EXECUTIVE SUMMARY

This document describes the final implementation (Release 2) of the EAGLE Aggregation and Image Retrieval system (AIM) Infrastructure in terms of:

- Current implementation against the specification given in "D4.1 AIM Infrastructure Specification" (Section 1).
- Details about the Metadata Aggregation System (Section 2).
- Details about the Image Retrieval System (Section 3).
- HW & SW requirements of the AIM (Appendix A).
- Sample of the Content Checker Curation Tool (Appendix B).
- Image Recognition and Similarity Search API (Appendix C).

This document being just a Release Note produced as accompanying document of the AIM infrastructure software (D4.2.2, deliverable of type "Product"), please refer to the released document "D4.1 AIM Infrastructure Specification" for details about the full featured AIM Infrastructure.

1 THE AIM INFRASTRUCTURE IMPLEMENTATION IN RELEASE 2

This section summarizes the components implemented by the Aggregation and Image Management infrastructure within the scope of the full system as defined in "D4.1 AIM Infrastructure Specification".

Figure 1-1 shows the overall architecture of the EAGLE system as defined in D4.1 and its final implementation status in Release 2. Different colors (and patterns) show respectively:

- **Green (no pattern):** components implemented in Release 1.
- **Yellow (dotted):** components implemented in Release 2.
- **Blue (vertical lines):** components whose responsibility is outside the scope of the AIM Infrastructure.
- **White (dotted grid):** component whose responsibility is outside the scope of the EAGLE project.

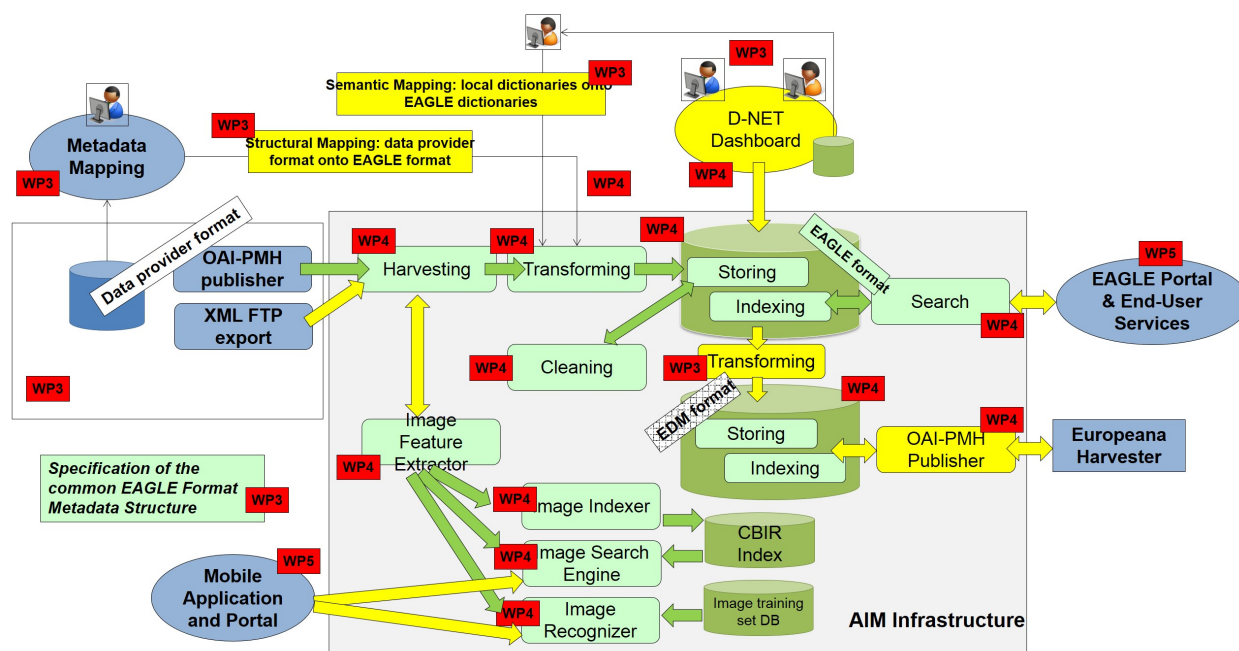

Figure 1-1 EAGLE Architecture – Global Picture – Status at Release 2

Figure 1-2 shows the global functional overview, the interaction and the flow of information between the different functional blocks and components of the AIM, i.e. the Metadata Aggregation System (MAS) and the Image Retrieval System (IRS). Here again, different colors show the different implementation status of the components.

