxy, which is possibly because Py is a Ni rich alloy(~81%).

Mo.H-P78 - Optical and Magneto-optical Spectroscopy of partially ordered Co_2MnSi

In the last years Co_2-based Heusler compounds received considerable attention as they exhibit relatively high Currie temperature and spin polarization [1]. These properties make them promising candidates for applications in novel spintronic devices. However, their structural, magnetic, optical and electronic properties are strongly correlated making the structural disorder an important parameter to consider. Co_2MnSi Heusler compound can exhibit various types of ordering, such as B2 (ordered Co sublattices, and statistical occupation of the two other crystallographic sites by Mn and Si in Co2MnSi) and $L2_1$ ordering where the Mn and Si occupy distinct sublattices [2]. Therefore it is an ideal model structure to study as it exhibits transition from B2 to $L2_1$ crystallographic ordering with increasing annealing temperature [3].
I this work, we present a systematic study of optical and magneto-optical properties of Co_2MnSi thin films with focus on different annealing temperatures. Spectroscopic ellipsometry as well as magneto-optical Kerr effect (MOKE) spectroscopy in linear and quadratic configurations were used as experimental techniques. Studied samples consisted of 30 nm thick Co_2MnSi layers epitaxially grown by inductively coupled plasma-assisted magnetron sputtering on a single MgO crystal substrate buffered with a 40 nm-thick Cr layer. The samples were capped with a 1.3 nm-thick Al layer. To achieve different degrees of crystallographic ordering, the samples were annealed at temperatures ranging from 300^{o}C up to 500^{o}C. Experimental data clearly showed differences in linear and quadratic MOKE spectra with different annealing temperatures suggesting an influence of $L2_1$ ordering. For more detailed analysis, a spectral dependence of complete permittivity tensor was deduced from experimental data using advanced theoretical modeling.

The deposition of Co layers on Si substrates and their reactions with Si are important issues in modern microelectronics technology. Indeed the interface between metal and semiconductor determines the device performance. In this work, Co films were grown on Si(001) and Si(111) substrates with a temperature range from room temperature to 500 oC. For investigating the Co structure inside the films and the formation of Co silicide at their interfaces, we performed 59Co Ferromagnetic Nuclear Resonance (Nuclear Magnetic Resonance in ferromagnets, FNR) measurements. We have observed that the dominant phase of Co was changed from hcp to fcc as the growth temperatures increase from room temperature to 300 oC. Surprisingly the detail study of the FNR measurements versus the deposition temperature shows that the diffusion process does not follow a monotonous behavior. This seems to be related to the ratio of fcc and hcp Co. The formation of fcc Co seems to limit the amount of intermixing at the Co/Si interface for both growth direction. No FNR signals were obtained for the films prepared above 400 oC, since the elements of the substrates are diffusing into the Co layer up to the top of the surfaces. The structural properties of the samples will be compared to their transport properties.

Mo.H-P80 - Multifunctional Fe-Au heterogeneous thin-films

A. Conde-Rubio[1], M. Kovylina[1], A. Labarta[1], X. Batlle[1]

1. Dept. Física Fonamental, Universitat de Barcelona and Institut de Nanociþncia i Nanotecnologia, Barcelona, Spain

Fe-Au heterogeneous thin-films have been deposited by radio frequency (RF) magnetron sputtering [1]. Nanostructural characterization, including transmission and electron microscopy, atomic and magnetic force microscopy and quantitative nanomechanical measurements, shows the granular nature of the thin films, while interferometric measurements reveal a well controlled surface roughness on the order of a few nanometers. Magnetic and optical properties are of special interest for the implementation of these compounds in the fabrication of multifunctional nanoparticles for biological applications such as hyperthermia treatments, magnetic resonance imaging enhancement, sensors, guided drug delivery to tumour cells etc [2]. By changing the Fe/Au composition, the RF power and the deposition time, a transition from superparamagnetism to ferromagnetic-like behavior can be observed in both magnetization and magnetoresistance measurements. In particular, superparamagnetism is present at room temperature in those alloys with lower Fe content, giving rise to giant magnetoresistance with non hysteretical behaviour. The absence of remanence should prevent particle agglomeration from magnetic interactions, which is one of the main drawbacks for bioapplications. Optical measurements revealed a maximum in the absorbance coming from the Au. This peak in the optical absorbance makes them suitable as a starting material for the fabrication of Fe-Au nanoparticles with an appropriate optical response for biological applications. By changing the size, shape and embedding medium the maximum absorbance region could be shifted to the near infrared, where biological tissue has high trasmitivity. The financial support of the Spanish MINECO MAT2012-33037 and Catalan DURSI 2009SGR856 projects and the European Union FEDER funds (Una manera de hacer Europa) are acknowledged. A. Conde-Rubio acknowledges Spanish MINECO for a Ph.D. contract (BES-2013-065377).

3. Department of Physics, UC Santa Barbara, Santa Barbara, United States
4. University of Colorado, Denver, United States

We present a nano SQUID-On-Tip (SOT) based scanning microscope for the study of magnetic materials. The self-aligned method allows fabrication of SQUIDs residing on the edge of a sharp pipette with diameter down to 50 nm. As a result high spatial resolution of 50 nm, and spin sensitivity of 0.38 Bohr magneton is achieved, which is about two orders of magnitude more sensitive than any SQUID reported to date. The Scanning SOT Microscope (SSM) integrates the SOT into a scanning system operating at 3He temperatures (300mK) - a temperature which enables the use of different SOT materials such as Al, In and Pb. The low temperature and the SOT's unique geometry enable us to scan at high fields: 0.3T for Al and In, and as high as 2T for the Pb SOT's which is about three orders of magnitude above the typical Scanning SQUID. We will show that the use of scanning SQUID-On-Tip microscopy can unveil new physics in the field of magnetism and current distribution at the nano scale. As an example of such a study, results from imaging the surface magnetization of magnetically doped topological insulators will be presented. These measurements demonstrate the unique ability of the SOT to have sub-Gauss sensitivity at high fields.

$L1_0$ FePt alloys are promising candidates for future applications as high density recording media or as magnonic crystals due to its high magnetic anisotropy up to 7.0×10^7 ergs/cm^2. $L1_0$ FePt is often fabricated by post-annealing of Fe/Pt multilayers which allows switching of magnetization easy axis from in-plane (multilayers) to out-of-plane ($L1_0$ alloy) direction. As an alternative method of controlling magnetization easy axis direction and simultaneously allowing patterning we applied ion beam irradiation of Fe/Pt multilayers in order to create $L1_0$ phase in intermixed region.
Changes of magnetic properties of irradiated Fe/Pt multilayers were studied in order to verify a possibility of $L1_0$ structure formation in the intermixed regions. Six series of Fe/Pt multilayers of different bilayer thickness and total number of bilayers were grown using MBE and subsequently irradiated with Ne+ ions of different energies and doses (10^{14}-10^{16} ions/cm^2) evaluated *a priori* with TRIDYN simulations. RHEED, LEED and STM *in-situ* measurements and *ex-situ* XRD revealed epitaxial growth and good quality of interfaces. All as grown multilayers showed in-plane magnetization easy axis as revealed by VSM M(H) measurements.
Full switching of magnetization easy axis from in-plane to out-of-plane direction was not achieved after ion irradiation but certain amount of perpendicularly magnetized phase appeared in most of irradiated samples. XRD spectra measured after irradiation revealed structural changes in multilayers responsible for modification of magnetic properties. Simultaneously extremely interesting effect of quasi-oscillating changes of magnetic properties such as remanence and coercivity in the out-of-plane direction of the applied magnetic field with increasing ion dose was found in some series of samples.

Mo.H-P83 - Interplay between interparticle interactions and particles' anisotropy in magnetic granular multilayers

The role of the interplay between interparticle interactions and magnetic anisotropy on the magnetic behavior of Fe/Ag multilayers has been studied for two different morphologies of the Fe grains inside the layers, using the Monte Carlo simulations technique[1]. The simulations have been performed for heterostructures with 2, 3, 5 and 10 granular Fe layers.
The Zero Field Cooled (ZFC) magnetization curves for different values of the in plane applied field have been calculated with dominant the in plane anisotropy axes orientation[2]. Our simulations showed that the strong competition between the anisotropy and the interparticle interactions in the granular multilayers with non-uniform Fe particle distribution inside the layers because of the in plane frustration of the nanoparticles moments coupling, results in higher blocking temperatures than those of a uniform system. The observed decrease of the blocking temperature with the cooling field for all these heterostructures is attributed to the fact that as the cooling field increases it masks the competition between the in plane and the out of plane interactions[3]. This effect is stronger in the monolayers and bilayers and weaker in multilayers because of the in plane field orientation.