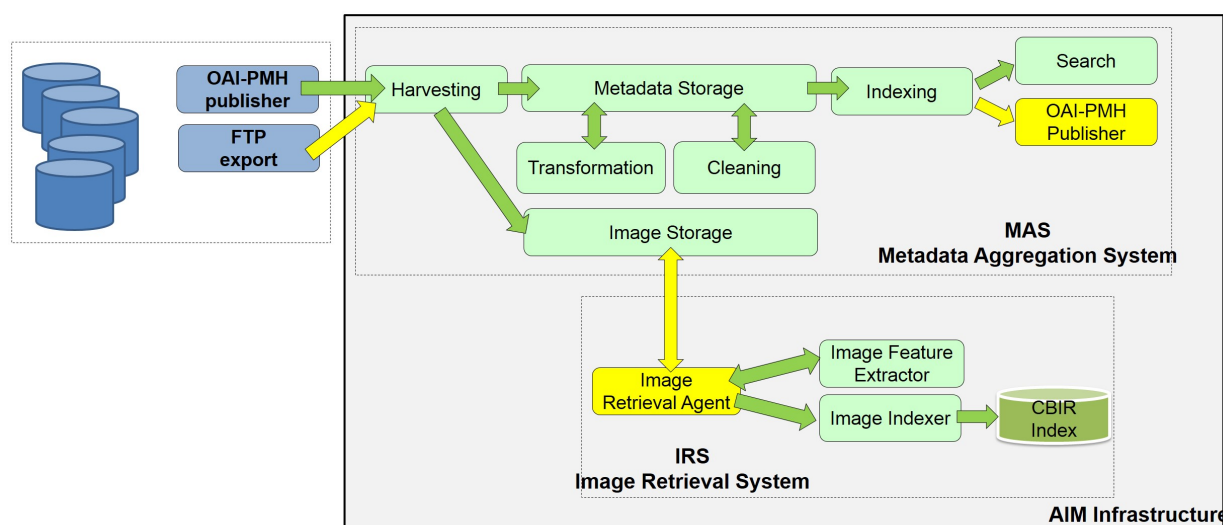

Figure 1-2 Functional AIM Infrastructure – Global Picture – Status at Release 2

The MAS will periodically harvest metadata records (Harvesting Service) made available from CPs and store them within the data infrastructure (Metadata Storage Service). Then, the MAS will start building the EAGLE Information Space step by step. Native metadata records enter a processing flow where they are structurally transformed to comply with a common metadata schema, the EAGLE Metadata Format - EMF (Transformation Service). At the same time, URLs to images pointed by metadata descriptions are visited and the relative images are persisted (Image Storage Service) in the AIM. Once metadata are transformed, metadata records are cleaned and can be further improved by curators via selective editing (Cleaning Service). Eventually they will get into their final revision and will be ready to be indexed (Indexing Service) and disseminated either to external public through the web portal and the mobile application (Search Service), or to third party software agents via OAI-PMH (OAI-PMH Publisher Service).

The IRS will periodically call the Image Storage Service via the Image Retrieval Agent to get new items to be indexed. For each new item collected, the IRS extracts its visual descriptors and encodes the visual descriptors in an efficient textual format (Image Feature Extractor Service), then puts the encoded descriptors into the CBIR¹ Index (Image Indexer Service).

¹ Content-Based Image Retrieval.