Mo.H-P84 - Cationic distribution and anomalous magnetic properties of epitaxial $CoFe_2O_4$ thin films probed by x-ray magnetic circular dichroism

V. Hari Babu[1], P. Gargiani[1], M. Valvidares[1], E. Pellegrin[1], F. Sánchez[2], G. Herranz[2], J. Fontcuberta[2]

Investigation of the epitaxial thin films made of insulating ferromagnets (e.g., cobalt-ferrites) has received a renewed attention due to their central role in spintronic devices involving the spin Hall effect [1]. The spin magnetoresistance (SMR) is generally known to depend upon the film orientation and consequently the chemical nature of the exposed film surface. Among other recent works on cobalt ferrite films [2], we report on the cationic distribution due to the fact that the SMR is mainly controlled by the interface orbital magnetic moments.
We have fabricated epitaxial $CoFe_2O_4$ (CFO) films on $SrTiO_3$(001) and $SrTiO_3$(111) substrates with different thicknesses (2-48 nm) by pulsed laser deposition. We employed x-ray absorption spectroscopy to investigate the electronic charge distribution and element-specific x-ray magnetic circular dichroism (XMCD) to unravel the spin and orbital magnetic moments of Fe/Co ions and their site occupancy. With the decreasing film thickness, the CFO films exhibit non-saturation in the magnetization and reduced magnetic moments. For example, 14 nm thick CFO films exhibit a net moment of 1.34 μ_B/f.u. which is smaller than the bulk moment (3 μ_B/f.u.). Spectral fingerprinting in the XMCD data reveal the presence of $Co^{2+}(T_d)$ (20% of Co) and $Fe^{2+}(O_h)$ cations, resulting in the smaller macroscopic moment by the interplay of reduced Fe^{2+} moments and the modified ferrimagnetic alignment in the partially inverse spinel structure. The CFO films exhibit anomalous magnetic properties, including a two-step magnetization reversal and a reduced coercivity with the film thickness. The site-dependent Fe/Co XMCD hysteresis loops hint at the existence of antiphase boundaries by exhibiting a non-saturation at higher magnetic fields. Our results show that the small changes in the cation ordering lead to significant changes in the magnetic properties.

Mo.H-P85 - Magnetic properties of surfactant assisted grown ultrathin Cr films on Fe(001)

A. Brambilla[1], A. Picone[1], A. Calloni[1], G. Berti[1], M. Riva[1], G. Bussetti[1], M. Finazzi[1], L. Du[1], F. Ciccacci[1]

1. Dipartimento Di Fisica, Politecnico Di Milano, Milan, Italy

Interfaces between ferromagnetic and antiferromagnetic materials are widely investigated systems, characterized in particular by interesting magnetic phenomena such as exchange bias. The case of the Cr/Fe interface is of particular relevance, due to the well-known mediating role of thin Cr films in exchange coupled superlattices and in GMR multilayers [1]. The Cr/Fe(001) system was extensively studied in the past (see e.g. Refs. 1,2), particularly by focusing on the surface morphology and on the chemical interactions occurring at the interfaces. By scanning tunneling microscopy (STM) and low-energy electron diffraction (LEED) [3], we have shown that a sharp Cr/Fe interface can be obtained through growth on the pre-oxidized Fe(001)-p(1x1)O surface, with different resulting configurations at different growth temperatures. In particular, at 300 °C a single layer of chromium oxide has been stabilized on the Fe(001) surface. We discuss the magnetic properties of such ultrathin Cr structures on Fe(001) as investigated by means of X-ray Magnetic Circular Dichroism (XMCD) and by Spin-Polarized PhotoEmission Spectroscopy (SPPES). The monolayer-range Cr oxide films show an antiparallel coupling with respect to the underlying Fe substrate [4]. When the thickness is increased, SPPES provides evidence of the immediate onset of an antiferromagnetic stacking of the magnetization of Cr (001) atomic layers right from the Cr/Fe(001) interface, in contrast with previous experiments, in which the stacking was observed to begin after a few monolayers, the delay being ascribed to chemical alloying at the interface [2]. These results are particularly interesting in view of embedding such a controlled interface in low-dimensional magnetic devices.

Mo.H-P86 - Geometrical effects on Barkhausen noise in a thin film

A. Roy[1], A. P. S. Kumar[1]

1. Indian Institute of Science, Karnataka, India

All nucleation models of Barkhausen noise exhibit a crossover form non-universal to universal avalanche statistics as the magnitude of the quenched disorder crosses the critical disorder RC. The universal region is characterized by power law distributions of avalanche sizes, durations and power spectra, each characterized by a critical exponent, which is characteristic to the universality class to which the system belongs. Below RC, critical scaling properties break down and extrinsic features depending on the disorder magnitude, system size etc., dominate the size distributions. We have observed, for the first time, a crossover from universal to non-universal behaviour in the same sample by changing the measurement configuration. Our system consists of thin films of Fe grown by PLD on GaAs(001) substrates under UHV. Barkhausen noise was measured though planar Hall effect on 100Ám wide Hall bars fabricated from these films. The external field was rotated out of plane of the sample and angular dependence was recorded. It was seen that the avalanche size distributions were non-universal when the applied field was in plane or close to it, with characteristic finite-size features. When the field was rotated significantly out-of plane, the size distribution changed to universal, with the power-law exponent approaching critical exponent values found in the literature. This phenomenon was remarkable as both the types of distributions were exhibited by the same samples without any change in the defect concentration. A nucleation model described as a Random Anisotropy Ising model has been employed to shed some light on this strange phenomenon. Simulations of the model have shown that it exhibits an identical sub-critical to critical transition as the angle between the external field and the anisotropy direction is increased. Our observations are explained in the light of this model assisted by micromagnetic simulations.

Mo.H-P87 - Suppression of Barkhausen noise mediated by collapse of the domain state due to strong inter-layer exchange bias

A. Roy[1], V. P. Mohanan[1], A. P. S. Kumar[1]

1. Indian Institute of Science, Karnataka, India

We discuss the effects of interlayer exchange coupling on the magnetization reversal of a thin ferromagnetic films grown by pulsed laser ablation under UHV. In particular, we observe a change in the reversal mode of Fe upon exchange biasing with antiferromagnetic FeMn. Reversal mechanism was studied by measuring Planar Hall effect on Hall bars fabricated out of the thin films, as well as by MOKE magnetometry. In the first case, 15nm thick Fe films capped with 5nm of Au on GaAs was studied. The hysteresis showed magnetization reversal by domain wall motion characterized by discrete steps in the magnetic signal. Statistics of the jumps recorded by both the methods, showed a power law distribution, with an exponent ~2.5. Apart from confirming the presence of Barkhausen noise, this measurement indicated a sample with very low disorder, due to the value of the exponent >1.5 characteristic of a sub-critical disorder level. In the second case, a sample GaAs-Fe(15nm)-FeMn(15nm)-Au(5nm) was studied. Magnetization reversal was characterized by smooth continuous M-H curves reminiscent of rotation mode of reversal. Exchange bias was measured by 2 methods. Planar Hall effect gave en exchange bias of ~13 Oe. In this case Barkhausen noise was absent. The observation may be understood by considering a strong exchange coupling between the Fe-FeMn layers. Strong exchange coupling implies that when a domain wall is created in the ferromagnetic layer, a corresponding wall is created in the AF layer also. In order to create a domain wall in FeMn, an additional energy cost due to the exchange energy of FeMn is required for domain wall formation. In the first sample the cost of domain formation was lower than the magnetocrystalline energy barrier to rotation whereas in the second case, the additional energy requirement offset the energy balance in favor of the rotation mode.