2 METADATA AGGREGATION SYSTEM

The EAGLE Metadata Aggregation System relies the D-NET software toolkit, developed within the DRIVER project efforts and extended within the OpenAIRE, OpenAIREplus², EFG, EFG1914³ and HOPE⁴ projects. Within the EAGLE framework, D-NET has been further extended and customized in order to meet new EAGLE-specific requirements and peculiarities.

This Section describes the customizations performed on D-NET in order to satisfy the EAGLE requirements.

2.1 EAGLE AGGREGATION WORKFLOW

The overall workflow of the EAGLE infrastructure is depicted in Figure 2-1, where all the blocks are selected D-NET components.

Figure 2-1 EAGLE Aggregation Workflow

The XML metadata records provided by the Content Providers are gathered (by harvesting, file transfer or other ad-hoc means) and stored into the Native Metadata Store. After that, metadata in native format are transformed into the EAGLE Metadata Format, making them structurally uniform, and stored in a Transformed Metadata Store. At this point the workflow forks into two: one branch deals with pure metadata enhancement, curation and indexing. The other branch is instead in charge of fetching images pointed to by collected metadata and storing them in an Object Store for later usage by the Image Retrieval System (see Section 3).

It is crucial to provide a staged metadata storage so that processing and elaborations late in the workflow can take place without repeating all the steps from the beginning. Thus, each Metadata Store can be considered as a “safe-point” in data processing.

2.2 EAGLE AGGREGATION KERNEL

Metadata Harvester Service

In Release 1 the Metadata Harvester Service has been deployed and tested against collection from OAI-PMH, and a prototypal implementation of a remote FTP collection service had been deployed. In Release 2 the FTP collection service has been completely tested and finalized.

²<http://www.openaire.eu/>

³<http://www.europeanfilmgateway.eu/it>

⁴<http://www.peoplesheritage.eu/>

Metadata Transformation Service

The Metadata Transformation Service is fully operational. The actual transformation step is based on an XSLT mapping which maps the properties of metadata records in input into one or more EAGLE entity in output, being them conforming to EAGLE metadata format as described in Deliverable 3.1 and its eventual amendments. In Release 1 a prototypal implementation has been deployed and tested, whilst in Release 2, a full test has been completed and a fine tuning of the whole service has been performed.

Image Harvester Service

Since Release 1 the implementation of the Image Harvester Service i) scans all the Visual Representation entities (ref. D3.1) present in the Information Space, ii) follows the URL pointing to the external file with picture extension (e.g. .jpg), and iii) collects the digital object into the Image Store Service (see below) for convenience of the IR subsystem. No updates have been implemented in Release 2.

2.3 STORE SERVICES

Metadata Stores

All the Metadata Stores and relative services were configured and integrated in the workflow in Release 1. MongoDB is the back-end on which the metadata storage service relies.

Image Store

The Image Store Service has been implemented and deployed in Release 1. It implements a REST interface for CRUD operations and tagging of collected items (pictures in this case). In Release 2 the full integration between the MAS and IRS (thank to this component) has been completed and tested. MongoDB-GridFS is the back-end on which the image storage service relies.

2.4 METADATA CLEANING AND CURATION SERVICES

Cleaner Service

The Cleaner Service component has been deployed and integrated within the workflow since Release 1. However, in its actual implementation no cleaning policy is in place. As a matter of facts, CPs made clear that they want to take care of the process of alignment of vocabularies right at the sources. Nevertheless, the component is in place in order to anticipate just in case any future need.

Curation tools

According to the DoW, the planned tools were the following: i) Metadata Editor, ii) Metadata Record Inspector (named Content Checker in Release 1) and iii) Vocabulary Editor & Vocabulary Checker.

As emerged during debates and plenary meetings, Content Providers currently chose not to edit their metadata in the aggregated information space using the Metadata Editor, as they always prefer to hold the most authoritative version of the information flowing in the infrastructure. Any modification or update of records thus will happen right at the CP repository; any change occurred is reflected in the aggregation system at the next scheduled harvesting process.