Mo.H-P88 - Atomistic studies of domain wall dynamics in Co/Ni multilayers interfaced with heavy metal layers

J. Chico[1], K. Koumouras[1], O. Eriksson[1], L. Bergqvist[2], A. Bergman[1]

1. Department of Physics And Astronomy, Uppsala University, Uppsala, Sweden
2. Departmen of Nano and Materials Physics, Royal Institute of Technology (KTH), Stockholm, Sweden

Materials with perpendicular magnetic anisotropy (PMA) are great candidates for spintronic applications where domain wall motion is a key ingredient. Experimental observations1,2 on Co/Ni multilayers interfaced with heavy metals such as Pt indicate that the contributions from Dzyaloshinskii-Moriya interactions (DMI) and the Spin Hall Effect (SHE) can here lead to domain wall speeds higher than the ones expected from the conventional spin transfer torque (STT). Given the narrow domain walls typically present in these PMA materials, electronic structure calculations and an atomistic description of their dynamics can give valuable insights in the underlying mechanisms that determine the domain wall velocities. In the present work the influence of the DMI and the SHE on the domain wall dynamics is studied by a combination of first principle methods and atomistic spin dynamics simulations. The chosen systems are Co/Ni multilayers on top of underlayers of Pt, Pd, Ir and Au, which are chosen for their high spin orbit coupling and to facilitate comparison with experiments. We have characterized magnetic properties such as interatomic exchange interactions, magnetocrystalline anisotropy, and damping by means of first-principles electronic structure calculations and based on these parameters we have then performed atomistic Landau-Lifshitz-Gilbert-Slonczewski based simulations on the dynamics of domain walls present in the materials. As experimentally observed, we find that the DMI stabilizes a Neél domain wall instead of a Bloch wall and that the choice of interfacing metal strongly determines the velocities of the domain walls.

Mo.H-P89 - Heusler ferrimagnetic multilayers with a perpendicular magnetic anisotropy

Q. Ma[1], X. Zhang[1], T. Miyazaki[1], S. Mizukami[1]

1. WPI-AIMR, Tohoku Univ., Sendai, Japan

One of the issues in spintronics is to explore magnetic materials exhibiting a large perpendicular magnetic anisotropy (PMA), small magnetization, and small Gilbert damping for applications, such as spin-transfer-torque magnetic random access memory [1,2]. There are many ordered alloys exhibiting large PMA, e.g., FePt, whereas those also have large saturation magnetizations [3]. Thus it is meaningful to investigate another class of magnetic materials. In this study we investigate a Heusler-based ferrimagnetic multilayers (MLs) with PMA. The MLs consist of a tetragonal ordered compound Mn-Ga and cubic Heusler alloy Co2FeAl (CFA), which have a strong uniaxial and weak magnetic anisotropy, respectively, and the both materials exhibit low Gilbert damping constants [4, 5]. Because of antiferromagnetic coupling at the MnGa/CFA interface [6], the MLs may exhibit artificial ferrimagnetism. The epitaxial MLs were grown by a sputtering method. By changing each layer thickness, the MLs exhibited widely tunable magnetic properties with the respective magnetization and the effective PMA constant varying from ~ 0 to 400 emu/cm3 and from -2 (in-plane magnetization) to 8 Merg/cm3 (out-of-plane magnetization). The coercivity values for the out-of-plane magnetized MLs increased up to 15 kOe, corresponding to the compensation of magnetization for MLs. These properties are suitable for spin-transfer-torque applications [7].
This work is partially supported by KAKENHI (No. 24686001), Asahi Glass Foundation, and ASPIMATT (JST).

Mo.H-P90 - Magneto-structural characterization and local probing of inhomogeneity effects on NI-MN-GA thin films

M. Pereira[1], L. Gomes[1], J. Amaral[1], N. Silva[1], A. Lourenço[1], V. Amaral[1]

1. Department of Physics and CICECO, University of Aveiro, Aveiro, Portugal,

Ni2MnGa is a ferromagnetic-shape-memory alloy with properties that show great potential for applications, especially in thin film form. Ni2MnGa thin films were simultaneously deposited by UHV-magnetron-RF sputtering at 400 C on Si, Al2O3, MgO and SrTiO3 substrates. Thicknesses between 10 and 160nm were obtained. Structural properties studied by XRD and microscopy techniques revealed low crystallinity and growing contribution of the martensitic phase as film thickness increase. Magnetic measurements by VSM and SQUID of magnetization vs magnetic field at 300K revealed ferromagnetic behavior with saturation magnetization ranging from 30 to 200 emu/cm3. Magnetization vs temperature measurements showed no sign of the martensitic transformation between 5K and 380K. Curie temperatures (TC) of the films increase with Ni content, as expected. There is no dependence of TC on the thickness of films deposited on MgO. For 20nm thick films, TC values vary according to the substrate. For 160nm thick films, TC remains the same for all substrates. The resistance versus temperature (R-T) curves obtained by the four-point method showed an abnormal initial thermal hysteresis and changes that suggest dependency on temporal effects as well as on structural effects. The R-T measurements under an external applied magnetic field showed an expected displacement of the structural transition. Scanning Probe Microscopy measurements at different temperatures show that different areas of the sample do not undergo the martensitic transformation simultaneously which is consistent with R-T results and may originate from compositional inhomogeneity. The use of Scanning Thermal Microscopy allows a local approach to the study of structural transition temperatures in these films. It consists in externally assisting the thermal nano-probe to induce local structural transitions while measuring the temperature at which changes on the morphology of the surface signal the structural transformation.

Mo.H-P91 - Tailoring of Gilbert damping constant and magnetic anisotropy of $Co_{20}Fe_{60}B_{20}$ thin films by excess Cobalt incorporation

D. Jhajhria[1], D. K. Pandya[1], S. Chaudhary[1]

1. Thin Film Laboratory, Physics Department, Indian Institute of Technology Delhi, Delhi, India

Spintronics based microwave devices and switching current density in spin transfer torque based applications are sensitive to damping constant α and magnetic anisotropy $H_{k.}$ In this regard, we have co-sputtered the $Co_{20}Fe_{60}B_{20}$ and Co targets to bring systematic changes in the film-composition and film-stress which would lead to tuning of α and H_k as per the need of the device application. The amorphous CoFeB (30nm) thin films were co-sputter deposited with constant power of 120 W supplied to the $Co_{20}Fe_{60}B_{20}$ target and the Co target power was varied from 0-70 W to prepare Co-00, 30, 40, 50, 60 and 70 samples. The relative Fe/Co concentration ratio determined from EDAX decreased from 2.9 to 1.0. Owing to co-sputtering from CoFeB and Co targets, the Boron concentration is expected to decrease in the films. Magneto-optical Kerr effect (MOKE) measurement showed monotonous decrease in coercivity H_c from 23 Oe in Co-00 ($Co_{20}Fe_{60}B_{20}$) films to 11 Oe in Co-50 ($Co_{34}Fe_{50}B_{16}$) films followed by a small rise thereafter. The Co-00 film exhibited highest anisotropy field $H_{k\text{-}static}$ of 170 Oe which is generally attributed to high anisotropic stress. In Co-50 co-sputtered film it drops down to 70 Oe and slightly increases thereafter like H_c. The observed ferromagnetic resonance (FMR) spectra (5-12 GHz) of all the films were fitted based on Landau-Lifshitz-Gilbert (LLG) equation. Results showed that the dynamic anisotropy $H_{k\text{-}dynamic}$ mimics $H_{k\text{-}static}$. The α damping parameter also followed similar behavior as that of H_k, with minimum value of 0.0045±0.00008 in Co-50 film compared to the highest value of α=0.0084±0.00009 in the Co-00 film. This interrelationship of α and H_k can be understood from grain boundary-two magnon scattering model. We thus establish a systematic correlation and tuning of H_c, H_k and α on excess Co addition in this technologically important $Co_{20}Fe_{60}B_{20}$ alloy system.

Mo.H-P92 - Influence of substituting Te for S on magnetization of EuS thin films

S. Senba[1], Y. Ueda[2], R. Kakimaru[2], S. Sakawaki[2], H. Asada[2], K. Kishimoto[2], T. Koyanagi[2]

Physical characteristics such as magnetic, optical, and electronic properties of europium chalcogenides have been studied extensively. Recently, EuS thin film has received much attention in fundamental studies of spin injection devices. In this study, we have investigated influence of partially substituting Te for S on epitaxial growth and magnetization of EuS thin films in order to manipulate the magnetic properties. We have successfully grown EuS1-xTex (100) epitaxial films on InP (100) substrates using molecular beam epitaxy at substrate temperatures from 180 to 250üïC. The result of roughness average (Ra) value measured by AFM indicates that smooth surface is obtained at around 200üïC. The full width at half-maximum (FWHM) of the x-ray diffraction peak decreases with increasing of Te composition x and becomes smaller around x=0.2. Magnetization curves of all samples obtained by using a SQUID magnetometer shows clear hysteresis behaviors, implying the well-defined ferromagnetism. Substituting effect on a coercive force is relatively small, although Curie temperature of EuS1-xTex films decreases with the increase of x. The ferromagnetic order would be weakened due to the antiferromagnetic exchange interaction induced by Te substitution.