They were partially implemented in Release 1. In Release 2, since the D-NET development finalized a redesign of all backend services - including curation - all of them have been merged in a single component featuring an updated user interface: the D-NET Dashboard.

The Metadata Record Inspector is a redesign of the Content Checker released in Release 1, running and available at <http://node0.d.eagle.research-infrastructures.eu:8080/is/mvc/lightui/index.do>. It offers a low-level portal with basic Search& Browse features through which a CP might check its own data post-transformation and explore the XMLs of the entities generated from its initial XML records. Sample screenshots of the Metadata Record Inspector are shown in "Appendix B – Using the Metadata Record Inspector".

2.5 INDEX SERVICE

The Index Service is fully operational since Release 1. The SOLR index holds XML documents being compliant to Eagle Aggregation Metadata Schema as described in Deliverable 3.1.

2.6 EXPORT SERVICES

Search Service

The SOLR index is publicly reachable thanks to Search Service at http://node0.d.eagle.research-infrastructures.eu:8080/is/mvc/index/EMF-index-cleaned/solr.do/select?q=* and replies to queries compliant with SOLR syntax.

Its counterpart accepting CQL queries can be found at http://node0.d.eagle.research-infrastructures.eu:8080/is/mvc/index/EMF-index-cleaned/cql.do/select?q=*.

The aforementioned Content Checker is based on results returned by the Search Service.

OAI-publisher

The OAI-publisher service has been deployed in Release 1 and the configuration has been completed in Release 2. These records are used in order to troubleshoot the ingestion process to Europeana and assess the quantity and quality of the records.

3 IMAGE RETRIEVAL SYSTEM

The Image Retrieval System provides two modes of recognition of an image provided in input as a query image. In the first mode, called Similarity Search, the query result will be a list of images contained in the database, ranked in order of similarity to the query image. In the second mode, called Recognition Mode, the result of the query will be the information associated with the recognized image, or a message indicating that the image was not recognized. In this second mode, it is possible for an epigraph to appear in the query image in any position, also as part of a more general picture (e.g. the picture of an archeological site, or the scanned image of the page of a book).

In addition, the system provides an API to perform text search and an API to retrieve the metadata of an epigraph.

In the following paragraphs, we describe the component developed in the second release of the AIM Infrastructure.

3.1 IMAGE FEATURE EXTRACTOR COMPONENT (IFE)

This is the component in charge of analyze the visual content of an image (to be added to the database or being provided as a query), to generate its visual descriptors. The IFE has a multi-threaded architecture to take advantage of multicore processors. It has a plug-in architecture, so that it is easy to add or delete the mathematical libraries supporting the extraction algorithms of many different features. In the second release we leveraged SIFT features, for their effectiveness in the image recognition context.

3.2 IMAGE INDEXER

The Image indexer module leverages the functionality of Melampo CBIR System⁵.

The SIFT⁶ features extracted by IFE are transformed into strings of text suitable to be indexed and searched by a standard full-text search engine. The search engine used in the current implementation is Apache Lucene.

In this second release, we used the Surrogate Text Representation (STR) approach applied to the Vector of Locally Aggregated Descriptors (VLAD) technique to effectively index the images into the Apache Lucene engine. This technique outperforms the Bag of Features (BoF) approach used in the first release.

3.3 IMAGE RECOGNIZER

The image recognizer, given a query image, uses the image training database to decide if the epigraph contained in the query image belongs to one of the stored training sets.

3.4 IMAGE SEARCH ENGINE

The Similarity Search components, given in input a query image, returns a list of images "similar" to the query image, ranked in decreasing order of similarity.

⁵ <https://github.com/claudiogennaro/Melampo>

⁶ Scale-Invariant Feature Transform.

3.5 IMAGE RECOGNITION API

The Image Recognition Service provides a REST API to query the index. It provides a service that gets an image and returns an XML response containing either the metadata of the recognized epigraph or a "NOT IDENTIFIED" message. The epigraph metadata are retrieved through the Metadata Aggregation System.