Mo.H-P94 - Structural and magnetic properties of (ultra)thin LaSrMnO films

Ferromagnetic metallic manganites are employed as prototypical spin injectors in several systems in order to reveal insights in a variety of spin related effects [1,2]. In particular, the La0.7Sr0.3MnO3 (LSMO) compound has stimulated an intense study since, in bulk form, it has one of the highest ferromagnetic transition temperature Tc = 370 K. Understanding and controlling the morpho-structural and magnetic properties of LSMO films as a function of thickness is crucial for realizing applications that commonly demand for ultrathin layers. For this purpose, LSMO films in the thickness range of 4 - 16 nm were deposited on single-crystal (001) SrTiO3 substrates by means of channel spark ablation [3]. The temperature and angular dependence of the magnetic properties were studied by a vector Vibrating Sample Magnetometer, in conjunction to structural and morphological results. Even the thinnest sample shows ferromagnetism (Tc = 250 K) and Tc enhances with increasing th, reaching a value of about 315 K for th = 16 nm. This gradual approach towards the ferromagnetic properties of bulk LSMO follows a strain driven trend from fully strained films with weakened magnetism towards robust magnetism with a sudden change at about 6 nm. Moreover, with increasing the temperature from 100 K up to 300 K, a change of the magnetic anisotropy from a biaxial to a dominant uniaxial symmetry was clearly observed in all the films. Such a behaviour - probably related to a crossover from a low-temperature regime, where crystalline anisotropy dominates, to a high-temperature one, governed by magnetoelastic anisotropy - occurs progressively, with a substantial isotropic behaviour actually existing in a narrow temperature range.

Fe/GaN heterostructures – a sister material system to the much-studied Fe/GaAs structures – provide excellent test grounds for future spintronic devices thanks to long spin lifetimes predicted in GaN [1] and the high thermal stability of the Fe/GaN interface [2]. Previous studies of Fe growth on GaN(0001) substrates demonstrated triple-domain Fe(110) growth [3] and six-fold magnetic anisotropy for Fe films with 5 – 70 nm thickness [4]. However, magnetic properties of ultra-thin (< 5nm) Fe films and the effect of the Fe/GaN interface remain a topic of active research.

In this work, thin Fe films with thickness between 1 and 10 nm were deposited by molecular beam epitaxy at room temperature (RT) on metal-organic chemical vapour deposited GaN(0001) substrates. *In-situ* reflecting high-energy electron diffraction patterns of GaN and Fe surfaces demonstrated a three-dimensional Fe growth up to 1 nm, and the doubling of Fe 1 x 1 streaks indicated Nishiyama-Wasserman (α-Fe (110) <001> // GaN (0001) <11-20>) and Kurdjumov-Sachs (α-Fe (110) <1-1-1> // GaN (0001) <11-20>) orientation relations as possible growth modes. Out-of-plane X-ray diffraction confirmed Fe(110) growth with estimated Fe domain sizes of around 20 nm. A linear relationship was observed between the saturation magnetisation per unit area and the Fe thickness, whose extrapolation suggested an onset of Fe in-plane ferromagnetism at around 0.6 nm (4 monolayers). Coercive fields measured along the *a*-axes (<11-20>) of GaN(0001) were found to increase from around 5 Oe at 1 nm to around 20 Oe at 10 nm at RT. Angular remanence measurements suggested dominant uniaxial magnetic anisotropy for Fe films thinner than 2.5 nm. For thicker films, signs of hexagonal anisotropies were observed with magnetic easy axes aligned with *m*-axes (<1-100>) of GaN(0001). This study of the magnetic properties of Fe thin films will be crucial in designing and processing future Fe/GaN diodes and transistors.