This API is used by the EAGLE user interface whenever it receives from a user (either through a browser or through the mobile application) an image to be recognized.

See Appendix C for details.

3.6 SIMILARITY SEARCH API

The Similarity Search REST API gets either an image or the ID of an image already in the CBIR index and returns an XML response containing a list of the most similar images to the query ranked in decreasing order of similarity.

The user can search similar images by uploading an image or by providing an URL to an image (this is known as Query by Example) or by providing the ID of an epigraph already in the index. This second case is useful to find epigraphs similar to the one already obtained as the result of a metadata search. The search result is a list of image IDs, ordered with respect to the decreasing value of the similarity.

See Appendix C for details.

3.7 TEXT SEARCH API

The Text Search API provides a REST API that gets in input a query string and returns a sorted list of the most relevant epigraphs related to that string. It calls the Metadata Aggregation System to perform the text search.

The response format is the same as the one provided in response to a simple query for artifacts done at the EAGLE portal

See Appendix C for details.

3.8 GET METADATA API

This REST Service gets an epigraph ID and returns the full metadata of that epigraph. It queries the Metadata Aggregation System to retrieve the epigraph metadata.

See Appendix C for details.

4 APPENDIX A - HW AND SW REQUIREMENTS

The hardware minimal requirements of a virtual machine to satisfy to run Release 1 of the production EAGLE Infrastructure are:

- Open Source XEN (no Citrix XEN Server) and lvm volumes (no raw files)
- CPUs: 4 (currently the production virtual machine has AMD Opteron(tm) Processor 6176, MHz 2300 CPUs)
- RAM: 8GB
- HD: 200GB (but it must be possible to extend it based on the size and number of input records)

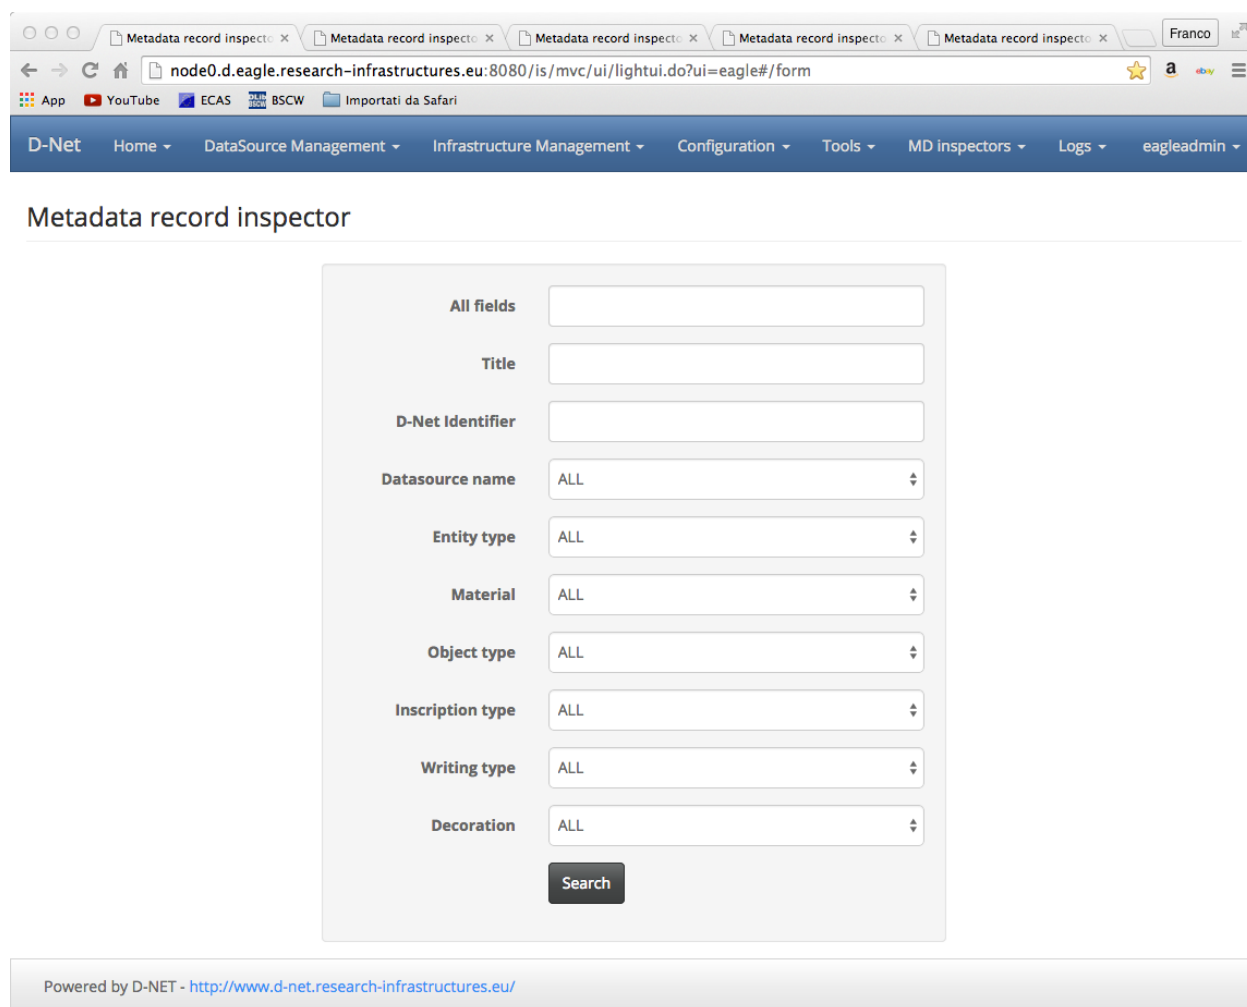

The software requirements are instead:

- OS: 64-bit Ubuntu 12.04 LTS
- Standard Packages and Libraries:
 - MongoDB
 - Apache2
 - Apache Tomcat 6
 - Apache Lucene 3.6
 - Jetty 6.1.11 (currently upgrading to Tomcat 7)
 - Java 6 (currently upgrading to 7)
 - OpenCV (<http://www.opencv.org/>)
- Specific Libraries:
 - Melampo (<https://github.com/claudiogennaro/Melampo>)
 - VIR (<https://github.com/ffalchi/it.cnr.isti.vir>)

5 APPENDIX B – USING THE METADATA RECORD INSPECTOR

This appendix shows some screenshots captured in a sample session of the Content Checker, i.e. the curation tool that will be used to check the both the quantitative results of the aggregation process and the quality of the aggregated metadata.

First, the tool shows the initial page allowing to express a query on the content of the aggregated information space (Figure 5-1 Metadata Record Inspector - Starting page); a query on this returns a set of records which satisfy the expressed condition (Figure 5-2 Metadata Record Inspector - Retrieving a set of results). This first result is then refined to restrict the number of records of interest (Figure 5-3 Metadata Record Inspector - Refining a query) and finally a single record is accessed to check its quality (Figure 5-4 Metadata Record Inspector - Accessing a record).

Figure 5-1 Metadata Record Inspector - Starting page

The screenshot shows the Metadata Record Inspector interface. On the left, there are three filter panels: 'Datasource name', 'Entity type', and 'Material'. The main area displays search results for the query '(*=*)', showing 429502 results. The first result is a 'documental' entity with a 'TXT' icon, titled 'Grabinschrift der papiria Quintilla'. The second result is a 'visual' entity with a 'JPG' icon, titled 'Block mit Dioskur und Mänade', with an image URL. The third result is an 'artifact' entity with a document icon, also titled 'Block mit Dioskur und Mänade', with multiple image URLs. The fourth result is a 'visual' entity with a 'JPG' icon, titled 'Block mit Dioskur und Mänade', with an image URL. The fifth result is a 'visual' entity with a 'JPG' icon, titled 'Block mit Dioskur und Mänade', with an image URL. The interface includes a navigation bar at the top with 'D-Net', 'Home', 'DataSource Management', 'Infrastructure Management', 'Configuration', 'Tools', 'MD Inspectors', 'Logs', and 'eagleadmin'. The browser address bar shows the URL 'node0.d.eagle.research-infrastructures.eu:8080/is/mvc/ui/lightui.do?ui=eagle#/results/1/(%253D*)'.