Ferromagnetic metal/semiconductor heterostructures with an oxide tunnelling-barrier in between have important technological implications in the context of spin-transport electronics [1,2]. Combining the spin-filtering properties of MgO [3] with the low spin-orbit interaction and subsequent long spin lifetime of GaN [4] makes such heterostructures promising candidates for spintronics research. In this paper, we studied the structural and magnetic properties of fully epitaxial Fe(110)/MgO(110)/GaN(0001) tunnel barrier structures grown by molecular beam epitaxy. The out-of-plane X-ray diffraction spectra showed an epitaxial Fe (110) film, while reflective high energy electron diffraction images confirmed the epitaxial growth of Fe(110) on top of epitaxial MgO(110) on GaN(0001). X-ray reflectivity measurements confirmed relatively smooth interfaces with roughness of approximately 0.3 nm and 0.7 nm for the MgO/GaN and Fe/MgO interfaces, respectively. In-situ magneto-optic Kerr effect measurements on Fe films indicated signs of ferromagnetism from as early as 1 nm at room temperature and demonstrated a rise in the coercive fields with increasing thickness. Angular remanence measurements on 5 nm Fe film displayed a strong uniaxial magnetic anisotropy with a weak cubic contribution, in contrast to the hexagonal anisotropy exhibited in the Fe(110)/GaN(0001) system [5]. This study of Fe/MgO/GaN system is expected to contribute in designing future GaN-based diodes and transistors.

Magnetic properties of 35 nm thick DyCo5 and YCo5 amorphous films have been studied from room temperature down to 5 K by Vibrating Sample Magnetometry (VSM, 9 T), Superconducting Quantum Interference Device (SQUID, 6 T), and X-ray Magnetic Circular Dichroism (XMCD, 6 T) at BOREAS beamline in Alba Synchrotron Light Facility. Two DyCo5 samples have been prepared with different magnetic properties. First sample, denoted DyCoC, is obtained by simultaneous co-sputtering of Dy and Co targets. Second sample is a multilayer, denoted DyCoM, obtained by alternating ultrathin pure Dy and Co layers, with thicknesses adjusted around a monolayer to give a similar average composition and total thickness than the first sample, but with a different local atomic environment. The same procedure has been applied to prepare two reference YCo5 samples. Magnetometry measurements with in-plane and out-of-plane applied magnetic fields indicate that DyCo films have perpendicular magnetic anisotropy (PMA) and show a ferrimagnetic behavior. However, there are differences between both samples in compensation temperature, which is 120 K for DyCoC and 90 K for DyCoM, and out-of-plane coercive fields, being magnetically softer the DyCoC film. On the contrary, reference YCo5 films have in-plane anisotropy. As YCo5 and DyCo5 are similar from the structural and chemical point of view, this indicates that there is no contribution of Co atoms to the PMA observed in the DyCo5 films. Finally, XMCD element selective hysteresis loops, acquired at photon energies corresponding to Co L3 and Dy M5 absorption edges, have been used to study the temperature evolution of the magnetic cones characteristic of sperimagnetic alloys.

Mo.H-P99 - Origin of Anisotropic Giant Magnetoresistance in magnetic nanostructures

The understanding of the magnetoresistance (MR) responses as related to the way how the magnetization reverses in any kind of magnetic material is of great interest, not only for fundamental study, but importantly also for the improvement of the current spintronics technology. In this work, we demonstrate that by having direct experimental access to the magnetization vector during the reversal (by using a vectorial-Kerr magnetometry) we can predict the magnetoresistive signals. We demonstrate so in spin-valve [1] and in its basic constituents, i.e. single FM layer [2] and bilayer FM / AFM. We performed RT angular and field resolved M-H loops and the corresponding simultaneous resistance changes, and demonstrate that the R(H) curves depend exclusively dependence on the reversal processes (ultimately dictated by magnetic anisotropy of the system). Very importantly, from the vectorial-resolved M-H we can experimentally determine the relative angle between the magnetization vectors of the two FM layers in spin-valve and the magnetic torque and the angle enclosed between the magnetization vector and the applied current direction in a single FM layer. This allows for the simulation and prediction of the giant magnetoresistance (GMR), anisotropic magnetoresistance (AMR) and Planar Hall Effect (PHE) in the whole angular range and for any magnetic field values.