Figure 5-2 Metadata Record Inspector - Retrieving a set of results

The screenshot shows the Metadata Record Inspector interface. On the left, there are several filter panels:

- Datasource name:** Epigraphische Datenbank Heidelberg (668)
- Entity type:** artifact (668)
- Material:** sandstein (668)
- Object type:**
 - altar (226)
 - stele (84)
 - tafel (84)
 - block (59)
 - unbestimmt (55)
 - altar? (24)
 - meilen-/leugenstein (18)
 - urne (16)
 - architekturteil (12)
 - grabbau (12)
 - statuenbasis (11)
 - platte (10)
 - tafel? (10)
 - basis (8)
 - block? (7)
- Inscription type:**
 - weihinschrift (275)
 - grabinschrift (218)

At the top right, there is a pagination control showing page 1 of 5. Below the filters, the search results are displayed:

Results: 668 **Query:** (repositoryname exact "Epigraphische Datenbank Heidelberg") AND (entitytype exact "artifact") AND (material exact "sandstein")

The first result is:

- Title:** Grabinschrift auf Tafel
- Entity type:** artifact
- Description:** [empty]
- Image at:** <http://edh-www.adw.uni-heidelberg.de/fotos/F025532.JPG> <http://edh-www.adw.uni-heidelberg.de/fotos/F025533.JPG> <http://www.ubi-erat-lupa.org/imagelink/index.php?Nr=4508>
- show record** button

Other results include:

- Title:** Altar
- Entity type:** artifact
- Description:** [empty]
- show record** button

- Title:** Ehreninschrift
- Entity type:** artifact
- Description:** [empty]
- show record** button

- Title:** Bau-/Stifterinschrift auf Block
- Entity type:** artifact
- Description:** [empty]
- show record** button

- Title:** Grabinschrift auf Stele
- Entity type:** artifact
- Description:** [empty]
- Image at:** <http://edh-www.adw.uni-heidelberg.de/fotos/F011792.JPG> <http://www.ubi-erat-lupa.org/imagelink/index.php?Nr=772>
- show record** button

At the bottom, it says: Powered by D-NET - <http://www.d-net.research-infrastructures.eu/>

6 APPENDIX C – IMAGE RECOGNITION AND SIMILARITY SEARCH SERVICE AND API

6.1 IMAGE RECOGNITION

Service address: <http://virserv101.isti.cnr.it/fma/services/IRServices/recognize>

Please note that the service address is temporary and it will change when the services are deployed on Eagle servers.

HTTP request type: **POST Multipart**

Supported images formats: **JPG, PNG**

Image encoding: either **binary** or **Base64** encoding (by *Apache Commons Codec* library).

Parameters:

- **img** *inputstream* of an image (mandatory).
- **correlationId** optional

Returns:

- XML structure containing the metadata of the recognized epigraph.

HTML Call Example:

```
<form method="POST" enctype="multipart/form-data" name="test" action="
http://virserv101.isti.cnr.it/fma/services/IRServices/recognize">
  Query <input name="img" type="file">
  <input type="submit" value="Search" name="submit">
</form>
```

HTML Testing page:

<http://virserv101.isti.cnr.it/fma/recognizeTesting.html>

6.2 SIMILARITY SEARCH

Service address: <http://virserv101.isti.cnr.it/fma/services/IRServices/searchSimilar>

Please note that the service address is temporary and it will change when the services are deployed on Eagle servers.

HTTP request type: **POST Multipart**

Supported images formats: **JPG, PNG**

Image encoding: either **binary** or **Base64** encoding (by Apache Commons Codec library).

Parameters:

- **img** *inputstream* of an image (mandatory)
- **correlationId** optional
- **nResults** optional, number of results (default 30)

Returns:

XML structure containing a list of the most similar images to the query ranked in decreasing order of similarity.

HTML Call Example:

```
<form method="POST" enctype="multipart/form-data" name="test" action="
http://virserv101.isti.cnr.it/fma/services/IRServices/searchSimilar">
  Query <input name="img" type="file">
  Num of Results <input name="nResults" type="text" size="5">
    <input type="submit" value="Search" name="submit">
</form>
```

HTML Testing page:

<http://virserv101.isti.cnr.it/fma/similarityTesting.html>

6.3 TEXT SEARCH

Service address: <http://virserv101.isti.cnr.it/fma/services/IRServices/textSearch>

Please note that the service address is temporary and it will change when the services are deployed on Eagle servers.

HTTP request type: **GET**

Parameters:

- **text** query text provided by the user on the mobile device (mandatory)
- **nResults** optional, number of results (default: 30)

Returns:

- XML structure containing a sorted list of epigraph metadata. The format is exactly the same as the one provided in response to a simple query for artifacts done at the EAGLE portal (see the Developer's Guide)

HTML Call Example:

```
<form method="GET" enctype="multipart/form-data" name="test" action="
http://virserv101.isti.cnr.it/fma/services/IRServices/textSearch">
  Text Query <input name="text" type="text">
  Num of Results <input name="nResults" type="text" size="5">
    <input type="submit" value="Search" name="submit">
</form>
```

HTML Testing Page:

<http://virserv101.isti.cnr.it/fma/textSearchTesting.html>

6.4 GET METADATA

Service address: <http://virserv101.isti.cnr.it/fma/services/IRServices/getMetadata>

Please note that the service address is temporary and it will change when the services are deployed on Eagle servers.

HTTP request type: **GET**

Parameters:

- **id** ID of the epigraph to get

Returns:

- XML Metadata of the required epigraph.

HTML Call Example:

```
<form method="GET" name="UITestForm" action="
http://virserv101.isti.cnr.it/fma/services/IRServices/getMetadata">
  ID <input name="id" type="text" size="30">
  <input type="submit" value="Search" name="submit">
</form>
```

HTML Testing page:

<http://virserv101.isti.cnr.it/fma/getMetadataTesting.html>

6.5 EXAMPLES

6.5.1 Java Examples

Eclipse project: **FMAClient**

This project contains some Java code and images to test the FMA services.

The code should work also on Android platforms.

- **ResponseCodes** contains the following response codes:
 - `RESPONSE_OK` = 200
 - `RESPONSE_NO_MATCH_FOUND` = 300
 - `RESPONSE_SERVER_ERROR` = 400
- **ImageRecognitionClient** is just a simple class to show how to call the Image Recognition Service by Apache **HttpClient** library.
- **ImageSimilarityClient** is just a simple class to show how to call the Image Similarity Service by Apache **HttpClient** library.
- **TextSearchClient** is just a simple class to show how to call **TextSearch** Service by Apache **HttpClient** library
- **GetMetadataClient** is just a simple class to show how to call **GetMetadata** Service by Apache **HttpClient** library
- **RecognizerExample** is a simple image recognition example.
- **SimilaritySearchExample** is a simple image similarity search example.
- **TextSearchExample** is a simple text search example.
- **GetMetadataExample** is a simple example to retrieve epigraph metadata.

6.5.2 Testing Images

The `EDR_Images` folder contains a test collection of 100 images from EDR archives.

6.5.3 XML Responses

6.5.3.1 Image Recognition Example

XML response complies with the requirements in *EAGLE_Adv_Architecture*.

```
<imageRecognition responseCode="200" correlationId="null">
  <result score="0.756">
    <id>EDR000019</id>
    <metadata>
      <response>
        <lst name="responseHeader">
          <int name="status">0</int>
          <int name="QTime">599</int>
          <lst name="params">
